Aim. To explore academic and clinical nurses' perceptions and experiences on academic-practice partnership in evidence-based practice. *Background*. Academic-practice partnership could promote evidence-based practice which is crucial for high-quality care. Academic and clinical nurses are the foundation of the partnerships; however, there is little knowledge of their perceptions and experiences on academic-practice partnership in evidence-based practice. *Methods*. This is an interpretive description study. Twenty-two eligible participants were interviewed through face-to-face or online videoconferencing meetings. Guiding questions for the interviews focused on the perceptions and experiences of academic-practice partnership in the context of evidence-based practice. Interviews were recorded, transcribed, and checked verbatim. We used constant comparative analysis to analyze the qualitative data. *Results*. Four themes with fifteen subthemes were generated: necessities, modes, challenges, and benefits of the academic-practice partnership in evidence-based practice. Participants believed that academic-practice partnership was a necessary strategy to promote evidence-based practice and could be built through different modes. Nevertheless, most academic-practice partnerships were superficial because of specific types of challenges. However, a good academic-practice partnership could create a win-win situation for both nursing academia and clinical practice. *Conclusion*. Academic-practice partnership is a win-win strategy for both the academic side and clinical side to promote evidence-based practice. Different modes of academic-practice partnership provide academic and clinical nurses with more opportunities to promote evidence-based practice with a higher likelihood of successful implementation. However, related challenges require multilevel measures to provide better environments to initiate, build, and maintain intensive collaborations between academic and clinical nurses. *Implications for Nursing Management*. Academic and clinical organizations, leaders, and individuals should take multilevel measures to initiate, build, and maintain a close academic-practice partnership to promote evidence-based practice, which is crucial for high-quality nursing care, patient safety, and nursing discipline development.

1. Introduction

Evidence-based practice (EBP) in nursing involves using the best available evidence to make nursing care decisions, by combining nurses' clinical expertise, the client's values and preferences, and the available resources [1]. EBP has been recognized as an effective way for nurses to provide patients with high-quality and safe nursing care [2]. It is also crucial for promoting the development of nursing as a profession and a discipline [3, 4]. The benefits of EBP have been recognized and appreciated by many healthcare policymakers, nursing executives, clinical nurses, and academic nurses [3, 5]. The foundations for EBP in nursing (e.g., nursing evidence based on high-quality studies, theoretical frameworks for EBP, and education resources) have been developed for decades [5, 6]. However, there are many barriers to EBP, leading to an unfortunate lack of EBP in most clinical settings, especially in low- and middle-income countries [7].

A systematic review of EBP in low- and middle-income countries found that there were multilevel barriers to implementing and sustaining EBP: institutional barriers, intradisciplinary barriers, and individual nurse-related barriers [7]. Institutional barriers to EBP included scant resources, limited access to information, inadequate staffing, and a lack of institutional support. Intradisciplinary barriers included a lack of communication between academic and clinical nurses, inconsistencies between education and practice in the nursing discipline, and lack of teamwork. Individual nurse-related barriers included the individual clinician's lack of time, high workload, inadequate knowledge and skills, and resistance to changes. However, among these barriers, lack of resources, insufficient evidence-based practice knowledge and skills, and low English proficiency of clinical nurses (in non-English-speaking countries) are the key barriers requiring solutions [1, 4, 8, 9]. Addressing these key barriers is the foundation for further providing institutional resources to promote EBP; academic-practice partnership offers a critical strategy for overcoming these barriers.

Academic-practice partnership has been recognized as having great potential to promote the implementation of EBP in nursing [10–12]. Academic-practice partnership is a formal or informal arrangement between cooperating parties to advance mutual interests [13]. The American Association of Colleges of Nursing (AACN) suggested that "academic-practice partnerships are an important mechanism to strengthen nursing practice and help nurses become well positioned to lead change and advance health" [14]. Researchers have suggested that academic-practice partnership may address the key barriers to EBP (i.e., lack of resources, insufficient knowledge and skills, and low English proficiency) by sharing resources across academic and clinical settings [10–12].

Based on a systematic and comprehensive literature search, we found that the existing evidence on academic-practice partnership in EBP was limited. Only 26 case reports were identified as related evidence in the systematic literature search and screening [15]. Furthermore, most literature discussed academic-practice partnership on an institutional level with a macro perspective, with limited focus on the individual perspectives of academics and clinicians regarding academic-practice partnership [10, 13, 16].

Yet, individual academic nurses (i.e., academic staff and postgraduate students in university nursing departments) and clinical nurses (i.e., head nurses and bedside nurses in hospitals) form the foundation and core of academic-practice partnerships because they are the persons involved in the specific collaboration activities [11]. A recent quantitative study indicated that academic and clinical nurses all have a high demand for collaboration in EBP [17]. Therefore, more individual-level studies focusing on academic and clinical nurses are necessary for the promotion of academic-practice partnership in EBP. To promote individual-level studies, it is essential to have a comprehensive understanding of the perceptions and experiences of academic and clinical nurses on academic-practice partnership in EBP. Such evidence is crucial for the development of related theoretical frameworks, models, and interventions for promoting academic-practice partnership in EBP. However, there is a lack of individual-level evidence on specific perceptions and experiences of academic and clinical nurses on academic-practice partnership in EBP.

2. Methods

2.1. Aim.
This study aimed to explore academic and clinical nurses' perceptions and experiences of academic-practice partnership in EBP.

2.2. Design.
This is an interpretive description study based on the interpretivist paradigm [18]. This methodology could orient data analysis towards the development of findings that contribute to the final goal of our project, which is to develop a theoretical model and an intervention for academic-practice partnership in EBP [18, 19]. This study was reported following the COREQ checklist.

2.3. Participants.
In this study, we defined "*academic nurses*" as academic staff or postgraduates in university nursing departments and "*clinical nurses*" as head nurses and bedside nurses working in hospitals.

Inclusion criteria for academic nurses were as follows: (1) nursing academic staff were responsible for teaching and/or research in nursing schools or universities and had completed a systematic EBP training program(s); (2) postgraduate nursing students were master or doctoral students who had completed an EBP course in a university nursing department. Inclusion criteria for clinical nurses were as follows: (1) head nurses were responsible for managing at least one unit in a hospital setting and had received EBP-related training. (2) Bedside nurses were responsible for providing direct care to patients in a hospital unit and have received EBP-related training. The inclusion of these four types of nurses was to provide diverse perspectives from both academic and clinical nurses, who are the most involved stakeholders in the academic-practice partnerships.

Participants were recruited through purposive and snowball procedures to improve the representativeness of the study sample [20]. One clinical nurse declined to participate in the interview due to heavy workload. 22 interviews were conducted to reach data saturation. General information about the participants is shown in Table 1 and the Supplementary Material Table S1, which was helpful for readers to understand the quotes cited in the results.

2.4. Data Collection. The data were collected between November 2021 and March 2022. Individual semistructured interviews were conducted through online videoconferencing meetings or face-to-face meetings in hospitals or in the office of the interviewer. The duration of the interviews ranged from 23 to 63 minutes.

The interviews were conducted by the first author (Q.C., Ph.D.) who has prior experience in conducting qualitative studies and is a core member of a JBI Affiliated Group for promoting EBP in a School of Nursing. Before the formal data collection, the interview questions were piloted in two interviews, and no adjustments were required. Therefore, the data collected from these piloted interviews were also included in the data analysis. The following key questions guided the interviews: (1) How do you think about academic-practice partnership in EBP? (2) Could you describe your experience of academic-practice partnership in EBP? (3) Will you participate, or why have you participated, in an academic-practice partnership for EBP?

Interviews were recorded, transcribed, and checked verbatim. Furthermore, a self-designed questionnaire was used to collect demographic information and some general information related to EBP (e.g., training experience and experience in academic-practice partnership) of participants. EBP competencies of participants were also measured by the Evidence-Based Nursing Practice Competence Scale which has good reliability and validity [21].

2.5. Data Analysis. The 22 interview transcriptions were uploaded and analyzed in NVivo 12.0. After transcribing the data, the first author (Q.C.) worked closely and intensively with the texts to conduct inductive coding for insights into the participants' experiences and perspectives. The second author, a Ph.D. candidate who has completed the qualitative study course and has experience in conducting qualitative studies, checked the coding of the texts. The constant comparative analysis involves the following six steps: immersing in the data, developing an initial thematic template, organizing the data based on the template, condensing data and reflecting, comparing and contrasting data within similar participant categories, and comparing and contrasting data with different participant categories [19, 22]. The identification of themes and subthemes evolved as both authors had multiple discussions. Four of the participants (one nursing academic staff, one nursing postgraduate student, one head nurse, and one bedside nurse) were invited to discuss and verify the results of the data analysis.

2.6. Rigour. The following strategies were used to improve the trustworthiness and rigour of this study [19, 23]. (1) We thoroughly immersed ourselves in collecting, analyzing, and understanding data, in order to ensure the saturation of data. Furthermore, data analysis was performed along with the data collection. (2) Participants had the freedom to speak, participants' voices were fully heard, and participants' perceptions were accurately represented. (3) Considering the role of promoting EBP and academic-practice partnership, the primary researcher may hold an inclination towards academic-practice partnership in EBP. Therefore, the primary researcher used a reflexive diary to maintain reflexivity and delimit subjectivity. (4) Member checking: member checking is a qualitative technique used to establish the tenet of credibility in trustworthiness. Two researchers were responsible for data analysis. Considering the time, cost, efficiency, and effectiveness comprehensively, we invited four of the participants to individually check our results to confirm the interpretation. (5) Thick and contextualized description: we provided specific information about the participants, which could help readers to understand the context of this study better. (6) Researcher credibility: the researchers either have Ph.D. degree or are Ph.D. candidates and all of them have completed systematic training in qualitative research.

2.7. Ethical Considerations. This study was approved by the Institutional Review Board of Xiangya School of Nursing, Central South University (No. E2021130). Informed consent was obtained from all participants. Each participant was informed of the goal and methods of this study, received a guarantee of confidentiality and anonymity, and agreed that the interview would be recorded. Only research group members could access the data, and potential identifiers of participants were removed from the quotes in the results.

3. Results

Four themes with fifteen subthemes relating to academic-practice partnership in EBP (Table 2) were generated: necessities, modes, challenges, and benefits of the academic-practice partnership. Participants believed that academic-practice partnership is a necessary strategy to promote EBP, and such partnerships could be built through different modes. Nevertheless, most current academic-practice partnerships are superficial and tokenistic because of common and specific challenges. A good academic-practice partnership could ideally create a win-win situation for both nursing academics and clinicians.

3.1. Necessities of Academic-Practice Partnership in Promoting EBP. All participants considered academic-practice partnership to be an indispensable for implementing and sustaining EBP. The complementary competencies and resources of the academic and clinical roles can offset the limitations of each other to promote EBP.

Table 1: Basic characteristics of participants ($n = 22$).

	Mean ± SD, range
Age (years)	31.14 ± 6.39, (22–48)
Evidence-based Nursing Practice Competence Score[a]	74.36 ± 6.46, (65–92)
	n (%)
Gender	
Female	28 (81.82%)
Male	4 (18.18%)
Educational degree	
Baccalaureate	5 (22.73%)
Master	10 (45.45%)
Ph.D.	7 (31.82%)
Position	
Academic staff	6 (27.27%)
Master's student (professional degree)	2 (9.09%)
Master's student (academic degree)	3 (13.64%)
Doctoral candidate	4 (18.18%)
Head nurse	3 (13.64%)
Bedside nurse	4 (18.18%)
Experience in EBP projects	
Yes	19 (86.36%)
No	3 (13.64%)
Experience in academic-practice partnership in evidence-based practice	
Yes	14 (63.64%)
No	8 (36.36%)

Note. [a]Total score on the evidence-based nursing practice competence scale ranges from 0 to 92. This Chinese measurement was developed and validated by Wang et al. in 2017 [21]. More details of this scale can be found in the note of Supplementary Material Table S1.

Table 2: Themes and subthemes generated in this study.

Themes	Subthemes
(1) Necessities of academic-practice partnership in promoting EBP	(1.1) Complementary competencies for partnership (1.2) Complementary resources for partnership
(2) Modes of academic-practice partnership in EBP	(2.1) Various academic-practice partnerships (2.2) Superficial academic-practice partnerships
(3) Challenges of academic-practice partnership in EBP	(3.1) Lack of supportive policies (3.2) Limited training in EBP (3.3) Invisible hierarchy between academics and clinicians (3.4) Insufficient attention to clinical nursing practice (3.5) Lack of interactive communication (3.6) Nonmutual needs on specific steps of EBP (3.7) Lack of theoretical guidance on collaboration
(4) Benefits of academic-practice partnership in EBP	(4.1) Improving competencies in EBP and collaboration (4.2) Promoting resource integration (4.3) Promoting EBP (4.4) Bridging research-education-practice gaps

3.1.1. Complementary Competencies for Partnership. All participants described that academic and clinical nurses had necessary and complementary competencies for conducting the key steps of EBP (i.e., proposing clinical problems, generating structured questions for evidence search, searching for evidence, appraising evidence, synthesizing evidence, disseminating evidence, and implementing evidence). All participants acknowledged that "*Academic nurses have more theoretical and methodological knowledge related to evidence-based practice. ... Clinical nurses have more clinical expertise, experience, and context knowledge.*" (Participant 10, Ph.D. student)

Considering that EBP is a combination of theory and practice, the complementary academic and clinical competencies of academic and clinical nurses are necessary for EBP. Academic nurses focus more on the steps requiring theoretical and methodological knowledge and thus are more competent in working with literature (i.e., evidence search, appraisal, and synthesis). As stated by one participant, "*Overall, in evidence search, appraisal, and synthesis, academic nurses have significantly better competencies than clinical nurses.*" (Participant 6, academic staff) However, clinical nurses have lived experience in dealing with complex and emergent clinical problems and thus offer valuable

insights into proposing clinical problems for further research. For example, *"Clinical nurses could propose many current and real-world clinical problems which are urgent to be solved. These problems are often specific and the starting points of evidence implementation projects. For academic nurses who do not have current clinical knowledge and experience, and do not know organizational environments and culture, it is impossible to propose these clinical questions."* (Participant 4, academic staff)

For other steps of EBP (i.e., generating structured questions for evidence search, evidence dissemination, and implementation), academic and clinical nurses play complementary roles, rather than one role being more competent in these specific steps. For example, one participant suggested that *"Academic nurses could better frame clinical questions into structured questions for evidence-based practice projects."* (Participant 10, Ph.D. student) Another participant shared, *"If the PICO [EBNP question] is related to clinical practice, it may be addressing issues that I have clinical blindspots or limited knowledge of. I will need help from clinical nurses to determine the specific inclusion and exclusion criteria of PICO."* (Participant 12, master student) For evidence dissemination, participants mentioned *"Academic nurses have a better competence in academic writing and presentations, which is essential for disseminating evidence through academic journals or conferences. . . . Clinical professionals have a better competence in patient education and communication, which is essential for disseminating evidence to patients and relatives in the clinical practice context."* (Participant 19, clinical nurse) For evidence implementation, participants described that *"Clinical nurses always know the crux of the matter better. They know the feasibility of the evidence implementation plan better."* (Participant 8, Ph.D. student) *"Academic nurses could provide us with some suggestions related to theoretical frameworks and methodology when we are designing the evidence implementation projects."* (Participant 21, clinical nurse)

3.1.2. Complementary Resources for Partnership. Most clinical participants expressed that they have insufficient resources for evidence synthesis. *"When I did the evidence searching, . . . I was not confident whether my literature search was comprehensive because I do not have the access to many databases. This limited me a lot. . . . If we were in an academic-practice partnership, we hope we could get database support from universities."* (Participant 22, clinical nurse) The academic-practice partnership could offset the limited resources for evidence synthesis on most clinical sides.

For evidence dissemination, the academic side and clinical side have different resources (e.g., human resources, media resources, and available targeted populations). *"For evidence dissemination, academic organizations have better resources for disseminating evidence through academic publications, conferences, and academic media mainly targeted on healthcare professionals and academics, while clinical organizations mainly disseminate evidence through clinical professionals, booklets, and patient groups mainly*

targeted on clinical nurses, patients, and relatives in the hospital." (Participant 17, head nurse)

Clinical organizations had exclusive resources for evidence implementations, such as clinical nurses, patients, head nurses with leadership, and clinical practice environments. *"Clinical side has its unique advantage-it is both the starting point and ending point of evidence because we need to first generate and finally use evidence in the clinical context."* (Participant 6, academic staff) *"The clinical side has evidence recipients, evidence implementers, and clinical practice environment for evidence implementation. . . . Universities do not have these."* (Participant 6, academic staff)

Meanwhile, a few participants noted that academic-practice partnership was not a "half and half" mode of partnership for the academic and clinical sides. This idea was embodied in two aspects. Firstly, the academic side needs to play a leading role in evidence synthesis, while the clinical side needs to play a leading role in evidence implementation. They do not share half and half the responsibilities in each stage of EBP. Secondly, two participants envisioned that *"With the improvement of evidence-based practice education of clinical nurses, in the future, academics may not be needed for the implementation of evidence-based practice. Although academics will still be needed to explore the theoretical and methodological topics and conduct novel research for generating evidence which could be used in future clinical implementation."* (Participant 9, Ph.D. student)

3.2. Modes of Academic-Practice Partnership in EBP. Participants described that academic-practice partnership had been built through many approaches. However, most partnerships were superficial without intensive collaborations.

3.2.1. Various Academic-Practice Partnerships. The academic-practice partnership in EBP could be and has been built through different forms. *"It (academic-practice partnership) has different forms. The role and responsibility of different persons may be different in different forms."* (Participant 5, academic staff)

The academic-practice partnership in EBP mentioned by participants could be divided into different types, such as formal and informal partnerships; individual level, organizational level, and individual-organizational level collaborations; and academic nurse-dominated and clinical nurse-dominated partnerships. Seven participants mentioned the informal and individual academic-practice partnership. For example, *"During that period (of making evidence synthesis), I contacted many people, such as Ph.D. candidates and master students in a nursing school. I consulted them on many issues."* (Participant 20, clinical nurse) Four participants mentioned the formal and organizational academic-practice partnership. For example, *"Our hospital signed with RNAO (Registered Nurses' Association of Ontario) to collaborate in evidence implementation. We will use their guidelines in our hospital."* (Participant 21, clinical nurse) One participant mentioned *the* formal and individual-organizational academic-practice partnership. *"We signed a contract of*

one year with a Ph.D. candidate of the University of *** who was experienced in evidence-based practice. Based on clinical nurses' needs, he shared lectures on evidence translation with us every month." (Participant 21, clinical nurse) The forms of academic-practice partnership described by participants indicated that most partnerships dominated by academic nurses were used for evidence synthesis, while partnerships dominated by clinical nurses were for evidence implementation.

The partnerships between EBP organizations (such as JBI, JBI Collaboration Entity, and RNAO) and clinical nurses were the form most frequently mentioned. "We (a JBI collaborating centre) trained many head nurses and clinical nurses in hospitals. ... and we decided to use the (evidence implementation) project-based training programs for promoting the academic-practice partnership in evidence-based practice." (Participant 2, academic staff)

3.2.2. Superficial Academic-Practice Partnerships.
Most existing partnerships described by participants were superficial although they had been built through different forms in different settings and contexts. These characteristics of superficiality were reflected by scattered tasks, independent working, and a lack of mutual and intensive interaction.

Most collaborators in academic-practice partnership regarded EBP as scattered tasks without a holistic view. They worked independently and just looked for temporary collaboration, i.e., help from the other role in a specific aspect of EBP, rather than persistent collaboration throughout the whole project. As one participant shared:

"We consulted academic staff in some steps. After we transferred the best evidence to the audit criteria in the evidence implementation project, we asked the academic staff for suggestions. They did not provide us with comments for revision. ... However, after I completed the paper of this evidence implementation project and asked for academic staff to review our paper, they found problems with audit criteria, such as not being comprehensive and specific enough." (Participant 19, clinical nurse)

Another participant explained: "There wasn't a good collaborative atmosphere, you do your things and I do mine." (Participant 9, Ph.D. student) There was a lack of interaction among collaborators. "There were no close connections between the clinical nurses and the mentors (academic nurses who were experienced in evidence-based practice) in the training program of evidence-based practice." (Participant 21, clinical nurse) There are many challenges to academic-practice partnership in EBP which could explain the superficial partnerships.

3.3. Challenges of Academic-Practice Partnership in EBP.
Participants reported multilevel challenges which hindered initiating, building, and maintaining the partnerships between nursing academics and clinicians for supporting EBP.

3.3.1. Lack of Supportive Policies.
Supportive policies from governments and organizations, which create a more friendly and encouraging environment for EBP and academic-practice partnership, are required for fostering, stimulating, and realizing the full potential of academic-practice partnership in EBP. These supportive policies are essential for strategic partnerships on organizational levels and intensive individual partnerships. However, participants reported that there was a lack of supportive policies from governments and organizations for EBP and academic-practice partnership.

"There are few supportive policies on evidence-based practice in our country and hospital. Clinical nurses do not think that evidence-based practice could bring them direct benefits. ... Many head nurses pay more attention to original research which could bring them more benefits than evidence-based practice. [This is] because achievements in scientific research are important indicators of many individual and organizational evaluation systems." (Participant 16, head nurse)

"The policy (which only recognizes the first and corresponding authors) on achievements identification in most organizations hinder the collaboration (between academic and clinical nurses)." (Participant 1, academic staff)

"Many supports are just limited [to a superficial positive] attitude [towards evidence-based practice], ... There is no specific support at the policy and practice level. For example, we do not have the policy to promote plans for human resources, time, and financial support to support evidence-based practice. Just saying "This is a good thing, and we need to do it."" (Participant 5, academic staff)

3.3.2. Limited Training in EBP.
Participants perceived that training was limited to equipping the academic and clinical nurses with essential evidence-based knowledge and skills. Insufficient and ineffective training on EBP could not provide qualified collaborators for academic-practice partnership in EBP.

"In our nursing school, only two academic staff received training programs on evidence-based practice. ... How can you talk more about an academic-practice partnership in the condition that there is very limited academic staff mastering the methodology of evidence-based practice? It is a real problem." (Participant 3, academic staff)

"(In the ward I worked before,) most senior clinical nurses are around 40 to 50 years old. Most of them never even heard about evidence-based practice. Although most young clinical nurses in hospitals know evidence-based practice. They did not receive systematic training programs on evidence-based practice." (Participant 7, Ph.D. student)

"(As a teacher of evidence-based practice,) I only accept systematic training programs on theoretical knowledge of evidence-based practice. However, I never conduct an evidence implementation in the real world. This brought me some problems in my teaching." (Participant 3, academic staff)

3.3.3. Invisible Hierarchy between Academics and Practitioners.

An invisible hierarchy between academics and practitioners was found in the interviews. In this hierarchy, academics were treated as being of a higher rank. Many participants' wording and statements reflected this subtle hierarchy although only one participant directly mentioned the exact word "hierarchy."

"I feel that some nursing academics sometimes are arrogant. . . ."Compared to clinical nurses," they think they are more. . . (pause). There is a hierarchy. Although we never talk about this frankly. But it indeed exists. Clinical nurses find it difficult to collaborate with academics." (Participant 9, Ph.D. student)

"Professors from universities guided us in the whole process of the project." (Participant 22, clinical nurse)

*"I'm a little embarrassed. Because I think the professors *** and *** in nursing school are so successful and busy. I feel embarrassed to bother them and ask too many questions." (Participant 18, Head nurse)*

This invisible hierarchy was an unspoken truth but hindered clinical nurses from establishing partnerships with academic nurses.

3.3.4. Insufficient Attention to Clinical Nursing Practice.

Insufficient attention to clinical nursing practice, especially by academic nurses, hindered the academic-practice partnership in EBP. Many participants mentioned that consistency in the concerned areas is important for establishing and maintaining a partnership. *"I have the research areas I am interested in, and my energy is limited. Therefore, I cannot help other people to realize (the things they are interested in)." (Participant 1, academic staff)* However, *"Many academic staffs in nursing schools do not focus on research closely related to clinical nursing practice. This would lead to a gap between research and practice. And can we find appropriate academic staffs and students to collaborate with clinical nurses to promote evidence-based practice?" (Participant 1, academic staff)*

The lack of evidence on many clinical nursing problems also suggested that there was a lack of nursing academics focusing on clinical nursing practice. *"We often found there was no evidence which could answer our clinical questions. Therefore, in evidence implementation projects, we have deliberately ignored these clinical problems without evidence." (Participant 22, Clinical nurse)*

3.3.5. Lack of Interactive Communication.

Lack of interactive communication between partners led to a lack of mutual and intensive interaction in academic-practice partnership. A common format of communication in the partnerships was *"[We] just asked and answered questions without fully understanding and discussing."* An academic participant shared, *"I felt that they (clinical nurses) often want a specific and clear answer. When they answer questions, they often expect an answer of YES or NO." (Participant 5, academic staff)* Conversely, a clinical nurse shared that *"Academic nurses do not have enough understanding of the issues related to our specialty. . . . Therefore, they did not understand some small points in nursing practice which we thought were important. We explained that to them. However, we found they did not accept and understand very well." (Participant 16, Head nurse)*

Furthermore, the different understandings of academic nurses and clinical nurses on evidence implementation also indicated that there was a lack of interactive communication between partners. Many clinical nurses thought evidence implementation should be conducted strictly following related methodology and steps. They often use words like "right" and "wrong" in their description of their experience in evidence implementation. *"I often felt that my theoretical knowledge is limited during every phase in the evidence implementation project. . . . I often worried I did something wrong." (Participant 18, Head nurse)* Three academic nurses mentioned clinical nurses were trapped by methodology in EBP. *"Evidence-based practice means the implementation of evidence. We have a set of methods. However, we should not be restricted by the methodology. Actually, it is a kind of practice model." (Participant 8, Ph.D. student)* We found that, because of the different understandings, clinical nurses focused more on the methodology and procedures of evidence implementation projects, while academic nurses thought clinical nurses should focus more on problems in the real context rather than be limited by the methodology.

3.3.6. Nonmutual Needs on Specific Steps of EBP.

Academic nurses and clinical nurses had collaboration intentions and needs for the overall EBP process. However, they did not have mutual needs on specific steps. For example, clinical nurses required the assistance of academic nurses in evidence synthesis, while they did not need academic nurses during the evidence implementation in the clinical context which was indeed the part academic nurses were interested in. In contrast, academic nurses required clinical nurses to implement evidence in nursing practice, while they did not need clinical nurses during the evidence synthesis–which was indeed the part clinical nurses were often most interested in learning about. The inconsistency of needs on specific steps led to independent work on scattered tasks, which hindered the establishment and maintenance of a strong partnership.

"I am most interested in the part of evidence implementation." (Participant 13, Master student)

"To be honest, I think I do not need the help (from academic nurses) relating to clinical issues." (Participant 16, Head nurse)

"For example, he/she (the clinical nurse) has gotten evidence from us. Once he/she started (the evidence implementation), he/she would not fully involve us in the process of the evidence implementation in the clinical context. . . .We did not need them (clinical nurses) in evidence synthesis once the PICO was confirmed." (Participant 4, academic staff)

3.3.7. Lack of Theoretical Guidance on Collaboration. Academic-practice collaborations in EBP described by participants were limited to the practice level and often lacked a theoretical basis. The lack of theoretical guidance for academic-practice partnership in EBP made it difficult to build and sustain effective and successful cooperation.

> *"I want to know how a clear pathway of collaboration deal with clinical problems. However, there is no clear pathway of collaboration (between academics and practitioners)."* (Participant 10, Ph.D. student)

> *"The problem is how to do this mode (of academic-practice partnership in evidence-based practice) in detail and what is the mode in detail, this is no relevant guidance yet. . . . How can cooperation be more effective and feasible?"* (Participant 5, academic staff)

Notably, all participants directly or/and indirectly mentioned that there were many barriers to evidence implementation (including institutional-related barriers, interdisciplinary barriers, individual-related barriers, and evidence-related barriers). However, many barriers could not be solved only by the academic-practice partnership. *"I felt that many people were reluctant to change because we are used to staying in an environment that we are very familiar with. If the working environment still works and it doesn't bring me any trouble, why should I change it? This kind of common thinking may be a big obstacle."* (Participant 7, Ph.D. student) These barriers (e.g., inadequate staffing, lack of institutional support, and lack of teamwork with other professionals) would also hinder the evidence implementation even under the academic-practice partnership.

3.4. Benefits of Academic-Practice Partnership in EBP. Still, for all of these challenges, participants believed that both academic and clinical nurses could benefit from the academic-practice partnership, and improved collaboration would influence the quantity and quality of the benefits of EBP. They listed several potential benefits: (1) improving competencies in EBP and collaboration, (2) promoting resource integration, (3) promoting EBP, and (4) bridging research-education-practice gaps.

3.4.1. Improving Competencies in EBP and Collaboration. Academic-practice partnership could improve competencies in EBP and collaboration. The group-level competency in EBP of academic nurses and clinical nurses could be improved immediately, once the partnership is established. *"As a group of clinical and academic nurses, we are certainly more capable and resourceful than the two parties alone in the practice of evidence-based nursing. And they can achieve the effects of that one plus one is more than two."* (Participant 6, academic staff) The individual-level competencies in EBP and collaboration could be improved through learning by doing and collaborative communications. *"While we were communicating with clinical teachers, they provided us with many suggestions from clinical perspectives. We had many*

communications, even only during the process of identifying a clinical problem, every person may have an improvement in evidence-based practice and collaboration competencies."* (Participant 7, Ph.D. student)

3.4.2. Promoting Resource Integration. Academic-practice partnership could integrate organizational resources of the academic side and clinical side required by EBP. *"When we were in the partnership, we shared the resources of our organizations."* (Participant 22, Clinical nurse) Academic-practice partnership can provide partners with more available resources, for example, academic resources of the universities such as training programs and databases, the clinical practice environment in the hospital, professionals in other disciplines, and leadership in evidence-based nursing."* (Participant 6, Academic staff)

3.4.3. Promoting EBP. Participants shared that academic-practice partnership could increase the quantity and quality of EBP. They suggested that partnerships could lead to persistence and success in implementing EBP initiatives:

> *"It would be great if academic nurses collaborate with us. If you can ask for some help when you are in trouble, . . . I will not feel it is difficult to achieve the desired goal. . . . In addition, when I want to give up, the academic partners can give me a push to persist and complete the evidence-based practice project."* (Participant 19, clinical nurse) *"The support from academic staff helped us to insist and then complete the project better."* (Participant 18, Head nurse)

3.4.4. Bridging Research-Education-Practice Gaps. Academic-practice partnership could bridge the gaps between research, education, and practice which are critical barriers to EBP. For bridging the research-education gap, the academic-practice partnership in EBP could promote academic and clinical teachers to provide nursing students with more knowledge based on research in nursing education. *"I found some contents in the textbooks were inconsistent with available and best evidence. . . . If the academic and clinical teachers could not provide nursing students with evidence-based knowledge. This would limit evidence-based practice. I think the academic-practice partnership may solve this problem."* (Participant 6, academic staff)

For bridging the education-practice gap, the academic-practice partnership in EBP could provide nursing students with more context-related knowledge and practice experience in the education of EBP. *"When I took courses in evidence implementation for students, it was hard for me to give many examples. If I could collaborate with clinical nurses on more evidence implementations. I think the courses will be more interesting and practical."* (Participant 4, academic staff) *"I only have the experience of evidence synthesis. . . . I went through a period of self-doubt and thought the things I did were useless. . . . If I could join this kind of (academic-practice partnership) group, I could go to the next steps (i.e., evidence dissemination and evidence implementation) rather than only limit myself to evidence synthesis."* (Participant 11, Ph.D. student)

For bridging the research-practice gap, the academic-practice partnership in EBP could promote more clinical-related nursing studies to provide more applicable evidence for nursing practice. *"Co-creating knowledge can make our research more likely to be used in practice."* (Participant 9, Ph.D. student)

4. Discussion

The study aimed to explore academic and clinical nurses' perceptions and experiences of academic-practice partnership in EBP. In this study, participants believed that academic-practice partnership was a necessary strategy to promote EBP and to create a win-win situation for both academic and clinical nurses and their organizations. Partnerships could be built through different modes. Nevertheless, most current academic-practice partnerships were superficial.

The complementarity of the academic side and clinical side leads to the necessity of academic-practice partnership in EBP [17, 24]. Considering clinical practice setting is the starting point and ending point of evidence (i.e., research questions and evidence implementation), clinical nurses and healthcare organizations are the essential elements in EBP. As some participants mentioned in this study, clinical nurses' need for academic nurses in EBP may decrease, with the popularization of high-quality education on EBP. However, as revealed in this study, the limited education opportunities available for clinical nurses are a big challenge that will not be solved in the short term. Similarly, other studies indicated that lack of relevant knowledge and skills has long been one of the biggest barriers for clinical nurses to conduct evidence-based practices [5, 25]. Our study findings showed that through the collaboration with academic nurses, clinical nurses could obtain immediate and complementary resources and guidance for evidence-based practice. Therefore, the academic-practice partnership would be an essential model for promoting high-quality EBP in a long time.

Different collaboration forms provide the academic-practice partnership with more possibilities for promoting EBP. However, most collaboration activities between the academic side and clinical side were superficial, which limited the effectiveness of academic-practice partnership. Close partnerships should be based on substantial, interactive, frequent, and lasting collaboration activities, which often occur in the context of strategic partnerships with organizational and leadership supports [14]. However, most collaboration activities described by participants in this study involved scattered tasks, independent working, and lacked mutual and intensive interaction.

We found that multilevel challenges hinder EBP. This finding is corroborated by previous research, which found multiple barriers to the initiation, building, and maintenance of the partnerships between the academic side and clinical side for supporting EBP. These barriers included the lack of supportive policies; limited training about EBP; invisible hierarchy between academics and clinicians; insufficient attention to clinical nursing practice; lack of

interactive communication; nonmutual needs on specific steps of EBP; and lack of theoretical guidance on collaboration [16]. Multilevel strategies are required to overcome these challenges to reach close academic-practice partnerships.

Firstly, policy supports are essential for long-term collaboration in that policies are essential for cultivating innovation-encouraging and collaboration-friendly environments which is the basis for close partnerships to promote EBP [26, 27]. Particularly, governments, academic, and clinical institutions should develop policies that integrate EBP-oriented and academic-practice partnership-oriented requirements and performance appraisal on staff and working teams. In addition to providing a supportive atmosphere, policies could also strongly push institutions and individuals to take measures to overcome other barriers to academic-practice partnership in EBP.

Secondly, individual education on EBP provides the basis for academic-practice partnership in EBP. Collaboration on activities of EBP requires academic nurses and clinical nurses to be equipped with basic knowledge and skills provided by effective EBP courses and training programs. However, the quantity and quality of education on EBP are still limited [28]. To present more EBP education opportunities, we should cultivate more academic and clinical staff to be equipped with the necessary competencies to teach EBP [5]. Meanwhile, we should include EBP into the curriculum at all stages of nursing professional higher education (i.e., bachelor, master, and Ph.D.) [5, 29, 30]. Registered Nurses'. A systematic review [5] proposed several suggestions to improve the effectiveness of teaching EBP: using the educational strategy of combination and married with clinical exposures; adequately contributing to the student nurses' acquisition of EBP knowledge and implementation; using theoretical frameworks and models, interactive teaching styles, and appropriately sequencing duration, timing, and content for teaching EBP within the curriculum; and using academic-practice partnerships for teaching EBP, especially in the resource-constrained settings.

We also found that an invisible hierarchy between academic and clinician nurses limits deep collaborations because real partnerships cannot be built when there is imbalanced power-sharing between the academic and the clinical staff [14]. In this study, the relationship between the two sides was more like guidance by academics to clinicians, rather than partnership. Other scholars have found that insufficient attention to clinical nursing practice leads to a lack of motivation for EBP and few academic nurses focusing on research related to clinical nursing practice, which hinders the academic-practice partnership in EBP [4]. To deal with these two challenges (i.e., invisible hierarchy and insufficient attention to clinical nursing practice), the emphasis on "high-quality practice-oriented" should replace the emphasis on "research-oriented" in policies and performance appraisal systems to reduce the invisible hierarchy between academics and practitioners, increase the attention of academics on clinical nursing practice, and promote "interactive communication" rather than "consultation

conversations" between academics and practitioners. Furthermore, the lack of interactive communication in the academic-practice partnership may be also because there was an "academic-practice gap" [31]. In other words, academic nurses and clinical nurses have different professional experiences and training systems, leading to gaps in theoretical knowledge, clinical experience, and ineffective communication between academic and clinical nurses. Therefore, compatible and understandable languages to achieve shared understanding for both sides, voluntary and frequent communications, deeper understanding of the context, and experience of the other side are crucial to overcoming the academic-practice gap for promoting interactive communication [31].

Finally, there is a lack of specific theoretical guidance on academic-practice collaborations in the context of EBP although there are models, frameworks, and principles guiding EBP and academic-practice partnerships, respectively [14, 32, 33]. Meanwhile, although there is theoretical guidance (i.e., academic-practice partnership logic model and AACN's guiding principles for academic-practice partnerships) proving implications for academic-practice partnerships on the organizational level, there is a lack of theoretical guidance on individual collaborations [14, 33]. Considering individual-level collaborations are the prerequisite and core elements of organizational-level partnerships, the specific and theoretical research guiding the organizational-level partnerships and individual-level collaborations are both necessary to promote effective academic-practice partnership in EBP. It is noted that, excepting dealing with the above challenges of academic-practice partnerships, the measures of other barriers to EBP are also crucial for promoting academic-practice partnership in EBP [4, 7].

This study suggested that successful academic-practice partnership could improve competencies in EBP and collaboration, promote resource integration, EBP, and bridge research-education-practice gaps. The quality and degree of academic-practice partnership would influence the quantity and quality of the benefits, which were supported by other studies [11, 16]. However, existing evidence on approaches to develop academic-practice partnership is limited. More high-quality studies with rigorous research designs (e.g., experimental trials) and applying multimethods (e.g., mixed-method studies) are required to evaluate the short-term and long-term outcomes effectively and comprehensively [13, 16].

5. Limitations

There are three main limitations in this study. Firstly, most of the participants (i.e., 19 participants) are from central China (which is at a median level on economic and healthcare service levels); other regions with different contexts might have different modes of collaboration. Secondly, participants having the experience of deep collaboration and close partnership in this study were limited because the academic-practice partnership in EBP was limited in the context of this study. The participants with

rich experience in close partnerships may provide richer or even different information on academic-practice partnership in EBP. Thirdly, the experience of academic-practice partnership in EBP of participants was in the past. The recall difficulty could also limit the information's accuracy and adequacy.

In the future, other qualitative data collections (e.g., observational method and timely interviews) during the process of academic-practice partnership in EBP are important, which could provide more exact and vivid examples of views and experiences on academic-practice partnership in EBP.

6. Conclusions

Academic-practice partnership is a win-win strategy for both the academic side and clinical side to promote EBP. Different modes of academic-practice partnership provide academic and clinical nurses with more possibilities and better chances to promote the EBP. However, challenges in academic-practice partnership in evidence-based nursing require multilevel measures to provide a better environment to initiate, build, and maintain intensive collaborations between academic and clinical nurses.

6.1. Implications for the Profession and/or Patient Care. The collaborations between academic and clinical nurses are the basis and core of academic-practice partnerships. The individual-level collaborations on EBP activities could improve EBP competencies, resources, and education, to promote EBP and the professional development of academic and clinical nurses. Meanwhile, to effectively initiate, build, and maintain close collaborations on the individual level, leaders in academic and clinical organizations should make efforts (e.g., providing supporting policies, signing a memorandum of cooperation, providing time, resources, and incentive system) to cultivate a friendly environment for academic-practice partnership in EBP.

Background. The high turnover rate of new nurses is significantly impacted by the transition issue. Practice readiness has been identified as a key factor in ensuring a smooth transition, but there is currently a lack of specific instruments available in China to measure it. *Aims.* To translate and adapt the Casey-Fink Readiness for Practice Survey and validate its psychometric properties in senior nursing students in the Chinese cultural context. *Methods.* The descriptive cross-sectional study design was used. The English version of the Casey-Fink Readiness for Practice Survey was translated into Chinese according to Brislin's translation guidelines. A total of 590 senior nursing students from three nursing schools in China were surveyed with the Chinese version of the Readiness for Practice Instrument. Data analyses were performed to assess the reliability and validity of the instrument. The STROBE guidelines were used as the reporting method. *Results.* The validated Chinese version of the Casey-Fink Readiness for Practice Survey contained 18 items in the same four dimensions as the original English version. The internal consistency was satisfactory, with Cronbach's α and composite reliability values for all four dimensions above 0.70. The final confirmatory factor analysis model also demonstrated good fit indices, with the average variance extracted values for all dimensions above 0.50. *Conclusion.* The validated Chinese version of the Casey-Fink Readiness for Practice Survey is a reliable and effective instrument for measuring the readiness for practice among senior nursing students in China. *Implications for Nursing Management.* This study presents a valuable contribution to adapting an effective and reliable tool to assess readiness for practice among Chinese senior undergraduate nursing students. This will enable the development of specific strategies based on cultural context to optimize the readiness for practice for senior nursing students and smooth the transition of new nurses in China.

1. Background

Newly graduated nurses (NGNs) play a critical role in the nursing workforce as a human resource supply. The State of the World Nursing Report 2020 proposed by the World Health Organization (WHO) highlights that the nursing profession receives an influx of 1.7 million NGNs each year [1]. However, the turnover rates of NGNs were especially high, ranging from 8% to 69% in the first year and 26.2% to 57% in the second year worldwide [2, 3]. In the United States, NGNs' turnover rate was 27.6% in the first year, accounting for 32.1% of all nursing turnover in 2019 [4]. A longitudinal study in China also demonstrated that the turnover rate of NGNs was approximately 33.2% [5].

The high turnover rate further exacerbated globally the nursing shortage problem.

Previous studies have shown that a variety of factors contribute to the high turnover rate among NGNs, including their low clinical competence, coping self-efficacy, and working environment. Among these reasons, low competency is identified as one of the main reasons for their intention to leave and actual turnover [6]. Low competency usually leads to negative experiences and feelings for new nursing graduates, such as low professional confidence, high confusion and challenges, and even transition shock [7]. NGNs often express feelings of being unprepared to apply clinical knowledge and technical skills in practical settings to perform the expected professional roles and responsibilities

when transitioning from an academic to a professional clinical setting. Thus, practice readiness is believed to be the key element in understanding reality/transition shock among new graduate nurses [8].

Readiness is usually described as a feeling or state of being fully prepared for the required action [9]. Practice readiness typically refers to the extent to which individuals are perceived to possess the knowledge and skills to practice autonomously [10]. Mirza et al. identified three attributes of practice readiness for newly graduated nurses, including clinical capability, cognitive capability, and professional capability [11]. Baumann et al. also identified the personal, clinical, and relational characteristics and organizational acuity as the four characteristics of practice readiness for new nurses [12]. Although different scholars may report different components of practice readiness, the maturity of nursing students, the knowledge and skills they learned in school, and their clinical practice experience during clinical practicums are believed to be the antecedents of new nurses' practice readiness [8].

Nursing students are an important resource for new nurses. Thousands of nursing students enter the nursing workforce and profession every year. In Australia, 10,000 nursing graduates enter the profession each year, and the majority of them work in acute care settings [13]. In China, 203,000 nursing graduates with advanced nursing degrees begin nursing practice each year [14]. Although nursing students do not carry the same level of roles and responsibilities as qualified clinical nurses, they still need to care for patients during clinical practicum with the professional knowledge and skills they learned in educational institutions [15]. They also face transition issues and encounter high levels of stress due to their limited clinical experience and insufficient readiness [16, 17].

Senior nursing students' readiness for practice refers to their perceptions of readiness and preparation for professional nursing roles, which are usually regarded as their ability to fulfill professional roles incorporating knowledge, behaviors, skills, and attitudes [2, 18]. Their readiness for practice largely hinges on their exposure to opportunities to practice the key dimensions of nursing during their education [19]. It has been proved that senior nursing students who possess a high level of practice readiness often experience less anxiety when transitioning to qualified nurses and are more likely to adapt to the work environment [20].

Due to the importance of practice readiness, many strategies and supports have been suggested to achieve and enhance the level of practice readiness of nursing students. The most widely employed strategies are the final clinical practicum and internship [21]. Undergraduate nursing education in China consists of a four-year program, with a clinical internship lasting over eight months in the fourth year [5]. However, nursing students are still intended to report their stressful and helpless experiences upon entering the clinical workplace [5]. Since nursing education does not always prepare nursing students for practice during the clinical practicum, they were not confident in their practice readiness [22]. Casey et al. [18] reported that only 3% of senior nursing students felt capable of independently

carrying out specific skills and procedures, such as urinary catheter insertion, in an actual clinical context.

The assessment of senior nursing students' readiness for practice with a culturally appropriate assessment tool is crucial in addressing low readiness upon entering the clinical workplace. However, specific instruments to evaluate the readiness for practice of senior nursing students in China are lacking. Since many instruments have been developed in this regard, adapting and validating an appropriate instrument are more efficient solutions. There exist several assessment tools that may be used to assess the readiness for practice among senior nursing students in the Chinese cultural context. The Work Readiness Scale [23] is one of the widely used assessment tools, but its evaluation is time-consuming due to its 64 items in four dimensions. Walker improved the original Work Readiness Scale to the Work Readiness Scale for Graduate Nurses (WRS-GN), adding 9 nursing items based on the original items [24]. While Li translated and validated the WRS-GN into Chinese [25], the scale is more suitable for assessing the work readiness of new nurses rather than senior nursing students. Shahsavari developed the Perceived Professional Preparedness of Senior Nursing Students questionnaire (PPPNS, [19]), but it is more effective to evaluate nursing students' perceived preparedness to enter the clinical setting. The Casey-Fink Readiness for Practice Survey (CFRPS) [18] was developed to assess the practice readiness of senior nursing students in the United States. It was further revised and validated in the New Zealand context [26].

Therefore, this study aims to translate and validate the CFRPS and evaluate its psychometric properties in Chinese senior nursing students to provide a culturally appropriate tool for assessing their practice readiness in senior nursing students in the Chinese cultural context.

2. Methods

2.1. Parallel Translation. With the permission of the scale developer, the original English CFRPS was translated into Chinese using a parallel blind technique to facilitate an open discussion and collaboration. Two associate professors with Ph.D. degrees and experiences as visiting scholars in Britain and the United States, respectively, completed the independent translation. Then, two English teachers working in nursing colleges with master's degrees completed the independent back-translation. Subsequently, different versions of CFRPS are cross-checked and modified. The final Chinese version of the instrument was confirmed after any discrepancies were resolved through consensus among the translators.

2.2. Study Design and Participants. In this study, a descriptive cross-sectional design was utilized and STROBE was employed as the reporting method. Participants were recruited from three nursing schools in North China. Senior undergraduate nursing students were invited to fill out a questionnaire including demographics and the Chinese version of the CFRPS, by convenience sampling from May

2021 to May 2022. The inclusion criteria were senior nursing students who (1) were in the last year of undergraduate study; (2) complete the practicum internship; (3) were preparing for clinical practice; and (4) were willing to participate in the survey. The exclusion criteria were as follows: senior nursing students who plan to work in non-nursing fields after graduation. The minimum sample size of this study was calculated on the principle of "above ten participants per scale item" [27]. Finally, 591 senior nursing students that met the criteria above accomplished the questionnaire, and 590 samples were included in the analysis after deleting one sample questionnaire with incomplete answers and missing values.

2.3. Measures. In this study, two parts of the survey questionnaire were used to measure participants' practice readiness. Section A collected demographic information, including age, gender, educational level, and questions related to clinical practicum. Section B used the Casey-Fink Readiness for Practice Survey-Chinese Version (CFRPS-C) to collect data about the practice readiness of participants. The original CFRPS is a 4-point Likert scale consisting of 18 items (1 = strongly disagree to 4 = strongly agree). It has four subdomains: clinical problem-solving (7 items), learning techniques (2 items), professional identity (5 items), and trials and tribulations (4 items). Higher scores in clinical problem-solving, learning techniques, professional identity, and lower scores in trials and tribulations indicate a higher level of readiness for practice. Cronbach's α of the original CFRPS was 0.69 for all items and 0.80 for clinical problem-solving, 0.50 for learning techniques, 0.65 for professional identity, and 0.63 for trials and tribulations, respectively, which indicates good internal consistency reliability. Exploratory factor analysis suggested that the four-factor set of correlated subscales accounted for 48.2% of the variance across all survey items [18].

2.4. Statistical Analysis. A descriptive analysis was employed to examine participants' demographic characteristics. Pearson correlation analysis was employed to examine the correlation between the four subscales of CFRPS-C. A four-factor confirmatory factor analysis (CFA) with oblique rotation was performed to evaluate the reliability and validity of CFRPS-C. Due to the ordinal nature of items in CFRPS-C, mean-variance-adjusted weighted least squares (WLSMV) estimation was employed to estimate the parameters of the factor model. The structural validity of CFRPS-C was evaluated by Kaiser–Meyer–Olkin (KMO) and Bartlett's test of sphericity, and the model fit indices included χ^2, df, root mean square error of approximation (RMSEA), comparative fit index (CFI), Tucker–Lewis Index (TLI), and standardized root mean square residual (SRMR). The criteria of a good model fit were: χ^2/df < 5, RMSEA < 0.08, CFI > 0.90, TLI > 0.90, and SRMR < 0.08 [28]. The reliability and convergent validity of the model were evaluated by standardized factor loadings, Cronbach's α, composite reliability (CR), and average variance extracted (AVE), where CR > 0.80 and AVE > 0.50 indicate good reliability and convergent validity

[29]. The discriminant validity of the model was evaluated by the bootstrap confidence interval test, where the bootstrap confidence interval not including one suggests discriminant validity [30, 31]. Statistical analysis was completed with SAS 9.4 and Mplus 8.3.

2.5. Ethical Considerations. Ethical approval for the survey was obtained from the Ethics Committee of the University of the Corresponding Author. All participants were informed of the purpose of this study and were free to participate in this survey. All participants gave written informed consent for their anonymized data to be used for research purposes, including publication. We also received permission from Dr. Casey (e-mail communication with Kathy Casey, 26 April 2020), the author of the CFRPS, to adapt and validate the scale in the Chinese context.

3. Results

3.1. Participant Characteristics. In this study, a total of 590 nursing students were enrolled, comprising predominantly female participants (83.1%, $n = 490$). The mean age of the participants was (21.73 ± 0.33). Notably, all of the senior nursing students had undergone an 8-month practicum in various clinical settings, including medical, surgical, gynecological, pediatric, emergency, and intensive care units.

3.2. Structural Validity. The KMO measure of CFRPS-C was 0.909, indicating enough items are predicted by each factor in the current study. The result of Bartlett's test of sphericity was statistically significant ($\chi^2 = 4874.185$, $P < 0.001$), suggesting the study data is suitable for factor analysis. The model fit indices of the confirmatory factor analysis (CFA) are illustrated in Table 1. The initial CFA model (Table 1, Model 1) with full items showed χ^2/df = 17.181, RMSEA = 0.166, CFI = 0.771, TLI = 0.735, and SRMR = 0.104, suggesting an unacceptable model fit. After deleting two items ("I am comfortable delegating tasks to the nursing assistant" and "I have had opportunities to practice skills and procedures more than once" in Trials and Tribulations) with low standardized factor loadings (<0.5), the CFA model (Table 1, Model 2) showed improved fit indices: χ^2/df = 7.329, RMSEA = 0.104, CFI = 0.922, TLI = 0.907, and SRMR = 0.060. To obtain the optimal and most parsimonious model, modification indices were evaluated and the correlations between error terms were added to further improve the model fit. The final model fit indices (Table 1, Model 3) were χ^2/df = 4.562, RMSEA = 0.078, CFI = 0.958, TLI = 0.948, and SRMR = 0.046, indicating the final CFA model showed good structural validity. Figure 1 displays the standardized loadings for the final 18-item CFA model of CFRPS-C.

3.3. Reliability and Convergent Validity. All four dimensions of the 18-item CFRPS-C showed statistically significant and satisfactory reliability and convergent validity, as evidenced

TABLE 1: Model fit of the confirmatory factor analysis.

| Model	χ^2	df	χ^2/df	RMSEA	CFI	TLI	SRMR
Model 1	2817.675	164	17.181	0.166	0.771	0.735	0.104
Model 2	945.510	129	7.329	0.104	0.922	0.907	0.060
Model 3	565.700	124	4.562	0.078	0.958	0.948	0.046

FIGURE 1: Confirmatory factor analysis of the 18-item CFRPS-C with standardized loading.

by the standardized factor loadings above 0.5 and significant (see Figure 1 and Table 2), Cronbach's α and composite reliability values (CR) above 0.7 (see Table 2). The average variance extracted values (AVE) of the four dimensions were all equal to or above the recommended value of 0.5 (see Table 2).

3.4. Discriminate Validity. The absolute values of the correlation coefficients between the four dimensions of the 18-item CPRS-C ranged from 0.213 to 0.898 (see Table 3). The confidence interval of correlations derived from 5000 bootstrap samplings all did not include 1, suggesting acceptable discriminate validity of the 18-item CFRPS-C [30, 31].

4. Discussion

Clinical internships are a crucial period for nursing students to experience clinical nursing and develop a professional identity, enabling them to transit smoothly into professional clinical nurses [32]. Yet we have no specific instruments to evaluate the practice readiness of senior nursing students during this critical period in China. Therefore, the primary objective of this study was to translate and adapt the Casey-Fink Readiness for Practice Survey (CFRPS) into the Chinese version through a parallel translation process.

The Chinese version of the CFRPS, which is an 18-item scale, has been validated through a parallel translation process. The results of the confirmatory factor analysis (CFA) showed that all the standardized factor loadings of the final 18-item CFRPS-C was statistically significant and above the recommended value of 0.5, indicating good commonalities of items [33]. Furthermore, the values of Cronbach's α and CR for the four dimensions were above 0.7, and the average variance extracted (AVE) of the dimensions was above 0.5. This suggests that the Chinese version of CFRPS has acceptable reliability and convergent validity [28]. In addition, the discriminate validity of the CFA model was acceptable according to the correlation coefficients between the four dimensions [30, 31]. Therefore, the findings indicated that the Chinese version of CFRPS is reliable and valid for the evaluation of readiness for practice in Chinese senior nursing students.

In the original CFRPS, Casey identified four factors closely related to the readiness for practice, including clinical problem-solving, learning techniques, professional identity, and trials and tribulations. Previous studies also focused on these domains singly or combined to reflect the practice readiness of nursing students or new nurses [8]. In our study, we found the final Chinese version of CFRPS has 18 items in the same dimensions as the original CFRPS. What's more, all the items in the dimensions of clinical problem-solving skills, learning techniques, and professional identity

TABLE 2: Reliability and convergent validity of the 18-item CFRPS-C.

Dimension	Indicator	STD	SE	Z	P	Cronbach's α	CR	AVE
Clinical problem-solving	Feel confident communicating with physicians	0.722	0.022	32.536	<0.001	0.828	0.893	0.546
	I am confident in my ability to problem solve	0.799	0.017	46.505	<0.001			
	I use current evidence to make clinical decisions	0.760	0.018	42.834	<0.001			
	I am comfortable communicating and coordinating care with interdisciplinary team members	0.706	0.022	32.439	<0.001			
	I feel comfortable knowing what to do for a dying patient	0.620	0.023	27.022	<0.001			
	I feel comfortable taking action to solve problems	0.787	0.018	43.402	<0.001			
	I feel confident identifying actual or potential safety risks to my patients	0.762	0.018	42.243	<0.001			
Learning techniques	Simulations have helped me feel prepared for clinical practice	0.833	0.018	46.488	<0.001	0.701	0.774	0.632
	Writing reflective journals/logs provided insights into my own clinical decision-making skills	0.755	0.019	38.86	<0.001			
Professional identity	Feel comfortable communicating with patients and their families	0.681	0.020	33.957	<0.001	0.781	0.832	0.500
	My clinical instructor provided feedback about my readiness to assume an RN role	0.654	0.022	29.165	<0.001			
	I am comfortable asking for help	0.724	0.020	37.088	<0.001			
	I am satisfied with choosing nursing as a career	0.718	0.021	34.68	<0.001			
	I feel ready for the professional nursing role	0.749	0.020	38.216	<0.001			
Trials and Tribulations	I have difficulty documenting care in the electronic medical record	0.502	0.038	13.338	<0.001	0.778	0.814	0.534
	I have difficulty prioritizing patient care needs	0.678	0.030	22.709	<0.001			
	I feel overwhelmed by ethical issues in my patient care responsibilities	0.753	0.028	27.338	<0.001			
	I have difficulty recognizing a significant change in my patient's condition	0.925	0.022	41.464	<0.001			

Note. STD, standardized factor loading; SE, standard error.

Table 3: Pearson correlation and discriminate validity of the 18-item CFRPS-C.

	D1	D2	D3	D4
D1	1			
D2	0.792 (0.691~0.892)	1		
D3	0.847 (0.801~0.891)	0.898 (0.801~0.994)	1	
D4	−0.213 (−0.361~−0.064)	−0.257(−0.412~−0.102)	−0.248(−0.405~−0.091)	1

Note. D1 = clinical problem-solving; D2 = learning techniques; D3 = professional identity; D4 = trials and tribulations.

have completely remained, indicating that these factors can also assess the practice readiness of Chinese senior nursing students. But in this study, two items in the "Trials and Tribulations" dimension were deleted from the original CFRPS, namely, "I am comfortable delegating tasks to the nursing assistant" and "I have had opportunities to practice skills and procedures more than once" due to their poor interpret-ability to the whole Chinese version of the CFRPS. In addition, these items are not consistent with the Chinese nursing education background. During the 8-month clinical internships, the roles and responsibilities of Chinese senior nursing students are almost the same as those of clinical nurses. They all have many opportunities to practice nursing skills and procedures [5]. But they have to practice under the supervision of experienced clinical preceptors without nursing licenses [34]. Thus, the deletion of these two items also implied the importance of the scale cultural adjustment.

5. Strengths and Limitations

From a methodological perspective, this study has notable strengths. First, to ensure the accuracy of the translation and adaptation process, four experts who are knowledgeable about undergraduate nursing education issues in China and possess good English language skills were involved. Second, the use of CFA in the validation process enabled the assessment of construct validity. Finally, with a sample size of 590 Chinese senior nursing students who fully completed the questionnaires, this study had a sufficiently large sample for psychometric testing.

This study has several limitations. First, the convenience sampling method used in this study may limit the generalization of the findings. In addition, the study only included senior nursing students from one region in China, which may not be representative of senior nursing students in other regions. Further studies that include participants from various regions are necessary to confirm the validity of the Chinese version of CFRPS. Another limitation of the study is that the CFRPS is a self-report instrument, which may be influenced by social desirability bias. Participants may give a subjective or socially appropriate answer that does not accurately reflect their actual level of practice readiness. Future studies that use a combination of qualitative and quantitative methods may provide more comprehensive and accurate data. Besides, the survey was conducted from May 2021 to May 2022. The clinical experience of senior nursing students may be limited due to the online clinical practicum during the COVID-19 pandemic. Thus, the result obtained in this study is difficult to work as the norm for practice readiness of Chinese senior nursing students to compare with other studies.

6. Conclusion

The 18-item CFRPS-C demonstrated good construct validity and provides stronger psychometric support for the original CFRPS. Thus, the CFRPS-C is a useful tool to assess practice readiness among Chinese senior nursing students. Its brevity also enhances its convenience and practicality in clinical settings.

7. Implications for Nursing Management

New Nurses are the main supplier to the nursing workforce, and the transition issue contributes a lot to their retention rate. Nursing management should recognize the importance of practice readiness in the clinical practicum for senior nursing students, as it is a critical factor in their transition to professional clinical nurses and can affect their high turnover rate. Yet there is a lack of specific instruments to evaluate the readiness for practice in China. This study's adaptation and validation of the Readiness for Practice Instrument for Chinese senior undergraduate nursing students provide a valuable tool for evaluating practice readiness in China. Data from surveys with this scale in China may enrich and deepen the understanding of readiness for practice. Culturally specific strategies should be developed based on different cultures to optimize the readiness for practice and promote retention of the nursing profession.

Data Availability

The datasets generated and analyzed during the current study are not publicly available to ensure data confidentiality.

Additional Points

What Does This Paper Contribute To the Wider Global Clinical Community? (1) It adapts and validates a reliable and valid instrument to measure the readiness for practice among Chinese senior nursing students. (2) It provides increased psychometric support for the original Casey-Fink Readiness for Practice Survey. (3) It makes it possible to enrich the understanding of readiness for the practice among different cultures with the same instrument, to optimize the readiness, and help retention of the nursing profession.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Aims. The aim of this study was to adapt the Safety Climate Survey and examine its validity and reliability for use in the Turkish healthcare context. *Background.* Maintaining patient safety is a challenge for healthcare systems world-wide, and healthcare professionals need valid and reliable tools to measure improvements in safety. *Methods.* The Safety Climate Survey is unidimensional and contains 19 items, which are all five-point Likert-type scales as follows: 1 (totally disagree), 2 (disagree), 3 (neither agree nor disagree), 4 (agree), and 5 (totally agree). Language adaptation of the Safety Climate Survey conducted in accordance with the International Society for Pharma economics and Outcome Research (ISPOR) and expert assessments to calculate the content validity indices was undertaken in the first phase of the study. In phase two, a survey of 434 nurses employed in three hospitals in İzmir (Turkey) was conducted to test the construct validity with confirmatory factor analysis and internal consistency with Cronbach's alpha, split-half reliability, and item-total correlation. The intraclass correlation coefficient was also checked via test-retest reliability for stability. *Results.* The content validity index score was 0.97 for the scale and above 0.90 for the items, confirming excellent validity. The confirmatory factor analysis showed an adequate fit, and all the factor loadings were positive and greater than 0.30. Cronbach's alpha was 0.90, and Spearman–Brown coefficient 0.83, indicating good internal consistency. The item-total correlation coefficients were between 0.33 and 0.70, exceeding the acceptable level. The intraclass correlation coefficient value obtained was 0.84, reflecting a good level for time stability. *Conclusion.* The Turkish version of the Safety Climate Survey is a valid, reliable, and practical tool which can provide essential data on safety issues for healthcare professionals and administrators. *Implications for Nursing Management.* The instrument can be used in hospital settings to measure the safety climate among nurses, and the results obtained can be used to inform the development of safety improvement strategies.

1. Introduction

Patient safety concerns the prevention of patient harm caused by healthcare-related errors [1]. However, only 60% of care is based on evidence, or in accordance with guidelines, systems waste about 30% of all health expenditure, and 10% of patients experience harm [2]. The World Health Organization (WHO) also estimated that 1 in 10 patients in high-income countries is harmed while receiving hospital care, and in low and middle-income countries, 134 million adverse events occur, resulting in 2.6 million deaths [3]. This indicates that it is crucial to establish high-quality and safe system designs to provide optimal healthcare services [1].

The prevention of errors in healthcare services and the elimination or reduction of harm require a patient safety culture characterised by continuous improvement involving repetitive evaluations of the safety climate [4, 5]. For a safety culture to be adopted and embedded in institutions, healthcare professionals need to work with the wider health care team in the assessment and improvement of the safety climate [1], and strategies to involve them in decisions and activities that affect them would increase the likelihood of safety initiatives being successful [6]. For example, it would

be beneficial for healthcare organizations to formally assess patient safety processes at regular intervals (e.g., every six months) to identify the weaknesses in the system. One element of such an approach could be to examine safety climate [5]. Moreover, developing an approach to organizational learning focused on what works well in complex healthcare systems would result in more rapid improvement than relying solely on conducting investigations when processes fail [7].

The concept of a "safety culture" generally refers to the corporate values, and practices necessary to ensure safety are maintained, whereas the term "safety climate" focuses attention on employee perceptions of how patient safety is defined and managed [5, 8]. Studies which have examined the nature and scope of the safety climate have identified a number of common dimensions. These include the following: leadership commitment to safety, prioritization of safety, teamwork, communication, and safety systems [9–11]. Challenges to the delivery of effective, high-quality, and safe care tend to be the obverse of those listed above including lack of leadership support, staff work pressures, inadequate risk management, communication barriers, and limited resources [12]. Therefore, it is essential to monitor the extent and impact of these factors using robust methods to gather reliable data on safety issues [5]. Tools designed for this purpose include the Safety Attitudes Questionnaire [13], Patient Safety Culture in Healthcare Organizations [14], Hospital Survey on Patient Safety Culture [15], and the Safety Climate Survey [16].

In the present study, the Safety Climate Survey (SCS) was selected because it is unidimensional, yet takes account of complex nature of safety climate, and focuses on institution-wide improvement processes. Its unidimensional format with its 19 items was also a factor in its selection as this was likely to increase the likelihood that participants would complete the survey [5]. A large number of the items with multiple subdimensions in a survey tool scale can be off-putting and result in participants failing to complete an instrument [17]. Hence, the survey length may affect the reliability of the results obtained [18]. The fact that the scale has also been used successfully in different cultures/settings was also a factor in its selection [19].

1.1. Aim.
The aim of this study was to adapt the SCS and examine its validity and reliability features when applied to the Turkish nursing population.

2. Methods

2.1. Design.
The study was conducted in two phases as given as follows: (1) Translation and language adaptation of the survey. (2) Administration of the survey to nurses working in the Turkish health care settings. The translation and adaptation of instruments for cross-cultural research require rigorous planning and a robust methodological approach. We followed three sets of guidelines [20–22] for the reporting of the psychometric and psycholinguistic properties of the scale.

2.2. Setting.
To increase the likelihood of the generalizability of the findings, a university hospital and two public hospitals were selected, as providers in other parts of the country were similar in size and structure. The university hospital employed 748 nurses; one public hospital employed 376 nurses, and the other 761 nurses.

2.3. Sampling and Participants.
It has been recommended that to perform confirmatory factor analysis (CFA) effectively in validity and reliability studies, the number of participants (varying between 100 and 1000) should be at least seven times (in between 3 and 20) the number of items on the scale [23]. For test-retest, the recommended number of participants is between 50 and 100 [24, 25]. Taking these recommendations into account, we aimed to recruit a minimum of 418 participants (20×19 items require 380 participants, plus a nonresponse rate of %$10 = 418$). The final sampling frame was set at 434 nurses for the survey and 82 for the test-retest reliability element.

2.4. Measurement/Tool

2.4.1. Safety Climate Survey (SCS).
The unidimensional SCS, developed by Sexton, Helmreich, Pronovost, and Thomas [16], consists of 19 items whose responses are rated on a five-point Likert-type scale. The participants are asked to rate the items of the survey as follows: 1 (totally disagree), 2 (disagree), 3 (neither agree nor disagree), 4 (agree), and 5 (totally agree), 6 (have no idea/comment). The option "I have no idea/comment" is not included in the calculations. Item 18 is reversely scored. The total score is calculated by summing the scores given to all the items and dividing the result by the number of the items. At the end of the procedure, a mean score ranging from one to five is obtained. A score ≥3.75 indicates a positive safety climate perception. The reliability coefficient of the scale was 0.87 in the original study [16]. We also included questions about age, sex, education, length of service, unit worked in, and weekly working hours in addition to the SCS items in order to identify the participants' characteristics.

2.5. Data Collection.
Nurses were invited to participate if they met the following inclusion criteria: working full-time providing direct patient care for at least one year post-qualification. These criteria were necessary because some of the survey items require direct patient care and nursing experience. Nurses not providing direct patient care (e.g., polyclinics) or on sick/annual leave were excluded. A convenience sampling approach was used. During data collection, the researchers visited the hospitals according to the nurses' shifts -initial visit with two additional reminding visits- and distributed the survey to the staff nurses by hand in sealed envelopes. As there was no collection point, the researchers received the completed forms back in sealed envelopes, in person. The returns were given sometimes just immediately after the first visit. In others, it was in a week. Participation was voluntary. The researchers gave

information on the survey form and asked participants to fill in it. The final sample who agreed and completed the survey form was 434 in total.

2.6. Data Analyses. SPSS 22.0 (IBM Corp., Armonk, NY, USA) and LISREL 8.80 (Lincolnwood, IL: Scientific Software International, Inc.) programs were used for the analysis. Analyses involved confirmatory factor analysis (CFA), split-half method, and item-total correlation, as these have not been undertaken in previous studies. In the assessment of reliability of the instrument for use in the Turkish nursing setting, the test-retest method was used to measure stability, and Cronbach's α coefficient, Spearman-Brown coefficient, and item-total correlation were examined to measure internal consistency. For the validity analyses, content validity was assessed. The CFA was performed for construct validity. The statistical significance level was set at $p < 0.05$ (See Table 1 for a summary of the analytical approaches used).

2.7. Translation. In the adaptation process, it is crucial to select idioms and sentence structure that are understandable in the target language but which are consistent with the meaning in the original instrument. This may involve the replacement of particular phrases to ensure they are suitable for the target culture. For this purpose, a pilot study is recommended following the forward and back translations [22].

Forward-back translation was undertaken. Three translators with a good command of English performed the forward translation from the original language (English) to the target language (Turkish). Following forward translation, the researchers (authors), as recommended in the guidelines, checked and modified the items as necessary to eliminate the inconsistencies in the translations (For example, in item 6, "paid attention" was changed to "acted upon"). During the back-translation process from Turkish to English, two different translators, who did not see the scale items beforehand, translated the scales. The researchers then combined the two translations into a single form, and on receipt of approval from its authors [16], a pilot study was conducted with ten nurses to evaluate the items in terms of clarity. In the final part of the translation process, the researchers amended and revised the scale items based on the nurses' recommendations (for example, the wording of item 2, in which "unit" was changed to "clinical area").

2.8. Validity. We used the content validity index for content validity and confirmatory factor analysis for construct validity.

2.8.1. Content Validity. It is recommended that at least 5–8 experts are involved in evaluating the extent to which a survey tool addresses the phenomenon of interest [22, 26] and that the content validity index (CVI) is used [27]. For CVI, the measurement tools are first scored by experts (1 = not relevant, 2 = somewhat relevant, 3 = quite relevant, 4 = highly relevant). Then, the number of experts who gave

TABLE 1: Analyses used in the study.

Validity	Reliability
Language adaptation (face validity)	Stability
(i) Forward-back translation	
(ii) Pilot testing	(i) Test-retest
Content validity	Internal consistency
(i) Content validity index	(i) Cronbach's α
Construct validity	(ii) Split-half reliability
(i) CFA	(iii) Item-total correlation

"three" and "four" points for each item is calculated and then divided by the total number of experts. The result gives the CVI value. The threshold CVI value is 0.78 and above for the scale items (0.75 and above with 10 or more experts) and ideally 0.90 and above for the total scale [28]. In the present study, ten experts (eight nursing faculty members from different departments - experienced in methodological studies, and two clinical nurse managers - one from the ward, one from the critical care unit) assessed the scale items for their suitability. In line with these expert suggestions, the researchers reviewed the scale items' content and made changes in the words used and sentence construction before the survey was conducted [28]. For example, the fifth item was changed after the recommendations, that is, from "There is a leadership approach that focuses on patient safety throughout the institution" to "There is a leadership approach in this institution that directs employees to focus on patient safety." The CVI was between 0.80 and 1.00 for the scale items and 0.97 for the total scale. We found the CVI value calculated for experts to be 0.97. The expert panel agreed that the scale items are related to the scope of the scale with an agreement rate of over 80% (Table 2). See Table 2 for the CVI indices.

2.8.2. Construct Validity. Construct validity is the level of representation of the factors/items that are related to the construct in the measurement tool [27]. Examining the accuracy of these factors in the scale structure helps determine the suitability of the subdimension items. Two forms of factor analysis (exploratory and confirmatory) and structural equation modeling are the main methods for determining the level of construct validity. While variables in exploratory factor analysis (EFA) produce loadings on all factors, only factors assigned to the model produce loadings in confirmatory factor analysis (CFA). Therefore, CFA is regarded as the approach of choice for the cultural adaptation of measurement tools [29, 30]. Acceptable values for fit indices obtained as a result of CFA are as follows: Chi-square/Degrees of freedom: $2 \leq 3$, Normed Fit Index–NFI: ≥ 0.90, Comparative Fit Index- CFI: ≥ 0.95, Incremental Fit Index- IFI: ≥ 0.95, Goodness of Fit Index–GFI: ≥ 0.90, and Root Mean Squared Error of Approximation- RMSEA: ≤ 0.08 [31].

2.9. Reliability. We used the test-retest method to measure the stability of the scale. Cronbach's α coefficient, split-half analysis, and item-total correlation were selected to determine its internal consistency.

Table 2: Content validity indices.

Expert–item	E1	E2	E3	E4	E5	E6	E7	E8	E9	E10	Agreement	CVI (agreement/total)
1	+	+	+	+	+	+	+	+	—	+	9	0.90
2	+	+	+	+	+	+	+	+	+	+	10	1.00
3	+	+	+	+	+	+	+	+	+	+	10	1.00
4	+	+	+	—	+	+	+	+	+	+	9	0.90
5	+	+	+	—	+	+	+	+	—	+	8	0.80
6	+	+	+	+	+	+	+	+	+	+	10	1.00
7	+	+	+	+	+	+	+	+	+	+	10	1.00
8	+	+	+	+	+	+	+	+	+	+	10	1.00
9	+	+	+	+	+	+	+	+	+	+	10	1.00
10	+	+	+	+	+	+	+	+	+	+	10	1.00
11	+	+	+	+	+	+	+	+	+	+	10	1.00
12	+	+	+	+	+	+	+	+	+	+	10	1.00
13	+	+	+	+	—	+	+	+	+	+	9	0.90
14	+	+	+	+	+	+	+	+	—	+	9	0.90
15	+	+	+	+	+	+	+	+	+	+	10	1.00
16	+	+	+	+	+	+	+	+	+	+	10	1.00
17	+	+	+	+	+	+	+	+	+	+	10	1.00
18	+	+	+	+	+	+	+	+	+	+	10	1.00
19	+	+	+	+	+	+	+	+	+	+	10	1.00
Agreement	19	19	19	17	18	19	19	19	16	19		CVI item 0.97
CVI	1.00	1.00	1.00	0.89	0.95	1.00	1.00	1.00	0.84	1.00		CVI expert 0.97

2.9.1. Test-Retest. This involves the measurement of the tool using the same sample group twice at a specified interval [27]. A recommendation for the sample size is between 50 and 100 [24, 25], and the interval between the two measurements should be at least 10–14 days to avoid the possibility of participants remembering the items [32]. The intraclass correlation coefficient (ICC) was used for interpretation with the ICC values being evaluated in four classifications (<0.5: poor, 0.5–0.75: moderate, 0.75–0.9: good, >0.9: excellent) [33].

2.9.2. Cronbach's Alpha. The alpha coefficient (or Cronbach's alpha) is normally calculated to evaluate internal consistency [27]. The range value varies between 0 and 1. High values support the internal consistency of the scale [27]. Ideally, threshold values should be equal to or above 0.70 [34].

2.9.3. Split-Half Method. It is another method for determining levels of internal consistency. It is calculated by dividing the total of items into halves. The Spearman–Brown coefficient is used [35], and 0.70 and above are regarded as acceptable [34].

2.9.4. Item-Total Correlation. It indicates the items' suitability (whether they will change or not) and the correlation values with the score of each item that is examined. An acceptable level value is above 0.20 [36].

2.10. Ethical Considerations. Ethical approval for the conduct of the study was provided by a University Research Ethics Committee (Decision No: 2015/02–20). Agreement to recruit nursing staff was obtained from the executive nursing management of the respective hospitals, and permission via e-mail to use the SCS was confirmed by its developers.

3. Results

The mean age of the participants was 35.29 (SD = 7.12), and the majority (92.9%) were female. Two-thirds of the nurses (66.6%) held an undergraduate degree. The distribution of nurses by hospitals was similar in numbers. The average length of professional experience was 13.38 (SD = 7.85) years, and the average weekly working hours were 45.42 (SD = 6.51) (further information about the respondents' socio-demographic details and work-places can be found in Table 3).

3.1. Psychometric Properties

3.1.1. Validity. Table 4 shows the confirmatory factor analysis results, presenting the fit indices for the current study findings and acceptable level indices. The scores indicate that the model satisfies the threshold values. Additionally, all the factor loadings of the items were positive and standardized loadings ranged from 0.31 to 0.78, which are above the accepted cut-off value of 0.30.

3.1.2. Reliability. We evaluated the scale's stability with test-retest (two weeks apart). During the analysis, we marked two-way mixed as the model and absolute agreement as the type. We then identified the intraclass correlation coefficient as 0.84 (95% confidence interval, lower limit 0.71, upper limit 0.91) between first and post-test total mean scores ($n = 82$). The results obtained indicate that the time invariance is good.

TABLE 3: Participants' socio-demographic and work-related characteristics ($n = 434$).

Characteristics	n	%
Age (35.29 ± 7.12)		
Sex		
Women	403	92.9
Men	31	7.1
Education		
High school graduate	26	6
Associate degree	66	15.2
Bachelor's degree	289	66.6
Graduate degree	53	12.2
Hospital		
University hospital	169	38.9
Public hospital 1	125	28.8
Public hospital 2	140	32.3
Units		
Internal medicine units	171	39.4
Surgical units	174	40.1
Critical care units (intensive care and emergency services)	89	20.5
Tenure (13.38 ± 7.85)		
Weekly working hours (45.42 ± 6.51)		

TABLE 4: Confirmatory factor analysis indices.

Fit indices	Acceptable fit	Present study
$\chi(2)/d.f.$	$2 \leq 3$	3.28 $\chi(2) = 482.2$, d.f. = 147, $p = 0.01$
NFI	≥0.90	0.95
CFI	≥0.95	0.97
IFI	≥0.95	0.97
GFI	≥0.90	0.90
RMSEA	≤0.08	0.07

We tested the internal consistency with Cronbach's alpha, split-half reliability, and item-total correlation. The score for the Cronbach alpha was 0.90 and for Spearman–Brown coefficient 0.83, which are above the acceptable level. Table 4 presents the item-total correlations.

We determined the item-total correlation coefficients to be between 0.33 and 0.70 (acceptable level). The lowest scores are in the first and nineteenth items, and the highest score is in the fifth item (Table 5). The original survey items presented in Table 5 are reproduced from [16].

4. Discussion

The analysis demonstrated that the scale has acceptable psycholinguistic and psychometric properties in the Turkish nursing context, which was confirmed on examination of CFA, split-half reliability, and item-total correlations. We discussed the results of the analysis under separate subheadings in the following sections.

4.1. Reliability

4.1.1. Stability. As a result of the test-retest performed at two-week intervals, the ICC coefficient in this study was 0.84. Kho et al. [37] determined the ICC value as 0.92 in their study conducted in four intensive care units in a tertiary medical center in Ontario, Canada. The results obtained support the good level of time stability for both studies.

4.1.2. Internal Consistency. In the current study, Cronbach's alpha value was 0.90, and the item-total score correlation coefficients were between 0.33 and 0.70. Kho et al. [37] found the Cronbach's alpha value to be 0.86, and in work with surgical residents in the Netherlands, it was 0.87 [38]. Similarly, a study involving 523 physicians and 1321 nurses

working in the operating rooms and surgical services of Swiss hospitals found a value of 0.86 for the German version and 0.84 for the French version [19]. A Cronbach alpha value of 0.70 and above in these adaptation studies in different countries provides evidence for the internal consistency of the scale.

We could not locate an adaptation study comprising split-half reliability and item-total score correlation analysis, and so, these analyses in the present study are the first to provide evidence of these elements of the internal consistency of the scale.

4.2. Validity

4.2.1. Content Validity. CVI values were equal to or above 0.80, which exceeded the threshold value of 0.78 in this study. Martowirono et al. [38] focused on the "appropriateness" of the items, in terms of their scale and scope, rather than of the CVI, and resident physicians evaluated the scale items against this criterion. They concluded that the scale items were appropriate for determining the nature of the safety climate. In the same study, the percentage values of the responses of "(6) I have no idea/comment" were calculated for each scale item to support the content validity. The percentage was below 10% for all scale items, and a value of ten percent was considered acceptable [38].

4.3. Limitations. Since the data reflect the participants' perceptions, it is important to take this into account when evaluating and interpreting the findings. In addition, nurses working in private hospitals did not participate, and so, caution may be needed when generalising to other settings.

5. Implications for Nursing Management

For patient safety to become embedded in the culture of an organisation, all management levels and the healthcare teams need to prioritize patient safety, establish manager-employee cooperation, and regularly revise patient safety policies and procedures and implement them [39]. The present study demonstrates that the SCS is suitable for use in the Turkish healthcare setting and could be used as part of a continuous programme of quality improvement. It is unidimensional, has 19 items, is acceptable to nurses, and helps highlight issues that require action to improve patient safety. It is not a solution but could certainly be part of a comprehensive approach to prioritizing patient safety, leadership, and learning from mistakes [10, 40]. The data

TABLE 5: Item-total correlation coefficients.

Items	r
(1) The culture of this clinical area makes it easy to learn from the mistakes of others	0.33
(2) Medical errors are handled appropriately in this clinical area	0.63
(3) The senior leaders in my hospital listen to me and care about my concerns	0.52
(4) The physician and nurse leaders in my areas listen to me and care about my concerns	0.67
(5) Leadership is driving us to be a safety-centered institution	0.70
(6) My suggestions about safety would be acted upon if I expressed them to management	0.66
(7) Management/leadership does not knowingly compromise safety concerns for productivity	0.40
(8) I am encouraged by my colleagues to report any safety concerns I may have	0.61
(9) I know the proper channels to direct questions regarding patient safety	0.61
(10) I receive appropriate feedback about my performance	0.52
(11) I would feel safe being treated here as a patient	0.64
(12) Briefing personnel before the start of a shift (i.e., to plan for possible contingencies) is an important part of safety	0.57
(13) Briefings are common here	0.62
(14) I am satisfied with the availability of clinical leadership	0.61
(15) This institution is doing more for patient safety now, than it did one year ago	0.66
(16) I believe that most adverse events occur as a result of multiple system failures, and are not attributable to one individual's actions	0.41
(17) The personnel in this clinical area take responsibility for patient safety	0.66
(18) Personnel frequently disregard rules or guidelines that are established for this clinical area	0.68
(19) Patient safety is constantly reinforced as the priority in this clinical area	0.33

also suggest that the SCS can be used successfully in a range of other geographical and health care settings [5, 19, 38].

6. Conclusion

The SCS is reliable, has good time stability, a good Cronbach's alpha value, and acceptable item-total correlation coefficients for use in Turkish health care. It is also valid in terms of language, content, and the model fit. These findings reinforce the evidence for the suitability of the scale for use in a range of settings. However, further work is needed to investigate the impact of the use of the SCS on patient safety outcomes.

Aim. To synthesise the available evidence on the applicability of artificial intelligence in nursing care. *Background.* Artificial intelligence involves the replication of human cognitive abilities in machines, allowing to perform tasks that conventionally necessitate human cognition. However, its application in health sciences is a recent one, and its use is currently limited to supporting the diagnosis and prognosis of hospitalised patients, among others. *Evaluation.* A systematic review was conducted in the PubMed-Medline, Scopus, CINAHL, Web of Science, and Nursing & Allied Health databases until September 2022, following the PRISMA guidelines. *Key Issues.* A total of 21 articles were selected for the review. The different applications of artificial intelligence in nursing identified comprised (i) advances in early disease detection and clinical decision making; (ii) artificial intelligence-based support systems in nursing for patient monitoring and workflow optimisation; and (iii) artificial intelligence insights for nursing training and education. *Conclusion.* Artificial intelligence-based systems demonstrated increased autonomy of patients and professionals in care processes such as wound management through guided instructions, improved workflows, and efficiency in terms of time, materials, and human resources. *Implications for Nursing Management.* Artificial intelligence applied to nursing practice can be a very useful resource for professionals, managers, and supervisors. It has the potential to change current working flow systems and may serve as a down-to-earth resource to support nursing professionals in their decision-making process that ensures high quality and patient safety care.

1. Introduction

Artificial intelligence (AI) refers to the simulation of human intelligence in machines that are designed to perform tasks that typically require human cognition, such as problem solving, decision making, and pattern recognition [1, 2]. Due to its access to information, AI-based support systems can assist in making clinical decisions and therefore achieve better medical attention based on evidence [3–5]. In order to understand what AI entails, it is important to consider the various functions that contribute to its intelligence. These functions include machine learning (ML), natural language processing (NLP), behavioural pattern recognition, search engine capabilities, image and sound analysis, environmental perception, databases, information classification, and artificial neural networks. Additionally, another important aspect of AI is robotic process automation (RPA), which refers to the use of software robots to automate repetitive and routine tasks and physical robots, which are physical machines that can be programmed to perform tasks in the physical world [6, 7] (Figure 1).

Machine-learning-based systems	Robotic process automation	Natural language processing systems	Physical robots
• Data analysis method based on algorithms to automatically improve their performance on a specific task through experience. • Automatic improvement through trial and adaptation. • Complex structures: neural network and profound knowledge. • Their success depends on the quality and quantity of data used for training, the choice of algorithm, and the design of the system.	• Allows for the automation of manual, repetitive, and time-consuming tasks through software robots. • Digital programmes that perfect workflows. • Ability to extract relevant data and update previous records. • They offer benefits such as increased efficiency, reduced errors and manual intervention, improved compliance, and lower costs compared to traditional manual processes.	• Ability to extract and analyse clinical information from descriptive data. • Classifies and predicts responses based on previous consultations. • Mimetic systems of expert reasoning based on a set of rules, favouring dynamic and adaptive knowledge. • Advancements in deep learning and language models have significantly improved the accuracy of NLP systems in recent years.	• Machines that usually have a human appearance designed to perform a specific task or set of tasks. • Ability to collaborate in healthcare processes. • They can range from simple, single-function devices to complex, multi-functional systems capable of operating in various environments, including industrial, domestic, and hazardous settings.

FIGURE 1: Types of artificial intelligence and their main characteristics in selected articles.

The application of AI as a support system in healthcare has gained special relevance in recent decades, mainly as a result of growing data ecosystems in healthcare systems [8, 9]. In general terms, AI-based support systems offer a potential resource for reducing the cost of healthcare, increasing the efficiency of said services, and creating a highly valued support system for the well-being of patients and the healthcare sector in general, contributing to the satisfaction and clinical safety of patients and their family members [3–5]. However, the introduction of AI-based support systems in nursing care continues to cause concerns and debates due to the fear that this type of technology could eventually replace human interactions, jeopardising the ethics of care, and above all, that AI could eventually replace the functions of nurses [10]. Other ethical issues include the management of bias in data and its use to generate algorithms [11]. Despite the challenges, the use of AI in nursing aims to provide support and improve outcomes. As observed in the literature, the technology can address certain issues such as lack of expertise or inadequacy in experience, streamline documentation, and provide access to current evidence-based practices to ensure high-quality patient care, thus reducing the feeling of frustration that professionals have due to the organisational burden [10, 12]. Nurses play a crucial role in the delivery of patient care, and the increasing demand for high-quality, evidence-based practices has put pressure on the nursing workforce to stay up to date with the latest technological advancements [12]. In this regard, AI has the potential to support nursing practices by providing real-time decision support, reducing the time spent on administrative tasks, and facilitating the efficient management of patient data and care [13, 14].

In light of the rapidly evolving technological advancements in healthcare, it is important to evaluate the potential applications of AI on nursing practice. In this vein, recent systematic reviews have revealed promising results that AI can offer in the area of diagnosis and prognosis of certain clinical situations, such as cancer or new-onset pathologies in hospitalised patients [15, 16]. However, to our knowledge, the current body of literature that focuses on the application of different types of AI-based support systems in nursing is still limited, despite constituting one of the largest potential users of this type of technology as experts in caregiving. Thus, the aim of this review was to synthesise the available evidence on the applicability of artificial intelligence in nursing care.

2. Methods

2.1. Design. A systematic review was conducted in September 2022, following the recommendations of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statements [17] (Supplementary File 1). The clinical question that responds to the aim of this review used a PCC structure (population-concept-context) [18] and is stated as follows: What is the applicability of artificial intelligence (C) in nursing (P) for patient care (C)? The review protocol was not registered.

2.2. Search Strategy. The databases that were consulted include PubMed-Medline, Scopus, CINAHL, Web of Science, and Nursing & Allied Health. In order to identify potential studies in the different databases, a search strategy was developed in collaboration with a research librarian and an information specialist that combined natural and structured language through the Medical Subject Headings (MeSH) (Table 1).

2.3. Selection Criteria. The inclusion criteria for the study were as follows: (i) original studies that focused on the use of AI in nursing and healthcare practice or (ii) nursing education, (iii) published in English or Spanish, and (iv) published until September 2022. Articles relating to nursing education were regarded as an integral part of nursing practice, as it furnishes the necessary knowledge and skills for providing quality patient care. On the other hand, (i)

TABLE 1: Search strategies used in each database.

Database	Search strategy
PubMed-Medline	((Artificial intelligence[Title/Abstract]) OR (artificial intelligence[MeSH terms])) AND ((((nurse[Title/Abstract]) OR (nurses[Title/Abstract])) OR (nursing[Title/Abstract])) OR (nursing[MeSH terms]))
Scopus	TITLE-ABS-KEY ("nurses") OR TITLE-ABS-KEY ("nurse") OR TITLE-ABS-KEY ("nursing") OR INDEXTERMS ("nursing") AND TITLE-ABS-KEY ("artificial intelligence") OR INDEXTERMS ("artificial intelligence")
CINAHL	(((((MH "nursing") OR (TI "nursing") OR (AB "nursing")) OR ((TI "nurses") OR (AB "nurses")) OR ((TI "nurse") OR (AB "nurse")))) AND ((TI "artificial intelligence") OR (AB "artificial intelligence") OR (MH "artificial intelligence")))
Web of Science	(((((((TI=(nurse)) OR AB=(nurse)) OR TI=(nurses)) OR AB=(nurses)) OR TI=(nursing)) OR AB=(nursing)))) AND ((TI=(artificial intelligence)) OR AB=(artificial intelligence))

review studies, (ii) republications, (iii) editorials, and (iv) studies on animals were not considered.

2.4. Data Screening. The initial selection process in this study involved searching through the main health science databases (as listed in Table 1) to locate relevant evidence on the topic being addressed. This was followed by a two-stage screening process. In the first stage, two researchers (A.M.-O. and M.R.-A.) conducted an independent and parallel reading of the titles and abstracts of the available articles, taking into account the predefined selection criteria [19]. After this stage, duplicates were removed.

In the second stage, the selected articles underwent a more in-depth reading by the reviewers. To ensure methodological rigidity, a third auditor (P.R.) was consulted in case of any discrepancies, and a consensus on article eligibility was reached through rechecking the information [20]. Finally, the authors evaluated the methodological quality of the selected articles and classified them based on the type of AI used, the target population, and the purpose for which it was implemented [21].

2.5. Quality Evaluation. Appropriate methodological quality analysis tools were utilised for each study, using the Joanna Briggs Institute (JBI) Critical Appraisal Tools [22]. For articles with a mixed design, methodological quality was assessed with the Mixed Methods Appraisal Tools (MMAT) [23, 24].

2.6. Data Abstraction and Synthesis. The reviewers held discussions to determine the variables, as well as the nature and extent of the information to be extracted from the eligible articles, to ensure consistency and clarity of charted data [25]. After piloting on a sample of 5 articles, a custom data extraction was created in Microsoft Excel and iterated on. The most significant data of the selected studies included (i) author(s) and publication year, (ii) study design, (iii) participants and population, (iv) variable(s), (v) type of artificial intelligence, (vi) application in nursing practice,

(vii) main findings, and (viii) mean level of compliance in the evaluation of methodological quality. Meta-analysis was not considered due to the heterogeneity of methodologies among the selected articles. Once the data were extracted, they were reviewed and discussed to deductively organise the main findings into clear and explicit categories in order to provide a critical synthesis of the cumulative evidence [26, 27].

3. Results

The initial search yielded a total of 3,443 documents. After eliminating duplicates and selecting the articles by title and abstract, 56 full-text publications were reviewed according to the established selection criteria. In the end, a total of 21 articles were included in this review (Figure 2).

3.1. Included Studies. The synthesis of the included studies can be seen in Table 2. The sample size of the studies ranged from 10 participants to 230,936 participants, with a mean sample size of 14,948 participants. The predominant study population consisted of ambulatory patients ($n = 10$), healthcare professionals ($n = 7$), hospitalised patients ($n = 5$), students ($n = 3$), and caregivers ($n = 1$). Regarding the aim of the study, the different applications of artificial intelligence were differentiated as a support system for early disease detection ($n = 4$), clinical decision making ($n = 3$), patient monitoring ($n = 7$), workflow optimisation ($n = 3$), and nursing training and education ($n = 3$). In addition, some descriptive studies ($n = 1$) analysed the acceptance of the use of AI in the healthcare setting from a social and occupational perspective. Overall, 18 studies (85.7%) showed positive results in the application of this technology in nursing practice, while 3 studies (14.28%) indicated no impact on their results.

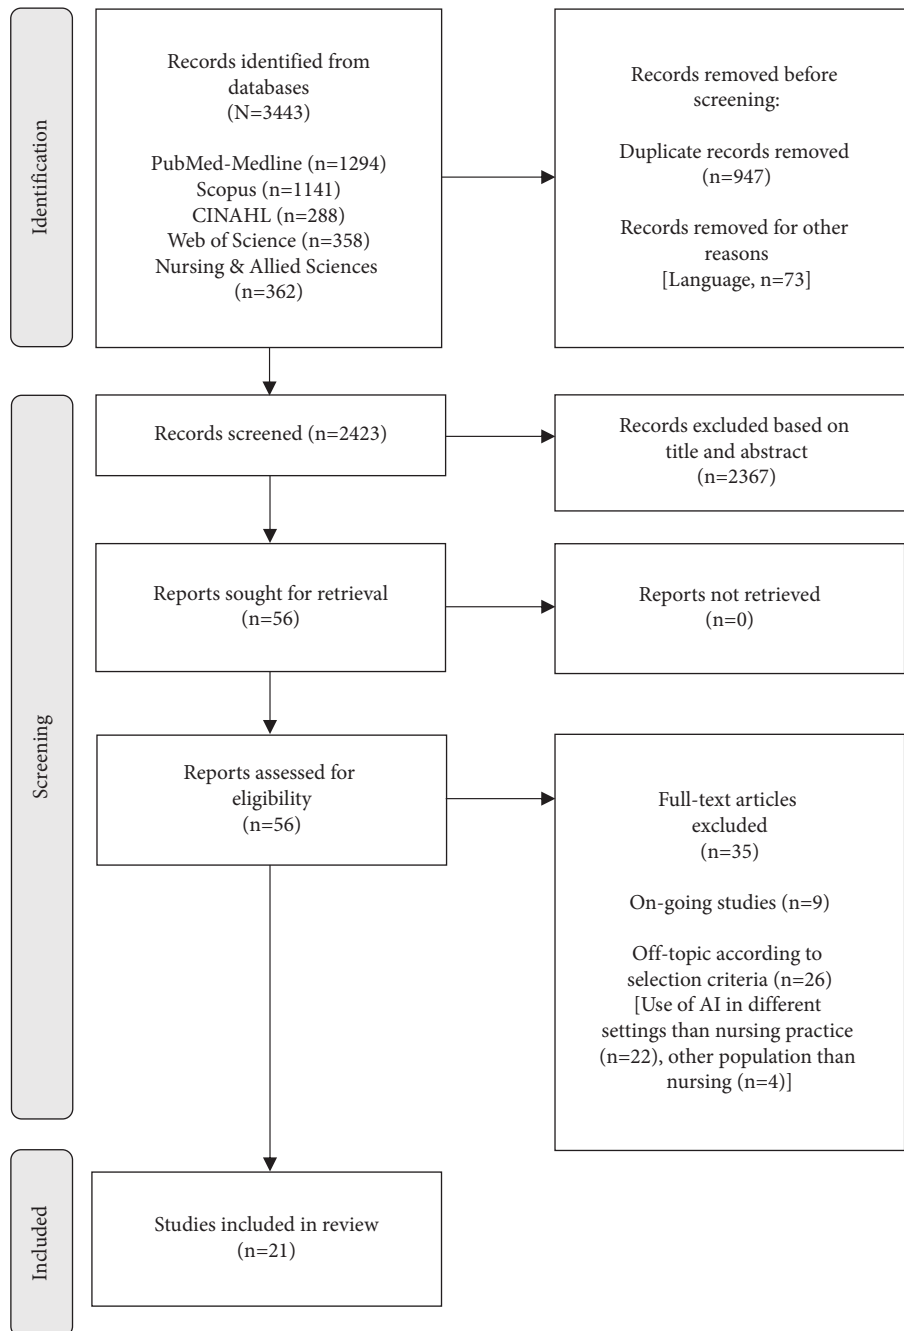
3.2. Methodological Quality: Assessment of Bias. The evaluation of the methodological quality of the articles included in this review showed a mean level of compliance of 74.60%. The interval risk of bias between the studies was


FIGURE 2: Flowchart depicting the article selection process.

88.8% ($n = 2$) to 42.85% ($n = 1$) (Supplementary File 2) [22, 23].

The results of this review were presented based on the application of each type of AI discussed in the selected articles [28]. Thus, the categories used for the qualitative comprised the advancements in early disease detection and clinical nursing decision making, the utilisation of AI-based support systems for patient monitoring and workflow optimisation, and the use of AI for nursing training and education. The main AI-based systems studied include ML, RPA, NLP, and physical robots (Figure 1) [29–31].

3.3. Advances in Early Disease Detection and Clinical Decision Making. Of the selected studies, 33.33% ($n = 7$) applied AI technology based on ML models, of which 57.14% ($n = 4$) were used for the early disease detection. The diagnostic criteria of nurses and doctors improved by 12% and 10%, respectively, as a result of assistance from AI. This led to improved diagnosis of complex conditions, enhancing the accuracy and effectiveness of patient care. Likewise, the professionals who used AI reported an increase in their confidence in evaluations and clinical decision making by providing real-time analysis and interpretation of patient data and a decrease in biopsy requests, highlighting the

TABLE 2: Overview of selected articles.

Authors (year)	Design	Participants (n) and population	Variable (s)	Type of AI	Application in nursing	Main findings	MLC (%)
Dinesen et al. (2022)	Exploratory study	39 patients with dementia	Perceptions about the response in the mood of the patients	Physical robot	Social work and accompaniment	The patient's mood improved, making them feel calmer and improving the interaction with the subject	88.88
Chang (2022)	Quasi-experimental study	43 postgraduate nursing students	Teaching intervention with virtual reality and learning achievements	NLP	Nursing education	The most valued positive aspects were the availability of a safe environment, the possibility of multiple attempts, overcoming difficulties, the consolidation of knowledge, and professional empowerment	88.88
Cho et al. (2022)	Prospective intervention study	19 triage nurses	Time, completion rate of records, and accuracy	NLP	Registration and classification of patients by voice	Improved patient registration and classification time, requiring a technical complement for improved sensitivity and accuracy	81.81
Chan et al. (2022)	Cross-sectional prospective descriptive study	28 ambulatory and hospitalised patients	Wound length, width and area, device reliability	Robotic process automation	Wound treatment	Excellent reliability. Useful for monitoring diabetic foot ulcers with a statistically significant difference compared to traditional measures.	87.5
Jain et al. (2021)	Case series study	40 doctors and nurses	Agreement with dermatologists and confidence in the diagnosis	Machine learning	Diagnosis and decision making	Improved nursing diagnosis by 10% and 12%, respectively	80.0
Lima-Roque et al. (2021)	Descriptive study	17 ambulatory patients, main caregivers, and nurses	Content validity (identify characteristics of the wound and healing process). Participant satisfaction.	NLP	Wound treatment	Excellent content validity. A great help for wound management and easy to use. Adapted to the general population.	50.0
Chang et al. (2021)	Quasi-experimental study	36 nursing students	Learning, student confidence in the course, and user satisfaction	NLP	Nursing education	The chatbot improved student learning compared to traditional teaching techniques with statistically significant results	77.7
García-García et al. (2021)	Retrospective cross-sectional descriptive study	11,586 ambulatory and hospitalised patients	System sensitivity, specificity, and precision with AI	Machine learning	Diagnosis and decision making	Able to better identify cases of cardiac amyloidosis when the sample contained many patients with heart failure. No external validity.	87.5

TABLE 2: Continued.

Authors (year)	Design	Participants (n) and population	Variable(s)	Type of AI	Application in nursing	Main findings	MLC (%)
Hong et al. (2021)	Randomised clinical trial	447 ambulatory patients with COPD	Quality of life, hospital stay, admissions for exacerbations, and visits to the doctor. Patient satisfaction.	Physical robot	Remote monitoring	Remote monitoring alerted healthcare providers to COPD complications. The exercises carried out with the robot reduced hospital admissions and improved the quality of life of patients.	53.8
Jang et al. (2021)	Descriptive study	117 doctors and nurses	Perceptions about the necessary functions of the robot	Physical robot	Remote monitoring	The most requested functions in the surveys were measuring vital signs, obstacle detection, and the alarm system, among others	62.5
Bian et al. (2020)	Mixed exploratory study	270 outpatients	On-call time, feedback, and type of patient feedback	NLP	Remote monitoring	The nurse received less feedback than the AI. The on-call time was similar in both. The AI tracked 5–7 patients at a time.	71.4
Poncette et al. (2020)	Descriptive study	86 ICU nurses and doctors	Opinions and perceptions of AI to improve work in the ICU	Machine learning	Remote monitoring	93% were in favour of using wireless sensors and reducing false positive alarms. Refusal to use a smart watch and augmented reality glasses for patient monitoring.	62.5
Shorey et al. (2020)	Qualitative study	30 nursing students and clinical professors	Advantages and disadvantages of virtual reality in learning communication skills	NLP	Nursing education	The most cited positive aspects were the availability of multiple attempts, a comfortable and safe environment, and instant feedback from the virtual patient	80.0
Lee et al. (2020)	Mixed study	198 hospitalised and healthcare centre patients	Perceptions about the necessary functions of the robot	Physical robot	Remote monitoring	Some of the advantages cited were access to clinical reports, communication with health professionals, and physical and emotional support	85.7
Sandhu et al. (2020)	Qualitative study	15 nurses and emergency room doctors	Perceptions and experiences about the usefulness of the application and considerations when implementing AI	Machine learning	Diagnosis and decision making	Triage nurses had a positive impression of sepsis control, while clinicians suggested that they would be more confident in the model if it had fewer false positives	80.0

TABLE 2: Continued.

Authors (year)	Design	Participants (n) and population	Variable (s)	Type of AI	Application in nursing	Main findings	MLC (%)
Ginestra et al. (2019)	Descriptive observational study	287 doctors and nurses	Usefulness of the alert, impact on care	Machine learning	Diagnosis and decision making	Despite the excellent predictive characteristics of the EAS, new clinical information or changes in treatment were rarely reported	87.5
Boumans et al. (2019)	Randomised clinical trial (pilot)	42 outpatients	Time to complete the interview. Fragility, well-being, and resilience index. Acceptance of the robot.	Physical robot	Diagnosis	The questionnaires were completed faster by the nurse than the robot. Resilience index data were more accurate in the nurse than in the robot.	76.9
Rojas et al. (2018)	Retrospective cohort study	24,885 hospitalised patients in the ICU	Sensitivity, specificity, and ABC of the AI system	Machine learning	Remote monitoring	The GBM obtained significantly higher sensitivity and ABC ($p < 0.001$) than the SWIFT and MEWS scales	63.6
Jibb et al. (2018)	Randomised clinical trial (pilot)	40 oncology Paediatric ambulatory	Pain and fear with FPS and BAAS scales. Time needed to complete interaction. Acceptance of the robot.	Physical robot	Management of pain and fear	The control group with a distracting robot felt more relaxed than the intervention group with a conductive therapy robot. Both managed to relieve pain and stress.	84.6
Horng et al. (2017)	Retrospective cohort study	230, 936 emergency room patients	Sensitivity, specificity, and ABC of the AI system	Machine learning	Diagnosis and decision making	The use of vital signs together with freely formulated text improved the criteria for an infectious diagnosis, increasing the sensitivity and specificity of the system. The ABC was higher in the model that evaluated all of the variables.	72.7
Parimbelli et al. (2016)	Mixed study (pilot)	10 ambulatory patients with AF	Compliance with prescribed treatment	NLP	Remote monitoring	MobiGuide increased treatment adherence for AF patients and the availability of up-to-date clinical data. Interdisciplinary work was improved.	42.8

ABC: area below curve; BAAS: behavioural approach-avoidance scale; COPD: chronic obstructive pulmonary disease; EAS: early alert system; AF: atrial fibrillation; FPS: face pain scale; GBM: gradient boosting machine; AI: artificial intelligence; MEWS: modified early warning score; MLC: mean level of compliance; NLP: natural language processing; SWIFT: stability and workload index for transfer; ICU: intensive care unit.

improvement in the dermatological field and in the detection of certain cardiac diseases, such as cardiac amyloidosis [31, 32]. In the same manner, the research by Ginestra and collaborators [33] and Sandhu and collaborators [34] used different AI-based support systems for early warnings of sepsis risk through static (demographics and previous illnesses) and dynamic (vital signs and laboratory data) patient characteristics. Conversely, Horng and collaborators [35] used a ML system combined with NLP to assess the ability to diagnose patients by adding comments that doctors and nurses wrote in medical records. Thus, the specificity, sensitivity, and area under the curve for the detection of sepsis were higher in the model that used the comments from medical records than those intelligent systems that only evaluated static and dynamic characteristics.

Finally, one of the main measures used in the studies to assess the effect of AI on clinical nursing practice was the use of reference diagnoses. [31, 32], in which at least three certified physicians independently reviewed each case. These diagnoses were obtained through a collective intelligence approach, in which the different differential diagnoses of each physician were ranked through a voting system to finally obtain a principal or reference diagnosis, in order to assess the effect produced by the AI in each case [7, 32, 36]. On the other hand, satisfaction surveys were used as a method of measuring the effect of AI on nurses, patients, and students [30, 36, 37].

3.4. AI-Based Support Systems in Nursing for Patient Monitoring and Workflow Optimisation.

Poncette and collaborators [38] demonstrated in their results that 93% of participants from intensive care units (ICUs) were in favour of the use of AI-based support systems, specifically the use of wireless sensors to reduce false positive alarms. In regard to predicting the risk of readmission in these units, the conventional scales used obtained significantly lower sensitivity and area under the curve, compared with models that used ML algorithms [39]. In 4.76% ($n = 1$) of the studies included in this review, programmes that integrated image recognition were also analysed to extract data and update the medical records of patients [40]. Specifically, programmes carried out to manage diabetic foot ulcers were evaluated by three different devices and their effectiveness was compared with an expert wound care nurse, demonstrating excellent intra-reliability and inter-reliability in their results with a value greater than 0.9 in length, width, and wound area.

Regarding the use of a conversational agent or chatbots, authors such as da Silva Lima Roque et al. [41] examined its use for examining and identifying personalised wound treatments. The content validity of this resource was rated as excellent by healthcare experts in wounds, and the images shown to the users were comprehensible in 88% of the cases. Among the participants, the most repeated assessments of the AI-based support system were easy to use, suitable for any user, dynamic, entertaining, and quick to

respond. However, they also pointed out negative aspects such as a lack of realism or failures to capture long sentences [29, 36]. Lastly, another AI modality, rule-based expert systems, was studied in 4.76% ($n = 1$) of the studies, with the aim of telemonitoring patients with known atrial fibrillation [42]. These intelligent systems were programmed with established guidelines recognised in a clinical practice guide with personalised recommendations for each patient, improving adherence to treatment, availability of clinical data in real time, and its control from the medical community. Likewise, another resource used was telephone follow-up for postsurgical patients [43], comparing the call time and the feedback received between an AI system and a nurse. The call time was shorter in the intelligent system (1-2 min) and with better feedback when compared to that of the nurse (3–6 min) ($p < 0.01$), though the effectiveness of the follow-up was the same in both situations.

Of all the articles analysed, 28.57% ($n = 6$) used robots with AI-based technology for various uses in patient monitoring and workflow optimisation, including rehabilitation and respiratory exercises [44], evaluation of the elderly and accompaniment of people with dementia [45, 46], and behavioural therapy [47]. Likewise, the characteristics and aspects to consider in the design and inclusion of robots in the healthcare field were examined [48, 49]. Using robots for rehabilitation and respiratory exercises in patients with COPD has been shown to be effective in reducing hospital readmissions, the workload of nursing professionals, and visits to health centres or surgeries [44]. On the other hand, in other studies that used these devices to study frailty in the elderly [45, 46] or in behavioural therapy to relieve pain in subcutaneous punctures in infants [47], no differences were observed in the average time of execution or precision and no statistically significant differences were observed in pain control. However, it did prove to be an effective way to distract children.

3.5. AI Insights for Nursing Training and Education.

There is a growing interest exploring the potential of AI-based support systems to improve nursing training and education. A recent study by Chang [37] investigated the use of AI-powered simulation to enhance nursing clinical decision-making skills. The results showed that students who underwent AI-enhanced simulation training performed significantly better on clinical decision-making assessments compared to those who received traditional simulation training. Chatbots were used with similar results to support nursing training about vaccines for pregnant women, showing significantly better results ($p < 001$) regarding the expertise and level of knowledge on the subject, thereby improving the care and safety received by the patient [36, 37]. Similarly, other studies concluded that AI-based educational resources have the potential to increase engagement and enhance their learning outcomes in nursing education. These findings suggest that AI has the potential to

play an important role in improving nursing training and education [29, 36].

4. Discussion

The aim of this review was to synthesise the available evidence on the applicability of artificial intelligence in nursing care. After analysing the selected studies, contrary to other studies on this topic, our findings suggest that the application of AI in the nursing field could improve care delivery, contingent on the type of artificial intelligence used and its various applications, such as early diagnosis, clinical nursing decision making, patient care management and monitoring, workflow optimisation, and nursing education [29, 41, 50].

Among the uses analysed in this review, similar to other recent reviews, one of the most commonly used types of support systems was based on ML models for diagnosis [15, 33–35, 51]. One possible explanation for the predominant use of this type of AI may be due to the use of its learning system for activities that are traditionally carried out by humans, but with much less time and expense [52]. These technological advances in AI are currently and predominantly focused on diagnosing diseases such as Alzheimer's, cancer, chronic or dermatological diseases, and more. This allows health professionals to have more time with their patients, use a holistic approach, and even improve patient satisfaction with health organisations [14, 15, 32, 40]. Therefore, diagnostic reliability should be considered in these studies, increasing the presence of comorbidities with the possibility of combining it with NLP models to improve the interpretation of comments from clinical histories [31, 33–35].

One of the types of artificial intelligence that has perhaps received the most attention in recent years within NLP is the rule-based expert system, not only for managing cases of COVID-19 symptoms, but also providing care for patients with social anxiety and older adults who are immunocompromised or at risk of isolation [46, 53]. These types of systems have proven to be effective in monitoring patients remotely in real time, improving the availability of updated clinical data, allowing more time for nursing care, and improving patient safety in primary care, special services, and remote areas [39, 42, 44, 54]. However, like other types of AI, the majority of systems that are based on monitoring patients from a distance still require longer learning phases to achieve clinical reliability, which impedes its implementation [54]. On the other hand, the use of other types of AI, such as the automation of robotic processes or physical robots [45–47], has been shown to be satisfactory in some studies through their use as a mobile application, by increasing the effectiveness and efficiency of nurses' work in the field of tissue injuries and optimising the identification and management of wounds, pain control during venepuncture, or adherence to treatment, among others [29, 55]. Nonetheless, there is still little known about these types of AI, unlike other more widespread ones such as systems based on natural language processing or explainable artificial intelligence [56].

The conversational agents developed through dialogue systems, NLP, and statistical models have demonstrated positive results in reducing the workload of nursing professionals in hospital administrative tasks [57], treatment and follow-up of wound management [41], triage and nursing diagnosis [11, 30], and the training of future professionals [29, 58]. Despite the growing amount of evidence on this type of AI, other authors point out the shortcomings that this type of technology still has, including poor voice recognition, lack of expression and emphasis in speech, and frequently interrupted conversation, all of which prevent results with clinical relevance greater than usual practices from being reached [36, 43, 50]. Having said that, there are a growing number of relevant organisations, such as the Nursing and Artificial Intelligence Leadership Collaborative group, as well as important tech-companies, such as OpenAI, that are currently thriving to identify priority areas for action, opportunities, and recommendations to address these concerns in healthcare practice [59–61].

However, there are some limitations to this study that should be noted. First, AI applied in healthcare and nursing care is still a growing practice with limited evidence due to studies which are in development and have a great heterogeneity in AI types and settings. Therefore, generalisations of the proposed results should be made cautiously. On the other hand, only the term "artificial intelligence" was used as a keyword to describe all AI methods. Although the MeSH term "artificial intelligence" includes most of AI-based systems in its tree structures, some features utilising specific AI methods but are not explicitly labelled as AI may have been overlooked. Carrying out a meta-analysis or meta-regression was not considered in this review due to the heterogeneity in the types of AI, populations, and study variables. In general, this review contributes to the existing knowledge of applying AI-based systems in the healthcare field and nursing practice. Although positive results were shown for most of the analysed types, a greater number of studies are needed to consider the current limitations of these systems and the needs of professionals-users for the development of AI-based systems. There is still abundant room for further progress with these systems in terms of guaranteeing not only professional autonomy but also improved access to health information sources in order to optimise their use in multitasking to cover the greatest number of variables that may affect the patient, environment, clinical practice, and different medical services. Further research is needed to investigate how previous research findings using AI-based systems with virtual reality or simulated scenarios can be implemented in real-life clinical nursing practice or analyse how these AI-based support systems may improve patient safety and assist nurses in particular clinical settings.

4.1. Implications for Nursing Management. AI applied to nursing practice can be a down-to-earth resource for professionals, managers, or supervisors, with positive results in

patient care and safety. It has the potential to change current working flow systems and provides support to nursing professionals when making decisions. AI-based systems are flexible tools which can adopt various essential functions in nursing care, such as guiding the patient with personalised instructions or remotely monitoring the patient in real time. Furthermore, it can be used in community care, remote areas, or in the hospital setting by identifying the possible diagnosis of the user early on, thereby accelerating the healthcare process. The greatest challenge in the development and implementation of this type of technology, however, continues to be the involvement and active participation of healthcare professionals and their commitment to its use.

5. Conclusions

This review offers a compilation of the available evidence on the different applications of AI-based support systems that can be implemented in nursing practice. The systems which are based on machine learning and natural language processing are the most widely used, demonstrating better results in different healthcare processes. Despite the limitations that still exist with this type of technology, the results of the different types of AI are promising. AI-based systems can assist in early diagnosis, clinical decision making, patient monitoring, and workflow optimisation. However, it is important to consider ethical and privacy concerns as well as ensure that AI is used to augment and enhance the role of nurses rather than replace them [61].

Aims. To explore band 5 staff nurses' perceptions of leadership and leadership development and derive insights and recommendations to inform future practice. *Background.* Band 5 staff nurses are increasingly expected to develop leadership skills but are not always well supported in this. *Method.* A qualitative methodology situated within a constructivist paradigm explored the shared meanings and understandings of band 5 nurses' leadership development within the context of current organisation, policy, and culture. *Results.* Three principal themes representing band 5 nurses' perceptions of leadership were identified: defining leadership, opportunities to lead, promoting leadership development. *Conclusion.* Band 5 nurses' leadership development is highly variable in frequency and quality. Key barriers and facilitators to development are discussed, including the wide provision of formally validated and bespoke leadership programmes that combine practice-based, informal training. *Implications for Practice.* Nurse leadership development at all levels remains integral to high-quality and safe health care. High rates of senior staff attrition and recent guidelines in England reinforce the need for band 5 nurse leadership. The multiple challenges impeding this are discussed, alongside ways of overcoming them.

1. Background

In England, there is at present a relatively heavy emphasis on nurses' development of leadership skills [1] to ensure the care nurses provide and delegate is person-centred and of a consistently high standard [1], and to act as a role model for others [1]. The NHS Healthcare Leadership model [2] emphasises how all individuals in a healthcare organisation can develop their leadership skills, not only those with formal leadership roles. Current workforce policy, therefore, requires all nurses to develop leadership skills, irrespective of band or grade. A strong relationship has been found to be linked between nurses' leadership skills and patient outcomes [3], including that good nursing leadership supports the provision of high-quality care [1, 2, 4, 5], improvements in quality of care provided [6], patient safety [7, 8], patient-centred care [9], patient satisfaction [10], staff recruitment, retention and job satisfaction [11, 12], effective change

management [13], costs reduction [14, 15], and financial performance [16].

Even newly qualified nurses are expected to lead on a day-to-day basis; however, they often lack the confidence to lead [17]. Nurses who are qualified for university degree level enter the NHS at band 5 and are expected to provide excellent professional, skilled, and effective person-centred, evidence-based nursing care [18]. At the current pay scale, band 5 nurses earn £27,055 to £32,934 [19]. As they gain further knowledge, skills, and experience, they may progress to higher bands within the nursing banding system [20].

Arguably, the current situation in England in which newly qualified nurses often do not receive the training they require to develop their leadership skills early in their careers, risks leaving a crucial skills gap that may extend into the longer term, stymying important leadership development and losing a valuable opportunity to enable nurses to further improve the quality of their patient care [17].

Conversely, there are multiple benefits associated with proactively identifying and developing internal candidates, yet fewer than 7% of healthcare organisations have implemented formal leadership succession planning programmes [14].

A strong argument exists therefore for prioritising nurse leadership training, with potential benefits for individuals and organisations, with "the need for leadership at all levels of nursing... overwhelmingly evident" [21]. Despite this, clinical leadership training has been predominantly focused on managers and management-focused training [22], a situation which has historically excluded band 5 nurses from leadership training [23] with a negative impact on workforce effectiveness, efficiency, and quality of care delivery [24]. Transitioning from band 5 to band 6 arguably demands high levels of leadership skills, and band 5 nurses may not possess which has led to calls for immediate action to prepare a new generation of nursing leaders [25]. Such calls take on greater urgency given high levels of attrition among experienced nurses in England, who are either leaving the profession or widely anticipated to through a combination of age (1 : 5 nurses in England are 56 years of age or over) and escalating work pressures [26].

Moreover, care service and quality demonstrate improvements where health professionals *at all levels* have access to appropriate leadership education [22]. Current leadership programmes tend to prepare nurses for leadership roles only *after* promotion [27], with scant opportunity to develop skills in advance. This may hamper leadership development at band 5 and impede the transition to higher levels within the service.

2. Leadership in Nursing

Despite current requirements for all nurses to develop leadership skills [1], there remains a lack of consensus regarding how "leadership" should be defined in nursing [28]. The essence of leadership includes nurses' ability to influence and direct patient care by demonstrating exemplary care [29]. However, leading care is not directly synonymous with leading other staff [30] although there may be much overlap between the two.

Additionally, there is a lack of consistency concerning the styles of leadership employed by senior staff that can be a pivotal role in inspiring band 5 nurses' own leadership development. Winston and Patterson [31] identified in excess of 90 dimensions of leadership which demonstrates the complexity of leadership as a concept. These can be combined and contribute to leadership styles in highly variable ways that may range along a spectrum from autocratic to transformational [32, 33].

While taxonomies detailing key attributes of leadership exist (e.g., NHS [2]), it is less clear how band 5 nurses themselves perceive leadership or opportunities to lead, how different perceptions emerge, how these may differ depending on different settings and circumstances, and which specific contexts currently contribute to leadership development or impede it. Leadership and how it is defined and practiced is likely to vary according to different care settings, bands, and grades that calls for greater specificity and a move away from using the term "leadership" too generically [34].

Although preceptorship programmes are highly valued by nurses [35], they are not a substitute for continuing leadership development [36] that is underpinned by active, structured support [37].

These issues have added gravitas given the significant attrition of nurse leaders in the UK within an ageing workforce [38] which necessitates the recruitment of younger and less experienced nurses to fill the gap. This is a situation further exacerbated by low staffing levels and high workloads during the pandemic [39] and subsequently that has led to less experienced staff having to take on significant levels of responsibility.

This study explored these issues and challenges by engaging with band 5 nurses across a diverse range of healthcare contexts, settings, and circumstances. Given the NMC's requirement for nurse leaders to manage and lead care [1] and RCN's [40] call to promote nurse leadership development to ensure high quality, safe, and compassionate health care, this represents a timely juncture to explore the issues and challenges surrounding band 5 nurses' leadership, alongside ways of overcoming them, and to use the insights gained to add to the current knowledge base.

3. Methods

The research team consisted of three academic staff who contributed equally to data collection and subsequent analysis. The lead researcher was an assistant professor of nursing with expertise in leadership and management. The other team members were an associate professor of nursing and a senior research assistant, both with research expertise in workforce development. The research team felt that this study's exploration of shared understandings within organisational, policy, and cultural contexts aligned well with Crotty's [41] view, "that all knowledge, and therefore all meaningful reality as such, is contingent upon human practices, being constructed in and out of an interaction between human beings and their world, and developed and transmitted within an essentially social context." This supported the rationale for adopting a qualitative methodology situated within a constructivist paradigm.

3.1. Sample. To gain insights into band 5 nurses' experiences of leadership across a diverse range of contexts, the plan was to locate the study in NHS primary care, community care, secondary care, and care homes operated by private and voluntary sector providers across North East England. Participants were accessed via gatekeepers who were service managers working in these providers (matrons, GP practice managers, care home managers, and lead community nurses). Gatekeepers provided their band 5 nursing staff with study information explaining the purpose/aims of the study and what participation involved. Staff were given time to read information sheets which emphasised participation was voluntary and that deciding not to participate would not

TABLE 1: Participants' characteristics.

Care provider organisation	Care service location	Care service	Participant	Gender	Age	Years qualified	Country of birth
NHS trust 1	Hospital 1	Surgical ward	P1	Female	20–29	<1 year	UK
NHS trust 1	Hospital 1	Medical ward	P2	Female	20–29	<1 year	UK
NHS trust 1	Hospital 1	Emergency department	P3	Male	20–29	6–10 years	UK
NHS trust 1	Hospital 1	Critical care	P4	Female	30–39	3–5 years	UK
NHS trust 1	Hospital 1	Emergency department	P5	Male	40–49	10–15 years	Philippines
NHS trust 1	Hospital 2	Medical ward	P6	Female	20–29	1–2 years	UK
NHS trust 1	Hospital 2	Theatres	P7	Male	30–39	3–5 years	UK
NHS trust 1	Hospital 2	Theatres	P8	Female	30–39	3–5 years	UK
NHS trust 2	Hospital 1	Medical ward	P9	Female	40–49	1–2 years	UK
NHS trust 2	Hospital 1	Medical ward	P10	Female	40–49	6–10 years	UK
NHS trust 2	Hospital 2	ITU	P11	Female	40–49	21–25 years	Czech Republic
NHS trust 2	Hospital 2	Theatres	P12	Male	50–59	2–5 years	Philippines
NHS trust 2	Hospital 2	ITU	P13	Female	20–29	<1 year	UK
NHS trust 2	Hospital 2	Admissions unit	P14	Female	30–39	<1 year	UK
NHS trust 3	Community 1	Community	P15	Female	20–29	<1 year	UK
Care home company 1	Care home 1	Care home for older people	P16	Female	30–39	1–2 years	UK
Care home company 2	Care home 1	Care home for older people	P17	Female	30–39	3–5 years	Romania
Care home company 3	Care home 1	Care home for older people	P18	Female	60–69	>30 years	UK

affect staff's employment in any way. Information sheets invited nurses to contact the researchers with any questions before agreeing to participate. Participants provided written consent.

In total, 18 band 5 nurses responded to the invitation to participate. All were accepted as participants in the study, and all consented to participate. The response rate was lower than predicted due to the outbreak of COVID-19. This impacted the availability of staff to participate, necessitating some scaling back of recruitment, particularly from primary care and voluntary sectors. Despite this, the remainder of the study protocol remained intact and recruitment possible from secondary care ($n = 14$), care homes ($n = 3$), and community nursing services ($n = 1$), reflecting a diverse range of nursing roles, NHS trusts, and care-provider operators (Table 1). As well as representing heterogeneity in terms of being drawn from different clinical settings, the sample was varied regarding age groups (20 to 69 years of age), sex, nursing experience from <1 year to >30 years, and country of birth.

3.2. Data Collection. Data were collected via individual semistructured interviews. All members of the research team conducted data collection. The first three interviews were face-to-face. Subsequent interviews were conducted online or by telephone due to COVID-19. Interview questions were informed by the findings of the literature review and explored participants' own experiences of leadership development and practice, and reasons underpinning them. Average length of interviews was 46 minutes, and none exceeded one hour. This afforded time to record participants' in-depth accounts of their experiences.

3.3. Data Analysis. Interviews were audio-recorded and transcribed verbatim. Thematic analysis (TA) was used to analyse the data and selected for its proficiency in organising, analysing, and reporting patterns (themes) within data in rich detail [42]. An inductive analytical approach was adopted, i.e., data-driven. The six-phase guide to conducting TA, as outlined by Braun et al. [42], was employed:

  (i) Familiarisation with the data
  (ii) Generating initial codes
  (iii) Organisation of the initial codes into patterns to generate themes
  (iv) Reviewing themes (checking themes against raw data to ensure a good fit and reclassification of themes into levels)
  (v) Defining and naming themes
  (vi) Interpretation

Trustworthiness was enhanced using three methods. Firstly, all transcripts were independently coded by all three members of the research team, and the codes were compared. This supported validation of codes, supporting valid theme development. Theme development was a collaborative process involving all three researchers meeting together to discuss themes. Secondly, attention was given to negative cases, which allowed for discussion of different perspectives and contradictions in the data. Analysis of negative cases helped to refine the interpretation of the data. Finally, reflexive strategies were used to reduce the risk of researcher bias. This was particularly important as the research team had prior knowledge and expertise in leadership and management, and workforce development. Two reflexive strategies were used: (i) "oppositional arrangement of perspectives" supports researchers to become aware of the range of perspectives at work within established frames of social norms [43] and (ii) "backgrounding" whereby "background" data (data that on first analysis may seem less significant) are foregrounded. The transformation from background to foreground prompts researchers to investigate whether any topics of potential significance that had not been expected were encompassed within the text [43]. Member checking by sending draft codes and themes to participants was attempted. However, none of the participants were able to respond, as they generally felt that time constraints due to COVID-19 made responding difficult.

4. Results

Findings from the thematic analysis revealed three key themes representing the staff's experiences of leadership: (i) defining leadership, (ii) opportunities for leadership, and (iii) promoting leadership development. Each of these and interview evidence supporting them will be presented in turn.

4.1. Theme 1: Defining Leadership. Participants struggled to agree on a clear definition of leadership in the context of nursing; in particular, there was some tension about whether nature/innate ability or nurture was most critical to leadership development. This respondent felt that leadership was contingent on experience; i.e., it was nurtured over time:

P1: ...if there's no manager or sister then the most experienced nurse on the ward [takes charge].

One participant felt leadership was contingent on the combination of nurture/nature:

P4: I think it's a product of your experience, but unless you've got the inherent qualities you can't just create a leader.

However, the general consensus was that leadership relied on nature/innate qualities, rather than a set of qualities that could be nurtured:

P6: . . .it's about having a natural trait.

P9: . . .unless you've got the inherent qualities you can't just create a leader.

These comments are interesting for their emphasis on leadership as primarily innate and an inherited trait, rather than universal, and how this appears to run counter to recent directives calling for all nurses to fulfil the requirement to develop leadership skills which assume it is a universal quality.

Participants also associated leadership with a higher level of seniority, beyond their own band 5 status and entrenched within the organisational, hierarchical structure:

P2: [Leadership is] The ward manager, the sisters, the band 6's.

P12: It's your senior staff-your Band 6s and 7s, Matrons and definitely the nurse-in-charge on that shift.

Despite this, some participants recognised that although (as band 5 nurses) they wielded less authority compared with higher bands, they nevertheless carried out a leadership role:

P3: My experiences are. . .right from a band 5 you're leading because you're delegating tasks [to health care assistants]. . .finding out who is competent to do those skills.

Participants, therefore, associated leadership with seniority/delegating responsibility to others, requiring a sound knowledge of other staff's competencies.

Despite the apparent majority view that leadership relies on inherent qualities, other evidence appeared to contradict this; i.e., a number of participants felt in nursing it relied on nurture/experience as opposed to natural talent:

P13: I don't think people take you seriously to do leadership when you're a little bit younger. . .

Moreover, this view seemed to present a bias as well as a barrier for younger staff who might aspire to lead:

P6: I find it hard to lead someone who is older or been on the job longer.

Despite these tensions/contradictions, there was consensus among participants that as band 5 nurses they may not specialise in leading staff, but they nevertheless specialised in leading care and participants acknowledged this important distinction:

P11: I am a leader of my own care for my own patients.

P1: Leading patient care, being in control of your own pod. . .

Taking leadership/responsibility for patient care was generally viewed as separate and discrete from leading staff but certainly not inferior to it:

P9: I think leading patient care, to me, is the most important part of leadership.

P3: [As leaders] we all have responsibility to strive and deliver best outcomes for patients.

While promotion beyond band 5 was perceived to increase opportunities to lead/manage others, it was also viewed by several participants as shifting away from leading patient care; something, they were opposed to:

P5: I don't want to lose patient contact and still be a nurse. I wouldn't want to be a band 6 because of the loss of patient contact.

Despite some reservations, the majority of respondents felt band 6 offered the best compromise between allowing nurses to continue to lead care while also leading staff. However, promotion to band 7 was perceived by many to denote the demarcation point at which directly leading patient care abruptly ended:

P2: The idea of being a sister is great, but I don't want my day monopolised by doing rotas/staffing. I want patient contact.

Furthermore, participants perceived band 7 as a point of departure from close, collegiate working towards a more distal, managerial role:

P11: I think we've got one Band 7 in the building. We rarely see her.

P11: I've never met a Matron.

While a range of perceptions, some contradictory, were uncovered regarding how band 5 nurses viewed leadership, greater consensus was found concerning leadership style. In general, participants' nurses preferred more democratic leadership styles, especially their perceived capacity to offer motivation/inspiration/mutual respect:

P5: Leadership is a person who you can always turn to who knows the answers but who will talk to you in a way that is encouraging. . . [not] in a derogatory fashion.

P10: I know my band 6, I can ask her anything. . .She just rings me all the time and tries to motivate me.

By contrast, autocratic leadership styles were generally viewed negatively:

P5: Very, very dominant. "I am the boss! This is how it's going to be!" I feel like she's very strict.

This participant highlighted how the autocratic leadership style discouraged close, collegial working, even where nurses demonstrated high levels of competency, inducing feelings of negativity:

P1: So, even if you might be a good nurse, I think, "well they're not going to like me as a person." Even if I do the job well. . .and that's disheartening.

By contrast, more democratic leadership styles were perceived in a positive light and as providing good guidance, especially where there was more an exchange of knowledge (transactional leadership) as opposed to a more didactic approach/style:

P13: [Leaders]. . .give clinical guidelines, policies and procedures for effective practice based on the knowledge and NICE guidelines as well, so they become our standard operating procedures to guide us.

A notable finding also was that transactional style was more likely to be evidenced in very acute care settings such as emergency departments, theatres, and critical care wards. This suggests that leadership style is not only determined by individual choice but also by context/setting which may be instrumental in facilitating (or impeding) certain styles. One explanation for the salience of transactional style found here in emergency departments/theatres/critical care wards may be that these settings require rapid, expert decision-making, and timely adherence to protocols that make good guidance/effective knowledge exchange a priority.

Moreover, leadership style may not only be influenced by context/setting but more specifically still the unique circumstances currently unfolding within that context/setting. This means leadership style may be more fluid than fixed:

P7: [He is] a democratic leader, but he can be a transactional leader and a rational leader.

In summary, band 5 nurses' perceptions of leadership and how it is best defined revealed a range of interpretations that were sometimes contradictory. Leadership in the context of nursing appears to be nuanced, complex, and variable and influenced by multiple factors, rather than representing a fixed/immutable concept that is easily pinned down.

4.2. Theme 2: Opportunities to Lead. Discussing band 5 leadership, many participants indicated their experience of leading people as a hallmark of leadership (as distinct from

leading patient care) was determined by *opportunities* to lead. This appeared very much contingent on work setting/working arrangements/practical necessity, rather than strategic or planned professional development. For example, participants who worked in care homes highlighted that they were often the only registrant nurse on their unit and therefore automatically expected to lead in terms of staffing/resources/resident care. This expectation fed into nurses' perception leadership was integral to this particular role:

P1: I think for each care home the nurse is like a leader. You need to take responsibility of your floor and your staff. . .

Similarly, participants working on wards in secondary care revealed opportunities to take charge of their ward that entailed leading both staff and patient care:

P12: There's always a nurse in charge for the shift. . .you're still in charge of the full 27 patients as well as the staff.

Opportunities for band 5 nurses to lead were especially prevalent where senior staff were unavailable and, of practical necessity, responsibility for leadership was delegated:

P3: You're leading the whole ward when your manager is not there.

Respondents working on wards in secondary care welcomed opportunities to take on a stronger leadership role, but some would like more frequent opportunities:

P1: I would like to get some more experience of being the nurse in charge of the ward when the sisters aren't there.

P13: I would really like to be the nurse in charge and get my skills. . .

Participants from the emergency department also reported opportunities to lead, though this tended to be limited to a lower level of leadership:

P13: I would normally lead on the floor. . .I will look after. . .health carers or a junior member of staff. . .the majority of the time. . .

By contrast, participants working in ITU settings indicated there were generally few opportunities for leadership. One respondent revealed that in their area of practice, band 5 staff is actively discouraged from leading:

P6: I am. . .more encouraged to stay at the bedside and try to limit my job to. . .doing observations-not expressing leadership skills.

Care setting also limited opportunities to lead where participants worked in the community. Although band 5 nurses were assigned case-loads conferring much responsibility, they primarily operated as lone workers that restricted them to leading patient care:

> P14: I am a leader of my own care for my own patients.

A key finding in general was that although band 5 nurses had ample opportunity to lead patient care, opportunity to lead people was highly variable and contingent on context/circumstances. Some participants were seldom offered the opportunity to lead people, while others were comparatively overwhelmed with opportunities. Often, this meant an imbalance regarding opportunities to lead people, as highlighted by these participants working in theatres and EAU who often faced emergency situations:

> P7: . . .a band 6 as team leader. . .rang in sick so I was moved up as the team leader. . .It was quite a struggle, obviously. I said. . ."it's not my choice to be the team leader, I was put here and I'll play that role, but if something happens, it's my name they're going to. . .chase up."

> P14: We went on shift one night-it was me and another junior member of staff. . .we were left in charge of the patient services as well because they'd gone off sick and no one could cover. So, we were in charge of bed management in the hospital, as well as running the suite. . .I was nervous. . .

While more experienced band 5 nurses may be very capable of taking on intensive leadership roles, there needs to be a choice, rather than an expectation of compliance. Such decisions should always place patient safety first. Band 5 nurses made a clear distinction between leading care and leading people with opportunities to develop the latter being highly variable and contingent on individual context/circumstances.

4.3. *Theme 3: Promoting Leadership Development.* Responses indicated a paucity of formal development via bespoke training/development programmes. In lieu, all participants reported heavy reliance on *informal* development that could be limited to being self-directed/opportunistic, i.e., observing colleagues, rather than planned or more deliberately co-ordinated:

> P3: I think from being a Band 5 I might not necessarily have done a course, but I've reflected. . .It's about observing leaders. Picking bits of how you would want to be and how you don't want to be develops me.

> P12: I think shadowing and mirroring are how I've learned. I wouldn't necessarily say that anyone has taken me aside

and taught me anything. . .when I've led, I've picked up on a lot of things that I've seen other people do.

However, that informal training can be effective is illustrated here:

> P14: I get the most out of the time I've shadowed "X" who is the band 6 because she is making all of these decisions. . .she's explaining how processes work, she'll go through anything with me and explain why she's made the decision. She's got all the qualities of a leader. . .

Where informal training seemed particularly effective was when senior staff demonstrated a transformational leadership style that inspired trust, motivation, and empowerment in band 5 nurses:

> P13: . . .if I work alongside the Band 7's they are good at developing us or empowering us to do some leadership assignment. Usually, this goes with the patient care itself, like managing the zone and. . .I can perceive a sense of empowerment. That they're trying to input encouragement for me.

While the opportunity to shadow/mirror good leadership and receive encouragement/opportunities to develop it may be vital, arguably band 5 leadership should also be encouraged through formal leadership training as an adjunct to this:

> P3: Watching and learning-that helps develop me as a leader. That's a challenge I would give myself. I would read some reading material. . .like if there's a new [leadership] practice of interest to me. . .

Participants also perceived how the provision of formal leadership training could benefit not only themselves but also the team and the wider organisation:

> P3: [Formal leadership]. . .to actually understand with theory how you put that into practice. How the theory can make you a better leader. How this will make you more insightful. . .to develop myself, to develop the service, to develop others.

Despite respondents' enthusiasm for formal leadership training, several band 5 nurses reported difficulties accessing it and even open discouragement:

> P6: They don't like that when I'm doing that [requesting leadership development]. They always try to keep me in the corner. So, it's very difficult to express or maybe to learn how to be a leader.

> P8: . . .they don't really emphasise leadership when you're a Band 5

P11: If I ask for leadership development I will get laughed at.

These examples illustrate how band 5 nurses may often be motivated/dedicated to the formal development of leadership skills, in accordance with guidelines recommending this (e.g., [1]), but can face systemic bias that prevents them. Moreover, this systemic bias appears to persist even among band 5's employed in settings where good leadership is essential to their role:

P7: . . .we're team leaders for night shifts, but we didn't get the formal training of what being a team leader is, what qualities you need to lead a team.

Even where an exception was found and one participant initially granted support for formal leadership training, the promised support was unforthcoming:

P8: I'm doing the Nightingale course so I'm meant to have a 1:1 mentor and to actually do some shadowing and things with them, but that hasn't happened. . .

Moreover, the Florence Nightingale Leadership Development Course represents one of only a handful of formal leadership courses currently available to band 5 nurses in England.

In summary, band 5 nurses valued good quality informal leadership training that included shadowing/mirroring. This could be facilitated by the senior staff's adoption of a transformational style [44]. However, informal training could be limited to being self-directed/opportunistic, rather than planned/more deliberately co-ordinated. Opportunities for formal training were limited/not fully supported.

5. Discussion

Thematic analysis of the data elicited several key findings, and a robust attempt was made to ensure proportionality between the data and the analytical claims and conclusions presented in this discussion.

Consistent with previous findings (e.g., [28, 45]), this study found a lack of consensus regarding how band 5 nurses perceived "leadership" in the context of nursing. While one participant held the view that leadership is created by an amalgam of nature/nurture, others felt that strong leadership required a particular set of innate qualities closely intertwined with personality traits. This latter view runs counter to recent evidence that traditional trait or personality approaches are of little value when it comes to delivering leadership training (e.g., [16]). Contradictions were also found in this study; e.g., while many respondents perceived leadership to be an innate quality, they also felt entitlement to lead was based on nurture/experience, rather than innate abilities/talents. This also appeared to present a bias against younger staff leading or aspiring to lead. These comments are interesting for the way they appear to run counter to recent directives calling for *all* nurses to fulfil the requirement to develop leadership skills (e.g., [1]) that carry

the assumption all nurses are capable of leading both care and people.

Leadership was most frequently associated with hierarchical staffing structures and "top down," from the management level to the staff nurse on the ward and particularly the managers and those who held band 7 and band 6 positions. This required the ability to delegate responsibility to others and sound knowledge of other staff's competencies. Notably, however, the majority of participants felt leadership was associated with higher seniority, *beyond* band 5, and therefore largely outside their domain. There was consensus that band 5 nurses had a leadership role in terms of leading *patient care*. Notably, though, leading care was perceived to be quite different and discrete from "leadership of other people." Participants perceived "leading care" to be as vital as "leading people," if not more so, but viewed them as mutually exclusive. A few band 5 nurses recognised that although they wielded less authority, they carried out a leadership role-albeit at a different, often lower hierarchical level. Taken together though, the findings support Stanley's [22] contention that more work is needed to outline what clinical nurse leaders are, and how they can recognise themselves as leaders.

The findings further reveal that band 5 nurses strongly perceive they work within a fairly rigid hierarchy in which clear divisions exist between themselves as subordinates on one side and leaders/management on the other in which "leadership" was frequently perceived to be synonymous with "management," especially beyond band 6. As Stanley [46] emphasises, "leadership" and "management" are not interchangeable concepts and there is danger in using them indiscriminately to delineate roles within healthcare systems. Management is primarily concerned with assuming control and maintaining a clear division between workers/patients [47], and this should not be conflated with leadership in healthcare which should ideally involve a more closely bound relationship between staff [48] and also patients [24]. Adherence to older 20th-century management models that promote hierarchical ordering of staff in which leaders and "subordinates" work in separate spheres have come under criticism for being outmoded/ineffective [49], particularly where they continue to be applied within the NHS [9].

A related finding was band 5 nurses' perceptions that promotion automatically signals a shift towards management and a concomitant move away from nurses' principal vocation to provide the patient care in close collaboration with colleagues. Such perceptions potentially presented serious barriers to seeking promotion or fulfilling aspirations towards leadership. These perceptions appeared to be reinforced when senior staff adopted more autocratic leadership styles consistent with more rigid/hierarchical ways of working, and the more arcane management models discussed earlier.

Greater consensus was found regarding band 5 nurses' perceptions of what constituted optimal leadership style where high value was placed on senior staff's adoption of more democratic styles. Regarding this, the transformational style of leadership was valued highly, especially where it was

manifest in senior staff's adoption of an approachable, motivating and reassuring stance that presented a good role model to follow and inspired trust [44]. As Gopee and Galloway [50] note, effective leaders tend to focus on influencing staff's behaviours and especially motivating, inspiring and energising individuals. It is not only how band 5 nurses perceive/define leadership that may be important but also the example/influence set, reflected in senior staff's leadership style. By contrast, autocratic leadership styles were perceived negatively.

Of note, this study found evidence that senior staff who promoted knowledge exchange in an approachable and collaborative way were more likely to be found in very acute care settings such as emergency departments, theatres, and critical care wards. This perhaps reflects the need in such settings for rapid, expert decision-making, ensuring the team closely adheres to set protocols in a timely manner. This finding underscores the importance not only of leadership style but also context/setting in providing ideal environments for certain styles to flourish. Participants working on wards in secondary care similarly reported opportunities to take charge of their ward and lead staff and patient care. Nevertheless, there needs to be a balance. Some band 5 nurses expressed concerns they sometimes felt overwhelmed with opportunities to lead and out of their depth. Arguably, there is a requirement for training in leadership in advance that should accompany opportunities to lead.

Meanwhile, band 5 nurses who worked in care homes were often the only registrant nurse on their unit and automatically expected to lead in terms of staffing, resources, and resident care. This expectation-reinforced nurses' perception leadership was integral to their role but not necessarily supported by specific leadership training.

By contrast, participants working in ITU settings indicated that, in general, there were limited opportunities for leadership with one participant reporting active resistance to this by senior staff. Similarly, band 5 nurses working in community settings rarely encountered opportunities to lead due to their role as lone workers.

Evidence was found for participants' motivation to acquire leadership skills. However, while this could be encouraged where senior staff adopted more democratic leadership styles (e.g., transactional or transformational styles), opportunities for leadership development were frequently found to be contingent on conducive care contexts/settings which were only available to some band 5 nurses. Moreover, leadership development trended to be limited to being self-directed and opportunistic, rather than planned and deliberately co-ordinated.

This study highlights how both these factors make access to informal leadership development by band 5 nurses highly variable and not always equitable. This inequity was likely to be exacerbated where there was a lack of support for band 5

nurses' *formal* leadership training, which this study also uncovered. This is a situation also made problematic by the paucity of training programmes currently available in England.

One way to restore equity/increase opportunities for leadership for *all* nurses would be the creation of nationally available, formally validated leadership development programmes dedicated to promoting *leadership of people* as distinct from leading care and bespoke/available to all band 5 nurses who wanted it, irrespective of age. Programmes should ideally focus on developing clinical leadership skills and potential, as distinct from managerial skills training and complement rather than detract from leading good patient care. Ideally also, training should be resourced and overseen by an external governing body to ensure that it combines formal training supported by mentors with ample opportunities for practice-based training alongside informal shadowing/mirroring of good practice as an important adjunct rather than a replacement to this.

5.1. Limitations. This was a relatively small-scale cross-sectional study involving 18 participants from North East England. The response rate was lower than planned due to the outbreak of COVID-19 which impacted on the availability of primary care and voluntary sector staff. Further research is needed in this area, including consultation with larger samples from other regions and a wider range of clinical settings to establish how band 5 leadership training could be better designed, resourced and implemented, and externally governed and validated.

6. Conclusions

This study explored band 5 nurses' perceptions of leadership across a diverse range of different healthcare contexts/settings in England. This revealed a number of deficiencies and inconsistencies regarding how leadership is defined, characterised, and promoted. Ways of improving quality and provision are discussed. Given high rates of senior staff attrition in England and recent guidelines promoting nurse leadership development at *all* levels as a prerequisite to high quality, safe, and compassionate health care, there is a burgeoning need for renewed discussion of band 5 nurses' leadership development.

Background. Worldwide, hospitals are required to prioritize the culture of quality in infection prevention (CQIP) for patient safety. Assessing CQIP is crucial, but there is limited research, especially regarding nurses' perceptions. Insufficient information exists due to scarcity of validated instruments in local languages to measure CQIP internationally. *Purpose.* This study assessed the "Leading a Culture of Quality in Infection Prevention Scale" Russian version's (LCQ-IPS-R) validity and reliability to assess the CQIP of hospitals in Kazakhstan based on nurses' perceptions. *Methods.* This study utilized a methodological design and analyzed data from 204 nurses at the "National Research Center for Maternal and Child Health" in Astana City, Kazakhstan. The "cultural and linguistic adaptation" process involved a "forward-backward translation" technique. Content validity and construct validity were examined. Internal consistency reliability was explored for scale reliability. *Results.* The scale's mean item range was from 3.56 (SD = 1.22) to 4.40 (SD = 0.85; SD = 0.92). The corrected item-total correlation ranged from 0.321 to 0.707. Six experts rated the I-CVI from 0.83 to 1.00, with an S-CVI/Ave of 0.90. The principal component analysis with Varimax rotation produced four distinct components of the LCQ-IPS-R, explaining 69.8% of the total variance. The tests of correlation between the LCQ-IPS-R's four components revealed medium to large positive associations among the components ($r = 0.25–0.55$, $p < 0.001$). The computed α for the LCQ-IPS-R was 0.909 while α values from four subscales ranged from 0.809 to 0.921. *Conclusions/Implications for Practice.* This study provides evidence of the LCQ-IP-R's reliability and validity in evaluating Russian-speaking nurses' perception of their hospital's CQIP. These findings open the door for further research on CQIP in healthcare settings in Kazakhstan, Central Asia, and other Russian-speaking countries. The scale provides essential baseline information to design effective interventions for achieving hospitals' infection prevention objectives.

1. Introduction

Healthcare administrators and policymakers are continuously engaging in developing an infection prevention culture that is very extensive, convenient, and economical in healthcare settings. According to Cruz ([1]; p. 3), a "culture of quality in infection prevention" (CQIP) is defined as the "shared perception among healthcare professionals towards

hospital infection prevention." Hospitals worldwide are expected to have the highest level of CQIP to ensure patient safety and better patient outcomes. The World Health Organization [2] reported that routine infection prevention practices in Kazakhstan are well documented, including risk assessment for infectious diseases, patient safety, and establishing primary healthcare coordination centers staffed by healthcare professionals.

The roles of nurses are critical in ensuring a CQIP in hospitals [3]. They are expected to comply with infection prevention measures and to participate in interventions and activities that promote a culture of infection prevention [3]. They are also a good source of information when assessing the CQIP of hospitals. However, despite the important part of nurses in infection prevention in hospitals, nurses' compliance with infection prevention measures remains substandard [3–5]. Abed Alah et al. [6] reported that inconsistent infection prevention and control (IPC) interventions increased the chances for healthcare-associated infections (HAIs), leading to prolonged hospital stays. Hence, efforts should focus on nurses, who play a vital role in infection prevention, to prevent the detrimental effects of noncompliance to infection prevention practices on patient safety [4]. Establishing baseline data on the organizational culture of infection prevention could lead to better infection prevention management. It could enable nurses to improve their compliance with infection prevention policies and guidelines [7].

The significance of assessing the CQIP in hospitals cannot be overstated. However, there needs to be more information on this area of research in Kazakhstan, specifically on the perceptions of practicing nurses. The lack of a validated instrument in the country's language to measure the CQIP of a hospital is one of the main reasons for the lack of data from this country. A recent study conducted by Abed Alah et al. [6] has thoroughly investigated this tool which contributed to the understanding of how to assess the reliability and validity, assuring its usefulness and robustness in several research settings. Likewise, having a valid and reliable tool will be instrumental in accurately measuring the perceptions of healthcare workers about their hospital's infection prevention climate, which could prompt improvements and innovations in infection prevention practice within healthcare settings [4, 8]. By using a valid and reliable LCQ-IPS-R, researchers and healthcare administrators can effectively assess nurses' infection prevention efforts, recognize improvement areas, and implement strategies in preventing and reducing HAIs. Hence, it is crucial to have a validated and reliable version of a tool that can be used to assess the CQIP of hospitals in Russian-speaking countries to ensure that studies in this area can be done in those countries. Conducting validity and reliability test on LCQ-IPS-R is also key in ensuring that this scale's version is a robust and accurate measurement tool for assessing the culture of quality in infection prevention within healthcare organizations.

2. Background

Healthcare-associated infections (HAIs) remain a significant challenge among hospitals worldwide, posing significant risks to patient safety and outcomes [9]. According to "European Center for Disease Prevention and Control" ([10], para. 1), "healthcare-associated infections are infections acquired by patients during their stay in a hospital or another healthcare setting." These preventable infections negatively impact the patient's "health, increasing their stay in the hospital and hospital costs, and causing considerable distress to these patients" ([10], para. 1). Some literature reported that HAIs increase the occurrence and undesirable complications. For example, before the pandemic, more than 4 million patients in Europe every year acquired HAIs, while approximately 37,000 died because of direct contact consequences [11]. In the United States, HAIs were listed as the fifth most common mortality causes in clinical settings [12]. In Africa, poor infection control practices in public hospitals pose a significant adverse public health challenge due to healthcare provider or patient-related factors.

In Kazakhstan, HAIs had increased, and the country's epidemiological situation is still a concern [13]. The COVID-19 pandemic contributed to many cross-infections between patients and nurses in the country, which posed a considerable challenge to healthcare institutions [14]. Due to this increase in HAI cases, the country's healthcare ministry has demonstrated its commitment to mitigating the impact of HAIs. The ministry also ensured access to essential healthcare services to accelerate improvement in health outcomes and respond better to its people's ever-changing needs and expectations [15]. The ministry promoted multidisciplinary teams in hospitals, supported by various health systems, to provide guidance in public health protection, one of which is IPC intervention.

IPC measures decrease the burden of unwanted hospital incidences and enhance the quality of health care in hospitals [9]. Accordingly, ensuring CQIP significantly impacts patient outcomes, including increased effectiveness of prevention strategies for hospital infections, promotion of effective communication, and encouraging individuals to learn from their mistakes [1, 16]. Hence, creating a CQIP in hospitals should be a joint priority among healthcare professionals, policymakers, administrators, and managers.

Nurses, who are primary care providers and have close contact with patients, are obligated to provide safe and effective nursing care and contribute to creating an infection-free environment [17]. Nursing has a crucial role in ensuring a safe patient care environment; thus, they must be competent in infection control skills. Moreover, they should also be competent in patient need prioritization, teamwork, and collaboration, which are essential in developing CQIP in hospitals [1]. Healthcare workers' lack of knowledge and competence in infection prevention often leads to failed CQIP [18]. Hence, assessing the hospital's CQIP as perceived by healthcare workers is critical to identify the areas that need to be intervened and develop interventions to ensure high IPC knowledge and competence.

The literature supports ways to improve knowledge and compliance on IPC among nurses. Alshammari et al. [7] found that IPC training seminars significantly influenced IPC compliance. Furthermore, attending "risk assessment seminar training, having sufficient personal protective equipment, and being completely aware of safety guidelines were related to better IPC practices" [5]. Data from this previous literature provide a valuable baseline understanding of nurses' knowledge and practices of IPC,

which could be essential in understanding the CQIP of the healthcare setting.

Considering the relevance of CQIP to patient safety, it is vital to use psychometrically sound tools in measuring the CQIP. A validated tool for assessing a hospital's CQIP is the "Leading a Culture of Quality in Infection Prevention Scale" (LCQ-IPS) [19]. The LCQ-IPS is the most widely used tool to measure healthcare workers' perceptions about CQIP in a clinical health setting. It measures four dimensions of CQIP: "improvement orientation," "psychological safety," "supportive work environment," and "prioritization of quality" [19]. To date, the psychometric properties of the LCQ-IPS have been tested in the US [19] and Saudi Arabia [1]. No Russian version of the tool is currently available, and no study has attempted to adapt and test the tool's validity and reliability among nurses in Kazakhstan. A valid and reliable Russian language version of the tool is necessary to assess the CQIP of hospitals in the country and other Russian-speaking countries. This situation will also hinder the conduct of cross-cultural comparisons on the CQIP between countries. Therefore, this study endeavored to produce a Russian version of the LCQ-IPS (LCQ-IPS-R) and test its psychometric properties among nurses in Kazakhstan.

3. Aim

This study assessed LCQ-IPS-R's validity and reliability to assess the CQIP of hospitals in Kazakhstan based on nurses' perceptions.

4. Research Questions

(1) To what extent can the LCQ-IPS-R demonstrate content and construct validity when administered to Kazakh nurses?

(2) What internal consistency reliability level does the LCQ-IPS-R and its subscales exhibited when administered to Kazakh nurses?

5. Method

5.1. Design. This study is a quantitative investigation utilizing a methodological design.

5.2. Samples and Setting. The data for this study were collected at the "National Research Center for Maternal and Child Health" (NRCMCH). The NRCMCH is a clinical research facility, one of the three medical centers under the "University Medical Center Corporate Fund" (UMC) in Astana City, Kazakhstan. There were approximately 950 nurses employed in the UMC hospitals, and invitations were extended to them to participate voluntarily. However, due to the nature of convenience sampling, only 204 nurses responded and voluntarily completed the questionnaire (response rate: 25.3%). However, since this is a validation study, the researchers used the "sample to scale item ratio" (1 : 10 ratio) in identifying the sample size, which is the commonly used method in identifying the adequate sample

size when conducting factor analysis [20]. Since there are 19 items in the scale, the needed sample size was 190 nurses. Hence, the present sample size was more than adequate for the study [20]. The following were the inclusion criteria: (1) citizen of Kazakhstan, (2) staff nurse at NRCMCH, (3) with nursing or midwifery certificate, (4) reads and understands the Russian language, and (5) with at least six months working experience at the NRCMCH.

5.3. Instrument. The online survey contained questions to elicit data for the respondents' age, sex, marital status, education, and length of experience. The online survey also contains the LCQ-IPS-R, translated from the original English version by Pogorzelska-Maziarz et al. [19]. The "cultural and linguistic adaptation" process followed a "forward-backward translation" technique [21]. Two translators independently translated the scale from English to Russian language. Another translator synthesized the two translations to develop a single tentative Russian translation. Two translators separately back-translated the tentative Russian version to English. The tentative Russian version and the two back translations were presented to a panel of experts (on infection control and prevention) with six members. The panel examined the "semantic, idiomatic, experiential, and conceptual equivalence" between those versions. The panel also examined the tool's content validity following Polit and Beck's [22] recommendations.

The LCQ-IPS comprises 19 items that capture the central dimensions of a healthcare organization's climate of quality of IPC. The items of the scale were originally from the "Leading Culture of Quality" questionnaire created by the "Institute for Clinical Systems Improvement and Satisfaction Performance Research" in Minnesota to be used by healthcare organizations to assess their "quality-oriented climate." Pogorzelska-Maziarz et al. [19] adapted the items and revised them to be focused on infection prevention. The scale can measure four aspects of the IPC climate of a hospital, including "psychological safety, prioritization of quality, supportive work environment, and improvement orientation." The items are responded to using a 5-point Likert scale (1 = "strongly disagree" to 5 = "strongly agree"). Mean dimension scores are calculated after reverse scoring item number 16 as it is a negatively worded item. Higher mean scores indicate a better or more positive IPC climate of the hospital. The scale had been used to assess the nurses' [4] and nursing students' [1, 8] perceptions of their hospitals' IPC climate. The LCQ-IPS had good internal consistency (Cronbach's $\alpha = 0.926$), criterion validity, and construct validity [19]. The copyright holder of the LCQ-IP permitted the use and translation of the tool through e-mail (M. Pogorzelska-Maziarz, personal communication, August 20, 2021).

5.4. Ethical Considerations. This report is part of a research protocol approved by the Institutional Research Ethics Committee of Nazarbayev University (Register Number: 448/24092021) and the Research Ethics Committee of UMC. The study strictly adhered to the guidelines set by these

committees in the ethical conduct of research and the Declaration of Helsinki on ethical principles in researching human subjects. The IRB assessed the study protocol, research instruments, and ethical considerations to ensure compliance with ethical guidelines and regulations. The approval was obtained before initiating data collection. Information about the study (study's purpose, procedures, risks and benefits, and voluntary nature) and the rights (right to refuse and withdraw from participating) of the respondents was provided at the beginning of the online survey. The contact information of the principal investigator was provided on the same part of the survey in case the respondents have clarifications or questions about their study. Participation in the study was voluntary, and those who decided not to participate were free to ignore and leave the online survey. Those who volunteered to join signed an electronic informed consent form by clicking the "I agree" button at the end of the consent. No personal information that can identify the respondent was collected, and data were treated and reported aggregately. The researchers programmed Survey Monkey to collect strictly anonymous responses (i.e., no IP address, e-mail address, or name will be saved). Moreover, in the tool settings, nurses were allowed to submit their responses only once, preventing them from submitting multiple responses. A rigorous data cleaning procedure was also conducted to identify and remove any duplicated entries. Data were handled carefully, with aggregated and nonidentifiable results presented. By upholding this ethical consideration, the online survey was conducted with integrity, ensuring that the participant rights, privacy, and confidentiality were protected.

5.5. Data Collection. The researchers sought permission to conduct the study from the head of NRCMCH, outlining the purpose, objectives, and methodology of the study. The data for the study were collected from November 2021 to April 2022 using an online survey (Survey Monkey). The online survey's link, containing the study's information, electronic informed consent, and questionnaire, was forwarded to the nurses working in NRCMCH through e-mail and WhatsApp. A reminder message was sent to the potential respondents every two weeks to remind them about the survey. The collected data downloaded from Survey Monkey were securely stored and managed to ensure confidentiality and data integrity. The research team organized and documented the data in a structured format, making it ready for analysis.

5.6. Data Analysis. Analyses were conducted using SPSS version 22.0. Descriptive analyses were performed to analyze the demographic variables in the study. The "item-level" (I-CVI) and "scale-level" content validity indices (S-CVI/Ave) were computed from the ratings given by a panel of six experts. The acceptable I-CVIs and S-CVI/Ave for a six-member panel of experts are ≥0.78 and ≥0.90, respectively [22]. Item-to-total correlation (ITC) was analyzed to support the scale's internal structure validity. Items with ITC values less than 0.30 and more than 0.80 and items that will cause ≥10% increase in the scale's "Cronbach's alpha score when

removed" were dropped from the scale. For construct validity, PCA with Varimax rotation was carried out. The "sampling adequacy" and the "appropriateness of the factor model" were determined by calculating the "Kaiser–Meyer–Olkin index" (KMO value ≥ 0.60) and "Bartlett's test of sphericity" ($p < 0.05$), respectively. Extraction of factors will consider an eigenvalue >1 and factor loading of >0.40 [23]. For reliability, internal consistency reliability was determined. Cronbach's alpha ($\alpha \geq 0.70$) was calculated for the scale's reliability [24].

6. Results

The nurses' age ranged from 20 to 60 years ($M = 34.63$; SD = 10.73) years. Less than 10% of the respondents were males, and more than half of the sample was married (56.9%). Most of the respondents had finished a certificate in nursing or midwifery in a nursing college (56.9%). The year of experience as a nurse ranged from 0.80 to 40 years ($M = 12.33$; SD = 10.12) (Table 1).

6.1. Item Analysis on the LCQ-IPS Russian Version. The results of the item analysis conducted on the LCQ-IPS-R are summarized in Table 2. The mean range of the scale's items was from 3.56 (SD = 1.22) to 4.40 (SD = 0.85; SD = 0.92). The corrected ITC ranged from 0.321 (item 16) to 0.707 (item 8). Cronbach's α values "if the item is deleted" ranged from 0.901 (items 5 and 13) to 0.910 (items 17 and 18).

6.2. Validity of the LCQ-IPS Russian Version. The six experts rated the I-CVI from 0.83 to 1.00, with an S-CVI/Ave of 0.90. All the items were subjected to the PCA. The KMO value was 0.87, and Bartlett's test of sphericity was significant ($p < 0.001$); thus, the sample was adequate to continue with the PCA. The PCA with Varimax rotation produced four distinct components of the LCQ-IPS-R with an eigenvalue greater than 1 (range = 1.23 to 7.80). The overall explained variance of the four components was 69.8%. Seven of the 19 items were loaded in component 1 (factor loading range = 0.724–0.862) with the highest explained variance (41.0%). Component 2 explained 14.3% of the variance with seven items loaded (factor loading range = 0.482 to 0.795). For component 3, four items were loaded on it with factor loading from 0.528 to 0.868 and an explained variance of 8.0%. Three items were loaded in component four (factor loading range = 0.687 to 0.878), contributing to 6.5% of the variance explained. However, items 13 and 14 were cross-loaded in components 2 and 3. The researchers decided to retain both items in component 3. Therefore, the final model comprises the following: component 1, "psychological safety" (7 items); component 2, "prioritization of quality" (5 items); component 3, "supportive work environment" (4 items); and component 4, "improvement orientation" (3 items) (see Table 3).

The tests of correlation between the four components of the LCQ-IPS-R revealed medium to large positive associations among the components ($r = 0.25–0.55$, $p < 0.001$) (see Table 4).

Table 1: Demographic characteristics of the respondents ($n = 204$).

Variable	Mean (SD)	Range
Age	34.63 (10.73)	20–60
Years of experience	12.33 (10.12)	0.80–40
	n	%
Gender		
Male	20	9.8
Female	184	90.2
Marital status		
Single	68	33.3
Married	116	56.9
Separated/divorced/widow/er	20	9.8
Highest educational attainment		
Certificate in nursing or midwifery (nursing college)	116	56.9
Certificate in nursing or midwifery (higher medical college)	15	7.4
Feldsher	12	5.9
Baccalaureate in nursing (applied bachelor)	15	7.4
Baccalaureate in nursing (academic bachelor)	41	20.1
Graduate program (master or doctorate)	5	2.5

Table 2: Item mean, corrected item-total correlations, and Cronbach's α if item is deleted for the Leading a Culture of Quality in Infection Prevention Scale Russian version ($n = 204$).

No.	Item	Mean	SD	Corrected item-total correlation	Cronbach's α if item is deleted
1	The climate in the organization promotes the free exchange of ideas	4.22	0.97	0.545	0.905
2	Staff will freely speak up if they see something that may improve patient care or affect patient safety	4.35	0.92	0.643	0.903
3	I feel free to express my opinion without worrying about the outcome	4.17	1.02	0.650	0.902
4	In general, people in our organization treat each other with respect	4.22	1.02	0.566	0.905
5	People in this organization are comfortable checking with each other if they have questions about the right way to do something	4.27	0.96	0.695	0.901
6	The people in this organization value others' unique skills and talents	4.21	1.05	0.603	0.904
7	Members of this organization are able to bring up problems and tough issues	4.13	1.03	0.636	0.903
8	The healthcare-associated infection prevention goals and strategic plan of our organization are clear and well communicated	4.40	0.85	0.707	0.902
9	Results of our infection prevention efforts are measured and communicated regularly to staff	4.33	0.80	0.626	0.904
10	There is a good information flow among departments to provide high-quality patient safety and care	4.29	0.84	0.658	0.903
11	People here feel a sense of urgency about preventing healthcare-associated infections	4.22	0.98	0.565	0.905
12	Employees are encouraged to become involved in infection prevention	3.96	1.10	0.551	0.905
13	Senior leadership here has created an environment that enables changes to be made	4.00	1.06	0.691	0.901
14	Where I work, people are held accountable for the results of their work	4.35	0.97	0.667	0.902
15	The quality of work suffers because of the amount of work staff are expected to do	3.67	1.25	0.453	0.909
16	Most people in this organization are so busy that they have very little time to devote to infection prevention efforts	3.56	1.22	0.321	0.913
17	I can think of examples when problems with patient infections have led to changes in our procedures or equipment	3.87	1.09	0.377	0.910
18	I know of one or more healthcare-associated infection prevention initiatives going on within our organization this year	3.94	1.02	0.376	0.910
19	I have a clear understanding of the organization's mission, vision, and values	4.40	0.92	0.529	0.906

6.3. Reliability of the LCQ-IPS Russian Version. The computed Cronbach's alpha for the LCQ-IPS-R was 0.909. For the subscales, Cronbach's alpha values of 0.921, 0.855, 0.813, and 0.809 were computed for "Psychological safety," "Prioritization of quality," "Supportive work environment," and "Improvement orientation," respectively (see Table 5).

Table 3: Results of the principal component analysis for the Leading a Culture of Quality in Infection Prevention Scale Russian version ($n = 204$).

Item	Factor 1 Psychological safety	Factor 2 Prioritization of quality	Factor 3 Supportive work environment	Factor 4 Improvement orientation
Q5	0.862			
Q4	0.833			
Q3	0.819			
Q2	0.786			
Q6	0.770			
Q7	0.733

Q18				0.878
Q17				0.865
Q19				0.687
Eigenvalue	7.80	2.71	1.52	1.23
Variance explained (%)	41.0%	14.3%	8.0%	6.5%
Cumulative variance explained (%)	41.0%	55.3%	63.3%	69.8%

Table 4: Correlation between the three factors of the Leading a Culture of Quality in Infection Prevention Scale Russian version ($n = 204$).

Factors	Psychological safety	Prioritization of quality	Supportive work environment
Prioritization of quality	0.55 ($<0.001^{***}$)		
Supportive work environment	0.34 ($<0.001^{***}$)	0.55 ($<0.001^{***}$)	
Improvement orientation	0.25 ($<0.001^{***}$)	0.37 ($<0.001^{***}$)	0.41 ($<0.001^{***}$)

Note. ***Significant at 0.001 level.

7. Discussion

This study showed evidence of the validity and reliability of the LCQ-IPS-R in assessing the CQIP of hospitals in Kazakhstan as perceived by nurses. When evaluating the various aspects of the hospital's CQIP from a nurse's standpoint, it is vital to use a valid and reliable measurement scale. This psychometric assessment is the first to test the suitability of LCQ-IPS in the Kazakhstan context and Russian language.

The result of the content validity test revealed that the IPC experts evaluated all the LCQ-IPS-R items as relevant or highly relevant in assessing the CQIP of hospitals in Kazakhstan context and language. The LCQ-IPS-R had undergone a rigorous translation process using the "forward-backward translation method" from the original language of the scale (English) to Russian. The excellent content validity indices of the Russian version ascertained its equivalency in both linguistic and cultural contexts with the original version [25]. This excellent content validity exhibited that the translated items effectively capture the content and the meaning of the original tool [19]. Thus, the Russian version is parallel with its intended construct and

maintains its validity when applied to Russian-speaking nurses in Kazakhstan. Previous studies reporting content validity of other scale versions also reported similar excellent content validity indices in various countries [1, 3, 19].

A descriptive analysis of the scale items was performed. The analysis reflected that "the healthcare-associated infection prevention goals and strategic plan of our organization are clear and well communicated" and "I have a clear understanding of the organization's mission, vision, and values" received the highest item mean. These high mean scores demonstrate that nurses clearly understood their hospital's goals and strategic plan related to HAI prevention goals, as well as their hospital's mission, vision, and values. This finding further suggests that the healthcare organization was successful in communicating with clarity regarding its infection prevention goals, strategic plan, and core values among its healthcare staff [16]. This result is worth noting since the health organization's values, goals, and strategic plan emphasizing the IPC climate are critical in promoting patient safety culture [6]. The nurses' knowledge and understanding of the hospital's mission, vision, and values could help them properly align their actions towards achieving quality and patient safety improvement, including

Table 5: Internal consistency reliability of the Leading a Culture of Quality in Infection Prevention Scale Russian version ($n = 204$).

Variable	Cronbach's alpha
Psychological safety	0.921
Prioritization of quality	0.855
Supportive work environment	0.813
Improvement orientation	0.809
Leading a Culture of Quality in Infection Prevention Scale Russian version	0.909

reducing infection risk and protecting the patients and other healthcare professionals (Alquwez et al., 2018). Additionally, ITCs were used to support the internal construct validity of the tool. The result showed that all ITCs were between 0.30 and 0.80, which implies acceptable ITC values based on the definition of Nunnally and Bernstein [24]. This also means that the items are reasonably connected to the overall construct and contribute significantly to its measurement [23]. The "Cronbach's alpha if the item is deleted" values also showed that none of the items, when deleted, will cause a substantial increase in the scale's overall Cronbach's alpha. The findings indicate that all the items are relevant to the totality of the scale. Thus, they were entered into the PCA.

The tool manifested a suitable construct validity, as shown by the 4-factor solution of the PCA explaining 69.8% of the overall scale's variance. This means that the four distinct factors in the scale contributed about 69.8% of the total variance in the nurses' perceptions of their hospital's CQIP. This overall explained variance of the four factors in the LCQ-IPS-R is indicative that the tool had a good construct validity [26]. This explained variance was higher than the explained variance of the English version (58.8%) but lower than that of the Arabic version (70.7%) [1]. Similar to the LCQ-IPS, the subscales were labeled "Psychological safety," "Prioritization of quality," "Supportive work environment," and "Improvement orientation" [19]. Our findings also confirm the previous results reported in the English and Arabic versions of the scale that "Psychological safety" (41.0%) has the most substantial contribution to the variance of CQIP, followed by "Prioritization of quality," "Supportive work environment," and "Improvement orientation" [1, 19].

However, items 13 and 14 were loaded on components 2 and 3. According to Al-Dwaikat et al. [27], if an item is loaded into two different domains, these items can be removed as it creates confusion in labeling all factors that share similar variables. However, Nunnally and Bernstein [24] argued that if items are loaded in at least two factors, they can be kept in the factor they had strong association. Item 13 states that "senior leadership here has created an environment that enables changes to be made," and item 14 states "where I work, people are held accountable for the results of their work." Both items were more related to the nurses' working environment than the concept of prioritizing quality. Also, items 13 and 14 were heavily loaded more on the "Supportive work environment" factor than in "Prioritization of quality." A supportive nursing leadership that promotes accountability is a characteristic of a positive work environment [3, 28]. A systematic review by Wei et al. [29] also reported that nurses' safe and positive work environment, empowerment, autonomy, positive relationships with

other team members, and organizational support significantly ensure IPC in hospitals. Therefore, in this study, we decided to retain both items in factor 3.

Factor 1, "Psychological safety," constitutes seven items. This factor is composed of items describing a hospital that promotes the free exchange of ideas about IPC and patient safety. It also includes issues and challenges related to these aspects in the hospital. This implies that the nurses value a hospital climate that promotes openness to these issues. They believed that having an organizational culture that allows a free exchange of ideas impacts the attainment of IPC and patient safety in the hospital. The data collection for this study was conducted between November 2021 to April 2022, when significant changes happened in Kazakhstan's healthcare work environment and practices. Several measures were carried out to mitigate the spread of COVID-19 infection in workplaces [15]. Smith et al. [30] explained that appropriate infection control measure implementation in the clinical setting might positively affect healthcare professionals, such as reducing anxiety and worries about contact/disease transmission while performing patient care. In a systematic review conducted by Lawrence and Kinnear [31], psychological safety promotes teamwork, open communication, and continuous improvement culture. When individuals feel safe psychologically, they are more likely to share their valuable insights, report errors or near misses, and actively participate in ward decision-making processes. Thus, psychological safety is crucial in healthcare facilities to ensure the effective implementation of IPC policies and guidelines and the attainment of patient safety goals.

The second factor, "Prioritization of quality," has five items. The items in this factor talk about the clarity of the hospital's IPC goals and plans, assessment of IPC efforts and communication of findings, effective communication regarding IPC, and the prioritization of IPC in the hospital. Hence, prioritizing the quality of IPC in hospitals during those times is essential to deliver safe and effective nursing care. Tumala et al. [8] reiterated that to ensure the best IPC practices in patient care, a clear technical guideline on IPC according to available resources and clear IPC goals and plans should be present. The "Ministry of Healthcare of the Republic of Kazakhstan" [32] mandated that all health centers, hospitals, and health clinics prioritize their IPC plan across all departments/areas to reduce the risk of infection and guarantee patient safety. Therefore, by prioritizing quality IPC, the country's healthcare system can enhance patient safety, improve healthcare outcomes, and reduce the HAI burden.

Four items constitute factor 3, "Supportive work environment." These items tackle leadership support to IPC, accountability of healthcare workers, and the effects of high workload and inadequate time on IPC practices. This factor generates an insight that nurses' working environment influences the nurses' provision of efficient nursing service and effective IPC initiatives [33, 34]. During the pandemic, nurses rendered most of their time to patient care, often facing a higher patient load that demands attention [35]. As this factor shows, the time and workload of nurses are crucial in determining if they can effectively practice IPC. According to Park and Kim [36], a nonsupportive work environment is associated with high burnout, higher turnover intention, and lower job satisfaction. Hence, the work environment is crucial to creating safe health care and reducing infection risks in a clinical setting.

Finally, three items made up factor 4, "Improvement orientation." This factor includes the following items: "I can think of examples when problems with patient infections have led to changes in our procedures or equipment," "I know of one or more healthcare-associated infection prevention initiatives going on within our organization this year," and "I have a clear understanding of the organization's mission, vision, and values." This factor highlights the alignment of IPC goals and the healthcare organization's "mission, vision, and values." Also, a healthcare organization that is serious about achieving IPC goals should have clear policies, guidelines, and plans in achieving its IPC goals. According to [9], regular assessments and monitoring practices and timely feedback for healthcare professionals are necessary to achieve continuous improvement orientation on infection control.

The scale's overall Cronbach'sα alpha is 0.909, with a range of 0.809 to 0.921 for its four subscales. According to Nunnally and Bernstein [24], a criterion of 0.70 or above indicates acceptable internal consistency. It suggests that the scale's items are highly correlated with each other and holistically evaluate the intended construct in a consistent and reliable manner. This result is higher than that of other previous studies, which reported similar good internal consistency reliability using the same tool. For example, Tumala et al. [8] conducted a survey using the Arabic version among 829 Saudi nursing students in six Saudi universities, which found Cronbach's alpha of 0.89. Meanwhile, in the study by Colet et al. [4] among nurses in Riyadh, Saudi Arabia, Cronbach's α was 0.87, signifying good internal consistency. In addition, it is crucial to note that Cronbach's alpha coefficients are affected by the item number on an instrument measurement [37]. Thus, the LCQ-IPS-R exhibits excellent internal consistency.

7.1. Limitations.

A few limitations need consideration when interpreting the study's results. The LCQ-IPS-R's validity was supported by "content validity" and "construct validity" through PCA. While these tests provided evidence for the tool's acceptable validity, other validity tests should be performed in the LCQ-IPS-R in the future. Also, the tool's structure was supported only by PCA. A CFA should be done to support LCQ-IPS-R's four-factor structure. The CFA omission might impact the validation process robustness and could influence the interpretation of the results. Therefore, further studies are warranted for CFA incorporation in enhancing the validity assessment and ensure a more comprehensive adapted scale validation. Also, the reliability of the tool was supported only by "internal consistency." Other reliability measures, such as stability reliability, can be done in the future to strengthen the evidence of the reliability of this version.

8. Conclusion

This investigation substantially contributes to the literature on the IPC of hospitals worldwide and in Kazakhstan by measuring the LCQ-IPS-R's psychometric properties. This research provides evidence of the LCQ-IP-R's validity and reliability in assessing the Russian-speaking nurses' perception of their hospital's CQIP. Specifically, the LCQ-IP-R's validity was supported by excellent "content and construct validity." The PCA affirmed the four subscales of the tool similar to the original versions, namely, "Psychological safety, Prioritization of quality, Supportive work environment, and Improvement orientation." The LCQ-IP-R and its four subscales had high internal consistency reliability. Therefore, the LCQ-IP-R can provide a valid and reliable assessment of the CQIP in hospitals in Kazakhstan and other Russian-speaking countries from clinical nurses' perceptions. This scale offers the opportunity to derive baseline information enabling the design and implementation of effective interventions to ensure the attainment of IPC goals of hospitals.

8.1. Implications.

The LCQ-IP-R was used for the first time among Kazakhstan's nurses, supporting the scale's validity and reliability. This result could pave the way for more research regarding CQIP of healthcare settings to be conducted in Kazakhstan, Central Asia, and other Russian-speaking countries. Also, the results are of great significance to the nursing profession as it established an effective measurement tool of CQIP, which can provide information for designing IPC policies and guidelines and planning IPC initiatives to ensure patient safety in clinical settings. Hospital administrators could use this tool to conduct continuous and regular assessments of the IPC situations in their hospitals. These assessments can improve the hospital's psychological safety, prioritize IPC, create a supportive working environment, and ensure quality improvement in IPC. Likewise, head nurses, managers, and nursing directors could actively promote CQIP by ensuring adequate resources for IPC measures using the baseline information gathered through the tool used and may stimulate the continuous improvement of IPC measures.

Data Availability

The data used to support the findings of this study have not been made available because participants were assured of their privacy and confidentiality.

Conflicts of Interest

Aim. The purpose of this study was to examine the association among doctor-patient communication, trust, and patients' negative stereotypes for healthcare professionals during COVID-19. *Background.* Patients' negative stereotypes for healthcare professionals have been considered a major cause of violence against healthcare professionals. During COVID-19, since the fear for illness could exacerbate patients' negative stereotypes for healthcare professionals, therefore, how to inhibit patients' negative stereotypes for healthcare professionals has become a top priority. *Methods.* From January 2020 to April 2020, a cross-sectional survey study was performed in which a total of 2000 patients were convenience-sampled from different regions of China. The survey measured doctor-patient communication, institutional trust, interpersonal trust, and patients' negative stereotypes for healthcare professionals, respectively. After standardizing the total data scores, the association between doctor-patient communication, trust and patients' negative stereotypes for healthcare professionals using the bootstrap method was built. *Results.* There was a moderate to the high correlation between doctor-patient communication, patients' negative stereotypes for healthcare professionals, interpersonal trust, and institution trust ($r = 0.36$–0.68, $p < 0.01$). Mediation analysis showed that patients' interpersonal trust ($\beta = -0.25$, 95% CI: -0.312–-0.209) than patients' institution trust ($\beta = -0.02$, 95% CI: -0.042–-0.007) played a greater role in suppressing negative stereotypes through doctor-patient communication. *Conclusions.* Through communication, healthcare professionals and patients increase their familiarity and identification, thereby reducing patients' negative stereotypes. Moreover, because interpersonal trust connotes emotional and cognitive trust, it was more beneficial than institution trust in reducing negative stereotypes. *Implications for Nursing Management.* The results of this study can tell governments, healthcare organizations, communities, and healthcare professionals that reducing violent behaviors based on negative stereotypes requires attention to institutional trust building, interpersonal trust development, and communication improvement.

1. Introduction

In China, the incidence of violence against healthcare workers reached 59.64%–76.2% [1]. In this regard, patients' negative stereotypes for healthcare professionals are identified as the main reason [2]. Stereotypes are defined as fixed, generalized, and abstract perceptions about a certain type of person or thing, and having negative stereotypes can interfere with an individual's cognitive work and lead to negativity and prejudice against the target group [3]. It was found that when patients have negative stereotypes for healthcare professionals, they are less likely to seek care and have fewer patient-provider interactions during the consultation process [4], which ultimately affects patient satisfaction with the providers.

During COVID-19, patients' negative stereotypes for healthcare professionals may be further amplified. Because of the rapid contagiousness and seriousness of COVID-19,

patients feel significantly more anxious and out of control [5]; meanwhile, the healthcare sector has implemented a series of policies to reduce the risk of COVID-19 transmission, such as patient isolation, and limiting the number of visits etc., all of which may lead to patients' negative stereotypes for healthcare professionals. Recently, a meta-analysis involving 11,938 healthcare professionals around the world confirmed that there was a general increase in stigma and violence induced by patients' negative stereotypes during COVID-19 [6]. Therefore, there are significant practical implications on how to effectively inhibit patients' negative stereotypes for healthcare professionals.

Intergroup contact theory states that intergroup contact can lead to more positive attitudes and a decrease in negative stereotypes [7]. In which communication, as the main mode of intergroup contact, has an important influence on negative stereotypes. Particularly in China, doctor-patient communication is a key indicator affecting patients' stereotypes for healthcare professionals. China has over 1.4 billion people but less than 5 million doctors [8]. The severely imbalanced doctor-patient ratio has led to a tendency for healthcare professionals to compress communication time with patients, in order to ensure that more patients are served in a given amount of time [9]. In this situation, Chinese healthcare professionals usually focus on disease in the process of communication with patients, neglecting emotional communication and lacking information sharing with patients, thus forming patients' negative stereotypes for healthcare professionals, such as hard attitude and lack of empathy [10, 11]. However, through high-quality doctor-patient communication, it will help convey positive messages and eliminate treatment misunderstandings between doctors and patients, which will improve patients' positive stereotypes for healthcare professionals [12]. Research confirms that by increasing the frequency of doctor-patient communication, patients conveyed more positive messages about healthcare professionals among themselves, while expressing more positive stereotypes for healthcare professionals [13]. In addition, during the communication process, both shared information and joint decision-making also suppressed negative stereotypes for healthcare professionals [14].

Although there is some research support for the effectiveness of doctor-patient communication in reducing patients' negative stereotypes, however, communication as a two-way interactive process, the effect of communication is influenced by the psychosocial aspects of the message sender and the message receiver [15]. For example, in the theory of information transfer, the sender and receiver of information consider the possible costs of sending or receiving information. Therefore, during the transmission of information, the receiver of the message critically evaluates the transmitted information, which in turn affects the effectiveness of the communication [16, 17]. On this account, psychological factors are important drivers for the effectiveness of doctor-patient communication. So, which psychological factors play a key role between communication and negative stereotyping?

It was found that trust is an essential element linking communication and stereotypes [18]. By trust, patients can feel the kindness conveyed in the doctor-patient communication [19], enhancing the patient's identification with the healthcare provider [20]. Besides, patient trust also helps sharing treatment information during communication [21], which in turn influences patients' stereotypes for healthcare professionals. According to Luhmann's (2018) classification of trust, trust is divided into interpersonal trust and institutional trust, which have different roles and psychological mechanisms, respectively. Specifically, interpersonal trust is an expected judgment and psychological state, in which patients and healthcare professionals believe that the other party will not act against them during the interaction [23]. Institutional trust is the expectation and belief whether the healthcare system is credible in the doctor-patient interaction [24]. Compared with interpersonal trust, institutional trust can control people's behavior within a certain range by approving and encouraging behaviors that conform to institutional regulations, and punishing behaviors that violate institutional regulations, hence greatly reducing social uncertainty and risk [25]. Thus, in the medical process, patients are able to demonstrate high interpersonal trust if the healthcare provider is an "acquaintance" or a family member or friend, but if the patient has low interpersonal trust in the healthcare provider, they are likely to seek institutional trust as a substitute [26]. During the effect of doctor-patient communication on negative stereotypes, interpersonal trust and institutional trust also have different psychological mechanisms. On the one hand, interpersonal trust builds mutual emotions and awareness among individuals in interpersonal interactions, which depend on mutual rational thinking and emotional identification [27]. Thus, interpersonal trust contains both cognitive and affective elements [28]. However, institutional trust is built by combining regulations, discipline, and preventive mechanisms, where people's trust in the institution depends mainly on its rationality and legitimacy excluding emotional elements [22]. Therefore, in the effect of doctor-patient communication on stereotypes, interpersonal trust can affect stereotypes through the tone emotion and content cognition in the communication process, but institutional trust only works by influencing the cognitive component of the communication process. Studies confirmed that interpersonal trust relies on influencing listener emotions to enhance the effectiveness of communication during COVID-19 [29], and that institutional trust is dependent on honest and transparent communication content acting on patients' cognitive [30]. On the other hand, interpersonal trust involves interdependence among individuals and promotes cooperation mainly by reducing the fear of individuals being used by others [31]. Once there is a breach of trust in others, individuals tend to pay attention to negative stimuli of others evoking negative stereotypes [32]. By contrast, institutional trust promotes cooperation through deterrence and balance [33]. When people do not trust the system that protects their rights and interests, they become less tolerant of the outgroup, which in turn increases

hostility toward the outgroup and creates negative stereotypes of the outgroup [34].

In summary, doctor-patient communication is closely related to patients' negative stereotypes for healthcare professionals, and also, trust as a psychological driver affecting communication and negative stereotypes, with different trust mechanisms playing different roles between communication and negative stereotypes. Especially during COVID-19, the emotional and rational components carried by interpersonal and institutional trust are likely to be further prominent in communication and stereotypes. Based on this, the study investigated doctor-patient communication, interpersonal trust, institutional trust, and patients' stereotypes for healthcare professionals during COVID-19 using a questionnaire method, aiming to further elucidate the association among doctor-patient communication, trust, and patients' negative stereotypes for healthcare professionals.

2. Methodology

2.1. Sample and Process. From January 2020 to April 2020, a nationwide cross-sectional survey was conducted using a convenience sample at hospitals from 28 provinces in China, including Beijing, Shanghai, Jiangsu, Anhui, Hunan, Xinjiang, and Guangxi, and a total of 2,000 participants were recruited. If the patients were 18 years of age or older, volunteered to participate in the study, and provided verbal informed consent, they were eligible to participate. After completing the research, patients will receive gifts that will be randomly selected. Regarding the survey process, we used a specialized survey platform "Questionnaire Star" for data collection. This platform has stable and reliable system and diversified service functions, which can guarantee the stability of access and data security. At the beginning of the web-based questionnaire, the researchers used standardized instructions about the purpose of the study and informed participants that they could leave the study at any time. Besides, the responses are administered online, allowing patients to fill out the questionnaire at their convenience and have the opportunity to ask the researcher questions. All study data were collected anonymously and confidentially. After the data collection was completed, we performed data cleaning to remove invalid samples, which involved excluding duplicate samples, logically contradictory answers, incorrect values, and clearly inattentive responses. When the data were deemed to have content accuracy, we further excluded data beyond 3 standard deviations of the mean response time, resulting in a total of 1445 valid data. Permission for this study was obtained from the Ethics Committee of Shanghai Normal University.

2.2. Questionnaire Measurement. The SEGUE Framework, developed by Makoul [35] and revised by China Medical University in 2006, was used to measure patient ratings for healthcare professionals' communication skills. This scale has five dimensions: preparation, requesting information, providing information, understanding the patient, and ending the consultation. These five dimensions consist of a total of 25 entries, such as "the doctor will greet me politely during the visit" and "the doctor will pick up on my cues." All questions were scored on a five-point Likert scale (1 = "never" and 5 = "all the time"), with higher scores reflecting better patient ratings for physicians' communication skills. Cronbach's alpha coefficient for the scale was 0.878.

The medical stereotype questionnaire developed by Ye et al. [36] was used to measure patients' stereotypes for healthcare professionals. The scale has a total of 24 items, such as "respect for life" and "professionalism," all of which are rated on a five-point Likert scale (1 = "completely disagree" and 5 = "completely agree"), with lower scores indicating a stronger patients' negative stereotypes for healthcare professionals. Cronbach's alpha coefficient for this scale was 0.980.

The Chinese version of the Wake Forest Trust Scale (CWFPTS) is used to assess patients' interpersonal trust in their physicians. The scale was originally developed by Hall et al. and was introduced and revised in Chinese in 2012 [37]. The scale consists of 10 items that cover topics such as "my doctor has my best interests at heart" and "I trust my doctor." All questions were scored on a five-point Likert scale (1 = "strongly disagree" and 5 = "strongly agree"), with higher scores reflecting higher levels of interpersonal trust. Cronbach's alpha for CWFPTS was 0.89.

A self-administered questionnaire was used to measure patients' institutional trust in the healthcare system. The scale assesses patients' trust in the process of access to care, trust in the professional practices of healthcare providers, trust in the quality and safety of the healthcare system, and trust in health insurance. All items were validated by seven front-line medical staff from different regional hospitals using the Delphi method, and there were 31 items, such as "the current medical system is not against social ethics" and "the current medical system reflects fairness." In addition, all questions were rated on a five-point Likert scale (1 = "completely disagree" and 5 = "completely agree"), with higher scores reflecting greater institutional trust. Cronbach's alpha coefficient for this scale was 0.899.

2.3. Analysis. Data analysis was performed using SPSS version 23.0. We performed descriptive analysis, Pearson correlation analysis, and mediation analysis (Model 4 of SPSS Hayes process macro3.3). We normalize all continuous variables and use Hayes' bootstrapping method to test the model. The bootstrapping method is less affected by sample size and does not assume the normality of the mediated paths, so it yields more accurate confidence estimates.

3. Results

3.1. Sample Characteristics. In this study, 2000 patients were invited to participate voluntarily in the survey. As subjects were allowed to freely choose to withdraw from this study, and also freely choose the time and place of completion, so after we implemented the exclusion criteria in strict

accordance with the statistical guidelines of psychometrics and epidemiology, the total number of valid samples recovered was 1445 (72.2%), of which the mean age of the patients was 35.9 years (SD = 11.5). The specific characteristics of the patients are shown in Table 1.

3.2. Descriptive Statistics and Correlation Analysis. Table 2 shows all mean scores, standard deviations, and Pearson correlation of the main variables. As expected, doctor-patient communication, interpersonal trust, and institution trust were positively correlated ($r = 0.36$–0.67, $p < 0.01$). The patients' negative stereotypes for healthcare professionals were negatively correlated with doctor-patient communication, interpersonal trust, and institution trust ($r = -0.36$ to -0.68, $p < 0.01$).

3.3. Mediation Role Analysis. When testing the relationship between doctor-patient communication and patients' negative stereotypes, we found a significant effect of doctor-patient communication on the total effect of negative stereotypes. After adding in interpersonal trust and institution trust, doctor-patient communication had a direct effect on interpersonal trust ($\beta = 0.67$, $p < 0.001$) and institution trust ($\beta = 0.36$, $p < 0.001$). Interpersonal trust ($\beta = -0.38$, $p < 0.001$) and institution trust ($\beta = -0.07$, $p < -0.001$) had a direct effect on patients' negative stereotypes. Doctor-patient communication ($\beta = -0.40$, $p < 0.001$) had a direct effect on patients' negative stereotypes (see Figure 1).

Further, the mediating effect was tested using the bias calibration nonparametric percentile Bootstrap method, and the results showed that interpersonal trust and institution trust mediated significantly, with a mediating effect value of -0.28. Specifically, the mediating effect was generated through two mediating chains: first, an indirect effect consisting of communication ⟶ interpersonal trust ⟶ stereotypes (-0.26), with Bootstrap 95% confidence interval not containing 0, indicating a significant mediating effect on interpersonal trust, second, an indirect effect consisting of communication ⟶ institution trust ⟶ stereotypes (-0.02), with Bootstrap 95% confidence interval does not contain 0, indicating a significant mediating effect on institutional trust (see Table 3).

4. Discussion

Our main findings suggest that the doctor-patient communication during COVID-19 was the main factor in reducing patients' negative stereotypes for healthcare professionals. Moreover, doctor-patient communication can indirectly influence patients' negative stereotypes through trust, suggesting that patients' trust is an important psychological process that contributes to patients' negative stereotypes. In addition, at the level of patients' trust, interpersonal trust and institution trust played different roles in reducing patients' negative stereotypes. Of these, interpersonal trust has a greater impact on reducing negative stereotypes than institution trust, and it can be argued that developing interpersonal trust between patients and doctors

has a greater benefit in reducing patients' negative stereotypes for healthcare professionals.

Specifically, our study found that doctor-patient communication is effective in reducing patients' negative stereotypes. This finding is both consistent with intergroup contact theory and with previously related studies. It was previously found that contact with the target group increased familiarity, mutual knowledge, and information, and increased identification with the outgroup [38], thereby reducing negative stereotypes of the outgroup. Therefore, doctor-patient communication as the main mode of intergroup contact will increase doctor-patient identification by balancing doctor-patient information and thus reduce patients' negative stereotypes for healthcare professionals. Notably, intergroup contact theory suggests that intergroup contact includes more than direct contact interactions, imaginative and online contact can also have a stereotype-reducing effect. For example, Schumann and Moore [39] conducted an 18-month-long intergroup contact intervention, which showed a similar reduction in negative stereotypes when 547 participants interacted with outgroup members by means of synchronous chat or online games. Thus, although the government adopted a policy of social distance maintenance and isolation to prevent the spread of the epidemic during COVID-19, it is still possible to reduce the patients' negative stereotypes for healthcare

professionals by using online web technologies, such as mobile devices, mobile apps, and rolling TV news.

We also found that interpersonal trust played a greater role than institution trust in the effect of doctor-patient communication on patients' negative stereotypes for healthcare professionals. In terms of the effect of doctor-patient communication on interpersonal trust and institution trust, doctor-patient communication has a greater contribution to interpersonal trust. This result is supported by previous studies. Previous research suggested that during COVID-19, real-world uncertainty increases and people face both emotional and cognitive stress. In this context, one is more likely to seek advice and trust individuals with whom one feels a sense of similarity or a close relationship [40]. In addition, social identity theory suggests that specific identity perceptions shape an individual's identification with the group, in which he or she lives and that individuals have positive evaluations in in-group members compared to outgroups. When there is no outgroup, shared destiny and similarity among members can also produce in-group identity [41]. As shared destiny is the result of two or more people experiencing congruence in response to external stimuli. Therefore, COVID-19 can be considered a shared destiny between doctors and patients. Accordingly, shared destiny can enhance the intergroup identity between doctors and patients, which in turn increases the interpersonal trust. On the other hand, between trust and patients' negative stereotypes, interpersonal trust has a stronger effect on reducing negative stereotypes. This result can be explained by risk perception theory. Risk perception theory suggests that people's subjective ratings and judgments of risk can trigger their own attitudes and decision-making tendencies [42]. Studies have found that individuals with high-risk perceptions are more likely to exhibit negative attitudes and evaluations of the target group [43], triggering negative stereotypes of the target. Meanwhile, people found that trust can help reduce patients' perception of risk [44]. However, trust from different sources is crucial when patients are assessing the risks of treatment. Hu et al. [45] used a scenario-based experiment to investigate the effect of trust on risk perception to 316 college students, finding that only individuals with high affective trust had high receptivity to risk, while cognitive trust had no effect on risk perception. Indeed, interpersonal trust has both emotional and cognitive dimensions, while institution trust has only cognitive dimensions. Thus, during COVID-19, where risk is uncertain, patients are more likely to reduce negative stereotypes through the affective dimension of interpersonal trust.

Although this study is based on a patient survey during COVID-19, the findings still have a guiding value for the issue of patients' negative stereotypes for healthcare professionals in nonepidemic periods. First, as for the effect of doctor-patient communication on negative stereotypes, patients' negative stereotypes are rooted in the asymmetry of doctor-patient information, which leads to patients' unreasonable expectations and subjective attitudes bias toward healthcare professionals [46]. However, doctor-patient communication is able to balance the information asymmetry between doctors and patients and change patients' unreasonable perceptions about healthcare professionals [47], which leads to the contextual universality in the effect of communication on stereotypes. Second, as for the effect of doctor-patient communication on interpersonal trust and institutional trust, there is still reason to believe that doctor-

patient communication has a stronger effect on interpersonal trust than institutional trust during the nonepidemic period, especially in light of the developing concept of "patient-centered communication." Because "patient-centered communication" emphasizes respect, empathy, and values between patients and doctors, which include positive emotions and attitudes [48], therefore, "patient-centered communication" is more conducive to the development of interpersonal trust between doctors and patients. Finally, as for the suppressive effect of interpersonal and institutional trust on negative stereotypes, interpersonal trust may still have played a greater role than institutional trust during the nonepidemic period. Because the healthcare situation is a risky environment with uncertainty, compared to institutional trust, interpersonal trust can further reduce patients' psychological defenses and enhance the shared value between doctors and patients through emotional connection [49]. Meanwhile, interpersonal trust has positive emotions which contribute to a more positive evaluation about others [50]. Accordingly, interpersonal trust remains more influential than institutional trust for negative stereotypes in nonepidemic periods.

There are several shortcomings in our study. First, this study used an online platform to distribute the questionnaire during COVID-19, so the survey sample mainly came from urban patients with developed online information and better medical conditions, which makes the results not generalized to all patient groups (e.g., patients in remote mountainous areas); however, considering the limitations of people mobility during the period of COVID-19, it will be a challenge to extend the coverage for more patient groups in the future during the period of major epidemics, which may require multisectoral cooperation among the government, healthcare sector, and scientific research institutes, and a combined online and offline method was used for questionnaire surveys. Second, the age of the patients in this study is concentrated between 18 and 40 years old, and less patients are older than 60 years old, which may be due to the fact that older patients cannot make good use of mobile devices, so the development of an intelligent web survey system faces challenges in the future, which requires a web survey system that can optimize the presentation of the questionnaire according to the reading habits and operating modes of different patients in the mobile smart terminals, offering a "user-friendly feedback interface," and providing intelligent auxiliary explanations for the corresponding groups. Finally, this study used a cross-sectional study, which has limitations on causal inferences; therefore, there are challenges in the future to provide more reliable causal evidence on communication, trust, and negative stereotypes, which may require the involvement of more rigorous experimental methods or longitudinal research methods.

In conjunction with the results of this study, we propose the following recommendations for inhibiting patients' negative stereotypes for healthcare professionals: first, doctor-patient communication is an important factor in reducing patients' negative stereotypes; therefore, it is necessary to train medical providers in communication skills by holding training sessions and standardizing the interpretation of questions. Besides, it is important to emphasize the appropriate emotional expression of medical staff and actively promote the sharing of information between doctors and patients [51]. Second, interpersonal trust and institutional trust both contribute to the reduction of negative stereotypes. In response, on the one hand, efforts should be made to develop interpersonal trust. For example, developing physicians' trustworthy traits such as competence, integrity, kindness, etc., and guiding patients to make proper attributions for negative events. On the other hand, attention should be paid to the building of institutional trust. In this regard, governmental departments should supervise the impartiality of the medicine institution design and facilitate the effective implementation of the medical institution, while medical organizations should ensure the openness and transparency of the institution to satisfy patients' security and to reduce their fear of epidemics, etc. Besides, it is important for communities to actively popularize the advocacy of the healthcare institution for further enhancing patients' understanding and recognition of the healthcare institution.

5. Conclusions

This study found that doctor-patient communication helped reduce patients' negative stereotypes for healthcare professionals; meanwhile, trust was an important psychological mechanism for communication to influence negative stereotypes, in which interpersonal trust played a greater role than institutional trust. These results also contributed to the reduction of negative stereotypes for healthcare professionals during the nonepidemic period. The government and the medical sector can provide an environment guarantee for institutional trust by improving institutional construction. The community and media can construct a culture environment for interpersonal trust by promoting and strengthening the image of healthcare professionals. Healthcare professionals can further enhance patients' interpersonal trust by developing "patient-centered communication."

Background. Missed nursing care, which has been explored in various acute care settings, results in adverse patient outcomes and job dissatisfaction in nurses. However, little is known about missed care in the operating room. *Objective.* This study tested a hypothesised model to identify relationships between nurses' age, years of experience in the operating room, job satisfaction, and intention to leave which have direct and indirect effects on the frequency of missed care. The frequency of missed care was hypothesised to be mediated by nurses reported perioperative competence and the reasons for missed care. *Design.* A cross-sectional design using an online survey of Australian perioperative nurses was undertaken in 2022. *Methods.* All Australian College of Perioperative Nurses members were invited to participate. Missed nursing care was measured using the MISSCARE Survey-OR. Age, years of experience, and intention to leave were single-item measures. Satisfaction was a three-item scale. Competence was measured by the 18-item Perceived Perioperative Competence Scale-Short Form. Structural equation modelling was used to test our hypothesised model. *Results.* Of the 5,500 nurses invited, 853 (15.5%) responded, but only 602 (10.9%) participant responses were usable for inclusion in the model. The model demonstrates that participants' age directly predicted the frequency of missed care, nurse role satisfaction, perceived perioperative competence, and reasons for missed care. The reasons for missed care and perceived perioperative competence were mediators that were negatively associated with the frequency of missed care. *Conclusions.* While the final model explained 22.6% of the frequency of missed care, other variables not identified in this study may influence this outcome.

1. Introduction

Missed care is any aspect of care that is omitted or delayed, in part or whole [1]. There is a large body of research on missed nursing care in inpatient units, including medical-surgical and intensive care units [2–5]. One review of 18 studies identified that 75% or more of nurses reported omitting care [6]. An overview of seven reviews identified missed care fell into four categories: communication and information sharing; self-management, autonomy, and education, including care planning, discharge planning, and decision; fundamental physical care; and emotional and psychological care, including spiritual support [7]. An integrative review of

54 papers identified that a combination of nurse, patient, and organizational contextual variables explained 12 to 32% of the variance in missed care across studies reporting this [3]. This same review acknowledged that predictors of missed nursing care included perceived team interactions, adequacy of resources, safety climate, and nurse staffing. Patient outcomes negatively affected by missed nursing care include hospital-acquired infections, pressure injuries, falls, discharge planning, mortality, patient mobilisation, feeding, and psychological and emotional support [1, 8–11]. Clearly, missed care may compromise patient safety [7].

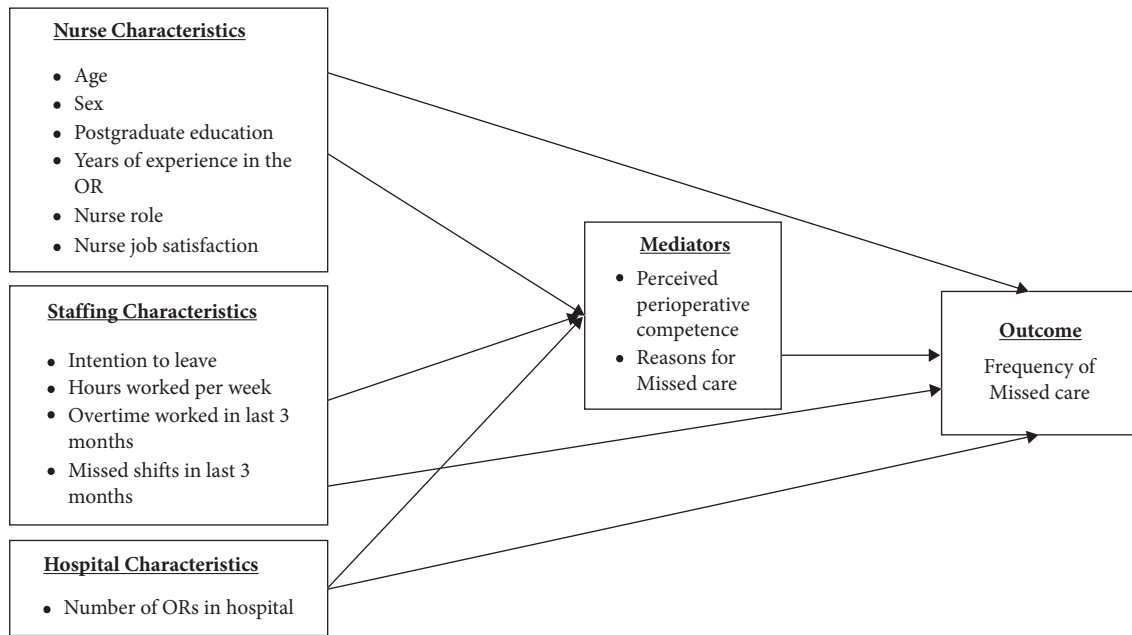
Several systematic reviews [3, 4, 6, 12–14] and an overview of reviews [7] have identified predictors of missed


FIGURE 1: Hypothesised model indicating expected pathways of association.

nursing care across a variety of hospital contexts but predominantly in medical-surgical settings [7]. Across these reviews, factors found to be associated with missed nursing care included skill mix, i.e., combination and distribution of clinical skills and competencies in the nursing workforce [6], staffing levels [3, 6, 13], a lack of material resources [3], patient acuity [3, 13], and teamwork and communication [3, 12, 13]. Only one study of missed nursing care in the operating room (OR) setting was identified. In a survey of 1,593 US OR nurses, Marsh et al. [15] found significant associations between the number of operating rooms at a facility, nurse education, job title, perceptions of staffing adequacy, and frequency of missed perioperative nursing care.

Kalisch's Missed Nursing Care Model [1, 11] has been seminal in this field. The Missed Nursing Care Model illustrates the various attribute categories nurses report in acute care settings that contribute to missed nursing care. This framework examines three concepts; structure (e.g., hospital, patient care unit, and nurse characteristics), process (missed care), and outcomes (staff outcomes such as job satisfaction and patient outcomes). Interestingly, despite the importance of nurse characteristics in this model, there is a paucity of research on the effect of nurses' competence on missed nursing care.

Competence broadly encompasses nurses' knowledge, skills, and attitudes required to undertake their professional role and clinical practice effectively and safely [16]. While these generic attributes apply across any nursing setting and speciality, they do not reflect the behavioural markers that specifically apply to specialities such as OR nursing [17]. In this highly specialised context, competence is conceived relative to technical and nontechnical skills [18, 19]. For instance, technical skills encompass practical and foundational knowledge, whereas nontechnical skills include

teamwork, communication, leadership, and holistic and empathic care [19–21]. Competence is a critical determinant of role performance, and thus, it is reasonable to assume that perioperative competence is related to the quality of care that nurses provide. However, paradoxically, the relationship between perioperative competence and missed nursing care has never been tested.

1.1. Missed Nursing Care in OR Nursing: A Hypothesised Model. We have built on Kalish's model to incorporate nurse competence as an essential structural predictor of missed nursing care (Figure 1). The empirical relationships between nurses' demographic characteristics, unit, and missed care have been well established across a body of research over the past two decades [2, 8, 9, 22–24]. The results of several studies also suggest that nurse job satisfaction and staffing levels contribute to missed care [2, 11, 13, 22, 24]. Kalisch and others examined the relationship between missed care and staff outcomes of job satisfaction, intention to leave, hours worked per week, and overtime as outcomes. However, in our hypothesised model, we have treated these staff outcomes as potential predictors of the frequency of missed care. Therefore, in this model, hours worked and overtime have been considered surrogates of staff fatigue, which may contribute to missed care. We also hypothesised that there is a relationship between the number of ORs and the frequency of missed care: larger OR departments have implications for an increased workload and time pressures, staffing, and resources. Additionally, the relationship between reasons for missed care and its frequency has not previously been established. We hypothesised that nurses' age, years of OR experience, job satisfaction, intention to leave, hours and overtime worked, and the number of ORs

and reasons for missed care have direct effects on the reported frequency of missed care.

However, we also wanted to describe the contribution of nurses' perceived perioperative competence on the reported frequency of missed care. Safe nursing care in the OR environment requires competence in practice, as nurses need to apply nontechnical skills such as coordination, communication, teamwork, and empathy [19]. Therefore, we hypothesised that nurses perceived perioperative competence would be inversely related to the frequency of missed nursing care and mediate the effect of nurse, staff, and hospital characteristics. Findings generated through this study may help nurse managers identify areas of OR practice where missed nursing care most often occurs and enable them to develop strategies that specifically target these areas.

2. Materials and Methods

2.1. Design, Setting, and Sample. A cross sectional design using an online survey design was used. Two members of the research team pilot tested the survey for flow, structure, and ease of navigating the electronic interface. A census of all 5,500 operating room nurses who were members or associate members of the Australian College of Perioperative Room Nurses (ACORN) was undertaken in 2022. Eligible participants included registered nurses (RNs) working in clinical (i.e., circulating, instrument, anaesthetic, and recovery room roles) and education roles across public and private sectors. Enrolled nurses were excluded due to the differences in their scope of practice. The conduct and reporting of the study were guided by the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) Statement [25].

2.2. Measures. The online survey had three components measuring (1) demographic characteristics; (2) preoperative and intraoperative missed care; and (3) perceived perioperative competence. The survey had 111 items and took approximately 25 minutes to complete. Fifteen questions were used to collect data on participants' age, sex, state or territory of residence, clinical role, years of OR experience, highest qualifications, job satisfaction, hours of overtime worked over the past three months, intention to leave current position, and staffing levels. Job satisfaction was measured using a 5-point Likert scale to indicate the degree of satisfaction ranging from *very satisfied* to *very dissatisfied* [24, 26]. We recoded this variable so higher scores indicated higher job satisfaction.

2.2.1. The MISSCARE Survey-Operating Room. Part A includes elements of preoperative and intraoperative missed nursing care, and part B includes reasons for this missed care [15, 27]. The 53-item survey with five subscales has been psychometrically validated in a US sample of 1,693 operating room nurses and has five subscales: legal, preparation, safety, communication, and closing routine. Response options for the preoperative and intraoperative care items include *never, rarely missed, occasionally missed, always,* and *not applicable.*

Response options for reasons for missed care include *significant, moderate, minor,* and *not a reason for missed care.* This measure was also recoded for interpretation, where higher scores indicated the item was frequently perceived as missed in the preoperative and intraoperative periods, as well as higher scores indicating agreement that the reason presented was a significant reason care was missed.

2.2.2. Perceived Perioperative Competence. Competence was measured with the Perceived Perioperative Competence Scale-Short Form (PPCS-SF) [28]. The scale has six dimensions of perioperative competence: foundational knowledge, proficiency, professional development, leadership, collaboration, and empathy. The short form 18-item scale was derived and psychometrically validated using items from the previously validated 40-item PPCS-revised form [19]. The PPCS-SF has been validated and includes the same six subscales that indicate different dimensions of perioperative competence: foundational knowledge, proficiency, professional development, leadership, collaboration, and empathy. Total scores for each subscale can be calculated and considered separately. Both measures were developed in Australia and tested with over 1,500 operating room nurses. Like the previous revised version, the short form has a five-point Likert scale: *never (1), sometimes (2), often (3), very often (4),* and *always (5).* Scale scores range from 18 to 90, with higher scores indicating greater levels of perioperative competence.

2.3. Data Collection. The university's research data capture (REDCap) hosted the online survey [29, 30] data management system. Recruitment was active for six weeks (March–April 2022), with three reminders emailed fortnightly to potential participants.

2.4. Data Analyses. Survey data were exported into SPSS version 27 (Armonk, NY: IBM Corp.) for data cleaning and assumption checks. The types of descriptive analyses used to describe the sample and both the competence and MNC scales were determined by the level of the data (i.e., categorical or continuous) and its distribution. For example, frequencies, including numbers and percentages, were used for categorical variables (e.g., gender, role, and type of facility), while means and standard deviation were calculated for continuous variables (e.g., age, years of OR experience, and scales: MISSCARE-OR and PPCS-SF).

In inferential analyses, the dependent variable was the overall missed nursing care score, based on the average amount of reported missed nursing care identified for each of the elements of nursing care for each participant on a five-point scale (i.e., 0 = *never missed* to 4 = *always missed*). Based on our hypothesis, we used a model-building approach [31], starting with bivariate correlations to determine associations between demographic factors (i.e., age, years of OR experience, education qualifications, role, and hospital facility), nurse factors (i.e., perceived perioperative competence, overtime worked, job satisfaction, intention to leave, and

Note. M = mean; SD = standard deviation; OR = operating room; RN = registered nurse.

staffing levels), and missed nursing care. Factors that shared a direct relationship that were statistically significant ($p < 0.05$) were subsequently entered into an SEM to predict any direct or indirect effects on the frequency of missed care in the operating room.

SEM was used because it allowed for the testing of both direct (observed) and indirect (latent) effects while accounting for mediating variables [32]. Additionally, one of the greatest advantages of using SEM is its ability to manage measurement error which may potentially weaken parameter estimates. The final hypothesised SEM was fitted to a covariance-based structural equation model with a maximum likelihood estimator using the lavaan package in R (lavaan version 0.6-13, R version 4.2.2. RStudio version 12.0). Standard errors and associated p values were calculated using the robust maximum likelihood (mlr) to account for any non-normality in the data. Maximum likelihood (ml) was also applied to account for missing data. Model fit was assessed using χ^2 Goodness-of-Fix Index, the Comparative Fit Index (CFI), and the Tucker–Lewis Index (TLI), which all should be above 0.9 for acceptable fit; the standardised root mean squared residual (SRMR), which should be below 0.08; and the root mean square error of approximation (RMSEA), which also should be below 0.08 and not significantly different from 0.05 ($\alpha = 0.05$, one-tailed). Standardised factor loadings over 0.4 were considered acceptable [33].

2.5. Ethical Considerations. Submission of the survey in the REDCap system implied consent. The study was reviewed and approved by the author's Human Ethics Review Board (HREC Griffith University reference number 2021/774).

3. Results

3.1. Sample Characteristics. Sample characteristics are displayed in Table 1. The total number of respondents was 853 (15.5% of an estimated 5500 invited). However, of the 853 that engaged with the survey, only 602 (70.6%) provided data that could be analysed as not all participants completed the demographic items. Thus, the sample used in the SEM was 602. The average age of the sample was 46 years (SD 11.4). Respondents were predominately female (82.6%), and their primary OR role was circulating/instrument nurse (50.5%). Under half of the sample held a bachelor's degree in nursing (40.4%). However, 121 (20.1%) reported having post-graduate education. The sample was highly experienced operating room nurses, with 64.1% indicating they had worked in an operating room for 10 or more years. All

surgery types and surgical specialists were represented in this sample.

3.2. Model Building. Before testing the model, a correlation matrix was used to examine the initial predictor relationships with the frequency of missed nursing care (Table 2). All potential predictors with a significant direct relationship were entered into the SEM model. The correlation matrix showed that the following variables were statistically associated with the reported frequency of missed care in the operating room: reasons for missed care in the operating room, perceived perioperative competence, age (years), intention to leave, and nurse satisfaction. Additionally, years of experience in the operating room were added to the model due to its moderate association with perceived OR experience. Overall, Spearman's correlations were weak to moderate ($|r| = 0.03–0.37$).

3.3. SEM of Frequency of Missed Care in the Operating Room. The model testing results demonstrate that participant age predicted the frequency of missed care, whereas younger participants reported higher frequency and satisfaction. In contrast, those with lower satisfaction in nursing roles reported a higher frequency of missed care. In relation to perceived perioperative competence, those with higher perceived competence reported less frequency and reasons for missed care. Respondents who reported higher agreement for potential missed care reasons also reported a higher frequency of missed care observed in their workplace. Reasons for missed care was the strongest predictor $\beta = 0.30$, followed by satisfaction $\beta = -0.20$ and perceived perioperative competence $\beta = -0.18$. However, in contrast to our hypothesised model, intention to leave in the next six months and years of OR experience in the operating room did not directly predict the reported frequency of missed care. Age and satisfaction also indirectly affected the frequency of missed care via reasons for missed care, as well as years of experience in the operating room mediated through perceived perioperative competence (Table 3). The total effect of age on the frequency of missed care was −0.23, while satisfaction was −0.32 and years of experience in the operating room was −0.10 (Table 3). The final model is displayed in Figure 2. The model predicted 15.1% of the variance in perceived perioperative competence, 15.9% of the variance in reasons for missed care, and 22.6% of the variance in frequency of missed care. All parameter estimates, including indirect and total effects, are presented in Table 3.

TABLE 2: Correlation matrix of study variables.

PPC = perceived perioperative competence; RMC = reasons for missed care. *Note.* *p ≤ 0.050; **p = 0.01 level; ***p = 0.001 level.

FIGURE 2: Final model with standardised coefficients. *Note.* The dashed lines with arrows represent nonsignificant relationships (p > 0.05). *p < 0.05, **p < 0.01. The dashed lines with arrows represent nonstatistically significant relationships (p > 0.05). *p < 0.05, **p < 0.01.

The analysis indicated an acceptable model fit to the data on most indices (CFI = 0.90; TLI = 0.90; RMSEA = 0.04 (0.037, 0.040), p = 1.00; and SRMR = 0.051) (Figure 2). However, the Chi-square value did not support good model fit (χ^2 (2499) = 4733.45, p < 0.001). In the measurement models, all items were significantly loaded onto their respective factors (all p's <0.05), and no items had negative variances or negligible standardised loadings (all loadings >0.4).

4. Discussion

To our knowledge, this is the first study to identify factors predictive of reported missed OR care using SEM. Previous research examining missed OR care [15] has only investigated the types and frequencies and relationships of missed care to facility characteristics. Generally, our findings relative to some nurse characteristics support the broader research in this area. Twelve nurse and hospital characteristics predictors were entered into the initial model as part of a model-building approach, but only five were explored in the final SEM. Moreover, some model paths were not statistically significant (i.e., intention to leave in the next six months and years of OR experience). We found that nurse age and job satisfaction had direct and indirect effects, and years of experience only indirectly influenced participants who reported perceived missed care in the OR. Reasons for missed care and perceived perioperative competence were mediators in the model. Relationships between reasons for missed care, perceived perioperative competence, and missed care have not been tested in *any* nursing context and thus are novel, adding new knowledge to what is already known. Notably, the reasons for missed care and perceived perioperative competence are amenable to change via interventions. Therefore, these results identify areas that nurse managers can focus on when developing strategies to address the reasons for missed care.

4.1. Mediators of Missed Perioperative Nursing Care. Reasons for missed perioperative care were the strongest predictor contributing to the reported frequency of missed OR care. Reasons for missed nursing care include team communications and interruptions, limited resources, and staff factors such as inadequate skill mix and staffing. Inadequate skill mix in the OR environment has been formerly identified as a major patient safety issue in previous research [34, 35]. An earlier literature review of 14 studies identified that lower staffing levels contributed to missed care across various nursing environments [6, 24]. In our study, other items with high loadings on the Reasons for Missed Care scale related to teamwork and communication breakdowns and lack of support from coworkers. Patients are at their most vulnerable during surgery; as such, the importance of effective teamwork and communication for safe OR care cannot be overstated [18, 19, 36, 37]. Notably, there is an even greater imperative for team members to work cohesively together in this high-dependency context [35–37]. Plausibly, ineffective teamwork in the OR can result in communication breakdowns, reduce efficiency and coordination, increase errors, and create an environment lacking support. Ultimately, this leads to job dissatisfaction, which in our study has been identified as a predictor of the frequency of missed nursing care. There is an abundance of research undertaken in OR contexts [36–39] describing the barriers to effective teamwork and communication among members of the interdisciplinary team. Our results support previous research undertaken in med-surg environments [11, 40] that has identified a lack of teamwork as a predictor

of missed nursing care. Clearly, the reasons for missed care are highly correlated to missed care and can potentially compromise patient safety.

Importantly, this study found a direct relationship between perceived perioperative competence and the frequency of missed care. This is the first study to identify a direct relationship between these constructs. Arguably, it is reasonable to expect that nurses reporting higher levels of perceived perioperative competence would also report fewer occasions of missed care. Competent nurses are often better at managing their time effectively, which can help them prioritise their tasks and ensure that important nursing care is not missed [16, 40, 41]. Additionally, more competent nurses are likely to have better clinical judgment. This can help them identify tasks requiring priority or immediate attention and ensure appropriate nursing care is provided [16, 19]. Second, competent nurses are likely to have a higher level of knowledge and skills related to patient care, which can help them provide more comprehensive and effective nursing care [17]. Third, competent nurses may be more confident and assertive in their interactions with patients and other healthcare professionals. This can help them advocate for their patients and ensure that important nursing care (e.g., pressure area care and intraoperative warming) is not overlooked.

The pressure to complete operations within tightly scheduled timeframes and finite resources may contribute to missed care. Additionally, there is often a disconnection between the priorities of surgeons, anaesthetists, and team nurse members [38]. Thus, establishing a hierarchy of priorities is important but not easy in this environment, as nurses must work interdependently with other disciplines, and these members have a different focus. OR nurses need to differentiate between care that must be immediately provided and care that can wait. Perhaps some tasks are viewed by nurses as not having any intermediate or measurable impact on patient outcomes, e.g., pressure area care, providing comfort measures, and communication of essential information. The results of this study may have implications for OR nurse education and on-the-job training. The emphasis on particular nursing tasks in the OR may shape the novice nurse's attitudes at the beginning and during their professional transition in deciding how to prioritise which care activities can be missed.

4.2. Limitations. We acknowledge several study limitations. First, because it was cross sectional, we identified associations but could not conclude causation; that is, our hypothesised predictors were the cause of the frequency of missed nursing care. Thus, results need to be interpreted with caution. Second, we cannot rule out selection bias despite inviting all OR nurses in Australia's peak professional organisation. Moreover, of the 5,500 perioperative nurse members, only 602 responded. To mitigate non-response bias, the survey was available for six weeks, with two email reminders and social media posts used to help advertise the survey (e.g., the ACORN Facebook page). Though the sample of those who responded was small, it was represented for all Australian states, and surgical specialities.

Third, variable effects were weak to moderate, and the total amount of variance explained by the model was 23%. This low amount of variance explained by our model indicates that other variables that influence the reported frequency of missed care in the operating room have not been identified.

Furthermore, while model fit statistics were acceptable, modification indices were not explored and may suggest measurement model improvements could be made. However, modification indices represent a statistical decision approach, and our model relied on previously validated scales (e.g., MISSCARE-OR, job satisfaction, and PPCR-SF). Thus, model improvement was not undertaken by removing poorly performing items, or correlating item and or latent variable pathways that were not hypothesised. Finally, this study's data source may be biased because all study variables were nurse reported. Future studies could include source data from patients to confirm the results, even though nurse-reported patient safety indicators have been used widely in research and are proven to be substantially associated with patient outcomes.

4.3. Implications for Nursing Management. The results of our study suggest that younger, more job-dissatisfied nurses reported higher frequencies of reasons for missed care and missed care in the OR. Nurse managers in the OR are critical in promoting nurses' job satisfaction, thus minimising the potential for missed care. To improve job satisfaction among OR nurses, nurse managers should invest in team-building exercises, effective communication training, and a culture that values collaboration, mutual respect, and continuous improvement. Nurse managers are well positioned to promote collaboration and interdisciplinary communication within the team. Fostering effective teamwork and communication can help prevent missed nursing care that arises from miscommunication or lack of coordination among different healthcare professionals. Additionally, providing support systems for OR nurses, such as debriefing sessions after challenging cases, can help alleviate stress and foster a sense of teamwork and job satisfaction. Nurse managers must advocate for necessary resources, including adequate staffing levels, appropriate equipment and supplies, and access to technology or tools that facilitate safe care provision. Appropriate resourcing will help to address job satisfaction and address some reported reasons for missed nursing care. Importantly, nurse managers are responsible for appropriate staffing levels and workload distribution and should ensure that an adequate number of qualified OR nurses are available to provide care to patients. By monitoring patient acuity and staff skill mix, staffing levels can be adjusted accordingly. Thus, OR nurse managers can help prevent situations where nurses are overwhelmed with excessive workloads, which may also lead to missed nursing care. Furthermore, they can encourage OR nurses to communicate their concerns, challenges, and workload issues.

5. Conclusions

This study showed that MNC in the OR setting is complex and is explained by several factors. Considering the modest effects found between the variables and the low variance explained by the final model, further studies are needed to identify other factors that may contribute to missed care in the OR. Nonetheless, our results are novel as we have identified relationships between the reasons for missed nursing care, competence, and frequency of missed nursing care, not previously explored. These relationships have not previously been identified, adding new understandings to this complex issue. Though further research is needed to confirm these findings, we present some key recommendations nurse managers can consider implementing to support their staff, reduce the missed care nurses are reporting in the OR, and improve patient outcomes.

Background. Vigilance and executive functions are integral to nursing practice. Prolonged working hours are associated with heightened fatigue and increased nursing errors. However, the impact of work duration on the vigilance and executive function of ICU nurses remains unexplored. *Objective.* This study aims to elucidate the association between ICU nurses' working hours, vigilance, and executive function. *Design.* A cross-sectional study. *Setting.* Intensive care medicine department of a tertiary hospital in Zhengzhou, China. *Participants.* A total of 51 registered nurses who participated in 12 h shifts in the ICU completed the survey. *Methods.* E-prime software was employed to develop four test tasks to measure the vigilance and executive functioning of ICU nurses. The test was performed before the start of the shift and after 4, 8, and 12 h. *Results.* The analysis revealed no statistically significant differences in the response time of vigilance for ICU nurses across shifts ($p = 0.503$) or working hours ($p = 0.078$). However, a significant difference existed in lapses across working hours ($p = 0.005$), significantly increasing after 8 and 12 h. The analysis indicated a significant difference in Flanker effect size across different working hours ($p = 0.035$). The analysis revealed no significant differences in the switch cost ($p = 0.200$) or response accuracy ($p = 0.479$) of the task switching across working hours. The response accuracy for the 2-back task differed significantly ($p = 0.003$) across working hours. *Conclusion.* Limited evidence demonstrated that vigilance and specific aspects of executive functioning (inhibitory control and working memory) of ICU nurses were negatively correlated with the duration of their work in a real clinical setting. Furthermore, no vigilance and executive function differences were identified between day and night shifts. *Implications for Nursing Management.* Nursing administrators should reconsider scheduling 12 h shifts, shortening shifts, or implementing short rest periods to reduce fatigue and cognitive load. In addition, flexible scheduling and rationalizing the order of work may help reduce the possible risks associated with prolonged work.

1. Background

It is well known that ICU patients have complex conditions, imparting a high workload on ICU nurses as they are responsible for observing patient condition changes and completing various nursing practices and records. Significant physical and mental demands pose significant challenges for ICU nurses [1]. ICU nurses must maintain high vigilance and executive function (EF) to ensure patient safety. However, research in psychology and neuroscience suggests that the human brain has limited cognitive resources, such as the attention span and working memory capacity. Multitasking and attentional interference can slow response times and increase the likelihood of errors [2, 3]. When ICU nurses lose vigilance in clinical settings, they may fail to detect patient condition changes, resulting in treatment delays. Furthermore, as EF declines, nurses may become more susceptible to interruptions, potentially leading

to nursing errors. Therefore, vigilance and EF are crucial for patient safety, and further research is being conducted in these areas.

Vigilance is the ability of an individual to maintain attention to tasks over time. Initially, vigilance research focused primarily on high-concentration occupations such as pilots and drivers [4]. Poor driver vigilance results in reduced sustained attention and increased risk of human error, which can have serious consequences. There is growing recognition of the importance of vigilance for the safety of both caregivers and patients. Monitoring and responding immediately to patient condition changes are fundamental nursing responsibilities, making vigilance at the core of nursing practice [5]. Subsequent nursing actions cannot be performed without constant patient observation.

Executive function is the ability of an individual to control and regulate complex cognitive tasks, which is a higher-order cognitive function [6]. Zelazo and Müller classified EFs into two types based on brain imaging: hot executive function and cold executive function [7]. Hot executive function involves emotional engagement and flexible evaluation of rewarding and stimulating tasks, whereas cold executive function lacks emotional involvement and is often characterized by logical and abstract thinking [7]. Numerous studies have been conducted on cold executive function, and the widely used model divides it into three aspects: inhibitory control ability, shifting, and working memory, each closely related to nursing performance [8]. Compared to other professions, nurses require multitasking skills and the ability to quickly shift attention and maintain memory between patients and different events. In nursing practice, nurses must carefully plan their workflow to avoid omissions or errors, a process requiring high executive capacity.

Vigilance and EF of nurses are not solely affected by disruption of the day-night sleep schedule but also the length of working hours, which should not be overlooked. In clinical practice, nurses routinely work 8 or 12 h shifts. Although a 12 h shift may reduce the number of shifts and commuting time while also allowing for more continuous patient care, it is believed that prolonged periods of uninterrupted work are associated with increased fatigue and poor performance [9]. A study demonstrated that nurses working 12.5 h or more had more than three times the risk of errors than those who worked less than 8 h [10]. Furthermore, a systematic review reported that nurses working 12 h shifts had a higher incidence of self-reported errors than those working 8 h shifts, posing a potential threat to patient safety [11].

Based on a comprehensive review of the existing literature, we found that vigilance and EF are impaired among day-night shift-working nurses. However, most studies attribute decreased vigilance and EF to shift nurses' circadian disruptions [12, 13]. The relationship between working hours, nurses' vigilance and EF has been widely underestimated. In addition, studies on the ICU nurse population are still lacking, and limited data on vigilance and EF of Chinese nurses are scarce. Furthermore, our study may be the first to assess EF through three computerized tasks based

on a theoretical model, which can contribute to further understanding of impaired EF in nurses [8]. Given these gaps in the literature, the present study used a computerized task to investigate the impact of working hours on the vigilance and executive function of ICU nurses. This study aimed to collect empirical evidence to help managers make informed decisions regarding scheduling practices.

The study is designed based on two hypotheses:

Hypothesis 1. ICU nurses' vigilance and EF were negatively correlated with work hours.

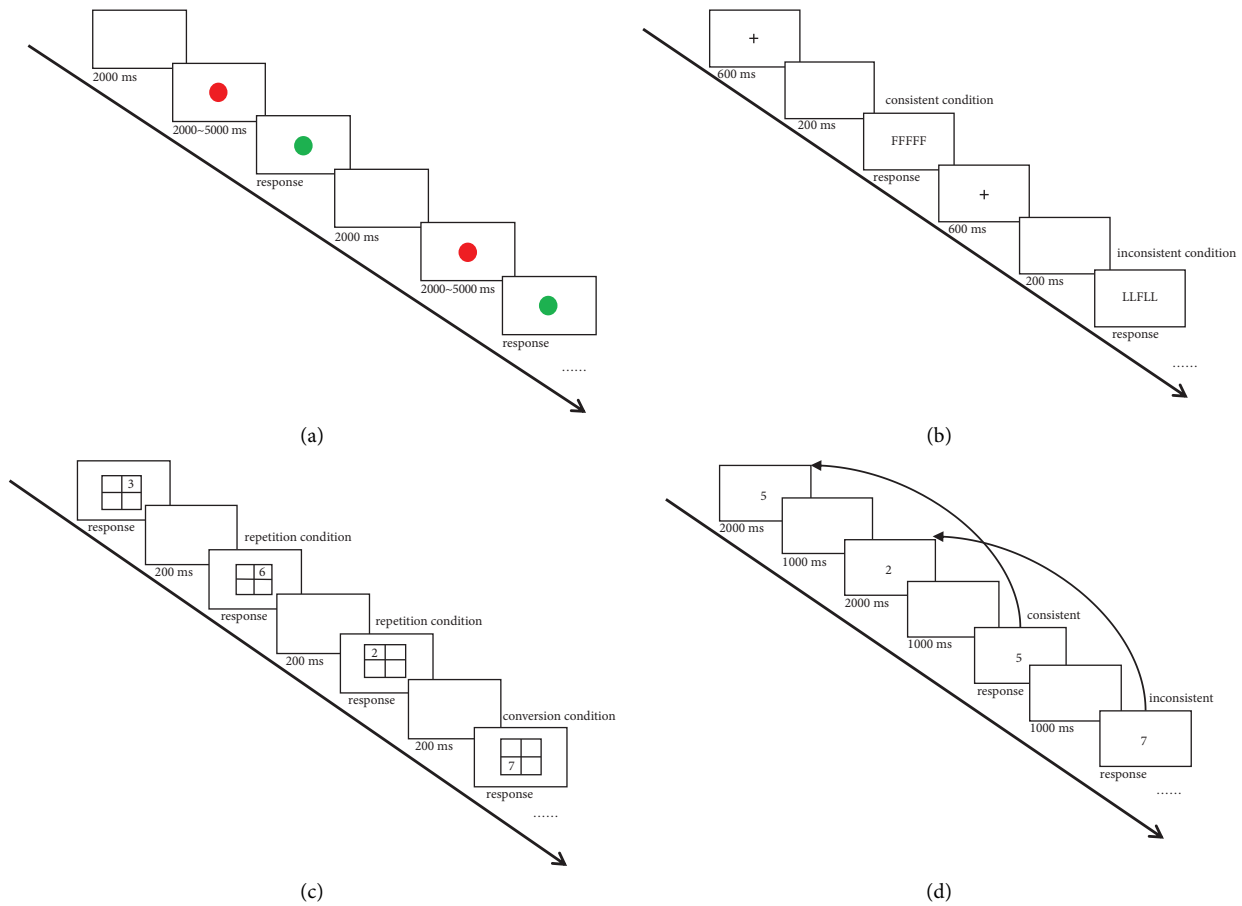
Hypothesis 2. Nurses exhibit lower levels of vigilance and EF during night shifts than day shifts.

2. Methods

2.1. Design. This study used a cross-sectional design with E-prime software for task programming and data collection. The practice session occurred from February 13 to February 26, 2023, and data collection was performed from March 6 to March 26, 2023. To ensure a thorough understanding of the task rules, all participants were required to practice for a minimum of 20 min with at least 80% accuracy during the practice session.

2.2. Participants. This study was conducted in the Department of Critical Care Medicine at Henan Provincial People's Hospital, Zhengzhou, China. The work schedule (day-night-off night and rest) aligns with hospital regulations and rules, ensuring continuous 24 h service for patient care, as is typical in ICUs in Chinese hospitals. Day-shift nurses worked from 8 a.m. to 8 p.m., and night-shift nurses worked from 8 p.m. to 8 a.m. Registered nurses working 12 h shifts were eligible for inclusion in the study. Individuals who had taken psychotropic drugs in the last three months or were pregnant were excluded. Considering that there were no relevant data in China before, the sample size was selected based on similar studies [14, 15]. A total of 52 nurses participated in the practice sessions. However, one nurse dropped out due to other training, resulting in a final dataset of 51 nurses.

2.3. Measures. The test task for the present study was developed using E-Prime 2.0, and the experimental paradigm is illustrated in Figure 1. The task was performed on a 14-inch laptop connected to an external 21.5-inch monitor with a 1920×1080 pixel screen resolution and a refresh rate of 75 Hz. The test was conducted in a quiet room approximately 50 m from the ward, with participants seated approximately 60 cm in front of a computer screen. Participants completed eight tests: before (day and night) shifts (T0), after 4 h (T1), after 8 h (T2), and after 12 h (T3) of work. Because clinical practice is unpredictable, data collection was permitted to be completed within 30 min before and after the scheduled time.

2.3.1. Vigilance. The present study used a 3 min version of the psychomotor vigilance task (PVT) to evaluate nurses' vigilance. PVT is widely recognized as the gold standard for


(a)

(b)

(c)

(d)

FIGURE 1: Experimental paradigm: (a) psychomotor vigilance task, (b) Flanker task, (c) task switching, and (d) 2-back task.

assessing behavioral vigilance and attention due to its high sensitivity to sleep deprivation [16]. Results of extensive experiments on PVT performance have demonstrated that the task is capable of capturing the effects of sleep loss on the stability of sustained attention and that it can reliably reveal the accumulation of cumulative state instability in chronic sleep loss. The reliability of the test has been reported to be 0.888, falling into the standardized "almost perfect" range for a measurement assay [17]. The test-retest reliability in our study was between 0.767 and 0.879. A red circle is displayed in the center of the screen in the PVT. When the color changes from red to green (randomly occurring between 2000 and 5000 ms) participants must press the "L" key as quickly as possible. The red circle reappears two seconds after the response, repeating the process. If no response was made within five seconds, the stimulus ended, and the timer for the subsequent stimulus was reset. A response time (RT) of less than 100 ms was excluded from the analysis, while more than 500 ms were recorded as lapses [16]. Longer mean reaction times or greater lapses indicated a lack of nurse vigilance.

2.3.2. Executive Function.
The Flanker, Stroop, and Simon tasks are commonly used to assess inhibitory control ability [18]. The letter version of the Flanker task was used in the present study to measure the inhibitory control ability of

Note. [a]F, [b]Waldχ^2.

Figure 2: Changes of RT and lapse of PVT.

middle letter was an "F") as quickly as possible. Both consistent and inconsistent conditions were randomly and equally presented. The Flanker effect size (FES) and incorrect responses (IR) for each subject were recorded during the task. The FES represents the difference in RT between consistent and inconsistent conditions. A smaller effect size indicates better inhibitory control ability.

Task switching was used to measure shifting [20, 23]. The high validity of the task has been demonstrated in extensive research. The reliability of the task has been reported to be between 0.859 and 0.910 [9, 22]. The test-retest reliability in our study was between 0.740 and 0.862. In this task, a 2×2 grid was displayed in the middle of the screen, and a number (randomly ranging from 1 to 9, excluding 5) was presented within the grid. The participants were asked to judge the size or parity of the number based on their location within the grid. They had to determine whether the number was greater or less than five if it appeared in the upper grid and its parity if it appeared in the lower grid. They were instructed to press the "F" key if the result was less than five or odd and the "L" key otherwise. The switch cost (SC), which is the difference in reaction time between the conversion and repetition conditions, and IR were recorded during the task. Lower SCs or higher accuracy suggest better cognitive flexibility.

A digital 2-back task was used to assess the working memory. The N-back task is a classical working memory paradigm frequently used in working memory-related studies [23, 24]. The validity of the test to measure working memory has been reported in several studies [25–28]. The split-half reliabilities of the test have been reported to be between 0.802 and 0.824 [29]. The test-retest reliability in our study was between 0.670 and 0.792. A series of stimuli were presented sequentially in the 2-back task, and participants had to judge whether the current number matched the number presented two stimuli earlier. They used the "F" key for a consistent match and the "L" key for inconsistency. The task recorded RT and IR. A shorter reaction time or higher accuracy indicates working memory.

2.4. Data Analysis. IBM SPSS version 26.0 was used to analyze the data. The demographic characteristics of ICU nurses were described using frequencies, percentages, mean/medians, standard deviation (SD), and range. MANOVA was used for the statistical inference of normally distributed data. Non-normally distributed data are presented as median (interquartile range), and nonparametric tests and generalized estimating equations (GEEs) were used for statistical inference. The statistical significance level was set at $p < 0.05$.

2.5. Ethical Approval. This study adhered to the 2000 revision of the Helsinki Declaration and followed the ethical standards outlined by the responsible committee on human experimentation. The study protocol was approved by the Institutional Review Board of Henan Provincial People's Hospital (approval date: 20220620). All participants provided written informed consent before they participated in the study.

3. Results

3.1. Demographic Characteristics of the Sample. Table 1 summarizes the demographic characteristics of ICU nurses. Most participants (70.6%) were females, and their mean age was 29.10 years, SD = 4.15. Over half of the participants (66.7%) had worked in the ICU for more than five years. All participants reported no symptoms of discomfort and were not colorblind. In addition, they reported no preference for coffee or tea at work.

3.2. Vigilance. Table 2 and Figure 2 reveal the changes in vigilance, RT, and lapse among ICU nurses. MANOVA revealed no statistically significant difference in RT for ICU nurses across working hours ($P_{\text{sphericity}} = 0.686$, $F = 2.320$, $p = 0.078$, $\eta^2 = 0.044$) and shifts ($F = 0.456$, $p = 0.503$ $\eta^2 = 0.009$). However, lapse occurrence varied significantly across working hours (Wald$\chi^2 = 12.844$, $p = 0.005$), with a significant increase observed after 8 and 12 h.

3.3. Executive Function

3.3.1. Inhibitory Control Ability. The changes in FES and IR among ICU nurses are presented in Table 3 and Figure 3. MANOVA indicated a significant difference in the FES across different working hours ($P_{\text{sphericity}} = 0.359$, $F = 2.943$,

Table 3: Comparison of inhibitory control ability at different working hours ($N = 51$).

| Variables	T0		T1		T2		T3		Statistical value (p)		
	Day	Night	Day	Night	Day	Night	Day	Night	Time	Shift	Interaction effect
FES	20.14 ± 18.96	18.30 ± 18.64	21.15 ± 18.37	19.43 ± 20.47	20.50 ± 16.24	22.54 ± 25.47	25.23 ± 22.05	27.08 ± 19.99	2.943^a (0.035)	0.002^a (0.963)	0.270^a (0.847)
IR	1 (1, 2)	2 (1, 3)	2 (1, 3)	2 (1, 3)	1 (0, 2)	2 (0, 3)	2 (0, 3)	2 (1, 3)	2.747^b (0.432)	1.477^b (0.224)	1.856^b (0.603)

Note. [a]F, [b]Waldχ².

FIGURE 3: Changes of FES and IR of Flanker test.

$p = 0.035$, $\eta^2 = 0.056$). However, the IR of the Flanker task did not differ significantly among different working hours (Wald$\chi^2 = 2.747$, $p = 0.432$) and shifts (Wald$\chi^2 = 1.477$, $p = 0.224$).

3.3.2. Shifting. Table 4 and Figure 4 represent the changes in SC and IR among the ICU nurses. MANOVA revealed no significant differences in the SC of the task switching among different working hours ($P_{\text{sphericity}} = 0.093$, $F = 1.568$, $p = 0.200$, $\eta^2 = 0.030$) and shifts ($F = 2.768$, $p = 0.102$, $\eta^2 = 0.052$). In addition, the generalized estimating equation indicated no significant differences in IR among different working hours (Wald$\chi^2 = 2.481$, $p = 0.479$) and shifts (Wald$\chi^2 = 0.588$, $p = 0.443$).

3.3.3. Working Memory. The changes in RT and IR to the 2-back task among the ICU nurses are presented in Table 5 and Figure 5. Repeated MANOVA revealed no significant difference in RT for the 2-back task among different working hours ($P_{\text{sphericity}} = 0.486$, $F = 1.483$, $p = 0.221$, $\eta^2 = 0.029$) and shifts ($F = 0.309$, $p = 0.581$, $\eta^2 = 0.006$). However, there was a significant difference in IR between working hours (Wald$\chi^2 = 13.916$, $p = 0.003$) for the 2-back task.

4. Discussion

Although previous studies have reported the impact of shifts and 12 h work on nurses' fatigue and vigilance, their findings remain contentious. Notably, the present study is possibly the first to investigate the vigilance and EF of Chinese ICU nurses in a real clinical setting. Furthermore, it may be the first to comprehensively assess EF using three computerized tasks based on a theoretical model. The present study contributes to our understanding of how consecutive 12 h rotating shifts affect the vigilance and EF of ICU nurses while providing research data from a different population to support the ongoing debate. There is limited evidence from our study that there is a negative correlation between vigilance and certain aspects of EF in ICU nurses and their working hours. Furthermore, our study revealed no

significant differences in vigilance and EF between night and day shifts among nurses.

The findings revealed that the vigilance reaction time of ICU nurses did not differ significantly across different working hours ($p = 0.078$), consistent with previous findings [14]. Although this result did not demonstrate statistical significance, we cannot conclude that the vigilance of ICU nurses is unaffected by working hours. Several factors may have contributed to these findings. First, given the busyness of clinical practice, we used a 3 min version of the PVT task rather than 5 or 10 min. Only 30 stimuli were presented in our task, which may have limited our ability to capture attention and effectively detect fatigue. Second, we set the lapse threshold to 500 ms. However, this threshold may have been relatively low for our PVT task. This is because, unlike some PVT tasks, our task did not present the RT after each stimulus presentation. This could have resulted in less positive feedback from our participants, resulting in longer RTs. Responses exceeding 500 ms were considered lapses and excluded from the average RTs analysis, which may have influenced our findings. Furthermore, the small sample size introduced sampling errors, which should not be overlooked as a contributing factor.

Another important observation indicator in the PVT task is the number of lapses, which reflects an individual's ability to maintain attention. Our study revealed that regardless of the day or night shift, the number of lapses among ICU nurses increased as the duration of work increased. This suggests a negative relationship between nurses' attention and work duration, implying that their vigilance decreases as nurses work longer shifts. This is unsurprising, given that nurses work 12 h shifts and accumulate significant fatigue and sleep debt. Nurses experience increased drowsiness and a gradual decline in vigilance as their shift lengthens [30].

Furthermore, pairwise comparison results indicate that the number of lapses among nurses at T2 and T3 was significantly higher than at T0 and T1. This suggests that ICU nurses consistently have low vigilance after 8 h. Therefore, we advise managers to reconsider the potential risks to patient safety associated with the current 12 h shift schedule in the ICU.

TABLE 4: Comparison of shifting at different working hours ($N = 51$).

| Variables	T0		T1		T2		T3		Statistical value (p)		
	Day	Night	Day	Night	Day	Night	Day	Night	Time	Shift	Interaction effect
SC	158.59 ± 103.22	144.15 ± 100.84	154.30 ± 118.83	136.54 ± 93.97	165.58 ± 109.07	165.56 ± 109.55	167.06 ± 114.10	151.85 ± 102.22	1.568^a (0.200)	2.768^a (0.102)	0.307^a (0.820)
	3 (1, 5)	3 (2, 4)	2 (2, 4)	3 (1, 5)	3 (2, 5)	3 (1, 4)	3 (2, 5)	3 (2, 4)			
IR									2.481^b (0.479)	0.588^b (0.443)	1.140^b (0.767)

FIGURE 4: Changes of SC and IR of task switching.

Most studies have indicated that night-shift nurses have lower and more unstable vigilance than day-shift nurses [31–33]. Although there is no interaction effect between working hours and shift for nurses' RT ($p = 0.069$) and the number of lapses ($p = 0.216$) and no within-group differences in terms of shift, the trend in changes in nurses' RT and the number of lapses (Figure 2) seems to suggest a similar pattern of instability in vigilance during night shifts. This is most likely due to circadian rhythm adaptation, as even experienced ICU nurses exhibit higher drowsiness during night shifts than during day shifts.

In summary, we conclude that the vigilance of ICU nurses decreases with increasing work duration, with more pronounced vigilance impairment after 8 h of work. Furthermore, the vigilance of ICU nurses during night shifts appeared to be more susceptible to work duration.

Another focus of our study was on the EF of nurses. Impaired EF among nurses in clinical settings can lead to serious medical errors. Inhibitory control is an important component of EF [34]. Individuals with poor inhibitory control may be easily distracted, have difficulty maintaining attention, and have difficulty suppressing impulsive behaviors. Nurses frequently encounter various distractions and stimuli during clinical work, such as noise from equipment and colleagues' interactions. Nurses with stronger inhibitory control can approach their work goals more rationally and efficiently. The findings of the present study reveal a significant difference in the FES of ICU nurses at different work durations ($p = 0.035$), implying that the inhibitory control of nurses decreases as work duration increases. This is mainly due to fatigue and stress caused by continuous work, which affect the activity of the prefrontal cortex, which is involved in higher-order cognitive processing. Therefore, the inhibitory control of nurses is compromised.

Shifting refers to the ability of an individual to switch behaviors flexibly in different contexts and is equally important for nurses. ICU nurses face other patients and situations at work, requiring them to adjust their care plans and behaviors based on the needs and conditions of their patients. The present study revealed no differences in cognitive flexibility among nurses with different work durations. This could be due to two factors. First, the participants

included in our study are relatively young (29.10 ± 4.08), and younger individuals often have an advantage in maintaining cognitive flexibility. Second, research suggests that learning and training can improve an individual's cognitive flexibility [35, 36]. Over half of the participants in the present study had more than five years of ICU work experience, which may have cultivated their flexibility and better adaptation to various cognitive tasks.

Working memory capacity is an important factor for nurses. In clinical practice, nurses must constantly grasp and remember patients' conditions, treatment progress, nursing measures, job tasks, and operational steps. These pieces of information must be acquired, processed, promptly, and accurately recalled. Consistent with a previous study [37], we identified statistically significant differences in the error rates of the 2-back task among participants with varying work durations ($p = 0.003$). This finding indicates a negative correlation between ICU nurses' working memory and work duration. Long periods of continuous work may deplete nurses' cognitive resources. As work duration increases, nurses must handle more tasks and information, which may exceed their working memory capacity, resulting in information loss or memory forgetting. Although there were no differences in working memory reaction times among nurses with different work durations in this study, we observed a slight increase in working memory reaction times at T1. We infer that this may be associated with the workload. Generally, T1 (12:00 p.m. or 12:00 a.m.) is one of the busiest times in clinical work, and nurses face a higher memory load when multitasking and memorizing multiple pieces of information simultaneously. This may affect the speed of memory retrieval during testing.

In summary, we believe that certain aspects of EF (inhibition control, working memory) of ICU nurses decline as work duration increases. Furthermore, ICU nurses have similar EF levels during night shifts compared to day shifts.

5. Limitations

The present study has several limitations. First, smoking and coffee consumption may have influenced the test results. However, only two participants in our study smoked, and none drank coffee at work. Therefore, we did not include

TABLE 5: Comparison of working memory at different working hours ($N = 51$).

| Variables | T0 | | T1 | | T2 | | T3 | | Statistical value (p) | | |
	Day	Night	Day	Night	Day	Night	Day	Night	Time	Shift	Interaction effect
RT	806.54 ± 152.66	820.63 ± 185.72	835.22 ± 172.16	857.23 ± 221.35	824.73 ± 187.91	832.30 ± 180.74	824.21 ± 190.78	814.95 ± 199.31	1.483[a] (0.221)	0.309[a] (0.581)	0.259[a] (0.855)

Figure 5: Changes of RT and IR of 2-back.

these factors in our statistical analysis, which may have limited the extrapolation of our study. Second, because we only tested nurses from one ICU, our sample size was likely to be small, which could have resulted in sampling errors. Moreover, due to the small sample size, we did not conduct subgroup analyses based on gender or the menstrual cycle. Finally, despite including a practice phase to minimize practice effects, they may still exist to some extent.

6. Conclusions

Nurses serve as the "eyes and hands" of the ICU, monitoring and intervening in patients' health. The vigilance and EF of nurses are crucial for patient safety. Although longer shifts have been praised for increasing productivity and lowering staffing costs, our study examined ICU nurses working 12 h shifts using objective computer tasks. There is limited evidence showing that vigilance and some aspects of EF in ICU nurses are negatively correlated with the duration of their shifts in a real clinical setting. Furthermore, no vigilance or EF differences were identified between day and night shifts.

7. Implications for Nursing Management

To reduce fatigue and cognitive load, nursing administrators should reconsider scheduling 12 h shifts, shortening shifts, or implementing short rest periods. Such adjustments are beneficial and necessary for nurses' well-being and patient safety. Flexible work may be another approach to address this problem. Allowing nurses to adjust their working hours according to their habits and status may help staff perform at their best and improve the quality and efficiency of their work. In addition, managers should pay attention to staff fatigue, especially after working for more than 8 h. Managers can also adjust the order of work, such as scheduling complex tasks at the beginning of the work as much as possible, while simple executive tasks are scheduled later, which may reduce the possible risks associated with prolonged work.

Data Availability

The data that support the findings of this study are available from the corresponding author upon reasonable request.

Additional Points

Tweetable Abstract. Limited evidence has shown that vigilance and executive function of ICU nurses are negatively correlated with work duration.

Background. Nurses demonstrate high burnout prevalence. Moreover, destructive leadership, as well as job demands and resources, are associated with burnout. However, these associations, particularly in the context of nursing, warrant further investigation. *Objective.* To explore the associations of destructive leadership, as well as job demands and resources, with burnout in registered nurses. *Design.* A cross-sectional survey. *Participants.* 2115 registered nurses in Finland. *Methods.* The self-administered questionnaire survey was distributed nationwide to 106,000 members of the Finnish trade union for health and social care professionals via an online newsletter in February 2023. Nurses' burnout was measured with the Burnout Assessment Tool (BAT). The data were analysed through descriptive statistics and linear regression analysis. *Results.* Destructive leadership and job demands were positively associated with burnout ($\beta = 0.39$ and 0.32, respectively; both $p < 0.001$), whereas job resources and burnout were negatively associated ($\beta = -0.41$, $p < 0.001$). The associations of destructive leadership and job demands with burnout became less positive when job resources were added to the regression model ($\beta = 0.21$ and 0.14, respectively; both $p < 0.001$). *Conclusions.* Job resources led to the greatest reduction in burnout among registered nurses. Moreover, job resources reduced burnout by diminishing the negative effects of destructive leadership and job demands. Providing a sufficient amount of job resources might reduce burnout and diminish the negative effects of destructive leadership and job demands among nurses. These relationships warrant examination in other cultural settings.

1. Introduction

The global shortage of the healthcare workforce, particularly nurses, is a major issue; the World Health Organization (WHO) projects that this shortage will reach 5.7 million by 2030. Population ageing has led to an increase in the demand for health services. However, the nursing workforce is ageing as well; approximately, one of six nurses is expected to retire by 2030 [1]. Other challenges, including the COVID-19 pandemic, have exacerbated these issues. Working in healthcare is stressful; furthermore, the nursing staff work under extreme pressure, which can lead to health problems, such as burnout, and to insufficient personnel retention and recruitment [2, 3]. Therefore, facilitating mental health improvement among nurses through the improvement of

their demanding working conditions is crucial. To support European countries with severely burdened healthcare systems, the WHO proposed 10 effective policy and planning responses; one of them is "protect the health and mental well-being of the workforce" [2].

Complex burnout syndrome, which most commonly results from prolonged exposure to work-related stress, is characterised by the dimensions of exhaustion, cynicism, and inefficacy [4]. In particular, overwhelming exhaustion is often the first sign of work-related health issues. Over time, it leads to detachment and withdrawal from work, as well as cynicism, followed by negative self-evaluation and the feeling of incompetence. The role of a few of these dimensions, particularly inefficacy, in burnout development has been re-examined; as such, the definition of burnout has

been revised [5, 6]. Schaufeli et al. [6] indicated four core elements of burnout, namely, exhaustion, mental distance, emotional impairment, and cognitive impairment. Exhaustion refers to an extreme lack of physical and mental energy, which reduces an individual's capacity to regulate emotions (e.g., anger and sadness) and cognitive processes (e.g., memory and attention). This results in the development of a coping strategy involving mental withdrawal and detachment from the job. In a Delphi study, an expert panel unanimously defined burnout as prolonged work-related exhaustion [7]. Exhaustion, generally considered the most essential dimension of burnout, is included in most burnout questionnaires [6].

The average burnout prevalence among nurses varies in different studies, ranging from 11% [8] to 52% [9]. The studies show differences between geographical regions and specialties [8] and educational levels [9]. The review by Ge et al. found a prevalence of 30% and indicated an increased trend over time [10]. However, the accurate estimation of this prevalence can be challenging because appropriate diagnostic criteria for burnout are unavailable [11] and burnout is not considered a medical condition in the International Classification of Diseases 11th Revision [12].

Burnout has several physical, psychological, and occupational consequences on workers' health and well-being; these consequences include type 2 diabetes, coronary heart disease, various types of pain and injuries, insomnia, job dissatisfaction, absenteeism, and the need for disability pension [13]. In addition, a positive association between burnout and depression among nurses has been found [14]. Furthermore, higher burnout levels appear to lead to a stronger occupational turnover intention [15–17]. Burnout-attributed turnover and burnout result in a major financial burden on organisations and societies [18–20]. Moreover, nurse burnout affects perceived patient safety, satisfaction, and quality of care [21]. Therefore, burnout is a severe health issue with individual, organisational, and societal consequences [22].

The job demands-resources (JD-Rs) model was originally tested in a study on German nurses and subsequently developed into a theory [23–25]. According to this model, different physical, psychological, social, or organisational aspects of a job, particularly if they are imbalanced, can affect employee health outcomes. Job demands, such as a high workload, require sustained effort and are associated with exhaustion. Job resources are job aspects that support the achievement of work goals and personal growth and development, reduce job demands, and protect from burnout; examples of these resources are autonomy and job security. In the JD-R model, resource insufficiency is associated with disengagement [24]. In the current study, we used the JD-R model as the theoretical framework.

The effect of job demands and resources among nurses have been studied comprehensively, and the association of job demands with burnout has been established [22, 26–28]. Among nurses, a high workload is also correlated with decreased patient safety and quality of care [26]. In contrast,

job resources are negatively associated with burnout [29, 30]; they may buffer the effects of job demands on strain [31, 32] and burnout [33].

A major determinant in work-related health outcomes in nurses is leadership, and the favourable effects of positive leadership styles are well known [34–36]. Recent management research has focused on adverse leadership styles and their effects on followers and organizations. One such adverse leadership style is the so-called destructive leadership style [37, 38].

Destructive leadership is a process involving a supervisor's systematic and repeated hostile behaviour or incompetence as perceived by their followers or subordinates. Destructive leadership can be intentional or unintentional and physical or verbal and has harmful consequences on the well-being, job satisfaction, and performance of the workers, and the goals of the organisation, or both [37, 39, 40]. Most empirical studies on destructive leadership have examined abusive supervision using Tepper's [41] abusive supervision scale [38]. In contrast to destructive leadership, abusive supervision excludes physical contact [41] and aims to control workers by creating fear and intimidation [39]. Furthermore, under toxic leadership, a leader's destructive behaviour or dysfunctional personal qualities have a debilitating effect on their followers [42]. In the toxic triangle model, toxic leadership is derived from the interaction between the leader, their followers, and the conducive environment [43]. Petty tyranny is described as authoritarian behaviour where a leader uses power oppressively, capriciously, and vindictively over their subordinates [44]. Einarsen et al. [39] categorised the leadership styles as tyrannical (including humiliation, belittling, and aggression), derailed (including bullying, manipulation, harassment, absenteeism, and shirking), supportive -disloyal, and constructive; these behaviours can have destructive and constructive effects on different dimensions simultaneously.

Destructive leadership is positively related to nurses' psychological strain, burnout, and intention to quit the job or leave the profession [31, 35, 45]. It is also associated with decreased work effectiveness and performance [46] and nurse-reported adverse events and quality of care [31, 47]. Strengthening nursing and midwifery leadership is one of the policy priorities of the WHO Global Strategic Directions for Nursing and Midwifery 2021–2025 [48].

Despite increasing scientific interest in destructive leadership, knowledge regarding this detrimental phenomenon, particularly in nursing, remains limited [36]. Thus far, the associations of destructive leadership, as well as job demands and resources, with burnout among nurses have not been explored. By gaining further insight into the roles of leadership and working conditions in burnout development among nurses, healthcare organisations may be able to develop and implement burnout prevention strategies. In the current study, we explored the associations of destructive leadership and job demands and resources with burnout among registered nurses in Finland. We also

analysed burnout by different background characteristics. Our results may clarify the need for leadership development and education for maximum staff retention.

2. Methods

2.1. Study Design. This was a cross-sectional study conducted in accordance with the STROBE guidelines for cross-sectional studies [49].

2.2. Data Collection and Participants. The data were collected over a 3-week period in February 2023 by using an online self-administered questionnaire. Participants were recruited via an online newsletter of a Finnish trade union for health and social care professionals, distributed to 106,000 of its members. The sampling method can be, therefore, called purposive sampling. We also sent a weekly reminder to every member, requesting them to respond to the questionnaire. In total, 4575 responses were received; of them, 2370 were from registered nurses. After respondents who performed supervisor tasks ($n = 247$) were excluded, the final sample size was 2115. Considering the survey invitation and distribution methodology, the accurate survey response rate could not be calculated.

2.3. Measurement Tools. The survey collected the following background characteristics: age, gender, education level, work experience (years), and workplace. Moreover, three scales were used to measure burnout, destructive leadership, and job demands and resources.

2.3.1. Burnout. Burnout was measured using the 4-item Burnout Assessment Tool (BAT-4) [50]—a shortened version of the original 23-item BAT (BAT-23) [6]. BAT-23 was developed to assess the four core dimensions of burnout, namely, exhaustion, mental distance from work, cognitive impairment, and emotional impairment. The BAT-23 can be applied based on group or individual assessments [6]; its applicability for the cross-country comparison of burnout has also been reported [51]. The BAT-23 has been validated and noted to have good psychometric properties; moreover, both the 12-item BAT (BAT-12) and the BAT-4 have shown to reliably explore the dimensions of burnout. The BAT-4 is strongly correlated with the BAT-12 ($r = 0.94$) and BAT-23 ($r = 0.92$), and its Cronbach's α is 0.73 [50, 52]. In the BAT-4, each item assesses one core dimension as follows: exhaustion ("at work, I feel mentally exhausted"), mental distance from work ("I struggle to find any enthusiasm for my work"), cognitive impairment ("at work, I have trouble staying focused"), and emotional impairment ("at work, I am unable to control my emotions"). Here, the frequency-based responses are scored on a 5-point Likert scale—ranging from 1 (never) to 5 (always); a higher score is considered to indicate more burnout [50].

2.3.2. Destructive Leadership Scale. Destructive leadership was measured based on nine statements related to the employee's relationship with the immediate supervisor as follows: authoritarian leadership (e.g., "I am treated in an authoritarian (i.e., bossy or commanding) way"), abusive leadership (e.g., "I am treated in an unfair or discriminatory way"), and aggressive leadership (e.g., "I am treated in an aggressive manner"). Similar questions have been used to measure the vulnerability caused by management as a dimension of precarious employment (e.g., [53]). The responses were scored on a 5-point Likert scale—ranging from 1 (completely disagree) to 5 (completely agree); a higher score was considered to indicate a higher prevalence of destructive leadership.

2.3.3. Job Demands and Resources Scale. Job demands and resources were measured using items that assess working conditions; these items have been widely used in surveys such as the European working conditions surveys [3]. The scale included the following 18 statements: 8 describing job demands and 10 describing job resources. Statements on job demands included those related to time pressure ("I have to work really fast" and "I have to work hard"), physical workload ("my job requires a lot of physical effort," "I often have to lift or move heavy loads," and "I have to work for long periods in uncomfortable positions"), decision-making opportunities ("I have few opportunities to decide how I do my work"), and insecurity ("I have no certainty about the future of my job" and "there is a danger that I will soon lose my job"), whereas statements on job resources include those related to participation in decision-making ("I have the opportunity to make a lot of decisions about my work" and "I have a say in many at my job"), task variety ("I am given a lot of different tasks" and "I have the opportunity to learn new things at my job"), professionalism ("my job requires a high level of professionalism"), the amount of time ("I have enough time to do my work"), work ("I do not have an unreasonable amount of work"), and security ("I could quickly get a new job if I wanted to"). The responses were scored on a 4-point Likert-type scale—ranging from 1 (completely disagree) to 4 (completely agree); a higher score was considered to indicate more job demands or resources.

2.4. Data Analysis. Descriptive statistics of all variables were calculated as frequencies and percentages, as well as means and standard deviations (SDs). Missing value analysis demonstrated low rates between 0.01% and 0.4% per scale; it was the highest at 2.0% for the variable of age. For each scale, the missing values were replaced with their respective mean values. The mean values for the study variables were calculated, and ANOVA was used to compare the average levels of burnout in terms of age, education level, and work experience. Independent sample t tests were used with dichotomous gender variables. A p value of <0.05 was considered to indicate statistical significance.

Scale reliability was analysed by calculating Cronbach's α, and the relationships between the variables were calculated as Pearson's correlation coefficients (Table 1). Multicollinearity of the data was also assessed. Furthermore, linear regression analysis was used to explore the associations of burnout with destructive leadership, as well as job demands

TABLE 1: Background characteristics of the nurses ($n = 2115$).

	Mean (SD)	n	%
Age (years)	45.6 (10.9)		
<35		423	20.0
35–50		867	41.0
>50		782	37.0
Gender			
Male		142	6.7
Female		1956	92.5
Education level			
Vocational degree		573	27.1
Bachelor's degree		1361	64.3
Master's degree		173	8.2
Work experience (years)	17.1 (10.8)		
<5		387	18.3
5–10		327	15.5
>10		1398	66.1

and resources. All models were adjusted for age, gender, and work experience. The assumptions of homoscedasticity and linearity of the models were tested and confirmed to not have been violated [54]. All statistical analyses were conducted using SPSS (version 27).

2.5. Ethical Considerations. There was no need for ethical approval; however, the Institutional Review Board of the participating trade union approved the study [55]. Our questionnaire cover letter included information regarding the study, and it indicated that by answering the questionnaire, the participants provided their informed consent. The questionnaire also included a privacy statement. No personal identification data were collected, and the data were stored on the university's secure server, protected by username and password. The data will be deleted three years after the end of the study.

3. Results

As listed in Table 1, the mean participant age was 46 years (range: 22–67 years). A majority of the participants were women (93%), had a bachelor's degree (64%), had >10 years of work experience (66%), and worked in the public sector (86%); of all the participants, 57% worked in hospitals, 21% worked in health and welfare centres and clinics, 13% were social service workers, 3% provided at-home services, 2% worked in private companies or were self-employed, and 4% provided other services such as state- or organization-level, or student, health services.

Table 2 presents the overall BAT scores as well as their distribution among different age, gender, education level, and work experience groups. The mean (SD) total BAT-4 score was 2.62 (0.64), with the score in the dimension of exhaustion being the highest (mean = 3.21 and SD = 0.86). Nurses aged <35 years demonstrated the highest BAT-4 scores, whereas those aged >50 years showed the lowest ($p = 0.003$). Women reported significantly higher scores

TABLE 2: BAT-4 scores (overall and stratified by background characteristics, scale 1–5).

	Mean (SD)	p
BAT-4	2.62 (0.64)	
Exhaustion	3.21 (0.86)	
Mental distance from work	2.66 (0.95)	
Cognitive impairment	2.60 (0.83)	
Emotional impairment	2.00 (0.77)	
Age (years)		0.003
<35	2.69 (0.63)	
35–50	2.64 (0.64)	
>50	2.56 (0.64)	
Gender		0.038
Male	2.51 (0.67)	
Female	2.62 (0.63)	
Education level		0.165
Vocational degree	2.58 (0.63)	
Bachelor's degree	2.63 (0.64)	
Master's degree	2.60 (0.65)	
Work experience (years)		0.016
<5	2.60 (0.63)	
5–10	2.71 (0.62)	
>10	2.60 (0.64)	

BAT = Burnout Assessment Tool.

than men ($p = 0.038$). The mean scores among nurses with work experience of <5 and >10 years were similar; however, after post hoc correction, nurses with work experience of 5–10 years demonstrated the highest scores ($p = 0.014$). No significant differences were noted between the different education level groups.

The results of the destructive leadership scale are presented in Table 3. The statement "my bosses make me feel like I am easily replaceable" demonstrated the highest score (mean = 2.76 and SD = 1.35), followed by "I am treated in an authoritarian (i.e., bossy or commanding) way" (mean = 2.57 and SD = 1.23). However, "I am treated in an aggressive manner" demonstrated the lowest score (mean = 1.57 and SD = 0.94).

On the job demands scale, the highest scores were demonstrated by the statements related to having to work hard (mean = 3.23 and SD = 0.72) and quickly (mean = 3.01 and SD = 0.78). The respondents also reported low job autonomy (i.e., having only few opportunities to decide how they perform their work; mean = 2.57 and SD = 0.78). In contrast, the statements that demonstrated the lowest scores were related to the uncertainty about the future of the job (mean = 1.82 and SD = 0.94) and the fear of losing the job soon (mean = 1.45 and SD = 0.69).

On the job resources scale, the highest scores were noted for the statements related to needing a high level of professionalism (mean = 3.82 and SD = 0.45) and learning new things (mean = 3.78 and SD = 0.46). In contrast, the lowest scores were demonstrated by the statements regarding not having sufficient time to do the work (mean = 2.25, SD = 0.84) and not having an unreasonable amount of work (mean = 2.24 and SD = 0.84), preceded by the statements

Table 3: Destructive leadership scale scores (scale 1–5).

	Mean (SD)
My bosses make me feel like I am easily replaceable	2.76 (1.35)
I am treated in an authoritarian (i.e., bossy or commanding) way	2.57 (1.23)
If I were treated unfairly, I would not dare to argue	2.26 (1.19)
If I wanted better working conditions, I would be afraid to ask	2.21 (1.10)
I am treated in an unfair or discriminatory way	2.10 (1.18)
I have to worry about being fired if I were to participate in a strike	1.67 (0.97)
I have to worry about being fired when I temporarily do not work as well	1.65 (0.92)
I have to worry about being fired if I do not immediately do what I am told	1.61 (0.91)
I am treated in an aggressive manner	1.57 (0.94)

regarding having the opportunity to make a lot of decisions about work (mean = 2.49 and SD = 0.77) and having a say in many things at work (mean = 2.49 and SD = 0.78).

Table 4 presents Cronbach's α values and Pearson's correlation coefficients of all the variables. All Cronbach's α values were acceptable. Moreover, burnout was moderately and positively correlated with destructive leadership and job demands but negatively correlated with job resources.

The bivariate associations of destructive leadership, job demands, and job resources with burnout were analysed in model 0 (Table 5). Background characteristics (i.e., age, gender, and work experience) that demonstrated between-group differences (Table 2) were adjusted in this model. Consequently, the association between destructive leadership and burnout was noted to be positive. Assessed as adjusted R^2, destructive leadership (along with age, gender, and work experience) explained 16% of the variation in burnout. Moreover, the association between burnout and job demands was positive, explaining 11% of the variation in burnout. In contrast, job resources were negatively associated with burnout, indicating that job resources reduce burnout and explain 17% of the variation in burnout. All these associations were significant.

Multiple regression analysis was conducted for the associations of destructive leadership and job demands with burnout in model 1, and the job resources variable was added to model 2 (Table 5). The positive association of destructive leadership and job demands with burnout remained significant in model 1. Based on their adjusted R^2 values, these variables explained 19% of the variation in burnout. After job resources were added, in model 2, these associations became less positive and they explained 24% of the variation in burnout overall.

4. Discussion

This study aimed to gain insight into the factors related to burnout in nurses. Our findings indicated that destructive leadership, as well as job demands and resources, are associated with burnout among registered nurses in Finland. To our knowledge, this is the first study to explore this multivariate association in the context of nursing. Moreover, job resources were noted to provide the strongest explanation for the variation in burnout; in particular, they were noted to be negatively correlated with burnout. Moreover, job resources were noted to diminish the negative effects of destructive leadership and job demands.

Burnout remains a major concern among nurses—as indicated by the mean exhaustion scores of 3.21 (on the 5-point Likert scale). Moreover, destructive leadership was significantly associated with burnout; therefore, destructive leadership may also be a serious threat to the well-being of nurses at work. The result was expected and is supported by previous relevant but scant research in the context of nursing [56, 57]. From the perspective of the JD-R model, destructive leadership can be considered a load factor. As a social and organisational factor, destructive leadership might lead to emotional exhaustion and a psychological withdrawal from the job [58]. Supervisors play an essential role in providing employees with job resources presented in the JD-R model (e.g., support, feedback, rewards, and various tasks) [24]. Therefore, a lack of job resources can be a result of destructive leadership. However, our results demonstrated that job resources can not only reduce burnout themselves but also mitigate the adverse effects of destructive leadership and job demands. Our results corroborate those of the JD-R model, which emphasises that job resources mitigate the negative effects of job demands [24].

Regarding the global shortage of nurses, our results indicated that the managers made the nurses feel easily replaceable, but they neither felt insecure about their job nor were they afraid about being terminated. In previous studies, nurses have reported that they felt easily replaceable, possibly because of a lack of professional respect and appreciation from their managers [59, 60]. In contrast, these feelings may occur in nurses who are temporary, from an agency or from a foreign country and have to prove their professional skills in several instances—all of which may lead to insecurity [61]. In nurses, significant associations have been noted between being temporary and vulnerability; this, in addition to some other factors, represents the feeling of being easily replaceable [62]. The amount of temporary work has increased in Nordic countries; in Finland, more than one-fifth of all nurses work under fixed-term contracts [63].

Our results also indicated that job demands are positively associated with burnout. Considering the current labour shortage, the most reported job demands include the workload and time pressure; these factors have generally

TABLE 4: Cronbach's α and correlation coefficients of all the study variables.

been associated with increased burnout among nursing staff [64–66]. In contrast, job resources were noted to reduce burnout in the current study, which is in line with previous findings [65, 67]. In particular, in addition to job autonomy and learning opportunities [29, 67], social support and rewards are related to decreased burnout [65, 67]. The relationship between job resources and destructive leadership in nursing is unknown; however, in fields other than nursing, job autonomy has demonstrated protective effects similar to those of job resources. Job autonomy can buffer the impact of abusive supervision on factors such as job stress [68, 69]. Job crafting, which is a job resource, buffers the negative impact of abusive supervision on emotional exhaustion. The current respondents reported low job autonomy. Therefore, nurse managers should increase nurses' autonomy and decision-making opportunities, encourage them to proactively improve their work situation, and develop their job-related skills [58].

Burnout demonstrated a significant association with demographic characteristics among nurses. Notably, younger, less-experienced nurses reported the most burnout, whereas the oldest nurses demonstrated the least burnout. This result is supported by previous results [28, 70–72]. Older, more-experienced nurses might, therefore, cope better with job demands. In contrast, less-experienced nurses work longer shifts and overtime more often [73], both of which are related to higher levels of burnout [74, 75]. There might even be generational differences in work-life expectations and job resource perceptions among these age groups. For example, younger nurses report less satisfaction with the feedback and rewards they receive [76]; this feeling may be related to the feeling of not being acknowledged or respected [77]. In terms of the JD-R model, the lack of feedback and rewards are major predictors of disengagement [23]. Consequently, we suggest that these differences should be considered by supervisors from multiple generations;

nurse managers should foster respectful and appreciative behaviours, especially among temporary and young nurses; they have to concentrate on building trust and giving feedback about good work and, on the other hand, guarantee professional autonomy and decision-making opportunities [78].

In the current study, men demonstrated less burnout than women. However, although previous studies have reported contradictory results, comparing their results with ours is difficult because of the differences in the burnout measures used. In some studies, compared with women, men demonstrated more depersonalisation, but this difference was not found for the other burnout dimensions [70, 79, 80]. In a study of mental health nurses, male sex was positively associated with emotional exhaustion [81]. Moreover, male transplant nurses reported significantly higher levels of personal accomplishment than their female counterparts [82]. In a meta-analysis, most studies demonstrated that women were significantly more emotionally exhausted than men [83].

The relationships between the nurses' demographic variables and destructive leadership were noted to be nonsignificant, consistent with previous findings [38]. Notably, the perception of destructive leadership is subjective and perceptions demonstrate cultural differences [41, 84–86]. Cross-cultural research on cultural differences in the relationship between burnout and destructive leadership is warranted. In addition, to develop leadership practices, the organisational context needs to be considered; social, cultural, or institutional contexts can either facilitate or constrain leadership practices [87]. Furthermore, the need for accurate data collection tools in nursing is evident; very few measurement tools to quantify different destructive leadership styles have been developed [88]. In addition, empirical research with a longitudinal, qualitative approach may aid in gaining further insight into the impact of destructive leadership.

4.1. Implications for Nursing Management and Practice. To improve leadership quality within the nursing profession, it is essential to recognise and acknowledge destructive leadership styles in healthcare organisations. Targeted leadership intervention programs might help focus on supportive and transformational leadership styles to reduce burnout among nurses [89]. Burnout risk factors, such as excessive job demands and inadequate resources, should be regularly assessed by management, and necessary support should be provided to nurses. The support could include well-being promotion measures focusing on resilience building, stress management, and coping strategies to mitigate the impact of destructive leadership and high job demands. Burnout prevention and stress management skills must be considered in nursing education [90]. However, the best results are obtained by investing in sustainable solutions that address structural and systemic issues and focus on creating a positive work culture. Furthermore, the effects of destructive leadership on nurses' and patients' outcomes require further examination, considering various cultural and contextual factors.

4.2. Strengths and Limitations. A major strength of the current study was the large, nationwide sample of registered nurses. Because the assumptions of regression were met, our findings are also generalisable. However, despite the sufficient sample size, the lack of accurate response rate calculation must be considered a limitation. Furthermore, the cross-sectional design of the study remains a limitation in this study. Therefore, the causality of relationships noted in this study should be examined further. Furthermore, the burnout-related results could not be fully compared with those from previous studies because the BAT is a relatively new measurement tool; nevertheless, most burnout questionnaires also include exhaustion as a core dimension. In this study, the Cronbach's α for the burnout dimension was similar to that in the original study on the BAT-4 [50]. However, further research on the relationships between the BAT and different constructs in different cultural settings [6] is warranted.

5. Conclusions

The current results supplement and strengthen the scant evidence on the relationship between destructive leadership and burnout among nurses. Results also confirm that among nurses, the association between job demands and burnout is positive and that job resources may alleviate the adverse effects of destructive leadership and job demands.

In healthcare organisations, strengthening job resources is essential for improving work-related well-being in terms of burnout among nurses, particularly younger nurses. To further improve the nurses' working conditions, organisations should pay attention to the evaluation of job demands and leadership styles. Through the creation of health-promoting work environments, nurse turnover may be reduced. Improved work-related well-being affects nurses'

job performance, which is essential for healthcare organisations to function effectively and provide high-quality healthcare services.

The current results may be used when planning intervention studies on burnout prevention and reduction among nurses; they may also guide nurse leadership educators. However, additional studies on destructive leadership and burnout in different healthcare and cultural settings are warranted [91].

Data Availability

The survey data used to support the findings of this study have not been made available because it is part of the ongoing project.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Aims. This study investigates how authentic leadership influences the psychological well-being of Australian nurses. We examined whether authentic leadership could reduce the prevalence of workplace incivility and tested whether shared values and person-organization (P-O) fit could moderate the relationship between workplace incivility and psychological well-being (PWB). A mediated moderation model underpinned by social learning theory was developed to test the influence of authentic leadership on PWB. *Design*. We adopted a descriptive correlational research design to test the hypothesized model with a cross-sectional sample of Australian nurses using an online survey. Data were collected across two-waves separated by a six-month interval ($N = 230$, response rate = 38.3%) to minimize the potential effects of common source bias. The hypotheses were tested using Hayes Process Macro (Model 14) on IBM SPSS. *Results*. The hypothesized model had good fit indices and supported the mediated moderation model. There was no support for the direct association between authentic leadership and PWB. The supervisor authentic leadership behavior was negatively associated with workplace incivility and PWB. The association between incivility and PWB was positively associated with P-O fit. Nurses with high P-O fit reacted strongly to the positive effect of authentic leadership in reducing workplace incivility, such that they experienced higher levels of PWB. *Conclusion*. Authentic leadership behavior is important in the healthcare workplace. It reduces workplace incivility and improves PWB for nurses with high levels of congruence. Implications: our study suggests that senior management should deploy strategies through which frontline supervisors can learn and enact authentic leadership behaviors. They will then be better equipped to improve the PWB of their followers by minimizing the prevalence of workplace incivility. Impact: the study found a significant indirect relationship between authentic leadership behavior and psychological well-being, as mediated by workplace incivility and moderated by person-organization fit. The findings highlight the importance of positive leadership behaviors on the well-being outcomes of nurses in Australia.

1. Introduction

Nurses work in a high-stress, high-demand environment that creates considerable job strain [1]. This challenging work context is made even more difficult by mistreatments such as workplace incivility [2], which is a source of psychological stress [3]. Workplace incivility is the result of workplace interpersonal as conflict, evident by rude, disrespectful, and discourteous behaviors that are in violation of mutual respect [4, 5]. Workplace incivility behaviors create situations where nursing and allied staff are distracted from their duties in ways that could

compromise the quality of nursing care [6]. Workplace incivility tends to be lower in intensity than most workplace deviant behaviors and has an ambiguous intent to cause harm to others, which makes monitoring and dealing with perpetrators and targets a challenging task [5]. Where it occurs, workplace incivility is disruptive to the work environment because it breaches accepted standards of professional conduct and norms of civility [7]. Such behaviors could result in significant harm to employees, to the organization, and patients [8] and could affect nurses' intention to stay [9]. In this study, we will focus on workplace incivility and the extent to which

authentic leadership can help reduce its prevalence and mitigate its negative effect on PWB. The influence of leadership behaviors on followers' well-being is an under-researched topic generally [10] and in the nursing management literature (see [11]).

In this paper, authentic leadership is defined as "a pattern of transparent and ethical leader behavior that encourages openness in sharing information needed to make decisions while accepting input from those who follow" [12], (p. 424). Lemoine et al. [13]; (p. 2051) noted that "authentic leadership is primarily concerned with a leader's self-awareness, self-regulation, and self-concordance, and modeling these characteristics to sub-ordinates. . . .." This positive, relational leadership behavior [14] is particularly relevant in the healthcare setting [15]. Authentic leaders promote healthy work environments to mitigate workplace incivility and, in turn, enhance their followers' well-being [13]. Authentic leaders are self-reflective, listen to feedback, and practice empowerment, which impact positively on nurses' well-being [15]. Nursing leaders who exhibit authentic leadership behavior are grounded in their moral and ethical values.

Nelson et al. [11] note that different ways of operationalizing PWB include a plethora of approaches that range from perceived work stress [16] to exhaustion [2] and psychological distress [17]. We deployed "psychological distress" to conceptualize and measure PWB [18] because PWB is an outcome of the interplay between interpersonal relationships at work [19]. This particular approach to operationalizing "psychological distress" is commonly found in other studies conducted on the work and well-being of nurses [17, 20, 21]. Psychological distress has been used as an indicator of well-being by the World Health Organization [22].

To the best of our knowledge, the hypothesized indirect relationships have not been empirically tested. The mediated moderation model we propose (see Figure 1) is theoretically informed by social learning theory (SLT) [23, 24]. SLT is used to conceptualize why followers learn from their leader's authentic, moral, and ethical behaviors to minimize workplace incivility. Followers learn what is socially acceptable by observing the values and behavior exhibited by their supervisors. When supervisors display authentic leadership behaviors, those they supervise are likely to adopt similar work values and behave accordingly. P-O fit is a form of subjective value congruence and is defined as the "compatibility between people and the organizations in which they work" [25], p. 1). The alignment of one's own values with their organization's values is critical to employees' work attitudes [26] and stress [27].

In this study, workplace incivility is an example of workplace mistreatment that impacts negatively on the PWB of nurses. It is hypothesized as a mediator, while person-organizational (P-O) fit is hypothesized as a moderating variable of the direct association between authentic leadership and PWB. This study contributes to the literature by unpacking the indirect (mediation and moderation) mechanisms driving the direct and indirect influence of authentic leadership on PWB.
Figure 1: Proposed mediated moderation model.

2. Background

2.1. Direct Relationship: Authentic Leadership and PWB. Nursing is an occupation where employees regularly encounter high levels of psychological stress, which often leads to chronic health problems [1]. Psychological stress is defined as "a particular relationship between the person and the environment that is appraised by the person as taxing or exceeding his or her resources and endangering his or her well-being" [19], p. 19). As an example of PWB [18], psychological distress is an outcome of the interplay between a person and their work environment [19]. Underpinned by positive psychology, authentic leadership has been proposed to be an effective tool for improving the PWB of nursing professionals [28]. Authentic leaders "are guided by sound moral convictions and act in concordance with their deeply held values, even under pressure, and strive to understand how their leadership impacts others" [29], p. 332). Authentic leadership is comprised of four components: self-awareness, internalized moral perspective, balanced processing, and relational transparency [28]. Authentic leadership contributes to a healthy work environment, which is beneficial for staff and patients [28]. Authentic leadership has the potential to build trust and confidence, which in turn results in higher PWB when employees feel valued and respected [11]. Followers' experiences of leader authenticity can be conceptualized as a resource that can be deployed to help improve their well-being at work [16]. We hypothesized that:

H1. There is a positive, direct association between the supervisor's enactment of authentic leadership behaviors and followers' PWB.

2.2. Authentic Leadership, Workplace Incivility, and PWB. We theorize that the direct relationship between authentic leadership and PWB is mediated by workplace incivility. To our knowledge (see the systematic review by [28]), there are few empirical studies that examine this mediation relationship. To address this gap in our knowledge, we contend that authentic leadership can help to eliminate workplace incivility, which then improves followers' PWB. While authentic leadership has the potential to reduce the incidence of workplace incivility, our review of existing research brought to light only one study in the context of nursing [2].

Workplace incivility has received considerable research attention over the past three decades (e.g., [5]). Incivility is a "subtype of workplace mistreatment that is characterized by low-intensity social interactions that violate norms of respect and whose harmful intent is ambiguous" [30], p. 316.

It occurs far more frequently [4] and can be just as harmful [31] as other forms of harmful behavior. Workplace incivility has a negative association with the PWB of targets [31, 32].

Bandura's [23] SLT can be used to explain the indirect association between authentic leadership and PWB in that while authentic leaders influence the ethical conduct of their followers as a result of role modeling, they also create the work environment by signaling to their team the importance of respect and trust in the workplace [28]. These behaviors form the acceptable standard, which then diffuses across and trickles down the organization via social learning [33], encouraging others to behave in a similar manner. In this way, authentic leaders encourage employees to treat others fairly and with respect while discouraging violations of these expectations [34]. This social learning process can be an influential mechanism through which authentic leaders can affect followers' well-being at work [35] by encouraging civility norms [2]. We hypothesize the following relationship:

H2. Workplace incivility has an indirect mediation effect on the association between the enactment of authentic leadership behaviors and followers' PWB.

2.3. P-O Fit as Moderator. As an example of value congruence [36], P-O fit allows "judgments of congruence between an employee's personal values and an organization's culture" [36], p. 875). Avolio and Gardner [37] noted that leaders who exhibit authentic leadership behaviors tend to develop and foster high relational quality and close relationships with their followers, which, in turn, foster greater value congruence (or P-O fit) and follower reciprocation in the behaviors consistent with the leaders' values. Such reciprocity is acquired in the process of social learning and affects followers' well-being (Zheng et al., 2022). Mackey et al. [27] conceptualize P-O fit as a personal resource to buffer workplace stress "because perceptions of organizational fit are generally sought after and valued, which provides stress-resistance potential" (p. 459) as it improves employees' health and well-being. Meta-analytical review findings from Kristoff-Brown et al. [26] support the notion that higher levels of P-O fit are associated with lower levels of work-related stress as employees tend to express a higher level of well-being when they perceive a fit of their own values with their employers. Workplace incivility as an example of stressful work events in the healthcare setting [2, 28] could then be buffered by the extent to which nurses perceived P-O fit. We therefore hypothesize that:

H3. The relationship between workplace incivility and PWB is moderated by P-O fit such that when value congruence is high, the negative effects of workplace incivility on PWB will be weaker.

3. Methods

At the time of data collection, there were 352,838 registered nurses and midwives (including registered nurses, enrolled nurses, and midwives), as reported by the Australian Institute of Health and Welfare [38]. PureProfile, a research company based in Australia, was engaged to assist with sending out an online survey to their panel members (inclusion criteria: nurses from Australia, between 18 and 65 years old, full and part-time employment, employment in public, private, and not-for-profit hospitals). This recruitment strategy is common in the literature (e.g., [39]. Our exclusion criteria included those who were not residents of Australia at the time of the study, not qualified as "nurses" as defined by the Australian Health Practitioner Regulation Agency, and those who were older than 65 years old.

We received useable responses from 600 Australian nurses in Wave 1 of data collection. They provided data on demographic and control variables, authentic leadership and P-O fit, and workplace incivility. The respondents were contacted again six months later to provide their responses for their PWB at Time 2. In this cross-sectional study, we obtained 230 useable matched responses (response rate = 38.3%). We decided to use a six-month temporal separation between waves as informed by the incivility literature (see [40]). G∗Power analysis concluded that this sample size has sufficient power and effect size to yield significant accuracy and flexibility of predictions with three predictors [41].

3.1. Measures. We adopted previously validated scales in this study. The composite reliability coefficient (CR), average variance estimate (AVE), and maximum shared variance (MSV) are reported below.

3.1.1. Authentic Leadership. We used the 16-item Authentic Leadership Questionnaire (ALQ) from Walumbwa et al. [14] to measure respondents' perceptions of their immediate supervisor's authentic leadership behaviors. It is deemed appropriate to ask employees to provide an assessment of their supervisor's leadership behavior if they have daily interaction with them and can observe whether they demonstrate those behaviors [34]. Sample item includes "Displays emotions exactly in line with feelings." The items were rated on a five-point Likert type scale, ranging from 1 "not at all" to 5 "frequently, if not always" (CR 0.98, AVE 0.93, and MSV 0.32).

3.1.2. Person-Organization Fit (P-O Fit). We used the 3-item scale developed by Cable and DeRue [36] to operationalize P-O fit. This scale has been used in the literature [42]. A sample item reads: "My personal values match the organization's values." These were rated on a seven-point Likert type scale, ranging from 1 "strongly disagree" to 7 "strongly agree" (CR 0.95, AVE 0.83, and MSV 0.32).

3.1.3. Workplace Incivility. We used the 5-item scale from Cortina et al. [31] to measure workplace incivility. A sample item asks respondents if they had experienced various workplace incivility in the previous six months, such as "Addressed you in unprofessional terms, either publicly or privately?" (ranging from 0 "never" to 4 "frequently "at least

once a day")". The content and discriminant validity of this scale are well established [31]. In this study, we found the validity and reliability coefficients to be satisfactory (CR 0.95, AVE 0.74, and MSV 0.13).

3.1.4. Psychological Well-Being (PWB).

We used the Kessler K-10 Psychological Stress Scale [43] to measure PWB at Time 2. This scale is comprised of 10 commonly found stress symptoms, and in Australia, the K-10 scale has been used as an indicator of well-being in the 2017–18 National Health Survey [44]. It has been used to measure PWB in the nursing profession [17, 20] and in workplace incivility research [45]. Respondents were asked to indicate how frequently they have experienced these stress symptoms over the past 30 days (sample item: "Did you feel that everything was an effort?"). Responses were recorded on a five-point Likert type scale ranging from 1 "none of the time" to 5 "all of the time." This scale was reverse-coded such that low scores represent distress (low PWB). Validity and reliability coefficients were found to be satisfactory (CR 0.95, AVE 0.64, and MSV 0.13).

3.1.5. Control Variables.

In addition to adopting temporal separation in data collection [46], we also controlled for the effects of gender, age, the average number of patients per shift, and organizational tenure because these variables have previously been found to be associated with incivility [47].

3.2. Ethical Considerations.

Ethics approval was obtained before data collection from Curtin University (reference: SOM 19–12). Consistent with good practice, we assured the participants' anonymity and confidentiality in the participant information letter.

3.3. Data Analysis.

We used IBM SPSS v.25 to perform bivariate correlations and descriptive statistics. Confirmatory factor analysis was conducted within IBM AMOS v25, and model testing was completed using Model 14 of Hayes' [48] Process Macro within IBM SPSS v27.

3.4. Validity and Reliability.

All of the scales exceed the recommended reliability thresholds [49]. The Fornell and Larcker's [50] Average Variance Extracted (AVE) test was used to establish the discriminant validity of the scales used in the survey. All of the scales met the 0.50 threshold for AVE, and the square root of the AVE for each scale was higher than its correlation with any other scale. This finding indicates that the scales measured distinct latent constructs.

We used a time-lag research design [46] to minimize common method variance (CMV). As noted by Podsakoff et al. [46], the inclusion of a moderator (incivility × P-O fit) in the model ensures that CMV would not produce statistically significant effects. We also employed proactive procedural remedies such as the random ordering of survey items and ex-post statistical tests (see [46]) to further minimize any potential effects of CMV. To this end, we also

conducted Harman's single factor test by subjecting all items to an unrotated exploratory factor analysis which revealed a single largest factor that explained 29.9% of the variance. Given this result, we were confident that CMV effects were not present.

Before testing the 4-factor hypothesized model (that is, authentic leadership, workplace incivility, P-O Fit, and PWB), we conducted several nested measurement model comparisons against three (authentic leadership + workplace incivility, P-O Fit, and PWB), two (authentic leadership + workplace incivility, P-O Fit and + PWB) and single (authentic leadership + workplace incivility + P-O Fit + PWB), factor alternate models. The results indicate that the hypothesized 4-factor model was the best fit to the data ($\chi^2/df = 1.33$, CFI = 0.98, TLI = 0.98, RMSEA = 0.04, SRMR = 0.04) and corresponds with our hypothesized framework.

4. Results

As previously reported, 230 Australian nurses completed the two-wave online questionnaire. The majority of the respondents were female (84.3%). Half of the respondents worked part-time (53.5%), and most were employed by public and not-for-profit sector health care organizations (66.1%). Respondents were from New South Wales (33.9%), Victoria (23.0%), Queensland (16.5%), South Australia (12.6%), and Western Australia (9.1%). Over half of the respondents were between 41 and 60 years old (53.9%), followed by those who were 31–40 years old (20.0%), which matches the 2017 data produced by the [51] report (53.6% and 19.6%, respectively) and is consistent with the nationwide health workforce data for nurses and midwives. The largest group of nurses had greater than ten years of organizational tenure (30.4%), followed by those with six to ten years (23.9%), and then those with three to five years (16.1%). The respondents had on average 18.7 patients per shift (SD = 36.7).

Descriptive statistics and zero-order correlations are reported in Table 1. On average, nurses reported their immediate supervisor's leadership behavior to be moderately authentic ($M = 3.27$, SD = 0.87). Ratings of incivility frequency showed 40 nurses had no experience with incivility (17.4%), 78 experienced incivility once every few months or less (34.0%), 51 experienced incivility once a month (22.2%), 46 experienced incivility at least once a week (20.0%), and 15 nurses experienced incivility at least once a day (6.4%). This finding is consistent with the literature, as nurses tend to experience a high level of workplace incivility (see [45, 52]). They also reported a moderate level of value congruence with their organization ($M = 4.06$, SD = 1.55).

To test the hypothesized relationships, we conducted a multiple regression analysis using Model 14 of Hayes's [46] PROCESS macro with 10,000 bootstrapped subsamples using IBM SPSS v25. Control variables were also entered into the model. There was a positive association between workplace incivility and average patients per shift ($\beta = 0.17$, $p < 0.05$) and a negative association with age ($\beta = -0.07$, $p < 0.05$). There was a positive association between PWB and

TABLE 1: Descriptive statistics and intercorrelations.

	Mean	SD	1	2	3	4
1. Authentic leadership (T1)	3.27	0.87	**0.98**			
2. Workplace incivility (T1)	1.14	1.03	−0.40***	**0.95**		
3. P-O fit (T1)	4.05	1.54	0.53***	−0.34***	**0.95**	
4. Psy well-being (T2) (Low scores in psychological well-being scale represent distress)	2.06	0.94	0.09	−0.49***	0.07	**0.95**

Note. $N = 230$. ***$p < .001$. Correlations of control variables are not reported. Bold, italicized text: Composite Reliability Coefficient. T1: time 1. T2: time 2.

gender ($\beta = 0.31$, $p < 0.001$) and a negative association with supervisory position ($\beta = −0.23$, $p < 0.01$). There was no support for a direct relationship between authentic leadership and PWB (hypothesis 1), while the remaining hypotheses were supported (see Table 2). There was a negative association between nurses' perception of their supervisor's authentic leadership and workplace incivility ($\beta = −0.33$, $p < 0.001$). Workplace incivility had a negative association with PWB ($\beta = −0.53$, $p < 0.05$).

Results of the indirect paths are reported in Table 3. Workplace incivility mediated the effect of authentic leadership on PWB (effect −0.13, SE 0.05, 95% CI [−0.24, −0.03]), and there was support for P-O fit to moderate the full mediation of authentic leadership on PWB (effect −0.048, SE 0.017, 95% CI [−0.084, −0.016]). Hypothesis 2 was supported. Nurses' P-O fit moderated the negative relationship between workplace incivility and PWB ($\beta = 0.16$, $p < 0.01$). The moderation plot (see Figure 2) indicates that P-O fit minimized the negative association between workplace incivility and PWB. As shown in Table 3, these results provide evidence to support a mediated moderation model.

5. Discussion

The main aim of this study was to respond to the call in the literature to investigate the impact of leadership behaviors on the well-being of followers. As part of this research, we tested the mediator effect of workplace incivility and value congruence (measured by P-O fit) as a moderator. Our findings have three main implications.

First, our study contributes to the literature by enhancing our understanding of authentic leadership [2, 28] in PWB, especially in minimizing psychological distress. This finding contributes to the underresearched topic of how leadership behaviors affect followers' well-being [10, 11]. By establishing an indirect association between authentic leadership and PWB, our study has provided additional evidence of the effect of authentic leadership in minimizing workplace incivility, and in doing so, sheds light on how authentic leadership influences the PWB of nurses at different stages of their work tenure beyond early career and initial job experiences [2, 53].

The application of social learning theory [23] allows us to unpack how this process takes place in the nursing context [24]. Supervisors who engage in authentic leadership behaviors are likely to discourage workplace incivility by openly displaying and upholding ethical norms and values regarding acceptable workplace conduct [2]. Followers learn that this is the accepted social norm and imitate their leader's positive behaviors. This in turn reduces the prevalence of workplace incivility and improves PWB. Authentic leadership behaviors enable nurse managers to create a more civil work environment and enhance employees' well-being at work (e.g., [35]).

Second, we found workplace incivility (a form of workplace deviance) had a negative association with nurses' PWB. While there are a variety of approaches to operationalizing and measuring PWB evident in previous research, in this study we have demonstrated how psychological distress as an indicator for PWB [18] could be enhanced by minimizing interpersonal deviance at work. Workplace incivility depletes the psychological resources of those who are affected by the behaviors [27]. Employees could learn positive leadership behaviors by mirroring the authentic behaviors of their supervisors, which in turn helps to minimize the prevalence of workplace mistreatment across the organization [54].

Third, P-O fit was found to be a moderator of the association between workplace incivility and PWB. As indicated by the moderation plot, the moderation effect occurs when the P-O fit is high. What we have is a situation where the enactment of authentic leadership behaviors leads to less workplace incivility. This leads to a higher level of PWB for nurses who exhibit a high level of P-O fit. P-O fit, as a form of value congruence, could be treated as a resource that nurses could draw upon to maximize the positive consequences of civility. This moderation finding represents a contribution to the literature as it has not been empirically tested [27]. Our finding also adds to our understanding of the contribution of P-O fit on employee well-being outcomes at work [26].

5.1. Practical Implications. This study has implications for nurse managers as well as managers in the health and public sectors generally. Our findings suggest that health care managers should be trained to develop their positive, relational leadership styles. The enactment of authentic leadership behaviors by frontline supervisors combats workplace stressors and improves well-being by minimizing workplace incivility in healthcare settings. Authentic leadership could lead to the development of more civil [2], heathy, and safe workplaces that minimize employee mistreatment [54]. This influence is reinforced through an improvement in the P-O fit between nurses' personal values and those of the organization where they work. As a form of ethical leadership behavior, authentic leadership has the potential to significantly reduce workplace incivility and increase PWB among employees in high-demand work environments like nursing.

Workplace incivility could be minimized by introducing workplace civility programs, which could be used to reduce incivility in order to improve job attitudes and well-being [2, 55]. An example is the 6-month workplace intervention model known as CREW - Civility, Respect, and Engagement at Work [56]. As part of the intervention, nurses would meet with their coworkers within their workplace on a " weekly or biweekly basis to work on effective interpersonal interactions at work" [56]. Trained facilitators would provide guidance to the groups on how to improve workplace communication. This intervention seeks to improve workplace social relationships in order to enhance respect. A civility toolkit could also be produced, similar to the one proposed by the UK's National Health Service (NHS). The NHS used the toolkit to create a civil and respectful culture to improve employee well-being and patient care [52]. These organizational practices are important as they could improve nurses' person-organization fit and are likely to reciprocate with affective commitment and a greater sense of belongingness. Nursing supervisors who exhibit authentic leadership behavior in the workplace by striving to build open, genuine relationships and by helping their followers fit in with their workplace create more civil work environments that promote employees' well-being and, ultimately improve the quality of care [6].

5.2. Limitations and Future Research Implications. Focusing on nurses in the Australian health care sector limits the generalizability of our findings. We applied procedural and statistical remedies to provide assurance that common method bias did not affect our results [46]. Control variables were incorporated to control for confounding effects. We should note the potential for reverse causality remains. Future studies should test the possibility of a reverse causal relationship between authentic leadership and PWB by collecting longitudinal data. Multisource data could be used to develop our findings by better isolating the predictors of PWB. It might also be valuable to explore further the extent to which and how authentic leadership is being measured by using experimental design or implicit measures, or to
FIGURE 2: Moderation effect of P-O fit. Note: control variables are not shown in the figure.

explore the relationship between leaders' intentions and followers' perceptions of authentic leadership behavior [57]. Recall bias could be another potential limitation, which can be addressed by using a daily diary design [58].

6. Conclusion

Our study aimed to examine how authentic leadership behavior affects the well-being of nurses where workplace incivility is present. Using data collected from a sample of nurses working in Australian health care organizations, we found evidence to support the argument that workplace incivility has a deleterious effect on PWB. Our study suggests that nursing managers have an important role to play in protecting and improving the well-being of those they supervise, and authentic leadership behavior is an additional and effective skill in this endeavor [59–63].

Data Availability

The survey data used to support the findings of this study have not been made available because of restriction imposed by institutional review board for sharing data. This was part of the ethics approval conditions.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Aim. This study aimed at evaluating the effects of a job crafting intervention program for nurses on their job crafting behaviors, harmonious work passion, and career commitment. *Background*. Nurses generally work in suboptimal environments with chronic low resources and high demands. Job crafting may be a cost-effective strategy to deal effectively with such environments. However, its effectiveness as a nursing intervention program remains unclear. *Methods*. An open-label randomized controlled trial was conducted at a hospital in Port Said, Egypt. The study enrolled 94 nurses. Participants were assigned randomly to the intervention group ($n = 47$) or the control group ($n = 47$). The intervention group had a 2-day workshop, 3 weeks of job crafting implementation, and a reflection session, whereas the control group participated in a 1-day workshop. Data were collected at baseline, 2 weeks, and 3 months after the intervention in both groups by using the Job Crafting Scale, Job Crafting Knowledge Questionnaire, Harmonious Work Passion Scale, and Career Commitment Scale. *Results*. Compared with the control group, the intervention group experienced a higher level of job crafting behaviors and reported a greater improvement in harmonious work passion, but not in career commitment. *Conclusion*. Nurses can be trained on job crafting behaviors, which can lead to the maximization of job resources, optimization of job demands, and enhancement of nurses' harmonious work passion. *Implications for Nursing Management*. Nursing managers should train nurses regularly on how to be job crafters because it is an effective tool that helps nurses deal with limited job resources and increased job demands and makes them more harmoniously passionate about their work.

1. Background

Nursing is a highly challenging profession [1]. Nurses worldwide are always under intense pressure [2, 3]. By their professional nature, they work in an environment with chronic high job demands and low resources [4]. In Egypt, nurses work in more complex conditions characterized by poor staffing, long shifts, extensive responsibilities, unclear job description, increased stress, high workload, and demotivation [5]. Working in such a suboptimal environment has adverse effects on nurses and places them in unfavorable circumstances [6]. To address these problems, nurses have proposed job crafting as a strategy to maximize these limited resources and optimize the increased job demands [7, 8]. Job crafting may be the solution for many problems nurses face in their workplace [9].

Wrzesniewski and Dutton initially presented the term "job crafting," resulting from the physical and mental changes that people experience in a certain task or relationship boundary of their profession [10]. Recently, job

crafting was viewed as a self-initiated behavior aimed at balancing between demands and resources of job [8]. Job crafting was operationalized from two dominant perspectives. The first is the Wrzesniewski and Dutton perspective, which theorizes that job crafting has three aspects, namely, task, relational, and cognitive crafting. Task crafting involves altering the scope or number of job tasks (e.g., considering taking an additional task as enjoyable). Relational crafting means improving the quality and/or the quantity of work relationships (e.g., less interaction with an unfavorable person). Cognitive crafting is changing the way people view their jobs (e.g., a nurses reframe their job from serving patients to saving patient's life) [10].

The second and most recent perspective is Tims et al.'s perspective, which is based on the Job Demands-Resources (JD-R) model. This study adopted this perspective. According to this perspective, job crafting is categorized into three aspects: increasing job resources, seeking challenge, and decreasing job demands [7]. Job resources are job elements that help in accomplishing work goals (e.g., colleagues' support, job autonomy, and supervisors' feedback). Challenging a job means accepting demands that are perceived as rewarding and worthy of one's effort (e.g., sharing of knowledge, participating in a certain committee, and mentoring nursing students). Job demands are job elements that need consistent physical, mental, and emotional efforts (e.g., time pressure and dealing with difficult patients) [8].

Practicing job crafting among nurses has become critical and can lead to multiple positive outcomes [11]. It is a cost-effective strategy by which nurses can improve their functioning at work [12]. Nurses who can craft their job are more able to balance between the needs of the organization and their preferences and abilities [13], to have higher levels of well-being, productivity, and meaningful work, and to give high-quality care [14]. Further, job crafting increases nurses' identity and autonomous internalization, which foster work passion [15]. One of the most important forms of work passion is harmonious work passion [16].

Harmonious work passion is a new concept in organizational behavior that has gained increased attention in the recent nursing management literature [17]. It is related to the autonomous internalization of one's activity, allowing one to perform such an activity freely and willingly [16]. Notably, work passion is categorized into two types: harmonious work passion and obsessive work passion [18]. In this study, we adopt harmonious work passion as it represents the former type of passion, characterized by individuals' identity towards an activity and their internal motivation for doing it [17], making it a suitable target for the study. Studying factors that foster nurses' harmonious passion has become crucial because this type of passion has tremendous benefits [19]. For example, harmoniously passionate nurses are highly intrinsically motivated to seek more information [17], are more satisfied with their work, are less susceptible to conflict, are less prone to burnout [20], engage more in their work, and experience less exhaustion and job stress [21].

Nurses are the main source of healthcare services in health institutions [22]. They are responsible for patient care

and treatment against disease and mortality [1]. Thus, enhancing nurses' career commitment is necessary [23]. Career commitment is described as individuals' identification with and attachment to their profession [24]. Nurses with a high level of career commitment are more likely to show favorable work consequences, including higher citizenship behaviors and organizational commitment and decreased deviant behaviors and intentions to quit their profession [25].

Generally, nurses have a unique role in modern medicine [26]. However, nurses' poor work conditions have deleterious consequences, putting the safekeeping and quality-of-care standards at risk [27]. Therefore, nursing scholars become more interested in studying job crafting [11], and others recommend interventions to foster it among nurses because of the urgent concern and the belief that it is a powerful strategy that can change their work environment positively [13]. Job crafting training empowers nurses to have greater control over their work, build a motivating work climate, maximize job resources, optimize increased job demands, enhance cognitive and behavioral attitudes towards change, and reduce exhaustion [28]. Additionally, it has been shown to enhance work engagement [29] and self-efficacy [30]. These benefits underscore the importance of providing job crafting training for nurses. However, job crafting studies in nursing are still few [31], and among them, only one focused on job crafting intervention [12]. Moreover, in the non-nursing field, studies that included job crafting intervention yielded contradictory results, and job crafting as a trainable behavior remains uncertain [32]. Therefore, to address these gaps, this study primarily aimed at testing if job crafting intervention can stimulate job crafting behaviors among nurses.

Training nurses on how to craft their job may lead to many positive outcomes. Job crafting training previously improved nurses' well-being and performance [12]. However, researchers found no published studies investigating the effect of job crafting intervention program on harmonious work passion or career commitment in nursing or non-nursing field, despite the critical need of studying factors that can increase nurses' harmonious work passion [19] and career commitment [33]. Hence, the secondary objective of the present study was to fill these gaps by examining the effect of job crafting intervention program on nurses' harmonious work passion and career commitment.

2. Theoretical Framework

Job crafting intervention is a training program designed to encourage individuals to proactively redesign their jobs by optimizing available job resources, managing increased job demands, and adapting to new job challenges [34]. Job crafting intervention is based on two main approaches: (1) the Wrzesniewski and Dutton approach, which frames job crafting as proactive changes in task, relational, and cognitive job aspects [10], and (2) the Tims et al. approach, which is based on the Job Demands-Resources (JD-R) theory [7].

The JD-R theory postulates that individuals require a sufficient amount of job resources to effectively cope with

the demands they encounter in their work. According to this theory, organizations play a crucial role in providing optimal job demands and resources to their employees. However, individuals also possess the autonomy to proactively modify their job demands and resources, thereby contributing to a better alignment between individuals and their jobs. Consequently, this leads to enhanced optimal functioning within the workplace [35]. Job crafting, when framed within this context, refers to the ability of individuals to change three types of job characteristics: job resources, seeking challenge, and job demands [7].

Previous studies have explored the outcomes of job crafting intervention and demonstrated its positive effect on enhancing work engagement, job performance [29], career satisfaction [36], and well-being [12]. Job crafting intervention increases individuals' awareness of their own preferences and needs, empowering them to take action to make changes. The job crafting intervention provides individuals with specific techniques and tools they can use to identify areas where they can make changes to manage their job resources and demands. Moreover, job crafting intervention encourages them to formulate a job crafting plan, which increases their adherence to job crafting behaviors [37]. Hence, job crafting intervention leads to an increase in job crafting behaviors and all related dimensions. Therefore, the study hypothesized that

> H1. Nurses participating in the job crafting intervention will exhibit higher levels of job crafting behaviors and all related dimensions after the intervention compared with those in the control group.

2.1. Job Crafting Intervention and Harmonious Work Passion.
Harmonious work passion is an essential factor that has significant implications for the well-being and performance of nurses [38]. However, nurses can lose their harmonious passion due to the intense physical, emotional, relational, and social pressures they face while practicing their profession [39]. Additionally, a lack of control over their work environment can also lead to reduced passion [40]. Training nurses on how to craft their job can be an effective strategy to help them manage physical, emotional, relational, and social pressures and gain control over their work environment [10]. Hence, training nurses on how to craft their job can enhance their passion towards their work. Therefore, the study hypothesized that:

> H2. Nurses participating in the job crafting intervention will experience a higher level of harmonious work passion after the intervention compared with those in the control group.

2.2. Job Crafting Intervention and Career Commitment.
Career commitment is achieved when nurses are able to align their career path with their personal preferences and interests [25]. Job crafting training equips individuals with the necessary tools to proactively shape their work environment to better fit their skills, values, and interests [41].

Additionally, practicing job crafting and gaining increased control over their work can foster a sense of ownership and investment in their careers [42]. Furthermore, job crafting training can enhance nurses' job engagement and well-being [12], which can further contribute to their career commitment [43]. Hence, job crafting training can improve career commitment among nurses. Therefore, the study hypothesized that

> H3. Nurses participating in the job crafting intervention will have a higher level of career commitment after the intervention compared with those in the control group.

3. Subjects and Methods

3.1. Study Design. This study was a two-arm, parallel, open-label randomized controlled trial (RCT) that conforms to the Consolidated Standards of Reporting Trials (CONSORT) guidelines [44]. The study protocol was registered at ClinicalTrials.gov (Identifier code: NCT05329805; 15/04/2022).

3.2. Participants and Setting. This study recruited nurses working 12 hours per shift for 186–195 hours a month at one of the universal health insurance hospitals in Port Said Governorate, Egypt. Nurses who were licensed staff nurses, worked in a ward, and had at least 6 months of experience were included in the analysis. In contrast, nurses who were involved in any other intervention program within the last 12 months, working in clinics, or holding an administrative position were excluded. Of the 224 invited participants, 58 did not meet the inclusion criteria, 62 declined to participate, and 10 were piloted. Ultimately, 94 were included and randomly allocated to the intervention group ($n = 47$) or the control group ($n = 47$). Overall, 79 (39 in the intervention group and 40 in the control group) completed the intervention up to T2 data collection. The attrition rate from the baseline (T0) until T2 data collection was 15.95%. Figure 1 illustrates the consort flow diagram of the participants.

3.3. Sample Size Calculation. A prior sample size was estimated using the G*Power 3.1.9.7 Software [45] for repeated measures analysis of variance (ANOVA) design (within-between interactions) with effect sizes of 0.26 and was obtained from the meta-analysis on job crafting intervention that included healthcare professionals [29] (α error = 0.001, power = 0.95). A sample of 72 participants (36 for each group) was estimated. Considering the possibility of a 30% attrition rate resulting from high dropout/loss to follow-up among Egyptian participants [46], the recruitment target was 94 participants (47 in each group).

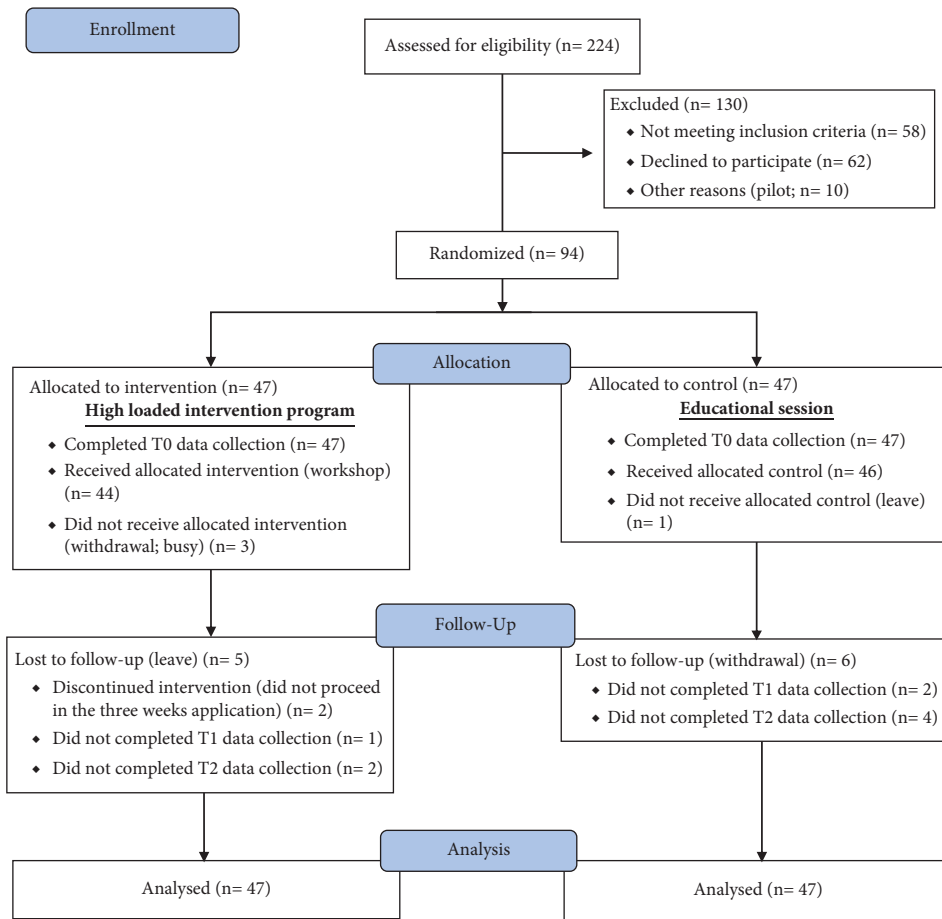
3.4. Randomization and Blinding. An independent researcher randomly assigned the participants to the intervention or control group by using the "Research Randomizer" web-based program [47]. The number of groups needed and the number of potential participants


Figure 1: Consort flow diagram.

were input into the program, which generated two sets of 94 unique, sorted numbers arranged from the least to the greatest and allocated randomly to either Group 1 (representing the control group) or Group 2 (representing the intervention group) in a 1 : 1 ratio. The allocation sequence was concealed by using opaque sealed envelopes.

Blinding was not feasible in this study because the intervention provided was an educational program, which made the blinding of the researcher or the participants to the group allocation difficult [48]. Nevertheless, to minimize the risk of bias, the data collection and analysis were performed by authors (SM, MS, and MZ) were not involved in providing the intervention program conducted.

3.5. Intervention. The job crafting intervention program was developed according to the Michigan Job Crafting Exercise [37] and was operationalized on the basis of the JD-R theory principles [49]. The intervention aimed to train the participants in maximizing their job resources, optimizing the increased job demands, and adapting new job challenges, which may be useful in enhancing their harmonious work passion and career commitment.

Prior to the intervention program, potential participants and nursing managers with different levels were interviewed to understand the work context, which included the

following: what does good performance mean from their point of view, what hinders them from doing so, what helps them to provide high-quality care, what tasks represent challenges, and why they did not assume such challenges. This information was utilized to prepare a tailored intervention and customized examples in creating the intervention.

Five-expert committee included two nursing administration professors, one nursing manager, and two staff nurses with master's degrees were asked for suggestions on the content and structure of the intervention materials. The intervention materials were modified based on their suggestions and sent back to the committee for approval. Then the intervention materials were pilot tested to ensure their quality and clarity.

Thereafter, the intervention was conducted, consisting of a 2-day workshop, 3 weeks of job crafting implementation, and a reflection session. The workshop consisted of four 60–90-minute sessions with 2 sessions per day and 30 min rest between sessions over 2 days. In session 1, the researcher introduced the theoretical background. In session 2, the JD-R model was discussed in detail, and the participants were requested to share their personal job crafting experiences. In session 3, they were invited to participate in the Michigan Job Crafting Exercise [37], which included job analysis, personal analysis, and job-personal analysis. As a result of

completing the exercise, each participant was expected to be aware of the following: resources that could be increased, the idea that demands could be decreased without interrupting the work, and areas that represent a challenge to them. In the fourth session, the participants were invited to prepare their own "Personal Crafting Plan." Table 1 details the content of the workshop.

At the end of the workshop, each participant received a booklet of the teaching material, which was developed according to an intensive literature review [8, 10, 37, 49–51] and the nurses' needs that were identified through interviews.

Furthermore, a list of job crafting activities was distributed. This list was developed by the researchers according to a previous job crafting study [31, 32, 52] and input from interviews. This list contained four sections. The first section included a set of points to increase job resources, such as "Asking for help from your colleague or your leaders if you need it" and "Clean your desk to work more efficiently." The second section included a set of points to increase challenging job demands, such as "Offer to be responsible for making the nursing schedule in a certain month" and "Share your head nurse in writing certain documents e.g., lab-ray or sterilization." The third section includes a set of points to decrease hindering demands, such as "Checking emails only at certain times during the day" and "Encourage patient to perform daily morning care by himself." The fourth section included five potential nursing situations with suggested job crafting activities. Each situation was accompanied by activities that can increase resources, increase challenging demands, and decrease hindering demands. Giving a list of job crafting activities makes it easier for nurses to practice job crafting [32].

After finishing the workshop, the participants were asked to engage in job crafting activities for 3 weeks guided by the job crafting activity list and the plan developed by the researchers. The participants were then asked to target activities related to increasing resources, optimizing job demands, and seeking challenges in weeks 1, 2, and 3, respectively. During this 3-week intervention period, the participants were invited to a WhatsApp group, which was formed to encourage, guide, share experiences, and send reminders twice weekly to engage in the assigned behaviors.

After completing the 3-week intervention program, a reflection session was held. In this session, participants were asked to evaluate their success, obstacles, solutions, and future plans for how they can craft their job. At the end of the session, the researcher expressed appreciation to each group member.

3.6. Control Group.

In the control group, the participants received only the content provided in the first and second sessions. They neither participate in the Michigan Job Crafting Exercise nor prepare the Personal Crafting Plan. Unlike the intervention group, the control group was not required to participate in the 3-week job crafting intervention or the reflection session.

3.7. Measures.

The study measures included scales that measure job crafting behaviors, knowledge about job crafting, harmonious work passion, career commitment, and the demographic information form. The researchers translated the scales, which were initially developed in English, into Arabic using the committee approach to translation [53]. The committee included four members who translated the scales independently and in parallel. These four members included 2 Egyptian nursing academics, 1 nurse who was proficient in English and familiar with the healthcare environments, and 1 English educator who was an Arabic native and fluent in English. All committee members approved the final version of each scale. All these scales were self-reported and completed by both group participants across the three time points.

3.7.1. Primary Outcome

(1) Job Crafting Scale. The Job Crafting Scale [8], which has 13 items, was used to assess the level of nurses' job crafting behaviors. It includes three dimensions: seeking resources (6 items), seeking challenges (3 items), and reducing demands (4 items). A sample item includes "I make sure that my work is mentally less intense." The scale answers range from 1 (never) to 5 (always). Higher scores indicate higher levels of nurses' job crafting behaviors. In its original version, the Cronbach's alpha for scale dimensions is 0.69–0.76. In our study, its reliability across the three time points was acceptable ($\alpha = 0.799$–0.901).

3.7.2. Secondary Outcomes

(1) Job Crafting Knowledge Questionnaire. This questionnaire is a 26-item multiple-choice questionnaire that was used to assess the level of nurses' knowledge of job crafting. It was developed by the researchers according to previous studies [8, 10, 49, 51]. The 26 questions particularly assessed nurses' understanding of the job crafting concept (1 question), the importance of job crafting (1 question), characteristics of job crafting (2 questions), models (8 questions), and JD-R theory and its application strategy (14 questions). The score ranges from 0 to 26, with higher scores indicating greater knowledge.

(2) Harmonious Work Passion Scale. The Harmonious Work Passion Scale, which has 7 items, was created by Vallerand et al. to assess nurses' harmonious passion toward their work [18]. A sample item includes "This work allows me to live memorable experiences." Responses were based on a 7-point Likert scale, with 1 representing "Not agree at all" and 7 representing "Very strongly agree." Higher scores indicate greater harmonious work passion. The Cronbach's alpha in its original version was 0.79. In this study, the reliability across the three time points was acceptable ($\alpha = 0.711$–0.894).

(3) Career Commitment Scale. The Career Commitment Scale [24], which consists of 8 items, was specifically designed to assess career commitment among nurses. The

TABLE 1: Job crafting training sessions, goals, and activities.

Sessions	Goals	Program activities
First session (theoretical background)	(1) Establish a group (2) Introduce the program (3) Introduce the concepts of job crafting (4) Distinguish between job crafting and the traditional job design (5) Explore the importance of being a job crafter (6) Identify the job crafting characteristics (7) Discuss different job crafting models	(i) Warm-up game and acquaintances (ii) Establishment of a group contract (iii) Clarification of the program's aim, activities, and timeline (iv) Explanation of the concepts of job crafting by the researcher (v) Group discussion about the difference between job crafting and the traditional job design (vi) Description of the importance of being a job crafter (vii) Demonstration of job crafting characteristics (viii) Explanation of the different job crafting models by the researcher (ix) Sharing of real-life examples in practicing each model by the participants
Second session (JD-R model)	(1) Focus on the job demands-Resources (JD-R) model (2) Exchange concrete experiences	(i) Lecture on JD-R model (ii) Provision of examples of job resources, demands, and challenges related to nursing career (iii) Sharing of personal job crafting experiences in terms of maximizing resources, optimizing job demands, and seeking challenges with each other by the participants (iv) Review of the day (v) Provision of homework that aims to identify job resources, demands, and challenges other than those mentioned in the session
Third session (Michigan job crafting exercise)	(1) Complete the Michigan job crafting exercise in terms of the following: (2) Job analysis (3) Personal analysis (4) Job-personal analysis	(i) Sharing homework from the previous session (ii) Brain storming about job resources they have in their workplace (iii) The group listed their job demands (iv) Group discussion about tasks which represent job challenges (v) Participants summarize individually their own strengths, motive, weakness point and obstacles they experience in their work and matched it with the task they performed
Fourth session (personal crafting plan)	(1) Create the personal crafting plan (2) Clarify the next intervention	(i) Participants individually formulating their own job crafting goals and activities they could practice to maximize job resources, adapt new challenges and optimize job demands to carry out in the upcoming three weeks (ii) Discussion about the upcoming application (iii) Concluding all sessions

scale has three negatively worded items that are scored in reverse. A sample item includes "I definitely want a career for myself in nursing." A 5-point Likert scale, ranging from 1 (strongly disagree) to 5 (strongly agree), was used. Cronbach's alpha in its original version was 0.85. In this study, the reliability across the three time points was acceptable ($\alpha = 0.736$–0.753).

3.7.3. Demographic Information Form. This form consists of questions related to age, gender, marital status, education, nursing tenure, and status of receiving job crafting training before.

3.8. Data Collection and Procedure. Data were collected from the beginning of February 2022 to July 2022 in a longitudinal setup with a three-wave measurement (i.e., T0 = the baseline measurement collected 2 weeks before the intervention, T1 = the second measurement collected 2 weeks after the intervention, and T2 = the third measurement collected 3 months after the intervention (Figure 2)). Initially, permission to implement the study was obtained from the hospital administrators. Participants were recruited through announcements in their hospitals. The study purposes and procedures were thoroughly explained to all potential participants. Nurses who met the inclusion criteria and agreed to participate were asked to sign an informed consent form. After completion of the baseline measurement (T0), the nurses were randomly assigned to either the intervention or the control group. Three workshops were held with a maximum of 16 nurses per workshop. These workshops were conducted in the hospital education room.

To ensure consistent and effective implementation, a detailed implementation plan was developed, which outlined the specific activities, resources, and timelines for the intervention. Evidence-based teaching strategies were adhered to during program delivery, which was provided by the first author, who holds a PhD in Nursing Management and has extensive teaching experience. In addition, validated intervention materials, including booklets, brochures, and a list of job crafting activities, were developed and utilized.

To ensure participant retention, the program was scheduled at a convenient time for the study participants. In addition, multiple ways of maintaining contact with participants (i.e., personal phone contact, WhatsApp group, and email) were utilized to remind them to attend sessions and engage in the assigned job crafting behaviors.

3.9. Validity. The intervention program and data collection instruments used in this study were validated by 5 experts working in clinical and academic settings.

3.10. Pilot Study. A pilot study was conducted to assess the clarity, feasibility, validity, and reliability of the study measures, the amount of time taken for data collection, and the quality and clarity of the intervention materials. Ten nurses who were not included in the study sample but met the inclusion and exclusion criteria participated in the pilot study. Results revealed that the study measures and intervention materials were understandable and that no modifications were required.

3.11. Data Analysis. Data were analyzed using the Statistical Package for Social Sciences version 24.0 (IBM Corp, Armonk, NY, USA). Normally distributed data were evaluated using the Shapiro–Wilk test. The participants' characteristics were summarized using descriptive statistics. The homogeneity of the intervention and control groups' baseline characteristics was tested using the independent samples t-tests for the continuous data and the chi-squared (χ^2) test for the categorical data.

The study used intention-to-treat analyses [54] on participants who completed one data point (i.e., T0) at least ($n = 94$). The missing data ($n = 15$) were compensated by the "last observation carried forward" (LOCF) method [55]. Changes in the study outcomes within groups (over time: T0, T1, and T2) and between groups (intervention and control groups) were analyzed by a two-way repeated-measures ANOVA. Pairwise comparisons to further assess the significance between groups were conducted using Bonferroni correction to guard against type I errors.

The effect size for the intervention was calculated using the partial eta-squared (η_p^2) for differences indicated to be statistically significant and interpreted as small (0.01–0.06), medium (0.06–0.14), and large (≥ 0.14) effects [56]. All statistics were two-sided, and the significance level was set at <0.05.

3.11.1. Ethics Consideration. The Research Ethics Committee of the Faculty of Nursing in the Mansoura University, Egypt, approved the study protocol (NO: P.0231). The study conformed to the principles of the Declaration of Helsinki. The participants were explained the study objective and protocol, and only those who provided informed consent were included. Voluntary participation, autonomy, and confidentiality of the information gathered were confirmed.

4. Results

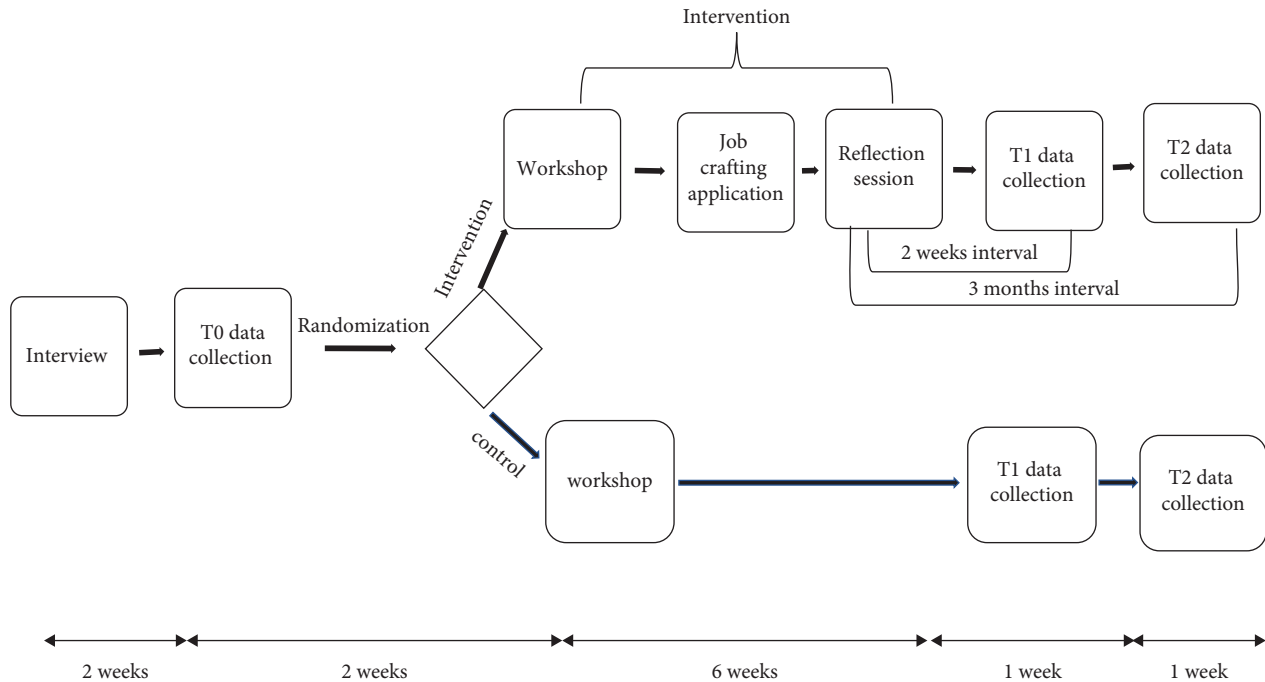
Most of the participants were female in both groups (intervention: 85.1%, control: 78.7%), with a mean age of 32.74 ± 6.18 and 34.29 ± 6.69 years in the intervention and control groups, respectively. Most of the participants in the intervention group were unmarried (55.3%) and held a diploma degree (31.9%), with a mean nursing tenure of 11.47 ± 5.86 years. In the control group, most of the participants were married (59.6%) and held an associate degree (44.7%), with a mean nursing tenure of 12.47 ± 6.93 years. Overall, the baseline characteristics were not significantly different between the two groups ($p > 0.05$), indicating that these characteristics were well balanced between these groups (Table 2).


Figure 2: Graphical representation of the study design.

Table 2: Participant characteristics at baseline in the intervention and the control groups.

Characteristics		Total ($N = 94$) N (%)	Intervention group ($n = 47$) n (%)	Control group ($n = 47$) n (%)	P
Age (years)	Mean ± SD	33.52 ± 6.46	32.74 ± 6.18	34.29 ± 6.69	0.246[a]
Gender	Male	17 (18.1)	7 (14.9)	10 (21.3)	0.593
	Female	77 (81.9)	40 (85.1)	37 (78.7)	
Marital status	Married	49 (52.1)	21 (44.7)	28 (59.6)	0.215
	Unmarried	45 (47.9)	26 (55.3)	19 (40.4)

SD, standard deviation. *Note.* All participants in both groups reported they ever received any training on job crafting before. [a]Analyzed by *t*-test while others by χ-square cross-tab analysis.

4.1. Primary Outcome

4.1.1. Job Crafting Behaviors. As shown in Figure 3 and Table 3, the total scores of job crafting behaviors and their dimensions (seeking resources, seeking challenges, and reducing demands) were not significantly different between the intervention and control groups at baseline ($p > 0.05$).

Regarding the total score of job crafting behaviors, the repeated measures ANOVA showed that the interaction effect of group × time was significant (F (2, 165) = 33.78, $p < 0.001$), with a large effect size ($\eta_p^2 = 0.27$). Furthermore, the pairwise comparison revealed that the intervention

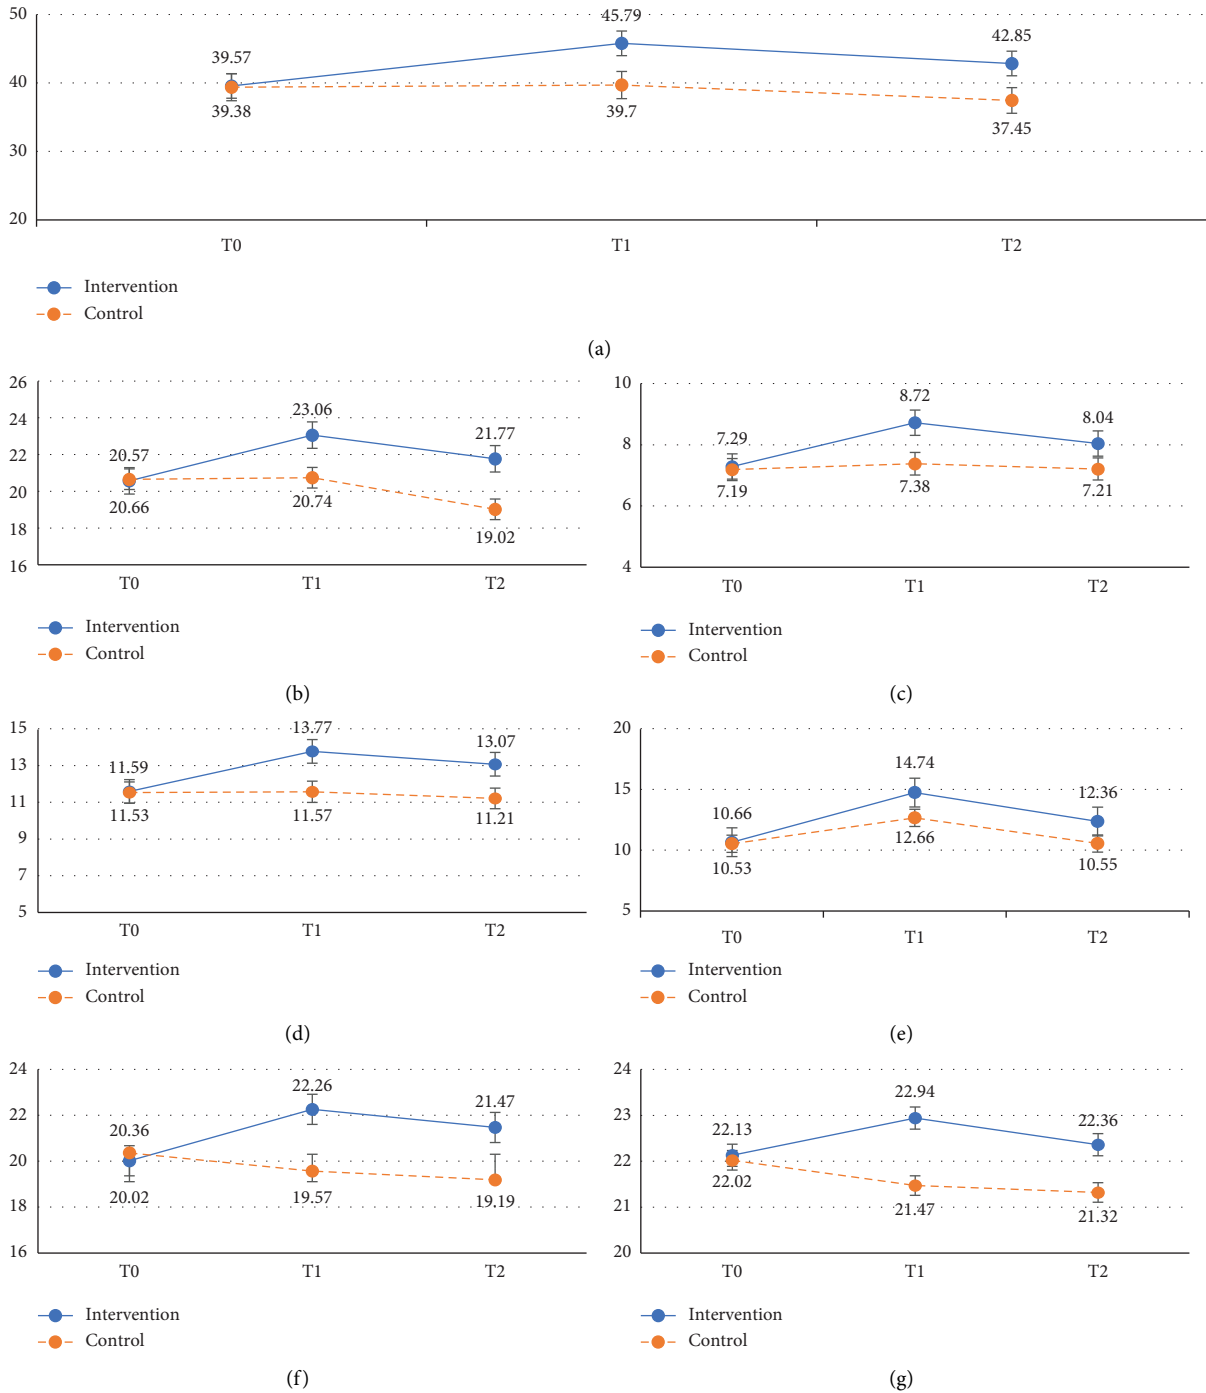
group had shown higher job crafting behaviors than the control group at T1 (M ± SD = 45.79 ± 5.19 vs. 39.70 ± 5.59, $p < 0.001$) and T2 data points (42.85 ± 5.01 vs. 37.39 ± 5.38, $p < 0.001$). In terms of time, the mean of job crafting behaviors of the intervention group was increased by 6.22 in T1 compared with that in T0 data collection; meanwhile, the result was nearly similar in the control group (difference = 0.32). However, the total score of job crafting behaviors declined to −2.94 in T2 compared with that in T1 in the intervention group and to −2.25 in the control group, but in the intervention group, it was still higher than T0 (3.28) (Figure 3, Table 3).


Figure 3: Mean changes of the primary and secondary outcomes. (a) Total job crafting, (b) seeking resources, (c) seeking challenges, (d) reducing demands, (e) job crafting knowledge, (f) harmonious work passion, and (g) career commitment.

Concerning job crafting dimensions, the results showed a significant group × time interaction effect for seeking resources (F (2, 184) = 15.45, $p < 0.001$), seeking challenges (F (2, 184) = 8.91, $p < 0.001$), and reducing demands (F (2, 144) = 14.17, $p < 0.001$). However, the main effect of groups on seeking challenges was not significant (F (1, 92) = 3.58, $p = 0.062$), revealing that after excluding the group effect, the level of seeking challenges was still significant over time. Moreover, the effect size was medium for seeking resources,

seeking challenges, and reducing demand ($\eta_p^2 = 0.14$, 0.09, and 0.13, respectively; Figure 3, Table 3). Thus, H1 was supported.

4.2. Secondary Outcomes

4.2.1. Job Crafting Knowledge. At baseline, job crafting knowledge was not significantly different between the two groups ($p = 0.837$). The results indicated a significant

Table 3: Change in study outcomes by the intervention and control groups overtime.

Outcomes	Time point	Intervention group ($n = 47$) Mean ± SD	Control group ($n = 47$) Mean ± SD	Pairwise comparison (p)	Group F (p)	Time F (p)	Group × time F (p)	η_p^2
Total job crafting behaviors	T0	39.57 ± 5.99	39.38 ± 5.14	0.868	14.67 (<0.001)	38.68 (<0.001)	33.78 (<0.001)	0.27
	T1	45.79 ± 5.19	39.70 ± 5.59	<0.001				
	T2	42.85 ± 5.01	37.45 ± 5.38	<0.001				
Seeking resources	T0	20.57 ± 3.33	20.66 ± 3.24	0.900	6.49 (0.012)	17.65 (<0.001)	15.45 (<0.001)	0.14
	T1	23.06 ± 3.99	20.74 ± 3.41	0.003				
	T2	21.77 ± 3.58	19.02 ± 3.46	<0.001				
Seeking challenges	T0	7.29 ± 2.21	7.19 ± 2.35	0.821	3.58 (0.062)	15.17 (<0.001)	8.91 (<0.001)	0.09
	T1	8.72 ± 1.99	7.38 ± 2.03	0.002				
	T2	8.04 ± 2.06	7.21 ± 1.99	0.051				
Reducing demands	T0	11.59 ± 2.79	11.53 ± 1.86	0.897	10.75 (0.001)	13.38 (<0.001)	14.17 (<0.001)	0.13
	T1	13.77 ± 2.42	11.57 ± 2.47	<0.001				
	T2	13.04 ± 2.44	11.21 ± 1.93	<0.001				
Job crafting knowledge	T0	10.66 ± 2.82	10.53 ± 3.17	0.837	4.07 (0.047)	94.29 (<0.001)	10.29 (<0.001)	0.10
	T1	14.74 ± 3.82	12.66 ± 3.96	0.011				
	T2	12.36 ± 3.29	10.55 ± 3.65	0.013				
Harmonious work passion	T0	20.02 ± 4.41	20.36 ± 3.00	0.663	4.87 (0.030)	3.28 (0.047)	14.95 (<0.001)	0.14
	T1	22.26 ± 4.68	19.57 ± 3.31	0.002				
	T2	21.47 ± 4.12	19.19 ± 2.68	0.002				
Career commitment	T0	22.13 ± 4.17	22.02 ± 3.37	0.892	1.76 (0.188)	0.80 (0.450)	2.89 (0.058)	—
	T1	22.94 ± 3.57	21.47 ± 3.62	0.051				
	T2	22.36 ± 3.37	21.32 ± 3.28	0.132				

SD, standard deviation; T0, baseline; T1, immediate postintervention; T2, 3-month follow-up.

interaction between the group and time factors (F (2, 167) = 10.29, $p < 0.001$), with a medium effect size ($\eta_p^2 = 0.10$). Both groups showed increased knowledge in the T1 data point compared with that in the T0 data point, but the intervention group gained more knowledge than the control group by a mean difference of 2.08 ($p = 0.011$). In the T2 data point, the knowledge of both groups decreased compared with that in the T1 data point, and it was similar to T0 in the control group, but in the intervention group, it was still higher than T0 by 1.7.

4.2.2. Harmonious Work Passion. At baseline, harmonious work passion showed no significant differences between the two groups ($p = 0.663$). The interaction effect of group × time was significant (F (2, 160) = 14.95, $p < 0.001$, $\eta_p^2 = 0.14$). The intervention group gained higher harmonious work passion than the control group at T1 (22.26 ± 4.68 vs. 19.57 ± 3.31, $p = 0.002$) and T2 data points (21.47 ± 4.12 vs. 19.19 ± 2.68, $p < 0.002$). In time comparison, the mean of harmonious work passion in the intervention group improved by 2.24 from baseline to T1 and by 1.45 from baseline to T2. Likewise, the harmonious work passion scores in the control group slightly declined over time (T0: 20.36 ± 3.00, T1: 19.57 ± 3.31, and T2: 19.19 ± 2.68; Figure 3, Table 3). Thus, H2 was supported.

4.2.3. Career Commitment. As shown in Figure 3 and Table 3, career commitment was not significantly different between the two groups at baseline ($p = 0.892$). The interaction effect of group × time was also not significant (F (2, 184) = 2.89, $p = 0.058$). Likewise, the main effects of group (F (1, 92) = 1.76, $p = 0.188$) and time (F (2, 184) = 0.803, $p = 0.450$) showed no significance. Consequently, H3 was rejected.

5. Discussion

Given that nurses constantly face high demands and few resources, which have negative outcomes on them [23], they must be trained on strategies that help them deal with such challenges, and the effectiveness of these strategies should be evaluated. Therefore, this study aimed at evaluating the effects of implementing a job crafting intervention program for nurses on their job crafting behaviors, harmonious work passion, and career commitment.

Results showed that nurses who underwent the program (the intervention group) reported significantly higher levels of job crafting behaviors than those who did not (the control group) immediately and 3 months after the intervention, with a large effect size. This finding is valuable because it indicates that job crafting is a trainable behavior. These results are in line with earlier studies showing that job crafting behavior could be fostered through intervention [57, 58]. However, these results are contradictory with a quasi-experimental study conducted among Dutch healthcare providers; in this previous study, the job crafting training did not improve job crafting behaviors [59]. The discrepancy in results may be caused by the difference in

work environment. Kuijpers et al. attributed their program's ineffectiveness to contextual factors such as poor leadership and organizational climate [59], whereas the present study was conducted in a universal health insurance hospital that has obtained accreditation and has a culture that reinforces such changes.

For job crafting dimensions, the intervention was effective in increasing seeking resources and decreasing job demands in the intervention group compared with the control group over time. However, for the dimension of seeking challenges, the intervention succeeded in enhancing seeking challenges in the intervention group compared with the control group immediately after the program, but during follow-up, the intervention group failed to maintain such behaviors. This result suggests that to maintain challenging behaviors among nurses, more reinforcement and ongoing support may be needed. Supporting this notion, Dubbelt et al. stated that seeking challenges is a less motivating behavior in an environment with high demands [36]. These results were partially supported by Gordon et al., who revealed that after offering job crafting training to nurses, the intervention group showed higher levels of seeking resources and decreasing job demands but not for seeking challenges [12].

Furthermore, job crafting knowledge increased in both groups, but the intervention group gained more knowledge than the control group. Despite the fact that nurses' knowledge in the control group was also increased, it was not enough to motivate them to adhere to job crafting activities. This result may be explained by the idea that the intervention activities performed by nurses in the intervention group after the workshop enhanced their intention and ability to practice job crafting. Interestingly, these results could help hospital managers design guidelines and programs to increase nurses' job crafting behaviors, considering that workshops and lectures are not sufficient for increasing such behaviors in nurses and should be accompanied with intervention activities.

Especially the job crafting intervention succeeded in improving nurses' harmonious passion toward their work. As anticipated, the intervention group gained a higher harmonious work passion than the control group over time. This result could be explained by the idea that job crafting behaviors enable nurses to create a more fitting and controllable working environment [60], which enhances nurses' feelings of self-efficacy and gets rid of a sense of powerlessness [61]. These positive outcomes may motivate nurses to invest their time and energy and experience more passion at work. Unfortunately, no study has examined yet the effect of job crafting interventions on harmonious work passion. Nonetheless, these findings are consistent with previous results obtained from an observational study that reported a positive relationship between job crafting and harmonious work passion [62].

Notably, the increased levels of job crafting behaviors, knowledge, and harmonious work passion among nurses in the intervention group began to decrease after 3 months of finishing the intervention. Therefore, nursing managers and hospital administrators should regularly organize job crafting training for nurses.

Contrary to our expectations, the intervention was not effective in enhancing nurses' career commitment. The reason may be that career commitment arises from the accumulation of perceived experiences [63]. Hence, the researchers suggest combining upcoming job crafting interventions with other activities, such as mindfulness, guided imagination, relaxation, and stress management activities. Another reason is the idea that the effect of the job crafting intervention on outcomes that go beyond one's job (i.e., career) is a sleeper effect, which needs more time to manifest. Thus, the intervention may work first by improving job engagement and satisfaction, and the effect on career commitment could be realized later in time. Despite being the first study to evaluate the effect of a job crafting intervention program on career commitment, the present findings are in line with those of Dubbelt et al., who implemented a job crafting program and reported that the effect of intervention on career satisfaction was not significant [36]. However, these results are contrary to the descriptive study of Chang et al., who showed that job crafting has a direct effect on career commitment [64].

5.1. Limitations. One of the limitations of this study is that the participants of the intervention and control groups were enrolled from the same hospital and potentially from the same units, possibly leading to cross-contamination. The study was conducted in one hospital to ensure that all study participants were subject to the same conditions, including working environment, serving the same patient populations, nursing practices, and workload. This approach aimed to increase the homogeneity of the study sample and reduce the potential for confounding factors that could affect the results of the study.

To avoid cross-contamination risk, the intervention group participants were asked not to share any information related to the intervention with others until study completion. To reinforce this message, regular reminders were sent to the participants via WhatsApp and e-mail. After completing the study, the control group participants were asked whether they had received any information about the job crafting activity during the study, and they confirmed that they had not. Another limitation is that the study lacked a guided website intervention. Nonetheless, a WhatsApp group was used to encourage, guide, and remind nurses; this application may be an alternative to the website. In addition, the study did not explore the mechanisms through which job crafting intervention works. Such mechanisms should be explored in future studies.

5.2. Implications. The study presents several meaningful practical implications for frontline nurses and nurse managers. The findings of this study provided evidence that nurse managers could promote nurses' job crafting behaviors by implementing tailored job crafting intervention programs. The study also highlighted the favorable outcomes that nurses and their managers can gain from the job crafting intervention. The job crafting intervention can be used as a promising method to help nurses cope with limited job resources and increased job demands and make them more harmoniously passionate about their work; thus, this study urges nursing managers to offer more opportunities for job crafting among nurses.

Moreover, the study findings guide nurse managers in designing job crafting interventions. This study suggests combining theoretical lectures with the intervention activity because workshops and lectures alone are insufficient to improve nurses' job crafting behaviors. In addition, to maximize the potential benefits, the study recommends adding other activities, such as mindfulness and stress management activities, to the job crafting activities. Nurses should also be trained on job crafting regularly.

Furthermore, the study yielded some theoretical implications. The current study contributes to job crafting literature and Job Demands-Resources (JD–R) theory in several ways. It provided evidence that job crafting is a trainable behavior within the nursing context. It also assured that job crafting interventions based on the Job Demands-Resources (JD–R) theory is effective in fostering harmonious work passion for nurses. However, the study results did not observe that the job crafting intervention has any effect on boosting nurses' career commitment. Further intervention studies are needed to confirm these results.

6. Conclusions

This RCT showed that in the context of the Job Demands-Resources (JD–R) theory, the job crafting intervention, which involves workshops and job crafting activities, proved to be effective in enhancing nurses' job crafting behaviors and harmonious work passion but not their career commitment. Further evidence is needed.

Data Availability

The datasets generated during and analyzed during the study are available upon reasonable request from the corresponding author.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Background. Burnout is a common psychological syndrome among nurses, especially in the first few years of working. However, limited studies have evaluated the factors related to burnout among junior nurses. *Aims*. To investigate the levels of psychological flexibility, stress, and burnout among junior nurses and examine the role of demographic and workplace relationship factors, psychological flexibility, and perceived stress on burnout among junior nurses. *Materials and Methods*. A convenience sample of 481 junior nurses was recruited from three tertiary hospitals in China from July 2021 to August 2022. Data were collected, including demographic data, workplace relationships, psychological flexibility (measured by experiential avoidance and cognitive fusion), perceived stress, and burnout. The Independent *t*-test, one-way ANOVA, Wilcoxon–Mann–Whitney test, Kruskal–Wallis test, Spearman correlation, and hierarchical regression were used to analyze the data. *Results*. Junior nurses had a high level of burnout in different dimensions. Nurses with an undergraduate education, nurses working in the first year, and a lack of support from supervisors and poor colleague (nurse-nurse and nurse-doctor) relationships had the lowest level of psychological flexibility and the highest level of perceived stress and burnout. Spearman correlation indicated that experiential avoidance, cognitive fusion, perceived stress, and burnout were positively associated with each other. The regression model showed that psychological flexibility (especially cognitive fusion) and perceived stress influenced burnout in junior nurses. *Conclusions*. Higher psychological flexibility and lower perceived stress appear to improve burnout in junior nurses. Therefore, interventions targeting these two factors may provide a viable direction for the reduction of burnout among junior nurses. *Implications for Nursing Management*. Hospital authorities should create a harmonious working environment and provide some psychology training programs for junior nurses.

1. Introduction

Burnout, as an occupational hazard, has received considerable research attention in nursing over the past few years [1]. While there is no complete consensus on how to define burnout, the classic structure remains to be Maslach et al.'s description of burnout as a three-dimensional model characterized by emotional exhaustion, depersonalization, and decreased personal achievement [2]. In primary care nursing, a meta-analysis showed a prevalence of 28%, 15%, and 31% for high emotional exhaustion, high depersonalization, and low personal achievement [3]. The high prevalence of burnout among nursing professionals is unquestionable across different countries [4–7]. Lots of evidence have shown that burnout is often accompanied by anxiety, depression, and other negative emotions [8]. High

levels of burnout reduce the quality of care and patient satisfaction, increase the rate of medical errors, and affect clinical nursing outcomes [1, 5, 9]. Meanwhile, it prompts more nurses to abandon the medical field, which may further exacerbate the current global shortage of nurses [10].

Junior nurses make up a large percentage of nurses and are important human resource reserves. However, studies show that young and inexperienced nurses are more likely to suffer from burnout [11], and most nurses leave in the early stage of their careers [12]. Junior nurses in China usually refer to nurses who have worked in clinical settings for less than three years after graduating from nursing school or university [13]. Junior nurses need to undergo standardized training to complete the transition to qualified nurses. The standardized training process includes rotation among different departments, such as internal medicine, surgery, obstetrics and gynecology, pediatrics, and emergency and intensive care unit, as well as regular and irregular theoretical and operational examinations [14]. The transition is difficult owing to unfamiliar working environments, different professional skills, and interpersonal relationship adaptation, which are significant physical and psychological challenges for junior nurses [15]. Over time, these challenges unconsciously become catalysts for their burnout and even resignation [16].

Burnout is a complex multifactorial problem that is not easily addressed, even among nurses. Individual-specific factors (such as demographic variables, stress, psychological flexibility, personality, and coping strategies) and existing workplace factors (like job demands, job control, and organizational support) have been found to have varying degrees of relationships with burnout levels in numerous studies [17–21].

The relationship between stress and burnout is obvious, both from a psychological and biological perspective [22, 23]. Generally, burnout is believed to be an extreme reaction when individuals cannot smoothly cope with work stress, and it is a state of exhausted emotions, attitudes, and behaviors caused by individuals under long-term work pressure [24]. The effects of chronic stress on the functioning of biological processes in an organism can affect psychological processes and social behavior. Thus, according to clinical psychologists, burnout is not necessarily related to work but to stress [25]. Results from a cross-sectional study of 799 nurses showed that stress indirectly affected burnout through perceived social support and psychological capital [26]. In addition, a cross-sectional survey of new graduate nurses revealed that 76% of participants reported moderate-to-severe stress [27]. While some stress can be helpful, overwhelming stress can lead to poor performance at work and serious illnesses such as high blood pressure, depression, and sleep disorders [28].

Psychological flexibility was defined as "the ability to more fully engage with the present moment as a conscious person and to change or persist in behavior in the service of a valued goal" [28]. Psychological inflexibility is the opposite of that and mainly includes two important aspects: experiential avoidance and cognitive fusion [29]. In short, experiential avoidance is the tendency for individuals to avoid or escape from some unpleasant internal mood, which could lead to psychological distress and ineffective behaviors. A higher degree of experiential avoidance is associated with more emotional distress and lower life function, thus reducing work performance [30]. Cognitive fusion refers to the domination of thinking in behavioral regulation over other available processes [31]. Cognitive fusion can enhance an individual's believability of negative thoughts, leading to emotional discomfort [32]. Studies have shown that the lower the psychological flexibility was, the more the clinical nurses were tired of their job [20]. Meanwhile, the literature indicated a direct and predictive relationship between psychological inflexibility and burnout among nurses in the acute phase of the epidemic [33].

Besides, organizational factors have consistently been implicated among the complex determinants of burnout. In a recent report, burnout was considered as a result of an imbalance between job demands and resources [34]. The resources of clinicians include tangible and intangible resources in the work environment, such as meaning in work, job control, and social support from peers and supervisors. Multiple studies have shown that, in addition to increasing the number of nurses, changing the characteristics of the work environment, including training support, positive physician-nurse relationships, nurse autonomy, and support from supervisors, can also increase job satisfaction and reduce burnout in nurses [35–37].

The retention and successful transition of junior nurses is one of the guarantees for the future stable development of health care [38], while burnout is a stumbling block. It is urgent to find ways to retain them, but there are few studies on burnout among junior nurses. Therefore, we aimed to investigate the levels of psychological flexibility, stress, and burnout among junior nurses in different sociodemographic and workplace relationships. Furthermore, we sought to explore the influence of these individual and organizational factors on burnout among junior nurses.

2. Materials and Methods

2.1. Setting, Sample, and Data Collection. A cross-sectional design was used in this study. Participants were nurses recruited online from three tertiary hospitals in China from July 2021 to August 2022. The inclusion criteria for all participants were as follows: (1) aged 18 years or older; (2) with at most three years of work experience; and (3) provided informed consent. The exclusion criteria included nurses with psychological disease or who were taking a long leave of absence (e.g., maternity leave).

The sample size was calculated using G*Power 3.1.9.7. In the multiple linear regression, a fixed model and R^2 deviation from zero were selected as the statistical method. The statistical significance level was set at $\alpha = 0.05$, with an effect size of 0.1 and a statistical power $(1 - \beta)$ of 0.95, considering a total of 12 predictors. Theoretically, a minimum sample size of 270 was calculated.

With the assistance of the department of nursing, the call to participate was sent to 526 targeted nurses by link via the WeChat platform. The nurses decided whether to participate after reading the purpose and content of the study and had the right to withdraw at any time. Researchers checked the

platform daily and stopped data collection once it reached the target. Finally, we collected 481 valid questionnaires (response rate: 91.4%) through the Wenjuanxing platform (https://www.wjx.cn/). All questions were set as mandatory, so there were no missing data.

2.2. Measures

2.2.1. Demographic and Workplace Factors.
Demographic data were collected, including age, gender, education level, salary, and working experience. Workplace relationships included the relationship between nurses, the relationship between nurses and doctors, and the support received from supervisors.

2.2.2. Psychological Flexibility

(1) Experiential Avoidance. The Acceptance and Action Questionnaire II (AAQ-II), a 7-item instrument, was used to assess the level of experiential avoidance [30]. The AAQ-II is a 7-point Likert scale from 1 (never) to 7 (always). A higher score indicates a higher level of experiential avoidance. The minimum and maximum total score of the scale is 7 and 49, respectively. Cronbach's α coefficient of the Chinese version of AAQ-II was 0.88 [39]. Cronbach's α of the scale was 0.95 in this study.

(2) Cognitive Fusion. The Cognitive Fusion Questionnaire-Fusion (CFQ-F), a 9-item instrument assessing personal cognitive fusion, was developed by Gillanders et al. [40]. Items are rated on a 7-point Likert scale from 1 (never) to 7 (always). The possible score can range from 9 to 63, with higher scores denoting more serious cognitive fusion. Cronbach's α coefficient of the Chinese version of CFQ-F was 0.92 [41]. Cronbach's α of the scale was 0.96 in this study.

2.2.3. Perceived Stress.
The level of perceived stress was assessed with the Chinese Perceived Stress Scale (CPSS) [42], which was revised from the Perceived Stress Scale (PSS) [43]. The CPSS consists of a total of 14 items, with each item rated on a 5-point Likert scale from 0 (never) to 4 (very often). The total score of the CPSS scale ranges from 0 to 56, and a higher score indicates a greater level of perceived stress. Cronbach's α coefficient of the CPSS was 0.84 [26]. In this study, Cronbach's α of the scale was 0.70.

2.2.4. Burnout.
Burnout was measured using the Chinese version of the Maslach Burnout Inventory: Human Services Survey for Medical Personnel (MBI-HSS-MP) [44, 45]. It consists of a total of 22 items across three dimensions of emotional exhaustion, depersonalization, and personal accomplishment. Each item is scored on a 7-point Likert scale from 0 (never) to 6 (every day). Scores of 19–26 or ≥27 on emotional exhaustion, 6–9 or ≥10 on depersonalization, and 34–39 or ≤33 on personal accomplishment were indicative of moderate or high burnout for the respective dimensions. For the sake of consistency of interpretation, the items of personal accomplishment were reverse-scored and renamed as low personal accomplishment when calculating the total score. The total score of the MBI ranges from 0 to 132, and a higher score denotes more severe job burnout. Cronbach's α coefficient for the Chinese version of MBI was 0.62 [45]. Cronbach's α of the scale was 0.80 in this study.

2.3. Data Analysis.
Data analysis was performed using IBM SPSS Statistics, version 25 (IBM Corp., Armonk, NY, USA). Firstly, descriptive data were generated for participants' overall characteristics. Then, based on the normality test, we used the independent t-test or one-way analysis of variance (ANOVA) to compare levels of perceived stress and burnout, and the Wilcoxon–Mann–Whitney test or Kruskal–Wallis test was used to compare levels of experiential avoidance and cognitive fusion between nurses with different demographic and workplace relationship characteristics. The relationship between these psychological measurements was examined using the Spearman correlation. Finally, hierarchical regression analysis was used to construct models to assess the individual strength of different variables affecting burnout and how much the models explained burnout.

2.4. Ethical Considerations.
Ethical approval for this study was obtained from the Clinical Research Ethics Committee of Peking University First Hospital (approval no. 2021-415). Informed consent was obtained voluntarily from all participants, and all the data were recorded and analyzed anonymously.

3. Results

3.1. Descriptive Statistics.
Table 1 shows the descriptive statistics for participants' demographic, workplace, and psychological characteristics. Of the 481 nurses who completed the questionnaire, most were female (86.7%), with a mean age of 24.2 years. Approximately half of the participants held undergraduate education, while only 10.2% had postgraduate degrees. In total, 42% of the participants had only one year of work experience, and nearly 90% had a monthly salary of less than ¥5000. When asked about social relationships and support in the workplace, the vast majority of respondents reported being satisfied with coworker relationships and supervisor support, while about one-quarter of the respondents reported poor relationships between doctors and nurses. The participants' overall scores of experiential avoidance, cognitive fusion, perceived stress, and burnout are shown in Table 1. The scores for each of the three dimensions of burnout suggested high levels of emotional exhaustion (mean = 33.48, SD = 6.53) and depersonalization (mean = 16.07, SD = 5.23) and low level of personal achievement (mean = 20.75, SD = 4.51), indicating high burnout.

Table 1: Demographic, workplace, and psychological measurement characteristics of the participants ($N = 481$).

Variable	N	%
Gender		
Female	420	87.3
Male	61	12.7
Education		
Postgraduate	49	10.2
Undergraduate	248	51.6
Junior college	184	38.3
Salary (yuan/m)		
≤5000	281	58.4
5001~10000	156	32.4
≥10000	44	9.1
Work experience		
1 year	204	42.4
2 years	164	34.1
3 years	113	23.5
The relationship between nurses		
Good	462	96.0
Poor	19	4.0
The relationship between doctors and nurses		
Good	370	76.9
Poor	111	23.1
Supervisor support		
Good	442	91.9
Poor	39	8.1
	M	SD
Age (years)	24.21	1.88
Experiential avoidance	31.70	9.61
Cognitive fusion	43.19	12.19
Perceived stress	25.50	6.44
Burnout	76.80	11.56

M = mean; SD = standard deviation.

3.2. Comparisons of Junior Nurses' Psychological Flexibility, Perceived Stress, and Burnout between Groups. Significant differences in the score of several scales were found according to participants' demographic characteristics and workplace factors (Table 2). The preliminary analysis showed that female nurses had significantly higher levels of experiential avoidance. Nurses with a junior college education had significantly lower levels of experiential avoidance, cognitive fusion, and burnout than those with undergraduate education. There was little difference between undergraduate and postgraduate nurses, although undergraduate nurses scored slightly higher on perceived stress and burnout than the other two groups. Additionally, there was a decreasing trend in the scores of all four scales with longer work years in new nurses. Perceived stress decreased significantly across all years of work experience, while the improvement in the other three aspects did not reach statistical differences until the third year. Moreover, self-reported data showed that poor relationships and support from colleagues or supervisors were accompanied by significant psychological inflexibility, stress, and burnout.

3.3. Correlations between Psychological Flexibility, Perceived Stress, and Burnout. The results of the correlational analysis between four psychological measurements are presented in Table 3. Overall, experiential avoidance, cognitive fusion, perceived stress, and burnout were positively associated with each other. For each dimension of burnout, the largest correlations observed were between depersonalization and other measures. The correlation between accomplishment and cognitive fusion was relatively weak, while that between accomplishment and experiential avoidance failed to reach statistical significance.

3.4. The Roles of Demographics and Workplace Relationship Factors, Psychological Flexibility, and Perceived Stress in Burnout among Junior Nurses. Table 4 displays the results of the hierarchical regression analysis. As can be seen from the table, demographics and workplace relationship factors were entered in the first step, psychological flexibility in the second, and perceived stress in the third. Working experience, the relationship between nurses, the relationship between doctors and nurses, and supervisor support were significantly associated with burnout in the first step, while none of these remained statistically significant after psychological flexibility was added to the model. By comparing models 2 and 3, it can be seen that the standardized beta coefficients of experiential avoidance reduced to no statistical significance when considering perceived stress. Moreover, the adjusted R^2 of each regression indicated that the three sequential models explained 9.9%, 35.2%, and 43.9% of the variance in burnout, respectively.

4. Discussion

Although burnout has been noted in nurses for years, few studies have focused specifically on junior nurses. Our study examined the role of demographic and workplace relationships, psychological flexibility, and perceived stress on burnout and reported levels of these psychological indicators among junior nurses.

Our findings indicated a high level of burnout in different dimensions in our sample, which confirms that young nurses are at high risk of burnout. The COVID-19 pandemic had significant impacts on nurses' mental health [27, 46, 47]. China was at a lull between outbreaks during data collection for this study, and there were only a few COVID-19 cases in the sample hospitals. However, the workload associated with the "dynamic zero-COVID policy" and demands put on hospital staff (e.g., frequent nucleic acid testing, strict epidemic prevention and control measures, and restricted mobility) may have increased burnout. Xie et al.'s cross-sectional study of newly graduated nurses from 13 provinces in China before the pandemic focused on nurses with less than three years of experience and reported less severe burnout than our findings [48]. Province, hospital levels, and epidemic status may primarily explain the differences. Moreover, our study demonstrated that several demographic and workplace relationships are associated with these variables. We found that nurses with a junior college education had the lowest level of psychological inflexibility, perceived stress, and burnout, while nurses with an undergraduate education had the worst scores among the three educational

TABLE 2: Differences in nurses' experiential avoidance, cognitive fusion, perceived stress, and burnout by demographic characteristics and workplace relationship factors ($N = 481$).

groups. This is partially inconsistent with previous studies, which showed that nurses with higher levels of education had lower levels of burnout [49, 50]. The reasons for the difference are unclear, given that education is confounded by other variables such as responsibilities, resources, and personal attributes [34]. For our findings, it is possible that junior college nurses have fewer responsibilities and encroachment on personal time. In addition, postgraduate nurses may have boosted their strategies to deal with adversity during education and may get more support and resource at work, while undergraduate nurses are more likely to experience a mismatch in job demands and resources, leading to stress and burnout. Future qualitative studies are needed to delineate the reasons behind this finding.

We also found that junior nurses with longer years of tenure had higher psychological flexibility and lower levels of stress and burnout, similar to the findings of earlier studies [21]. This finding can be explained by capacity and maturity gained from work or life experience, although it may also be due to survival bias. Longitudinal studies are needed to eliminate the bias caused by resignation and support the idea that experience can improve psychological flexibility in the absence of additional psychoeducation. Interestingly, perceived stress declined significantly across each additional year of work experience, while the improvement in burnout was not so rapid. The finding suggests that the accumulation of work experience can reduce stress caused by a lack of professional knowledge and skills, while the contributors of burnout may be more complex and require additional attention.

In the univariate analysis as well as the first model of hierarchical regression, our results showed a significant association between workplace relationships and nurse burnout. However, these effects were no longer statistically significant when psychological flexibility was entered into the model. This appears to be contrary to other studies and reports of burnout among health workers [34, 51]. One likely reason is that we used subjective questions rather than objective scales when assessing workplace relationships; thus, the responses obtained highly depend on subjective perceptions. In addition, some aspects of psychological flexibility, such as cognitive integration, may distort or reinforce the individual's perception of external evaluations to some extent. The relationship between workplace relationships and psychological flexibility in Table 2 supports this inference. Social support from coworkers and supervisors has been reported to reduce stress reactions and promote personal meaningfulness at work [52, 53]. The perception of relationships and support at work could increase nurses' confidence and alleviate adverse emotions by changing the process of cognitive appraisal [54]. The individual's psychological flexibility may have a similar effect in the process.

Our finding of a negative association between psychological flexibility and burnout corroborates with many other studies among nurses and nursing students [21, 33, 55, 56]. In addition, consistent with the concept of burnout as an outcome of chronic stress [57], the effect of perceived stress was reflected in the final model. Notably, psychological flexibility had an independent effect on burnout, suggesting that some aspects of psychological flexibility can directly affect burnout instead of indirectly through stress reduction. An imbalance between job demands and resources is considered to be the reason leading to stress and burnout [58, 59]. Psychological flexibility, as an intangible personal resource, helps individuals adhere to value-based actions in the presence of uncomfortable feelings [60]. The positive feedback that comes with effective work will guarantee that individuals are engaged in their work, realize their value in the workplace, and ultimately reduce burnout [61].

A strength of this study is that it was a multicenter study that focused exclusively on junior nurses. In addition, we considered both organizational and individual factors. However, the study has some limitations. Due to the cross-sectional design of the study, it is impossible to determine the causality between the variables. Furthermore, workplace relationships were evaluated using self-designed questions, which may reduce the objectivity of these factors. Nevertheless, this, in turn, suggests that stress and burnout resulting from perceived workplace relationships may be modifiable through specific processes of psychological flexibility.

Future researchers should carry out longitudinal and qualitative studies to clarify the different processes of burnout and how psychological flexibility regulates these processes. Path analysis would help assess the causal relationship and potential moderators. In addition, future studies should explore the possibility of providing extensive training for junior nurses to improve their psychological flexibility, such as mindfulness and acceptance commitment therapy.

4.1. Implications for Nursing Management. Junior nurses' job burnout will affect their professional identity, professional ability, and career development. In order to prevent early turnover and job change, it is necessary for hospital authorities to help junior nurses improve their burnout levels. We recommend that nurse managers prioritize improving organizational culture and enhancing the mental health of their employees, which may include creating a fair, non-blaming, supportive working environment; sharing tips for junior nurses to quickly acquire skills and deal with relationships in a new department; and providing some psychology training focused on psychological flexibility, stress, and burnout, such as mindfulness and acceptance and commitment therapy.

5. Conclusions

The results of this study corroborate that new nurses are at a high risk of burnout. Workplace relationships, psychological flexibility, and perceived stress impact burnout, while the latter two may be more fundamental.

Aim. The aim of this article is to report the process and outcomes of codesigning a nursing leadership program for fundamental care. The leadership program is designed to empower nursing leaders, across research, education, clinical practice, and policy, to challenge and change how fundamental care is valued, prioritised, and actioned within health and care systems. *Background*. Deficits in fundamental care represent an intractable problem adversely impacting care recipients, care providers, and health and care systems globally. These deficits stem from the minimal value placed on fundamental care and its subsequent invisibility across research, education, clinical practice, and policy. Sustainable systems change requires effective nursing leadership; however, existing nursing leadership programs tend to address only one area of health and care systems, typically clinical practice, and do not focus specifically on fundamental care. *Methods*. The Fundamentals of Care Leadership Program was codesigned with current and emerging nursing leaders using a participatory action research approach. The collaborative codesign process involved two stages: (1) idea generation and preliminary program development via Nominal Group Technique ($n = 60$ participants from 11 countries) and (2) refinement and trialling of program content and process via a three-day workshop ($n = 19$ participants from 9 countries). *Results*. Participants prioritised a program that provided clear understanding of the concept of fundamental care, enabled the development of influencing and negotiating skills to advocate for this care, and offered resources on knowledge translation, implementation, and measurement strategies. Participants also wanted allotted time to design research and quality improvement projects that would allow them to transfer the skills learned to the real-world issues occurring within their respective organisations. *Conclusions*. The codesign process, embedded within a participatory action approach, enabled the development of a Fundamentals of Care Leadership Program that is shaped by, and meets the needs of, current and emerging nursing leaders. The leadership program will enable nursing leaders to challenge value systems on fundamental care and to champion this care across research, education, clinical practice, and policy, working towards enhanced fundamental care outcomes and experiences.

1. Introduction

1.1. Background. Fundamental care is often considered the foundation of nursing practice [1], underpinning seminal nursing theories as well as frameworks and guidelines for care delivery [2–4]. Fundamental care is defined as nurse actions that respect and focus on a person's essential needs to ensure their physical and psychosocial wellbeing [5]. These needs are met through a trusting, therapeutic relationship between care providers and care recipients, whilst taking into consideration the context in which care is taking place [5]. Despite the centrality of fundamental care to nursing practice and care outcomes, internationally, care recipients report negative experiences of this care, including missed, infrequent, or poor-quality mouth care, toileting, bathing, mobility, information provision, education, and psychosocial support [6–11]. In turn, care recipients experience numerous adverse outcomes when fundamental care is poorly delivered, including pressure injuries, falls, new infections, readmissions, and death [8, 12–17].

There are several complex reasons for the global deficits in fundamental care. They include the predominance of biomedical approaches to care, the prioritisation of productivity and efficiency within health and care systems, and workforce issues (e.g., high workloads and inadequate nurse-to-patient ratios) [18–22]. As a result of these

pressures, fundamental care, particularly psychosocial and relational aspects, is afforded minimal priority, rendering it invisible and devalued across health and care systems [19]. For a decade, there have been calls to address the invisibility of fundamental care by empowering nursing leaders to champion change and affect a cultural shift in the way in which this care is valued and enacted at micro, meso, and macrolevels of health and care systems [23–26]. Commensurate with these calls is a growing body of research on leadership for fundamental care, albeit focused primarily on how this leadership relates to the delivery of fundamental care within clinical practice [26]. This research has shown that care recipients, nurses, and nurse managers all view appropriate and effective nursing leadership as central for facilitating high-quality fundamental care delivery [27, 28].

The importance of nursing leadership is not a new concept; more than 20 years ago, researchers argued that effective leadership was critical for positively influencing nursing practice and policy [29, 30]. In turn, there are numerous leadership programs designed to enhance nurses' leadership capabilities and to influence change [31, 32]. More recently, there is a growing body of work on how different leadership styles, particularly relational styles such as transformational leadership, can positively influence nursing practice, care-recipient outcomes, and nurses' job satisfaction [33–35]. Nursing leadership was emphasised once again during the global COVID-19 pandemic, with a focus on how effective leadership during times of crises can maintain quality standards and nurses' emotional and mental well-being, in both academic and clinical practice settings [36–38].

Despite these advances, knowledge and action around leadership specifically for fundamental care are lacking. Fundamental care remains a relatively under-researched area of nursing leadership [39], and there is limited guidance to support nursing leaders across all areas and at all levels of health and care systems to champion change in the way in which this care is valued, prioritised, and actioned [26]. Furthermore, the sustained deficits in fundamental care globally demonstrate that existing leadership programs, whilst undoubtedly successful in influencing change in some areas [40], are not necessarily supporting leaders to affect systems change in ways that translate to improved fundamental care outcomes and experiences. This is likely for two reasons. First, many existing leadership programs focus on only one aspect of health and care systems, most commonly clinical practice [41, 42], without an accompanying focus on leadership within research, education, or policy. Second, programs typically focus on general leadership capabilities rather than specifically on fundamental care and the individual system and policy level factors that influence its perceived value and subsequent prioritisation within health and care systems.

To achieve sustained system-level impact for fundamental care, leadership programs must influence all facets of healthcare: research, education, clinical practice, and policy. Continuing to operate in siloes will only perpetuate poorly integrated health and care systems, where nursing education does not readily translate to real-life clinical practice;

practising nurses find it difficult to see the relevance of research evidence, and policy initiatives do not reflect the realities of everyday clinical practice [43–45]. In addition to focusing on all areas of health and care systems, leadership programs must focus specifically on fundamental care rather than general leadership capabilities. The nursing education literature demonstrates that when fundamental care is not explicit nor reinforced within nursing curricula, it is rendered invisible and devalued [46, 47]. Implicitly embedding fundamental care within a general leadership program is similarly insufficient. Health and care systems already fail to value the role of fundamental care in enhancing care outcomes and experiences [19]; leadership programs that do not explicitly emphasise fundamental care only reinforce this devaluing. The need for targeted nursing leadership programs is also supported by existing literature, which has argued the importance of designing and implementing tailored programs that address the different facets of nursing leadership [48, 49].

To support nursing leaders in changing deeply entrenched organisational cultures and value systems on fundamental care, they must have the knowledge and skills to advocate for this care in a politically informed way and to foster sustainable change [50]. The International Learning Collaborative (ILC) is supporting nursing leaders to develop the skills required to affect real systems change for fundamental care. The ILC is a member-based international network aiming to transform how fundamental care is delivered, taught, and researched globally. It has been a long-held vision of the ILC to grow a critical mass of leaders globally who are courageous and skilled to champion and lead change. To achieve this vision, the ILC has engaged with current and emerging nursing leaders worldwide to codesign the Fundamentals of Care Leadership Program. The program aims to enhance the capacity of current and emerging nursing leaders within research, education, clinical practice, and policy to advocate for and affect systems change around fundamental care, thus ensuring the delivery of high-quality fundamental care within any health or care environment. This article outlines the collaborative codesign process undertaken to develop the leadership program and considers how this program might be sustained into the future.

2. Methods

2.1. Design. The development of the Fundamentals of Care Leadership Program was underpinned by participatory action research (PAR) [51, 52]. PAR requires active involvement of key stakeholders—those with a vested interest in or potential to benefit from the research findings—in the research process, with the aim of generating societal and system-level change [52, 53]. In the present study, the first step of the PAR process involved several discussions amongst the ILC's governing body (its steering committee) regarding how best to meet the challenge of shifting prevailing organisational cultures and value systems on fundamental care. At the time this study was conducted, the ILC's steering committee comprised of 13 nursing leaders from eight countries, all with relevant leadership expertise across research, education, clinical practice, and/or policy.

Through these discussions, and based on their own leadership experiences, the steering committee identified the need for a leadership program specifically for fundamental care that would equip nursing leaders with the knowledge and skills to effect change at a systems-level and which would meet the needs of a global nursing audience.

Aligning with the PAR principles of collaboration and participation [53], the proposed leadership program was then codesigned with an international cohort of nursing leaders via an iterative, two-stage process (see also Figure 1).

(i) Stage 1: Idea generation and preliminary program development via modified nominal group technique

(ii) Stage 2: Refinement and trialling of program content and process via a three-day workshop

The codesign process drew on the expertise and experience of both current and emerging nursing leaders within and across healthcare research, education, clinical practice, and policy. Current nursing leaders were defined as individuals who successfully influence others to achieve a common goal and who are often employed in managerial or executive positions within their organisations [54]. Emerging nursing leaders were defined as individuals who are developing the skills to influence others but who might not yet occupy designated leadership positions.

2.2. Stage 1: Idea Generation and Preliminary Program Development.

Aligning with the PAR approach, the first stage of the codesign process involved working with current and emerging nursing leaders to identify their priorities and preferences for a leadership program on fundamental care. This was achieved via nominal group technique (NGT) [55]. NGT is a structured consensus-generating approach that aims to develop ideas and solutions to a problem and facilitate agreement on the relative importance of the proposed ideas/solutions [55]. This study used a modified NGT approach [56, 57], involving online interactive workshops to enable idea generation, sharing, and clarification, follwed by an online ranking process to determine which ideas participants prioritised.

2.2.1. Online Interactive Workshops.

The workshops were conducted in June 2021 as part of the ILC's annual conference. The aim of the workshops was to identify the leadership program's goals, parameters, and deliverables.

(1) Setting and Participants. Workshops took place online via Zoom breakout rooms. Sixty participants from 11 countries (Australia, Canada, Denmark, Italy, Japan, New Zealand, Sweden, the Netherlands, Norway, the UK, and the US) took part. Participants self-selected to participate upon registration to the ILC conference.

(2) Data Collection. Four workshops were run simultaneously, each focusing on a different area: research, education, clinical practice, and policy. Participants nominated the workshop they preferred to participate in. Workshops were repeated a further two times, enabling participants to take part in workshops on different topics ($n = 12$ workshops total). Workshops were guided by a template with open-ended prompts (see Table 1). The template was developed by the first author with the expertise of the ILC's steering committee. Each workshop ran for 45 minutes and was managed by a facilitator, with a maximum of 15 participants. Workshops were audio and video recorded.

(3) Data Analysis. Following transcription of workshop recordings, the data were analysed using qualitative content analysis (QCA) [58, 59]. QCA allows for a focus on the frequency of patterns within the data [59], thus aligning with the NGT aim of consensus-generation. Following initial reading and familiarisation of the written transcripts, the data were coded inductively and deductively. The second author coded the data to the workshop questions and identified additional codes that did not align with these questions. Data from the different workshops, research, education, clinical practice, and policy, were considered as one dataset rather than separate as the initial familiarisation showed that there were no substantial differences in the content generated between the different workshops. Codes were refined via discussion with all authors, with the first and second authors then categorising the codes, based on similarity, into themes. The themes were further refined following discussion with all authors, nursing academics at Flinders University, and the ILC's steering committee.

2.2.2. Online Ranking Process.

The ranking process involved all workshop participants being invited to rate their preferences, from a list of options derived from the QCA, in relation to the leadership program content and outcomes.

(1) Setting and Participants. Participants were sent a link to an online Qualtrics survey in February 2022. Of the participants who took part in the workshops ($n = 60$), forty responded to the survey (response rate = 67%).

(2) Data Collection. The online survey consisted of four sections:

(1) Program content

(2) Program activities

(3) Program outcomes/outputs

(4) Draft program

Sections 1–3 each had predetermined responses, derived from the analysis of the workshop data. Participants were asked to rate their top five responses in order of preference, with 1 being the most preferred. The ranking of five priority ideas is common in NGT [55]. Section 4 provided a draft of the proposed leadership program, developed based on the ideas generated in the workshops. Participants were asked to provide feedback on this draft via a series of open-ended questions. The draft program comprised four parts:

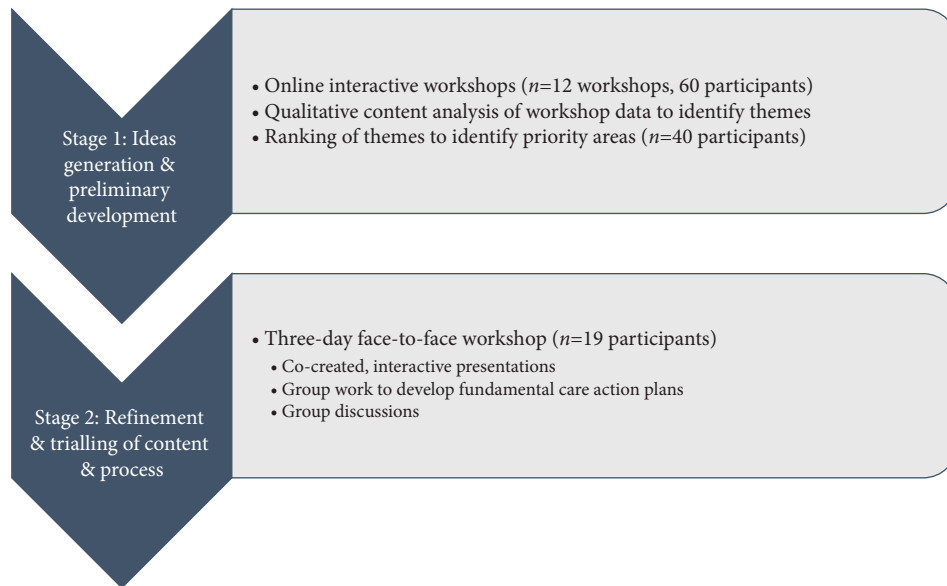
(i) Part 1: An overview of the Fundamentals of Care Framework [25]. The Fundamentals of Care Framework is a conceptual framework,


Figure 1: Fundamentals of care leadership program codesign development process.

Table 1: Workshop template.

Role of facilitators
Your role is to elicit the required information from workshop participants. Use the below prompts to encourage group discussion. If you are facilitating multiple groups on the same topic, feel free to summarise the results from the previous group and encourage participants to add their thoughts

Prompts
(1) What should the leadership program deliver in terms of attitudes, behaviours, skills, and competencies for nursing leaders?
(2) How would we know that a leadership program for nursing leaders had achieved its objectives? What could we observe or measure to determine this?
(3) Which nursing leaders should the leadership program be aimed at?
(4) What would be the unique selling point of a leadership program focused on fundamental care for nursing leaders?
(5) How can nursing leaders identify and tap into opportunities for enhancing and leading fundamental care research/education/ clinical practice/policy?
(6) What else do nursing leaders need to know to lead change around fundamental care research/education/clinical practice/ policy?

developed by the ILC, that outlines what high-quality fundamental care should look like in clinical practice. The Fundamentals of Care Framework outlines three core dimensions for high-quality fundamental care delivery: (1) developing trusting relationships with care recipients and carers; (2) integrating and addressing care recipients' physical, psychosocial, and relational needs; and (3) being aware of how the care context can influence care delivery (see Figure 2).

(ii) Part 2: Group discussion of self- and context-assessments, completed by participants in their own time prior to the Stage 1 workshops. These assessments determined participants' readiness for leading transformation as well as their organisations' readiness for change.

(iii) Part 3: Working with a mentor to develop a fundamental care action plan around an identified area of need and presenting the plan to all participants for feedback.

(iv) Part 4: A one-day debrief 12 months after program completion, enabling participants to provide an update on their action plans and share their experiences with the next cohort.

(3) Data Analysis. The top five responses for Sections 1–3 were collated. The open-ended responses in Section 4 were analysed via QCA.

2.2.3. Ethical Considerations. Ethical approval was received from Flinders University Human Research Ethics Committee (approval number: HEL1858). Participants were informed upon registration that the workshops would be video and audio recorded and that their participation in the workshop implied their consent for the recordings to be used in the research. The ranking survey was anonymous.

2.3. Stage 2: Refining and Trialling of Program Content and Process. The last stage of the codesign process used the ideas prioritised by the participants in Stage 1 to refine and trial the content, structure, and process of the leadership program. The result would be a structured leadership program for piloting in 2023. Stage 2 consisted
FIGURE 2: The Fundamentals of Care Framework. Image was obtained, with permission, from https://ilccare.org/the-framework/ and the content within the image was derived from [5].

of a three-day, face-to-face, codesign workshop led by the third and fourth authors.

2.3.1. Setting and Participants. The workshop took place in June 2022 at Saïd Business School, Oxford University, UK. Current and emerging nursing leaders were identified from the ILC's steering committee, organisational members, and international networks and were invited to take part. Participants were selected to ensure a breadth of experience and geographical representation. Nineteen participants from nine countries (Australia, Canada, Denmark, Iceland, New Zealand, Norway, Sweden, the UK, and the US) took part.

2.3.2. Data Collection. The workshop consisted of interactive presentations followed by the development of fundamental care action plans. These were interspersed with group discussion where participants provided real-time feedback on and subsequently refined the proposed program content.

(1) Cocreated Interactive Presentations. Prior to the workshop, participants were allocated to one of three groups and tasked with cocreating a presentation on a specified topic that could form a part of the 2023 pilot. The topics, derived from the prioritisation process in Stage 1, were as follows.

(i) Overview of fundamental care and the Fundamentals of Care Framework

(ii) Influencing change in fundamental care now and into the future

(iii) Knowledge translation and implementation strategies

Groups delivered their presentations to the wider group for refinement. This refinement took place during the presentations themselves, with participants offering suggestions for improvement.

(2) Fundamental Care Action Plans. Participants self-selected into groups to develop a fundamental care action plan, a tailored approach to addressing value systems and leading change at multiple levels within their respective organisations. The aim of including action plan development in the codesign process was to test how this development might work practically within the leadership program. Each group had a fellow participant who acted as a mentor to assist in plan development. Mentors were self-nominated or identified by groups based on relevant expertise. The groups were tasked with delivering a 10-minute presentation on their action plan to the wider group and reviewing the plan based on group feedback.

(3) Group Discussions. Time was allotted across the three days for group discussion on the evolving leadership

program content, including participants' recommendations for the 2023 pilot. The third and fourth authors made notes of these discussions.

2.3.3. Data Analysis. The notes from group discussions were consolidated by the third author to generate the next iteration of the leadership program.

2.3.4. Ethical Considerations. Ethical approval was granted by Flinders University Human Research Ethics Committee (approval number: HEL1858). Participants were informed that notes would be taken of group discussions, which would be used for program development and research.

3. Results

3.1. Stage 1: Idea Generation and Preliminary Program Development

3.1.1. Online Interactive Workshops. Four main themes were identified from the workshop data, as illustrated in Table 2. The first theme, "advocacy and lobbying," demonstrated that participants wanted a leadership program that provided them with the tools to advocate and speak up for fundamental care across health and care systems and with their interdisciplinary colleagues. The second theme, "understanding fundamental care," demonstrated that participants wanted a program that would strengthen their conceptual understanding of fundamental care, including the use of appropriate terminology. The third theme, "measurement and implementation," described participants' preference for a program that would equip them with the skills to identify and use appropriate implementation and measurement strategies, enabling them to effect real change within their respective organisations. In the fourth theme, "providing a supportive network," participants emphasised the importance of the leadership program providing a forum where program participants can motivate one another and build global connections, enabling collaborative problem-solving.

3.1.2. Online Ranking Process. The results from the ranking process are presented in Table 3. Participants prioritised program content and outputs that focused on understanding the concept of fundamental care, implementation strategies, advocating for fundamental care, designing quality improvement or research projects relevant to their organisation, self and organisational readiness assessments, and fundamental care measurement tools. The importance of the leadership program providing a supportive network was not prioritised.

Participants' responses to the draft leadership program were positive, describing it as well-structured, relevant, comprehensive, and innovative. Participants liked the 12-month follow-up, the use of mentors, and the practical focus, exemplified by the action plans. Participants also identified potential gaps in the program, offering the following solutions: (1) providing participants with a summary of fundamental care and the Fundamentals of Care Framework prior to the program to assist with self- and context-assessments, (2) including a stronger focus on knowledge translation and implementation in both the prereading and program content, and (3) incorporating a focus on sustainability into the action plan development.

3.2. Stage 2: Refinement and Trialling of Program Content and Process. Table 4 provides an outline of the revised Fundamentals of Care Leadership Program. Based on participants' real-time feedback, the leadership program was refined to include additional prereading and video resources on the Fundamentals of Care Framework and knowledge translation. To assist with action plan development, the program will also include additional resources and content on project planning, program logic, and mentoring. Seven fundamental care action plans were successfully developed during the three-day workshop, demonstrating the feasibility of including this process within the leadership program. The plans ranged in content from establishing regional ILC networks in America and Sweden to measuring the interrelated dimensions of the Fundamentals of Care Framework; generating an innovative, strategic approach to introducing fundamental care into preregistration curricula; and implementing the Fundamentals of Care Framework into clinical practice to guide care delivery. Each group is being provided structured, virtual mentoring over 12 months, with evaluation to occur thereafter.

4. Discussion

Improving fundamental care requires nursing leaders to challenge and change how this care is valued within health and care systems [19, 25]. The Fundamentals of Care Leadership Program aims to equip current and emerging nursing leaders with the skills and knowledge to make this change a reality. Codesigning the program through a participatory action research approach has generated considerable buy-in for fundamental care and its leadership globally, as illustrated by the number of participants across both stages and the number of action plans developed. The participatory action codesign approach also provided a platform for participants, who were at all levels and areas of health and care systems, to see the value in and advocate for fundamental care. The leadership program will be available to all current and emerging nursing leaders, regardless of whether they are ILC members, and will be hosted face-to-face in a different country each year, thus enhancing accessibility.

Whilst our leadership program is designed to challenge value systems, making sure the program gains traction and is sustained will be a system's challenge in itself. Numerous leadership programs have shown initial promise yet failed to sustain long-term impact. To avoid our program following the same path, we must ensure it achieves its vision and, in doing so, secures a place in the broader health and care landscape. In this discussion, we consider what we might learn from other healthcare movements, namely, quality and

TABLE 2: Main themes identified in Stage 1 with examples of illustrative quotes.

Theme	Examples of illustrative quotes from participants
Advocacy and lobbying	The [leadership program] needs to develop brave and courageous leaders who are not afraid to speak up, irrespective of the consequences [Fundamental care] is important at all levels of healthcare, not just nursing. Leaders need to have the ability to influence and gain support from other leaders outside of nursing Nurse leaders. . . they're not trained in or skilled in advocating for nursing. They are trained in leadership, they take masters' degrees in public administration and public leadership and so forth, [but] they're not equipped to advocate or speak up for nursing, so a leadership program would have to equip them [with] that
Understanding fundamental care	Leaders, irrespective of their health profession, need to understand what fundamental care means Creating a common, accessible, and consistent language about fundamental care
Measurement and implementation strategies	It is easy to believe that fundamental care is important but more difficult to implement into practice. The leadership program should assist people in how to implement changes in fundamental care in their setting Quality indicators in healthcare are often centred around process-type measures or misses and near misses, but they really don't address the core of the Fundamentals of Care Framework, which is that relationship. . . it would be nice to learn how to measure this
Providing a supportive network	Developing a network of fellow nurses, researchers, and leaders would be very motivating. It helps people to connect internationally and discuss challenges The program could provide a platform for worldwide fundamentals of care initiatives to inspire others, connect, and build stronger networks

TABLE 3: Results from the Stage 1 NGT ranking process, showing the top five rated responses.

	(%)
Section 1: Program content	
(1) Implementation strategies (in research, education, clinical practice, and policy)	16.36
(2) Understanding what fundamental care is and how to deliver it using the Fundamentals of Care Framework	14.49
(3) Influencing, lobbying, advocacy, empowering, and challenging value systems	11.21
(4) Measuring fundamental care	9.81
(5) Partnership building/collaboration (with care recipients, healthcare professionals, executives)	7.48
(6) Leadership styles, attributes, and skills	7.48
Section 2: Program activities	
(1) Participants choose a quality improvement or research project	24.19
(2) A self-assessment for fundamental care readiness (knowing what leader they are now and what they need to be a leader for fundamental care in the future)	22.58
(3) An organisational assessment for fundamental care readiness	16.94
(4) Development of a fundamental care measurement tool	12.90
(5) A quality improvement project that includes three phases: Phase 1: Diagnose (issue and evidence), Phase 2: Plan and prioritise (recommendations, policy impact, responsibility), and Phase 3: Implement and evaluate	11.29
Section 3: Program outcomes/outputs	
(1) Participants are better equipped to implement fundamental care in their workplace	18.09
(2) Participants have tools to advocate for fundamental care and are more confident to speak out for fundamental care	15.08
(3) Participants more strongly advocate for the nursing profession	14.57
(4) Participants have a better understanding of their own and the organisational barriers and enablers to fundamental care	12.56
(5) Participants and organisations have access to long-term support to implement and monitor fundamental care	10.55

TABLE 4: An outline of the Fundamentals of Care Leadership Program to be piloted in 2023.

Prereading	Key readings and video resources on: (i) Why we need to focus on fundamental care (ii) The development of the Fundamentals of Care Framework (iii) Mentoring (iv) Leadership and influencing (v) Knowledge Translation and implementation
Day 1	Presentations and group work: (i) Session 1: Making the case–Why fundamental care matters (ii) Session 2: What is fundamental care–The history of the Fundamentals of Care Framework (iii) Session 3: Knowledge translation–How to get fundamental care into research, education, clinical practice, and policy
Day 2	Presentations and group work: (i) Session 4: Project planning and program logic, including preliminary development of fundamental care action plans (ii) Session 5: Leadership and influencing (iii) Session 6: Mentoring–What it is, why it matters, and how you do it
Day 3	Receiving feedback on and finalising fundamental care action plans

safety and evidence-based practice, as well as the few larger-scale fundamental care initiatives that are gaining momentum, at least at national levels. Our aim is not to provide an exhaustive overview of these agendas; however, learning from their relative success will help to identify some of the policy and systems levers that we must consider in ensuring the Fundamentals of Care Leadership Program is successful in the long term.

The quality and safety movement, which focuses primarily on keeping care recipients safe from preventable harm [60], has gained considerable traction worldwide. It forms a part of the World Health Organisation's agenda [61] and has spawned several agencies, commissions, policies, and journals globally. The quality and safety movement has likely gained traction for three reasons: (1) it has primarily been medically driven [60]; (2) it aligns with the risk-averse culture of most health and care systems [19]; and (3) it has a strong economic driver (i.e., safety incidents cost money) [62, 63]. Like quality and safety, the evidence-based practice movement has gained traction in the last few decades. Although an evidence-practice gap still exists in healthcare [64], evidence-based practice is nonetheless seen to hold value. This is likely because it also relates to discourses around harm and risk, that is, failing to practise based on the latest evidence means possibly providing care that is ineffective, unnecessary, and unsafe. Fundamental care cannot necessarily or immediately leverage some of the drivers that have underpinned quality and safety and evidence-based practice; for instance, the economic case for relationship-based, integrated fundamental care, as espoused in the Fundamentals of Care Framework, remains unclear [65]. Nonetheless, there are lessons to be learnt from these agendas in terms of gaining traction for, and ensuring sustainability of, the Fundamentals of Care Leadership Program.

First, we must consider whether and how to align fundamental care initiatives, including the leadership program, with existing healthcare agendas. We know that failures in fundamental care compromise care quality and safety. Ensuring the safety of care recipients is also a key aspect of fundamental care delivery, as exemplified by the Fundamentals of Care Framework (see Figure 2 and [66]). Perhaps the goal for nursing leaders, then, is to incorporate fundamental care into quality and safety policies, agendas, and standards. Aligning with the quality and safety movement might also strengthen the economic case for fundamental care, demonstrating the monetary cost to health and care systems for failing to deliver this care to a consistently high standard. However, nursing leaders must navigate carefully; aligning with quality and safety can potentially reinforce, rather than challenge, prevailing value systems focused primarily on risk aversion [19]. Our leadership program must therefore empower nursing leaders to advocate for fundamental care as central rather than peripheral to existing care agendas [50]. The work of nursing leaders at Sinai Health System provides an example of how this can be achieved [67], that is, how we can leverage and even shape existing health and care drivers and values.

The Sinai Health System team, through collaborative partnership between leaders and clinicians in academia and clinical practice, has developed an evidence-informed Science of Care Framework. This framework situates fundamental care as the nexus point that intersects caring with safety, symptom, implementation, improvement, and innovation sciences, to provide holistic guidance for care delivery [67]. Efforts such as this align with but also expand current understandings of quality and safety, working to reframe what health and care systems value. By placing high-quality fundamental care as the goal of care delivery, the Science of Care Framework positions quality and safety as a mechanism to support fundamental care rather than as the driving force of care delivery itself. This also aligns with calls for the quality and safety agenda to evolve by shifting away from a focus on risk and harm, towards codesigned safety measures that encapsulate what matters most to those receiving care, including relational aspects [67]. Whilst the

Science of Care Framework is yet to be tested in clinical practice, it is an example of how we can work with, rather than against, existing healthcare agendas to challenge value systems and advance fundamental care. By equipping nursing leaders with the courage, knowledge, and skills to engage in partnership and advocate for the centrality of fundamental care, the Fundamentals of Care Leadership Program can meet its intended vision and ensure its continued presence in the health and care landscape.

A second lesson to be learnt from existing healthcare movements is that gaining traction is only one piece of the puzzle. Even the quality and safety agenda has more work to do in terms of ensuring long-term success and widespread adoption of safety interventions [60]. Hence, changing value systems around fundamental care, whilst a crucial first step, will not automatically and inevitably translate into improved care. Our leadership program must also equip nursing leaders with the requisite skills to implement and evaluate new ways of thinking, practising, and collaborating across research, education, clinical practice, and policy. There are local, small-scale efforts to improve fundamental care in these areas [23, 68]; however, large-scale efforts are rare [67, 69, 70]. The Fundamentals of Care Leadership Program must provide current and emerging nursing leaders with the skills to scale-up local initiatives, thus enabling change in the valuing, prioritisation, and actioning of fundamental care at micro, meso, and macrolevels. By becoming courageous and skilled leaders at all levels and areas of health and care systems, nurses will substantially shift organisational and system values for fundamental care, ultimately enhancing how this care is delivered.

5. Conclusions

Nurses are present in all areas and levels of health and care systems and make up the largest healthcare profession globally; their potential to influence culture, value systems, and care delivery must be fostered. A leadership program for fundamental care that, at its core, emphasises the value of this care will enable nursing leaders to positively influence how fundamental care is perceived and actioned within and across health and care systems. Using a participatory action approach to codesign, we were able to draw on the collective knowledge and active involvement of current and emerging nursing leaders globally, ensuring the development of a leadership program for fundamental care that is relevant and targeted to its intended audience and proposed aim. The resultant Fundamentals of Care Leadership Program can equip current and emerging nursing leaders across research, education, clinical practice, and policy with the requisite skills and knowledge to challenge value systems on fundamental care and to champion and sustain much-needed change, thus working towards improved care delivery and outcomes. Our goal moving forward is to assess the impact of the program and ensure its continued sustainability.

Data Availability

The workshop data from Stage 1 used to support the findings of this study have not been made available to protect participant confidentiality and anonymity (the workshops were video and audio recorded, which means the participants are easily identifiable). The transcripts of the workshops and the data from the Stage 1 ranking process are restricted by the Flinders University HREC to protect participant confidentiality. Data are available from the first author for researchers who meet the criteria for access to confidential data.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Background. Altmetric Attention Score (AAS) is a quantitative measurement of the online impact of research and has a potential correlation with traditional bibliometrics. However, the correlation for nursing journal articles is still unknown. The objective of the study was to analyze the correlation between AAS and traditional bibliometrics in the top nursing journal articles. *Materials and Methods.* Articles published in top nursing journals (the journals with the top 20 5-year impact factors) from 2010 to 2019 were included. The correlations between AAS and citations, AAS and Relative Citation Ratio (RCR) score, AAS and Category Normalized Citation Impact (CNCI) value, and AAS and impact factors were analyzed. Statistical analyses were performed using Stata 25.0 software. *Results.* A total of 15,212 journal articles were included in the study. Very weak correlations were found between AASs and citations [0.124 (95% CI, 0.108–0.14)], AASs and RCRs [0.26 (95% CI, 0.244–0.275)], and AASs and CNCIs [0.207 (95% CI, 0.192–0.223)]. The weak correlations were also found between AASs and impact factors in several journals. The weak correlations between AASs and citations, AASs and CNCIs, and AASs and RCRs were also found for most journals based on subgroup analysis. *Conclusions.* There is very weak correlations between AASs and traditional bibliometrics in top nursing journal articles. More studies should be conducted to assess how AAS influence bibliometrics, and how they can help manage nursing journal articles and research.

1. Introduction

Bibliometrics is the use of statistical methods to analyze publications, especially for scientific contents [1, 2]. It is used to justify the role of the researchers and the research team [3] and also to identify key partners [4] and the progress of a specific research field [5]. The most widely used bibliometrics method is based on citations [6], such as citation times, impact factors [7], *H* index [8], Eigenfactor score [9], and CiteScore [9]. However, these metrics have limitations. It would take time to accumulate citation times [10], and

different journal articles could not be compared directly even in the same research field [11, 12]. Absolute citation times favor older journal articles and have limited utility in comparing journal articles from different fields [12, 13]. Thus, new metrics have been developed. RCR [14], developed by NIH, is defined as the total number of citations that a paper received per year divided by the average field-specific citation rate for a peer companion group [14, 15]. It allows the comparison of articles in different fields. CNCI is another metrics to assess the paper's impact and has been analyzed in different studies [16, 17], which can also be used

to assess scientific articles from different research fields [16, 18].

In recent years, with the development of digital technology and the use of online platforms to discuss research, alternative-level metrics (altmetrics) have been introduced in research fields [12–14]. They were used to measure the journal articles with attention, dissemination, overall influence, and impacts [14]. The main altmetrics platform is Altmetric [19, 20], which compiles the number of mentions of a paper across the most used social media platforms such as Twitter, Facebook, and LinkedIn, and public policy documents, mainstream media, online reference managers, and other online platforms, to generate a weighted score, Altmetric Attention Score (AAS) [14]. AAS is a dynamic bibliometric which captures the online impact of a paper. It has been used to assess the online impact of journal articles across different fields [7, 14, 21] and provide potential evidence for research impact or journal strategy.

Nursing is an important discipline, and research helps the progress of the discipline by improving nursing practice and finally helping nursing management. Factors that influence the characteristics of nursing journal articles could further help journal articles to be quickly transformed into nursing practice and applied to nursing management. It has been reported that bibliometric analysis might help nursing management and nursing practice, and thus some studies have been performed in the field of nursing management [2, 16]. However, these studies did not analyze the important impact of online platforms on nursing management. It is still unclear whether the online impact would be associated with traditional bibliometrics and whether the online impact would help nursing paper citations. Furthermore, it is also unclear whether the nursing manager could use social media, public research platforms, or online platfroms to help nursing research impact. Although several articles have used bibliometrics methods to assess the top cited [2, 16] or the top impact nursing articles [2, 16], whether impact from social media, public research platforms, or online platforms will help higher citations is a mystery. Therefore, in the current study, we analyzed the Altmetric and bibliometric data of journal articles published in nursing journals, to assess the correlation between AASs and the citation metrics.

2. Methods

2.1. Inclusion and Exclusion Criteria for the Selection of Nursing Journal Articles. The inclusion criteria were as follows: (1) the journal articles should be published in top nursing journals. Five-year impact factors were used to identify the top nursing journals, and thus the top 20 5-year impact factor journals in the nursing category in the JCR report in 2021 were used in the current study. (2) The journals should be indexed by PubMed. Thus, the journals included in the study were as follows: Australian Critical Care, Birth-Issues in Perinatal Care, BMC Nursing, European Journal of Cardiovascular Nursing, Intensive And Critical Care Nursing, International Journal of Mental Health Nursing, International Journal of Nursing Studies, International Nursing Review, Journal of Advanced Nursing, Journal of Clinical Nursing,

Journal of Nursing Management, Journal of Nursing Scholarship, Nurse Education Today, Nursing Ethics, Nursing Outlook, Research in Nursing & Health, Seminars in Oncology Nursing, Women and Birth, Worldviews on Evidence-Based Nursing, and Asian Nursing Research. (3) The paper type should be an article or review. (4) The paper could be found in Incites, iCite, Altmetric, and PubMed. The following exclusion criteria were used: (1) duplicated journal articles; (2) mismatched journal articles; (3) editorial articles, corrections, and letters.

2.2. Paper Searching. The journal articles were searched by the selected journal names in the three databases (Incites [16], iCite [14], and Altmetric [12]). All search results were downloaded. If any data for an article was missing, the article was further searched in PubMed or the specific journal websites.

2.3. Paper Screening and Data Extraction. All articles were screened according to the inclusion and exclusion criteria. Only articles which had all the required data (RCR, citation time, AAS, and CNCI) were included. The following information was extracted from each article: journal, author, impact factor, RCR score, citation time, CNCI value, AAS, etc. The RCR scores were extracted from the downloaded file from the iCite database, the CNCI values were extracted from the downloaded file from the Incites database, and the AASs were extracted from the downloaded file from the Altmetric database. The journals' impact facotrs were downloaded from the Web of Science.

2.4. Statistical Analysis. The characteristics of the included studies were analyzed. The correlations between AASs and citations, AASs and RCRs, AASs and CNCIs, and AASs and impact factors, were analyzed using Spearman correlation coefficients [12]. Subgroup analyses were performed according to journals, and years. All analyses were performed by SPSS 25.0 software.

3. Results

3.1. The Main Characteristics of Included Journal Articles. The data were collected by September 9th, 2022. After screening all data of the journal articles according to the inclusion and exclusion criteria, a total of 15,212 journal articles were included. The impact factors for all the selected 20 journals from 2010 to 2019 are shown in Table 1, and the impact factors of most journals increased from 2010 to 2019. The average citation of all journal articles was 17.36 times, and the median citation was 11 times. A total of 318 journal articles were cited 0 times, 14,059 journal articles were cited 1 to 50 times, 660 were cited 51 to 100 times, and 175 journal articles were cited more than 100 times.

3.2. The Performance of Included Journal Articles. The average RCR score of included articles was 1.71, and the median RCR score was 1.14. The RCR scores of 258 articles

—: not available.

were 0; 6,576 articles had RCR scores between 0 and 1; 8,236 journal articles had RCR scores between 1 and 10; the RCR scores of 142 journal articles were higher than 10. The average CNCI value was 1.52, and the median CNCI value was 1.05. The CNCI values of 318 journal articles were 0; 7,017 journal articles had CNCI values between 0 and 1; 7,785 journal articles had CNCI values between 1 and 10; the CNCI values of 92 journal articles were higher than 10. The average AAS was 8.92, and the median AAS was 3. The AASs of 2264 journal articles were 0; 9,950 journal articles had AASs between 0 and 10; 2,866 journal articles had AASs between 10 and 100; the AASs of 132 journal articles were higher than 100. The citations, RCRs, CNCIs, and AASs of all journal articles in the 20 journals were summarized in listed in Table 2.

3.3. The Contribution of Different Sources to AAS. The sources that contributing to the AAS were individually analyzed from 2010 to 2019. For all years, Twitter was the most frequent contributor to AAS followed by news outlets and Policy (Table 3).

3.4. The Correlation of AASs with Citations, RCRs, CNCIs. The correlations of AASs with citations, CNCIs, and RCRs are shown in Figures 1–3. In summary, the correlation coefficient was 0.124 (95% CI, 0.108–0.14) between AASs and citations, 0.26 (95% CI, 0.244–0.275) between AASs and RCRs, and 0.207 (95% CI, 0.192–0.223) between AASs and CNCIs. The correlations for each journal are shown in Table 4.

For the International Journal of Nursing Studies, which ranked first in the JCR report (2021) with an impact factor of 6.612, a total of 1,437 journal articles were included. The total citation times was 43,729 (ranging from 0 to 582 by paper,

median 19), the total AAS was 12,975 (ranging from 0 to 703 by paper, median 3), and the total RCR score was 3,985.92 (ranging from 0 to 35.94 by paper, median 1.79). Very weak correlations were found: 0.207 (95% CI, 0.158–0.258) between AASs and citations, 0.371 (95% CI, 0.325–0.418) between AASs and RCRs, and 0.267 (95% CI, 0.219–0.317) between AASs and CNCIs.

The Journal of Clinical Nursing ranked fourth in the JCR report (2021) with an impact factor of 4.423, from which we collected the highest number of journal articles in the current study. The total number of citations was 48,236 (ranging from 0 to 262 by paper, median 10), the total AASs was 17,842 (ranging from 0 to 251 by paper, median 2), and the total RCR score was 4,709.72 (ranging from 0 to 21.32 by paper, median 0.98). Very weak correlations were found: 0.133 (95% CI, 0.097–0.166) between AASs and citations, 0.312 (95% CI, 0.28–0.346) between AASs and RCRs, and 0.23 (95% CI, 0.199–0.264) between AASs and CNCIs.

The Journal of Nursing Management was the only management journal in the field of nursing, from which a total of 783 journal articles were included. The total number of citations was 13,906 (ranging from 0 to 203 by paper, median 11), the total AASs was 3,007 (ranging from 0 to 228 by paper, median 1), and the total RCR score was 1,593.84 (ranging from 0 to 17.58 by paper, median 1.43). Very weak correlations were found: 0.158 (95% CI, 0.086–0.229) between AASs and citations, 0.239 (95% CI, 0.162–0.304) between AASs and RCRs, and 0.206 (95% CI, 0.137–0.274) between AASs and CNCIs.

Nurse Education Today was the only education journal in the field of nursing, from which a total of 1,566 journal articles were analyzed. The total citation was 26,555 (ranging from 0 to 770 by paper, median 11), the total AAS was 15,837 (ranging from 0 to 373, median 3), and the total RCR score

was 3,104.38 (ranging from 0 to 81.92, median 1.34). Very weak correlations were found: 0.086 (95% CI, 0.038–0.134) between AASs and citations, 0.269 (95% CI, 0.223–0.317) between AASs and RCRs, and 0.188 (95% CI, 0.139–0.234) between AASs and CNCIs.

3.5. The Correlation Analysis by Years. Spearman rank correlation coefficient was calculated between citations and the AASs by years (Table 5). The results showed very weak correlations between AASs and citations, AASs and CNCIs, and AASs and RCRs in all years.

3.6. The Correlation between AASs and Impact Factors. The correlations between AASs and impact factors were individually analyzed based on years. Weak correlations were found in most of the years (Table 6). Spearman rank correlation coefficient was calculated between the impact factors and AASs based on journals (Table 7). Weak correlations were found for the Australian Critical Care, International Journal of Mental Health Nursing, International Journal of Nursing Studies, Journal of Advanced Nursing, and Nurse Education Today.

4. Discussion

In the current study, the Altmetric and traditional bibliometric of journal articles published in 20 top nursing journals were analyzed. A very weak correlation between AASs and citations was found. AAS was also found to be correlated with RCR and CNCI, which were novel metrics of research influence based on citation times. The results suggest that traditional bibliometrics and AAS cannot be used interchangeably but rather complementarily when assessing the impact of journal articles in the nursing field.

Further analysis by journals and publication years found that the International Journal of Nursing Studies (IJNS) had more correlation between the AASs and citations, and no correlation was found in the Nursing Ethics. This difference might be due to the difference in the breadth of journal topics since one is a comprehensive nursing journal and the other is a subspecificity nursing journal. Articles from IJNS with high online attention might also impact the scientific community and thus increase citations. However, articles from Nursing Ethics, which are likely to be controversial articles for the public to garner public interest, thereby increasing AAS, while they might not impact the scientific community in the same manner [12].

With the COVID-19 pandemic [22], more training programs in the nursing practice field have been performed via the social media platforms and other online platforms. That should be of interest to nursing managers, nurses, and journals. It indicates that the social media and other online platforms would not only help the scientific community but also help the public community, especially during the COVID-19 pandemic period [23]. Implementing new research works on the online platforms will contribute to these results and further help the scientific community.

The study has several strengths. First, the current study was a study with large sample size analyzing alternative metrics and bibliometrics based on articles in top nursing journals. Second, it analyzed the AASs with 3 citation-based metrics and found weak correlations between these parameters. Third, we analyzed the correlation by journals, which was a unique contribution to the nursing field. The paper also has several limitations. First, to analyze the precision correlations, we excluded journal articles that missed any data of the four variables (AASs, citations, RCRs, and CNCIs). Second, the correlations might be different when analyzing at a different time. Third, the study only

analyzed the journal articles from top nursing journals, and nursing-associated journal articles published in other journals could have different kinds of correlations, especially for those articles published in low-impact factor journals. Fourth, the study did not include other bibliometrics [24, 25], such as the Eigenfactor score and CiteScore; in the future, a new study should be performed to assess these correlations.

In conclusion, the study of articles published in high-impact nursing journals between 2010 to 2019, finds very weak correlations between AAS and citation-based metrics, which suggests promoting journal articles on online platforms may help research, journals, and nurses. Future studies are needed to assess the long-term correlations among these metrics for nursing journal articles.

5. Implication to Nursing Management

Understanding the correlation of online impact with traditional bibliometrics of research is critical to nursing practitioners, which in turn helps manage nursing journal articles and research. Nursing managers should develop targeted strategies to increase the online impact of research or nursing practice and increase research impact.

Lihui Zhang and Yangyang Liu contributed equally to this work.

Aim. To develop a valid, reliable assessment tool to measure risk factors associated to low back pain (LBP) in intensive care unit (ICU) nurses. *Background*. LBP is defined as the pain extending from the 12th rib to the iliac crest and often coexists with buttock pain. Nursing has been identified among the top professions at risk of LBP. A mean of 70% prevalence per year in ICU nurses was reported, exceeding those employed in heavy industry. Environmental factors in workplace were also most important risks related to LBP in this population except factors including individual, physical, psychosocial, and lifestyle. However, there is lack of tools to assess environmental risk related to LBP for nurse managers currently. *Methods*. Focus group interviews, field research, and panel discussion were used to develop item pool. Two-round expert reviews and preinvestigation were carried out to form initial scale named Environmental Risk Assessing Instrument-Occupational Low Back Pain in Nurses (ERAI-N). A cross-sectional survey with 188 ICU participants in Hunan Province in China was implemented to collect data. Cronbach's alpha, split-half reliability, and test-retest reliability were used to test ERAI-N's reliability. Expert review was performed to test ERAI-N's content validity, and confirmatory factor analysis (CFA) was performed to assess its construct validity, being carried out in IBM SPSS Amos 26 Graphics. *Results*. Final version of ERAI-N scale had five dimensions with 18 items that were space, equipment, belief, guideline, and safe culture. ERAI-N scale's score of Cronbach's alpha, Guttman split-half, and intraclass correlation coefficient (ICC) was 0.958, 0.927, and 0.994, respectively. Item-level content validity scores ranged from 0.89 to 1.0, and scale-level content validity was 0.983. Standardized factor loadings ranged from 0.567 to 0.974. Model adjusted fit statistics were as follows: the chi-square statistic and degrees of freedom (χ^2/df) = 3.943, root mean square error of approximation (RMSEA) = 0.071, incremental fit index (IFI) = 0.905, comparative fit index (CFI) = 0.904, parsimony normed fit index (PNFI) = 0.641, and parsimonious comparative fit index (PCFI) = 0.661. *Conclusions*. ERAI-N scale had moderate reliability, content validity, and construct validity. *Implications for Nursing Management*. Designers may use ERAI-N scale to plan the interior layout when design a new ICU. Nurse managers might utilize this instrument as a managing tool to assess whether there is environmental risk factors related to LBP in ICU.

1. Introduction

Low back pain (LBP) is defined as the pain extending from the 12th rib to the iliac crest and often coexists with buttock pain [1]. LBP is one of the most common public health problems, especially in middle-aged to older women, with the prevalence [2] ranging [3] from 40% to 90% [4]. LBP has some other prominent features such as high annual

incidence leading to severe functional limitation [5] in addition to high prevalence. A study done in 195 countries found that LBP was the leading cause of worldwide productivity loss as measured in years and the top cause of years lived with disability [6].

Nursing has been identified among the top professions at risk of LBP [7], especially for those on duty in intensive care unit (ICU). A mean of 70% prevalence per year was reported,

exceeding those employed in [8] heavy industry [9]. It is also reported that being a nurse is independently related to spinal pain [10]. LBP can induce disrupted or reduced proprioceptive signaling which likely plays a pivotal role in driving long-term changes in the top-down control of the motor system via motor and sensory cortical reorganization [11]. There were lots of publications which revealed that LBP for ICU nurses may lead to work absenteeism, reduction of nursing workforce efficiency [12], and burnout [13] and may incur economic costs of personal or national finance.

In order to reduce the prevalence of LBP among ICU nurses, investigations have been focused on individual, physical, psychosocial, and lifestyle factors which might play an essential role on the [14] occurrence of LBP [15] in recent decades. Based on human factors theory [16], lots of publications revealed that environmental factors in workplace were the most important risk factors for LBP [17, 18] in ICU nurses [8]. Omura et al. [19] proved that the use of a sliding sheet can significantly lower levels of low back subjective fatigue for caregiver in clinic when performing patient repositioning [19]. Alamgir et al. [18] found that healthcare workers preferred to use ceiling lifts because of less physically demanding work [18]. It is also reported that high-level lift availability was half as likely to have work-related LBP [20]. However, less than half (46%) of respondents working in ICU reported that their employer provided lifts [20], and this means limited availability and adoption of lifting equipment have been a persistent problem [21].

On the other hand, spatial requirements for a bed space are also essential in a critical care setting [22]. It is reported that an average of $23.26\,m^2$ was needed for a bed-to-bed transfer followed by $22.87\,m^2$ for a resuscitation task [23]. Nevertheless, little investigations were made to make sure whether the bed space in ICU meets the requirements. In terms of culture of safe nursing activities for the prevention of LBP in ICU nurses, there is research indicating that it is urgent to make efforts to broadcast safety operations, to formulate nursing procedures for nurses such as manual handling task, and to carry out guidance for safe handling patients, so as to reduce the occurrence of occupational LBP [24] in ICU nurses [25].

In spite of this, there are currently less reports about these strategies and no established research instruments designed to measure them as well. The aim of the current study was to develop and validate the Environmental Risk Assessing Instrument-Occupational Low Back Pain in Nurses (ERAI-N), with the intent of providing a high-quality instrument with clinical practical value that may be utilized by nurse administrators or researchers.

2. Methods

2.1. Participating Units.
This was an instrument development and validation study. Sample and data collection was performed in the tertiary general hospitals in Hunan Province in China from March to May 2022, except those specialized hospitals like military hospital, child care hospital, maternal and child health care hospital, stomatological hospital, tumor hospital, reproductive hospital, and traditional Chinese medicine hospital. The final scale used in this investigation has 20 items. The sample size was calculated according to 5 to 10 times of the number of items, 100 to 200 ICUs would be selected for this assessment, and the final sample size was about 110 to 220 ICUs, considering a 10% sample failure rate. There were 2 ICUs being assessed in every tertiary general hospital with random sampling principle. A flowchart of the sampling method is shown in Figure 1.

2.2. Procedure

2.2.1. Item Generation.
A qualitative study was conducted from January to March 2022. The initial questionnaire was developed through focus group interviews and field research, which were instructed by human factors theory. A convenience sample of 5 head nurses and 3 registered nurses working in a single prestigious general health care center was selected for group interviews. The interview was carried out by 3 of our research team in one conference room in the hospital. Participants were asked to discuss about LBP and environmental risk and safe culture related to the pain. Interviews continued until data saturation was achieved. For further certainty in addition to the focus group interviews, a field research was performed, and descriptive observation and focal observation were used by 2 of our research team in two ICUs. Subsequently, based on the qualitative study and literature review, the preliminary questionnaire containing 27 items was developed.

2.2.2. Content Validity.
An expert reviews process based on Delphi [26] was used for this study. The number of experts to be consulted for the Delphi method ranged from 15 to 30, depending on the depth of the research content [27]. Because the instrument is intended to measure factors of working environment and safe culture related to LBP in the context of an inpatient department, 20 researchers in the field of nursing management, ergonomics, or occupational safety were identified as experts, who were from the provinces of Taiwan, Beijing, Hunan, Gansu, Shanghai, Jiangsu, Chongqing, Guangxi and Anhui in China, respectively. All experts were contacted by WeChat and consented to participate in the study.

Two rounds of expert reviews were conducted. Nineteen of these twenty reviewers (95.0%) completed the first round review and 18 of them (94.7%) completed the second round. All of nineteen experts have achieved the top class technique title in the research, and 11 of them had completed postgraduate degree education. For the two-round reviews, the authority coefficient of experts (Cr) was 0.76~1.00 (0.90 ± 0.08) and 0.75~1.00 (0.89 ± 0.08), respectively, greater than 0.7; Kendall's W values of the measurement items were 0.223 $(P < 0.001)$ and 0.107 $(P < 0.001)$; and coefficient of variation (CV) was 0.05~0.29 (0.11 ± 0.06) and 0.05~0.22 (0.09 ± 0.03), less than 0.25, indicating that the overall coordination degree of expert scores was at a relatively high level. Experts used Likert 5-score scale to rate each questionnaire item's relevance and its respective concept; a score of 5 means very important, and a score of 1

FIGURE 1: Flowchart of the cluster stratified sampling with random principle.

means not important. The screening criterion was the combination of an item importance score with a mean of ≥4 and CV ≤ 0.25. In the first round, 11 experts put forward suggestions for modification, accounting for more than 57.9%. In the second round, 5 experts put forward suggestions for revision, accounting for 26.3%. After synthesizing expert opinions and group discussions, 6 items were merged, 2 were deleted, 1 item was added, and 2 items were modified. The initial scale with 20 items was obtained.

2.2.3. Preliminary Investigation. To further screen the items of the initial scale that whether their descriptions were suitable for ICU nurse administrators, preinvestigation was performed in 31 ICUs of tertiary medical institutions in Changsha, which were half of nonprofit tertiary hospitals in Changsha. Critical ratio, correlation coefficient, and factor analysis method were used for the screening criteria for project analysis.

2.3. Instruments. The final ERAI-N instrument was used as the instrument to collect the data. Participants responded to each item of the scale using a Likert-type scale with five response options: very inconsistent = 1, not very consistent = 2, uncertain = 3, fairly consistent = 4, and very consistent = 5.

2.4. Statistical Analysis

2.4.1. Validity Test. After the initial scale was formed, 9 authoritative and highly motivated experts who participated in the first reviews were consulted to test its content validity, evaluating fit degree between the measured content of the

scale items and the expected measured content. Experts used the content validity index (CVI) to rate each questionnaire item's relevance and its respective concept. The item CVI (I-CVI) is determined by calculating the proportion of experts rating each item as "quite relevant" or "very relevant." The I-CVIs were averaged to calculate a scale CVI (S-CVI). I-CVI and S-CVI were used to evaluate item-level and scale-level content validity, respectively.

Construct validity was assessed using confirmatory factor analysis, being carried out in IBM SPSS Amos 26 Graphics. According to the literature, the chi-square statistic and degrees of freedom (χ^2/df) and the root mean square error of approximation (RMSEA) were used as absolute fit indices, comparative fit index (CFI), incremental fit index (IFI), and normed fit index (NFI) were used as incremental fit indices, and parsimony normed fit index (PNFI) and parsimonious comparative fit index (PCFI) were used as parsimonious fit indices [28]. The overall model fit was confirmed to be acceptable when χ^2/df was between 3 and 5 and excellent if it was between 1 and 3. Other acceptable fit criteria were RMSEA < 0.08, CFI > 0.9, IFI > 0.9, NFI > 0.9, PNFI > 0.5, and PCFI > 0.5. Guided by modification indices, residual correlations were specified for several items. Standardized factor loading was used for item-level content validity assessment. Factor loading greater than 0.40 was considered to be adequate. After confirming the model fit, individual standardized parameter estimates of paths (i.e., coefficients values) were assessed for magnitude, statistical significance ($p \leq 0.05$), and direction.

2.4.2. Reliability Test. Internal consistency reliability was assessed using coefficient alpha and split-half reliability, calculated in SPSS (IBM 26). McDonald's omega reliability

Figure 2: Distribution of the hospital locations.

coefficient was calculated using SPSSAU (https://spssau.com/). Nunnally and Bernstein [29] suggest that internal consistency reliability values greater than 0.7 are generally sufficient [29]. In this study, test-retest reliability was also performed to assess the instrument's reliability. Forty ICUs were reevaluated 2 weeks after the initial survey. Intraclass correlation coefficients (ICCs) were used to determine test-retest reliability. A series of two-way mixed-effects models with measures of absolute agreement were used. ICCs were determined as <0.40 (poor), 0.40~0.75 (fair to good), and >0.75 (excellent) [30].

2.5. Ethical Considerations.
The Medical Research Ethics Committee of Xiangya Hospital of Central South University approved the study protocol (#202109003). Prior to collecting the data, written informed consent was obtained from each participant. The study was conducted in accordance with the Declaration of the World Medical Association and the Helsinki Declaration on the testing of human subjects.

3. Results

3.1. Characteristics of the Participating Units.
Of the 94 third-level hospitals surveyed, 19 were in Changsha, accounting for 20.2%, followed by Shaoyang, Changde, and Zhuzhou, with 10 (10.6%), 9 (9.6%), and 9 (9.6%), respectively. The distribution is shown in Figure 2. Fifteen (16.0%) hospitals had <1000 available beds, 50 (53.2%) had 1000–1999 beds, 12 (12.8%) had 2000–2999 beds, and 17 (18.1%) had ≥3000 beds. 56.4% of ICUs were available with 10–19 beds, and 28.7% of ICUs were available with 20 and more beds. In 57.4% of ICUs, half or more of the nurses complained of low back pain due to nursing operations. In 27.7% of ICUs, half or more of the nurses suffered acute low back muscle injuries caused by nursing operations (Table 1).

3.2. The Final ERAI-N Instrument.
Our hypothetical model, the ERAI-N, theorized that five distinct mechanisms in hospital units contribute to LBP in nurses. These mechanisms are spatial requirement, equipment, belief, guideline, and atmosphere of safe culture. An initial set of items was developed based on human factors theory and was refined through focus group interviews and field research. The final ERAI-N instrument comprises 18 items, with each construct measured by a minimum of 3 and a maximum of 5 items. The total scale score was 18-90. The maximum value in this survey was 90, and the minimum value was 21, with a mean value of 54.7 ± 16.3.

3.2.1. Reliability

(1) Cronbach's Alpha Score. Cronbach's alpha scores ranged from 0.793 to 0.982 for the instrument's five factors. Guttman split-half scores ranged from 0.708 to 0.928. McDonald's omega reliability coefficient ranged from 0.866 to 0.986., The overall scale was 0.963 (Table 2). These scores all exceed the 0.7 standard proposed by Nunnally [29].

(2) Test-Retest Reliability. In this study, ICC was further analyzed to comprehensively examine the reliability level of the scale, ICC scores ranged from 0.616 to 0.924, and the scale's ICC was 0.994 (Table 3).

3.2.2. Validity

(1) Content Validity. In this study, 9 authoritative and highly motivated experts were consulted for the evaluation opinions on the correlation of scale items. The results show that item-level CVI ranged from 0.89 to 1.0, greater than 0.78 [31]. A total of 17 items in the scale were unanimously rated as "relevant" by all experts (3 or 4 points), the scale-level unanimity CVI was equal to 0.85, greater than 0.8 [32], and scale-level average CVI was 0.983, greater than 0.9 [32], which mean the content validity of both item level and scale level was good.

TABLE 1: General information of participating units ($n = 188$).

Characteristics	Number (n)	Percentage
Type of ICU you work in		
Comprehensive ICU (central ICU)	90	47.9
Specialty ICUs	98	52.1
Respiratory ICU	40	21.3
Emergency ICU	22	11.7
Neurology ICU	8	4.3
Neurosurgical ICU	16	8.5
Cardiac surgical ICU	2	1.1
PICU	4	2.1
Cardiovascular ICU	6	3.2
Number of beds available in your ICU		
<10	28	14.9
10–19	106	56.4
≥20	54	28.7
Have any nurses from your ICU complained of low back pain as a result of nursing operations?		
75–100%	48	25.5
50–74%	60	31.9
26–49%	68	36.2
1–25%	8	4.3
0%	4	2.1
Have nurses from your ICU suffered acute low back muscle injuries as a result of nursing operations?		
75–100%	24	12.8
50–74%	28	14.9
26–49%	82	43.6

The overall scale	65.73 ± 16.76	62.20 ± 18.50	0.994**

ICC, intraclass correlation coefficient. ** $p < 0.001$.

(2) Construct Validity. Construct validity was assessed by confirmatory factor analysis. The maximum likelihood method was used to estimate the factor loadings. In the initial model, χ^2/df was approximately 5, and neither IFI nor CFI was equal to or greater than 0.9. After several times adjusting of model and group discussion, 2 items were deleted. The final model fit indices showed acceptable model fit (Table 4). All parameters in the model were significant at $p < 0.001$ (Figure 3).

The five-factor hypothesized adjusted model resulted in the following goodness-of-fit indices. The standardized factor loadings ranged from 0.567 to 0.974 and exceeded the recommended 0.40 threshold (Table 5).

3.2.3. Minimum Detectable Change. Nurses' complaints of low back pain due to nursing operations were negatively correlated with scale scores, with a Spearman correlation

TABLE 4: Modified model fit test.

Index classification	Indices	Evaluation criterion	Fitted value	Meet the standard
Absolute fit indices	$\chi^2/\mathrm{d}f$	<3 good 3~5 (fail to good)	3.943	Yes
	RMSEA	<0.08	0.071	Yes
Incremental fit indices	IFI	>0.9	0.905	Yes
	CFI	>0.9	0.904	Yes
Parsimonious fit indices	PNFI	>0.5	0.641	Yes
	PCFI	>0.5	0.661	Yes

$\chi^2/\mathrm{d}f$, the chi-square statistic and degrees of freedom; RMSEA, root mean square error of approximation; IFI, incremental fit index; CFI, comparative fit index; PNFI, parsimony normed fit index; PCFI, parsimonious comparative fit index.

FIGURE 3: CFA model diagram of Environmental Risk Assessing Instrument-Occupational Low Back Pain in Nurses (ERAI-N).

coefficient of −0.434. Using receiver operating characteristic (ROC) curve analysis, ICUs in which ≥50% of nurses had complained of low back pain due to nursing operations were considered high risk. The AUC was 0.745, $p = 0.001$, the maximum Yordon index was 0.414, and the cutoff value was 62.5 (Figure 4).

4. Discussion

Environmental factors in the work place have been found to be an important risk related to LBP in ICU nurses [8, 33]. HealthWISE published by the World Health Organization and International Labour Organization indicated top ten

Table 5: Scale items and standardized factor loadings.

Scale items	Standardized factor loadings
Space	
Spatial requirements for a bed space meets the standard of 15 to 18 square meters	0.567
The height of the sickbed is adjustable	0.630
The height of the work surfaces (desks, trolleys, and shelves) is adjustable for nurses working with the natural posture	0.771
The height of the seat and the height of the lumbar support pillow are adjustable, and the structure of the lumbar support pillow is elastic and rigid enough, so it is comfortable and stable	0.798
Equipment	
Auxiliary equipment such as slip and bed easy is available at any time	0.610
Patient lifting system is available at any time	0.772
The height of the interface of common devices is suitable. Nurses do not need to bend or bend excessively when operating the interface (such as monitoring devices and ventilators).	0.709
Belief	
An organizational policy system of working safely has been established	0.917
Promote the concept of "safe patient handling, no manual lift" in the work place	0.952
Training nurses about the knowledge of ergonomics related to the prevention of lumbar and back musculoskeletal injury	0.974
Training nurses on the skill of biomechanics of lumbar spine related to the prevention of lumbar and back musculoskeletal injury	0.973
Evaluate nurses' knowledge and skills in the prevention of lumbar and back musculoskeletal injury	0.965
Guideline	
There were safe work procedures for nurses to prevent low back musculoskeletal injury	0.985
There was risk assessment checklist of safe patient handling	0.856
There were emergency plans to deal with lumbar and dorsal musculoskeletal injuries for nursing staff	0.929
Atmosphere of safe culture	
Nurses have the vision of "I want to work safely"	0.636
Nurses have the initiative to carry out the risk assessment of safe patient handling	0.877
There was a culture of safety named "team work, safe patient handling" in the work environment	0.646

ergonomic principles including working in neutral positions, keeping everything within easy reach, and maintaining a comfortable environment [34]. However, these were instructive principles, and a tool with the capacity of accurately identifying risks in clinic would be more popular than those theoretical principles for clinical administrators. Therefore, we sought to develop such a simple instrument to help clinical administrators complete the identification of environmental risk factors related to LBP in nurses.

4.1. Scale Content Analysis. ERAI-N scale had five dimensions with 18 items that were space, equipment, belief, guideline, and safe culture. Jafari et al. [35] developed a scale for predicting LBP occurrence among nurses, including three dimensions with 40 items, which were occupational, psychosocial, and individual [35]. Kazemi [36] developed an instrument to assess occupational low back pain prevention behaviours among nurses, including six aspects that are knowledge, attitude, behaviour, self-efficacy, reinforcing factors, and enabling factors. But the knowledge subscale was with low reliability [36]. However, previous scales related to the low back pain risk assessment in nurses have focused less on the direct and controllable factors that produce these risk behaviours. In addition to safe working procedures [37] and improving nurses' work posture, a safe working environment is also essential. A study showed that providing ceiling lifts was associated with reduced LBP in nurses [21]. Therefore, the instrument is intended to measure factors of working environment and safe culture related to LBP in the context of an inpatient department.

4.2. The Results from the Expert Consultation Are Reliable. The experts participating in this review were involved in the fields of nursing management, ergonomics, or occupational safety. The authority coefficient of experts for two reviews was higher than the standard, and it indicated that the experts in this study were highly authoritative. More than half experts put forward suggestions for modification and participated in the consultation for the evaluation of model fit degree, and they fully expressed their concern and support for this study. Furthermore, CV scores were less than 0.25 in two-round reviews indicating that the overall coordination degree of expert scores was at a relatively high level.
Figure 4: ROC curve.

4.3. ERAI-N Had Moderate Reliability. In terms of the internal reliability, this scale only had a moderate internal consistency.

Reliability analysis is to test the reliability of measuring tools, which is an index reflecting the consistency degree of the result measured from the tool. In this study, coefficient alpha, split-half reliability, and test-retest reliability were used to test ERAI-N's reliability. Coefficient alpha reliability coefficient is the most commonly used reliability coefficient, and it is often used to test scale's intrinsic consistency. The method of split-half reliability means to divide the survey item into two halves and then calculate the correlation coefficient of the scores of the two halves, and it is also used to test scale's intrinsic consistency. For the data analyzed in this study, both coefficient alpha reliability and split-half reliability surpassed generally accepted standards, and this means ERAI-N had moderate reliability. In order to test the results' stability, 40 ICUs were reevaluated 2 weeks later. The scale's ICC was 0.994, greater than the standard of 0.75, indicating that the stability of ERAI-N was excellent [36].

4.4. ERAI-N Had Moderate Validity. In this study, in order to ensure the accuracy of phrasing and the importance of entry item, two-round expert consultation was carried out. In the consultation letter, open information collecting columns of "Indicators to be added" and "Opinions and suggestions" was set to obtain experts' advice as more as possible. The evaluation from authoritative experts showed that the CV of both item level and scale level exceeded the standard, this indicated that ERAI-N had excellent content validity, and its items had a good correlation with the corresponding dimension and content.

In order to ensure the scientific research, it is necessary to test the suitability of the questionnaire model. The indices of the initial model including absolute fit indices, incremental fit indices, and parsimonious fit indices basically meet the relevant parameter requirements. Based on it, the initial model was modified in this paper so as to pursue better fitting results. The fitness test results of the modified model showed that χ^2/df was not at the range of excellent, but at the range of fair to good. Meanwhile, CFI, IFI, PNFI, and PCFI reached up to the level of excellent. These findings indicated adequate internal consistency of the items within each factor and a close alignment with the ERAI-N's theoretical factor structure. Therefore, it can be illustrated that ERAI-N had a moderate goodness of fit.

4.5. Implications for Nursing Management. There are several clinical and research implications that follow this study. When a new ICU is built, ERAI-N may help the designer to decide the number of sickbed for an area so that a bed space meets ICU spatial requirement standard. It also can help them to determine the location of special equipment such as invasive ventilators that are frequently operated by the nurse so as to keep operators in a natural posture while operating the equipment's interface. Nurse managers can utilize ERAI-N as a managing tool to assess whether there are environmental risk factors related to LBP in their own unit and then form an improvement report and put forward it to supplementary departments. Researchers may tentatively utilize the tool to assess the status quo of environmental risks leading to LBP in ICU.

4.6. Limitations of ERAI-N and Future Directions. ERAI-N was developed and tested on a sample from one province; therefore, there is a need for future research focusing on further evaluating the ERAI-N's reliability and validity. For example, it would be national and cross-cultural study with variation in the ERAI-N structure and distribution. The individual factors related to LBP in ICU nurse population can be summarized and set up a connection with the ERAI-N scale. Otherwise, it is urgent to develop practical intervention strategies according to specific conditions for ICU. Of course, it is important for researchers in the future to focus on the study of putting into effect interventions to reduce or eliminate these risk factors, so as to realize its real value of research and development.

5. Conclusion

This study introduces a reliable and valid instrument (ERAI-N) for clinical administrators to measure risk factors of low back pain in ICU nurses. The ERAI-N scale had five dimensions with 18 items that were space, equipment, belief, guideline, and safe culture. It demonstrates good levels of reliability, content validity, and construct validity in the process of initial testing and appears promising. Clinical administrators or researchers may tentatively utilize the tool to assess the status quo of environmental risks leading to LBP in ICU. There is a need for future research focusing on further evaluating the ERAI-N's reliability and validity, developing and putting into effect interventions to reduce or eliminate these risk factors, so as to realize its real value of research and development.

Data Availability

Data are available on request from the authors.

Ethical Approval

The Medical Research Ethics Committee of Xiangya Hospital of Central South University approved the study protocol (no. 202109003).

Disclosure

Lihui Zhang and Yangyang Liu are co-first authors.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

Lihui Zhang and Yangyang Liu collected and analyzed the data and prepared the first version of the manuscript. Su'e Yuan helped develop ideas for the study, designed the study, and prepared the manuscript for publication. Lihui Zhang and Yangyang Liu contributed equally to this work.

Aim. To investigate the current status of NBDs' core competencies through latent profile analysis, identify potential subgroups and their population characteristics, and analyze the influencing factors of different categories. *Background*. NBDs are essential in the treatment and rehabilitation of burn patients. However, the core competencies of Chinese NBDs are seldom reported. *Methods*. Our analyses were based on a cross-sectional and multicenter study of 267 Chinese NBDs. Latent profile analysis was employed to identify NBDs' core competence profiles using the NBD Core Competencies Self-rating Scale (NBD-CCSS). We then explored the characteristics among different profiles and determined socio-demographic variables associated with profile membership by conducting ANOVA, Chi-square test, and multinominal logistic regression analyses. *Results*. A 3-profile model provided the best fit. The three profiles were titled "skillful competencies" (Class 1, $n = 77$, 28.8%), "moderate competencies" (Class 2, $n = 140$, 52.4%), and "poor competencies" (Class 3, $n = 50$, 18.7%). Regression analysis suggested that professional title, years of employment, and BICU experience were influencing factors of NBDs' profile membership of core competencies. NBDs who were supervisor nurses or above (OR = 0.802, 95% CI: 0.009, 0.759), with more than 7 years of employment (OR = 0.091, 95% CI: 0.009, 0.906) and BICU experience (OR = 3.564, 95% CI: 1.423, 8.925) were more likely to fall into Class 1. *Conclusions*. Our findings could provide evidence for nursing administrators to develop training programs to enhance NBDs' core competencies. In particular, variables associated with profile membership determined in the study may facilitate more tailored training strategies.

1. Background

Burns can be caused by various factors such as fire, chemicals, or electricity, and they can lead to a significant financial burden on families and society [1]. Severe burns in China have an overall mortality rate ranging from 9.79% to 14.21% [2], highlighting the severity of this public health problem, particularly in developing countries where access to medical care is often limited [1]. Burn injuries can result in high rates of morbidity and disability, severely impacting the quality of life

and psychological well-being of burn victims [3]. Treatment of burns can be costly and often requires long-term care [4]. Given that nurses are the primary healthcare providers who interact with patients frequently during their hospital stay, it is imperative for nurses in burn departments (NBDs) to be equipped with advanced professional knowledge and specialized skills to provide high-quality care.

As is known, the definitions, mechanisms, and development of nurses' competencies have been explored in-depth in western countries [5–7]. Similarly, studies on specialized nurses in intensive care, operating rooms, emergency medicine, oncology, wound care, and intravenous therapy have been conducted frequently in China [8]. Relevant studies have also expanded to address vulnerable populations (elderly, infants, children, and pregnant women), chronic diseases (e.g., diabetes, chronic cardiovascular, and cerebrovascular diseases), and the improvement of quality of life (e.g., nutrition and rehabilitation) [9–12]. Moreover, previous literature suggests that practical assessments of nurses' critical thinking and clinical reasoning competencies in real-world contexts could improve the quality of nurses' work [13]. Despite the progress made in these areas, there is still a lack of research on the current status and training of NBDs' core competencies in China. Furthermore, the scope and standards of NBDs' core competencies have not been standardized yet.

To date, registered nurses are expected to possess core competencies that encompass knowledge, skills, and attitudes to provide high-quality and safe care to patients. The Burn Nurse Competency Initiative (BNCI) developed 45 burn nurse practice competency statements through a multistaged consensus-building method by the American Burn Association (ABA) [14]. In light of their contributions, Chinese researchers have also developed instruments to assess NBDs' competencies [15], while the "National Expert Consensus on Professional Standards for Chinese Nurses of Burn Department" was constructed with definitions, operating contexts, occupational/skill requirements, training, assessment, and certification. The Chinese Expert Consensus categorizes NBDs into junior, intermediate, and senior groups based on their professional level [16]. However, it is important to note that the Chinese expert consensus was not specifically for burn-specific principles but established for job qualifications.

As noted earlier, NBDs are crucial in burn prevention, emergency care, and continuity of care in developing countries [17–19]. Despite their importance, newly hired NBDs are often placed directly in burn wards or BICUs without specialized training. Instead, their training focuses on fundamental knowledge, leaving them lacking in the specific competencies necessary for burn care. Developing specialized skills in clinical settings requires repeated practice, which many novice NBDs are not receiving. At present, the competency profile of NBDs is inconsistent across China, as this field of work is still in its early stages. Thus, a comprehensive assessment of NBD competencies is necessary to ensure they are fully equipped for their vital roles.

To better understand NBDs' core competencies, we have previously reported their overall competencies and factors

affecting them [20]. In this research, we tried to utilize latent profile analysis (LPA) to help nursing administrators and policymakers tailor training programs. LPA allows researchers to identify subgroups of individuals based on shared attributes, enabling them to determine potentially diverse patterns of NBDs' competencies [21]. This person-centered approach has been used in previous nursing studies to identify subgroups related to workload, mental health, healthcare beliefs, or behavior, revealing associations with demographic characteristic [22–24]. By leveraging LPA findings, targeted actions can be taken to achieve favorable outcomes.

1.1. Study Aims. The purpose of this study was to investigate the current status of NBDs' core competencies through latent profile analysis, identify potential subgroups and their population characteristics, analyze the influencing factors of different categories, and provide a basis for developing targeted training programs.

2. Materials and Methods

2.1. Study Design. A cross-sectional study utilizing purposive sampling was carried out in 12 tertiary hospitals in China from March to June 2020. All study procedures followed the Karolinska Institute's ethical standards and the 1964 Helsinki Declaration and its later amendments. In addition, this study was reviewed and approved by the Ethics Committee of Changhai Hospital affiliated to Naval Medical University (No. 2020-54), and participants gave consent to complete the online survey.

2.2. Participants. The study was conducted amongst Chinese NBDs who delivered burn care from March to June 2020. Eligible participants were nurses who: (a) were registered nurses; (b) had work experience in burn departments (burn wards or BICUs) over one year; (c) gave informed consent and voluntary participation in this study. NBDs absent from work or taking time off for illness throughout the survey period were excluded.

2.3. Data Collection. We calculated the sample size of this study using the following formula: $N = Z^2 * S^2/d^2$, with Z (95% confidence level) = 1.96, S (overall standard deviation) = 0.8, and d (permissible error) = 10%. The minimum sample size N was obtained as 246, and we decided to deliver 296, considering a nonresponse rate of 20%. Through Wen Juanxing (https://www.wjx.cn, an online data collection website), we distributed an anonymous online survey (https://www.wjx.cn). We trained the administrators in charge of the participants over the phone and with WeChat to help survey before the questionnaires were distributed. Sampling was separated for each institution. All the participants responded to the online Wen Juanxing survey independently by scanning the QR Code via WeChat without the presence of researchers or nursing administrators. With a response rate of 98.6%, a total of 292 NBDs

working in burn departments at 12 tertiary institutions were recruited. There were no missing items in the 292 completed surveys because of the restriction of the answer system settings, but 25 of them were invalid and were removed from the dataset because of the detected all-the-same options. As a result, we received 267 valid questionnaires, and the effective response rate was 90.2%.

2.4. Measures. We collected data via online questionnaires, which included a socio-demographic questionnaire and the NBD Core Competencies Self-rating Scale (NBD-CCSS). The socio-demographic questionnaire collected general information such as age, professional title, length of employment, whether the participant had work experience in BICUs, and educational level. Based on a systematic literature review, we previously used the core competencies in the ICN framework for nurse specialists as a theoretical framework to develop NBD-CCSS [15]. The ICN framework was chosen due to its recommended competencies of a specialist nurse, which include knowledge, skills, judgment, and attributes, all under the premise of ethical and legal compliance. Health promotion, nursing process, therapeutic communication, and interpersonal relationships are among the fundamental care principles. However, the NBD-CCSS lacked dimensions on psychosocial help, aftercare guidance, end-of-life care, and team collaboration compared to the ABA's Burn Nurse Competencies. In China, we have not yet constructed tertiary hospitals radiating to community rehabilitation and postrehabilitation psychosocial support.

The NBD-CCSS includes nine dimensions and 100 items (see supplement 1). The nine dimensions are basic specialized knowledge, related specialized knowledge, basic specialized skills, related specialized skills, condition assessment, adverse nursing events, mass casualty care, critical thinking, and teaching skill. The items were rated using a Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). Sixteen experts assessed the content validity of the measure. The NBD-CCSS items' content validity index (I-CVI) was 0.8–1, while the scale's overall content validity index (S-CVI) was 0.976. The internal consistency test revealed that the NBD-alpha CCSS's Cronbach's coefficient was 0.984 and that each dimension's Cronbach's coefficient ranged from 0.824 to 0.958. The scale underwent exploratory factor analysis, and the entire scale's KMO coefficient was 0.951.

2.5. Statistical Analysis. SPSS (version 25.0) and Mplus (version 8.4) were used for data analysis. All the missing data were not included in the statistical analysis because 4 questionnaires were not submitted and 25 questionnaires had identical answers. After the data were cleaned, descriptive statistics were conducted for all variables. Continuous variables are displayed in mean ± standard deviation, and categorical variables were displayed in frequency and percentage. To accomplish the study aims, we identified latent profiles (subgroups) of NBDs' core competencies based on the nine dimensions of NBD-CCSS. Based on a specific set of factors, LPA enables the identification of latent subgroups within the population. To start, we determined the number of subgroups using the Bayesian information criterion (BIC), entropy, and bootstrapped likelihood ratio test (BLRT). Lower values of the BIC indicate higher fitness as it takes into account model fit and parsimony. Individual classification accuracy is referred to as entropy (values close to 1 are preferred). Significant p values indicate that the k-class model has more excellent fitness when BLRT compares it to the $k - 1$ class model.

Meanwhile, the one-way analysis of variance (ANOVA) and Chi-square analysis were used to analyze the distribution of the identified classes and their relationships with socio-demographic variables. Furthermore, we performed multinomial logistic regression to investigate the variables influencing profile membership. A statistically significant difference was accepted at a two-sided p-value <0.05.

3. Results

3.1. Fit Statistics for Latent Profiles. In this study, LPA was performed on NBDs' core competencies. We assumed equal variance between but zero covariance profiles while estimating for 2–5 profile models. The results of LPA are shown in Table 1. When comparing models, if the AIC and BIC are smaller, the entropy is higher, and the BLRT-p is less than 0.05, and the better the model fit is. As can be seen in Table 1, the 3-profile model has the highest entropy. The 4-profile model was not significantly better than the 3-profile model (p-value close to the critical value of 0.05) and had the lowest entropy. The 5-profile model had the lowest ABIC and AIC, but the proportion for the most minor class was only 0.022. Therefore, combining all indicators and model simplicity, the 3-profile model was found to be the optimal model for interpretation and additional analysis.

3.2. Distribution of Core Competencies in the 3-Profile Model. The distribution of core competencies in the 3-profile model is described in Table 2 and Figure 1. The mean scores of the NBD-CCSS's dimensions significantly differed among the 3 profiles (all $p < 0.001$). Class 1, the second largest profile ($n = 77$, 28.8%), had the highest levels of core competencies. Class 2 was the largest group ($n = 140$, 52.4%), while class 3 formed the smallest group ($n = 50$, 18.7%) and was characterized by the lowest levels of core competencies. Based on the results, class 1 was labeled as "skillful competencies," class 2 was labeled as "moderate competencies," and class 3 was labeled as "poor competencies."

3.3. Interprofile Characteristic Differences. The differences among the profiles concerning socio-demographic variables were examined (Table 3). Among the socio-demographic variables, significant differences were noted across profiles in age, professional title, education, length of employment, and experience in BICU (all $p < 0.05$). In

Table 1: Fit statistics for 2–5 latent profile models ($n = 267$).

Model	AIC	BIC	ABIC	Entropy	LMR-p	BLRT-p	Proportion

particular, Class 3 included the largest proportion of NBDs who were ≤25 years old, junior nurses, had junior college degrees, had less than three years of employment, and had no BICU experience.

3.4. Variables Associated with the Latent Profile Membership. In order to analyze whether different socio-demographic variables lead to different profiles of core competencies in NBDs, a multinomial logistic regression analysis was conducted. In this study, profile membership (Class 1–Class 3) was used as the outcome variable, and the predictor variables were age, professional title, length of employment, experience in BICU, and education. During the analysis, Class 3 was set as the reference group. The final results are shown in Table 4.

It can be seen that professional title, length of employment, and experience in BICU impacted profile membership, while age and education had no significant impact. In the comparison between Class 1 and Class 3, senior nurses were more likely to be grouped in Class 3 compared to supervisor (or above) nurses. However, in the comparison between Class 2 and Class 3, there was no significant tendency to profile membership for NBDs with different professional titles. Secondly, NBDs with 4-5 years of work experience were more likely to be assigned to Class 3 than those with more than 7 years. However, there was no tendency to profile membership when comparing Class 2 and Class 3 concerning the length of employment. In terms of experience in BICU, NBDs with BICU experience tended to be more likely to fall into Class 1 and Class 2, with a 2.564-fold and 1.304-fold increase in the probability of profile membership, respectively.

4. Discussion

This study identified three potential profiles of core competencies for NBDs: "skillful competency" at 28.8% ($n = 77$), "moderate competency" at 52.4% ($n = 140$), and "poor competency" with a percentage of 18.7% ($n = 50$). With an overall mean score of (3.69 ± 0.79), the mean core competencies of the 267 NBDs were at a medium level. Professional titles, years of employment, and BICU experience were determined as influencing factors of NBDs' profile membership of core competencies. Moreover, NBDs who were senior nurses with 4-5 years of employment were more likely to be grouped in Class 3, while those who were supervisor nurses or above, with more than 7 years of employment and BICU experience, tended to fall into Class 1.

Among the nine dimensions, the critical thinking (2.78 ± 0.88) and teaching skills (3.47 ± 0.76) dimensions were of the lowest scores—the same cases in the NBDs' three

potential profiles. Yue et al's team [25] also identified low evidence-based competencies in their previous study on burn specialist nurses in Hunan Province. Additionally, for the training of specialist nurses in China, there are training programs organized by nursing associations, such as the training of intensive care specialist nurses and operating room specialist nurses. Nevertheless, such programs are desired to be more systematic and standardized since 62.7% of them do not carry out recertification (Ding et al. [26]). Most Chinese specialist nurses gain progress through experience in relevant departments instead of systematic training [27, 28, 29]; Wang et al. This could explain our findings why NBDs lack the competencies necessary to recognize clinical issues, use scientific approaches to solve problems, raise awareness of research and teaching, and integrate theory with

practice. In the United States, colleges, boards, or organizations administer specialty certification programs that evaluate whether a nurse meets the criteria they have established in a specialty field of practice. Previous studies have widely reported correlations between specialty nurse certification and better patient outcomes and care quality [30]. Therefore, it should be a key concern for nursing administrators to develop a training and certification system for NBDs underlining critical thinking and teaching skills.

In addition, we also found that NBDs' sociodemographic characteristics differed across the potential profiles. NBDs' professional titles, length of employment, and BICU work experience influenced their profile membership of core competencies. NBDs who were supervisor nurses or above, had over seven years of employment and

BICU experience, had more probability of being grouped into the "skillful competencies" class than those who were senior nurses, and had 3–5 years of employment and no BICU experience. However, these factors did not impact the profile membership of the "moderate competencies" class. We are inclined to propose the following reasons: Firstly, there is a significant difference in the severity of burn patients, especially those with severe burns who are in critical condition and require a high level of competence in specialist burn care [31]. Therefore, their burn care requires more skilled nurses. Moreover, nurses with more seniority and BICU experience have more opportunities to care for severe burn patients. As a result, they are more likely to possess expertise in burn care, such as monitoring circulatory, respiratory, urinary, and other systems. Secondly, experienced nurses might realize their value in the care process, especially after solving complex clinical problems. This serves as their intrinsic driving force, coupled with support and empowerment from nursing administrators, which also enhances their extrinsic drive. All these drives could be facilitators for the self-transcendence of specialist nurses, as formerly reported by Wang et al. [32].

Furthermore, NBDs in the "poor competencies" profile were featured as having the largest proportion of those who were ≤25 years old ($n = 24$, 48.00%), junior nurses ($n = 26$, 52.00%), with a junior college education background ($n = 29$, 58.00%), with less than three years of employment ($n = 22$, 44.00%), and no BICU experience ($n = 39$, 78.00%). In accordance with Rizany et al's study [6], our findings gave more evidence to highlight the systematic training of novice nurses with lower educational levels. Through literature review, nursing associations have developed the concept of continuing competence, which has drawn attention worldwide [33]. Prior studies revealed that NBDs should possess emergency response capabilities due to burns' abrupt and batch nature Feng et al. [34]. Similarly, the literature on emergency nurses has also highlighted the need to understand their lack of knowledge and capability for a long-term career [35]. Hence, in addition to entry-level competencies, NBDs need to be continuously assessed regarding their core competencies. However, administrators are challenged with a lack of unified standards, practices, and frameworks for continuously assessing NBDs' competencies. This, therefore, makes our research more meaningful.

4.1. Recommendations for Future Research. Based on our study, we offer the following recommendations for cultivating NBDs' core competencies. It is important to provide enhanced training and support for both nursing managers and staff, as proposed by Avery and Cleaver [36]. Further research is needed to fully understand the impact of competence management methods on nurses. For example, previous studies have explored how contextualized simulation, such as burns suite [37] or Advanced Burn Life Support (ABLS) course [38], affects effective learning. Additionally, it is crucial to examine how nurses who fulfill their responsibilities can support clinical leaders. A noteworthy study conducted in Canada by Kandakoglu's team developed a system to assist administrators of nephrology departments by creating daily visit schedules and routes for nurses providing home dialysis treatment [39]. These recommendations can guide future research and help inform the development of targeted training programs to promote NBDs' core competencies.

4.2. Clinical Implications for Nursing Managers and Policymakers. The results of this study hold significant implications for nursing managers and policymakers who are responsible for designing and implementing training programs to recruit competent NBDs. The findings demonstrate that the professional titles, length of employment, and BICU experience of NBDs are closely linked to their core competencies. Hence, it is crucial for nurse managers to consider these subgroup characteristics when tailoring advanced practice programs for NBDs. This will enable them to match subgroups to appropriate training courses, thereby enhancing the overall quality of care provided by NBDs in hospitals. Policymakers can also utilize these study results to formulate evidence-based policy decisions related to the recruitment and retention of qualified NBDs in healthcare facilities. Overall, this study underscores the need for nursing managers and policymakers to be cognizant of the importance of targeted training programs that align with NBDs' specific core competencies.

4.3. Limitations of the Study. Although we made great efforts to ensure the accuracy of our data, this study still has several limitations. First, because the participants in this study were not randomly selected and primarily recruited from tertiary hospitals, the sample may not be sufficiently representative. Therefore, we advise broadening the study's scope to include more institutions. In addition, the competency assessment used self-reports, which might have led to possible bias. Several of the LPA's weaknesses should also be taken into account. On the one hand, while grouping based on LPA makes data presentation and interpretation easier, participants do not actually belong to a single group. Every participant's profile is assigned in light of the highest likelihood of belonging to a latent profile. On the other hand, although LPA makes it easier to identify associations between sociodemographic variables that may vary between profiles, it does not accurately reveal the specific factors driving these associations.

5. Conclusions

Based on potential profile analysis, this cross-sectional study explored the subgroup characteristics and influencing factors of NBDs' core competencies. We identified three profiles of NBDs' core competencies across the nine dimensions of NBD-CCSS, consisting of skillful competencies (Class 1, 28.8%), moderate competencies" (Class 2, 52.4%), and poor competencies (Class 3, 18.7%). NBDs in Class 1 had the best performance across all dimensions, while those in Class 3 had the reverse performance. Moreover, we found that potential influencing factors of profile membership

included professional titles, length of employment, and BICU experience. Nursing administrators and educators can form alternative professional training and career development plans depending on the subgroup characteristics of NBDs' core competencies. Meanwhile, it is advised that more research be done in order to create specific training programs geared to those subgroups.

Data Availability

Data presented in this study are available on request from the corresponding author.

Additional Points

Implications for Nursing Management. Our results indicate a critical need to improve Chinese NBDs' core competencies and optimize the training system. Interventions at the departmental and organizational levels are desired to support specialized training for NBDs.

Ethical Approval

All study protocols adhered to the Karolinska Institute's ethical guidelines as well as the Helsinki Declaration of 1964 and its subsequent amendments. In addition, this study was reviewed and approved by the Ethics Committee of Changhai Hospital affiliated to Naval Medical University (No. 2020-54), and participants gave consent to complete the online survey.

Disclosure

All authors have approved the manuscript for publication, and it is an original study that has never been published previously and is not being considered for publication elsewhere. Ping Feng, Ping Feng, Jianling Hao and Yuan Wang are cofirst authors.

Conflicts of Interest

All authors declare that they have no conflicts of interest.

Authors' Contributions

Zhang Lingjuan, Liyan Gu, and Ping Feng designed the study. Yuan Wang, Xiaoying Lu, Yuanyuan Zha, Xinyu Li, Lin Zhou, Ning Li, Jianfang Zhang, Qin Zhou, and Shujun Wang collected the data. Jianling Hao and Yuan Wang designed and developed a database for the study. Liyan Gu and Ping Feng carried out data analysis and produced the initial draft of the manuscript. Lingjuan Zhang and Jianling Hao contributed to revising the manuscript. All authors have read and approved the final submitted manuscript.

Background. Nursing educational research is very important for the development of the nursing discipline. There have been many randomised controlled trials (RCTs) of nursing education, and the outcomes are highly heterogeneous and waste resources. The study aims to report the methodological framework to establish a core outcome set (COS) for RCTs of nursing education. *Methods.* The study will be conducted in the following five steps: (a) establish nursing education COS working groups; (b) develop an initial list of outcomes of nursing education by systematic review and semistructured interview; (c) Delphi survey with different stakeholders to reach a preliminary consensus on the core outcome of nursing education; (d) expert consultation to form the outcome pool; (e) expert consensus meeting to form the nursing education COS. *Results.* The goal is to develop a COS that includes stakeholders' interest in nursing education to determine which outcomes should be reported and how they should be measured. *Conclusions.* By performing the study, the nursing education COS will be established, which will help to reduce reporting bias and resource waste, and provide enough results for nursing education systematic reviews.

1. Introduction

With the increasing aggravation of the ageing population, the nursing discipline's development is increasingly important [1, 2]. Nursing discipline depend on the development of nursing education [3–5]. New nursing teaching theories [6], teaching methods [7], and teaching models have been applied more and more in nursing education, such as the problem-based learning teaching model [8], integrated teaching model [9], core ability teaching model, massive open online course teaching model, and flipped classroom teaching model [10]. They have promoted the development of nursing education. In addition, new technologies such as artificial intelligence and virtual reality [11] have been increasingly applied to nursing education. With the introduction of new theories, methods, and models in nursing education, evaluating the effect of these methods is very important and designing randomised controlled trials (RCTs) is very important [12, 13].

In the nursing education field, an RCT is always performed to compare the different effects of the intervention and control methods and to identify the importance of the

teaching method [14–17]. It aims to find the importance of improving outcomes and strategies for promoting nursing education [18–23]. There have been many RCTs on nursing education; however, the reported outcomes were heterogeneous [18–23]. Some used test scores [19], some used satisfaction [14], some used success rate [21], and some used 'nursing students" knowledge and confidence [23]. Inconsistencies of outcomes will lead to the low use of studies in the systematic review [24]. It also makes the results inaccurate and unlikely to meet the needs of stakeholders. Therefore, outcomes must be standardised to reduce heterogeneity and waste resources for nursing education.

Developing a core outcome set (COS) will address these issues [25, 26]. The COS is a collection of the smallest and most important outcomes that should be measured and reported in a trial in the same health problem or social care area [27, 28]. It aims to improve research utility by involving stakeholders' perspectives and reducing inconsistency, reporting bias, and research waste [29–32]. In recent years, with the continuous application of new technologies in nursing education, implementing new RCTs requires the standardisation of outcomes. However, there was no COS for nursing education. Therefore, developing nursing education COS is needed. The development of COS will not only help to demonstrate different perspectives in this important area but also provide, for the first time, a standardised set of outcomes to be used in nursing education research and practice to assess the effect of nursing education and help to design research of nursing education.

2. Methods

2.1. Ethical Consideration and Registration.
The current study is a methodological framework for producing a COS but not for patients. When it is needed, ethical approval will be obtained from West China Hospital of Sichuan University. To be transparent, the methodological framework will be submitted to the peer-reviewed journal, and the methodological framework has also been submitted to register in the Core Outcome Measures in Effectiveness Trials (COMET) database. The methodological framework of the COS was reported according to the core outcome set standards for protocol items [33]. The main steps of the nursing education COS study are showed in Figure 1 and as follows.

2.2. Step 1: Establish Nursing Education COS Working Groups.
According to the handbook, a steering group will be established [33]. The COS steering group will be composed of 3 multidisciplinary experts, including a nursing education manager with at least 20 years of work experience, an evidence-based medicine methodologist with at least ten years of research experience, and one nursing expert with at least 20 years of work experience. The primary responsibilities of the committee are: to determine the scope of COS, to approve COS methodological framework, to oversee the COS development process, and to provide advice and guidance for COS development as necessary. In addition, the

research group will also be established. The research team will invite experts from universities in China, such as Sichuan University, Peking University, Fudan University, and so on.

2.3. Step 2: Develop an Initial Outcome List Covering All Relevant Outcomes.
There will be three parts of the work, namely, [1] systematic review, [2] semistructured interview [24, 30, 34, 35], and merge and group outcomes.

2.3.1. Systematic Review of the Outcomes in the RCTs for Nursing Education

(1) Search Strategy. The research group will search the following databases to identify outcomes reported in RCTs for nursing education published in 2021 and 2022: PubMed, Embase, The Cochrane Library, CNKI, CBM, and WanFang Data. The search strategies of PubMed are as follows: (nursing education OR nurse education OR nursing students OR nurse students OR nursing student OR nurse student) and (trial OR RCT OR randomised clinical trial OR systematic review OR meta-analysis). The language will be limited to English and Chinese.

(2) Eligibility Criteria. The inclusion criteria are as follows: the study should be RCT, the study should be for nursing education, the language should be Chinese or English, and the outcomes should be involved with the effectiveness of nursing education. The exclusion criteria are as follows: the page number of the study is only 1 page, the single author's publication, the study is for the patients, the study is for evaluating disease mechanism or pharmacokinetics of drugs, and the full text of the study could not be obtained.

(3) Study Selection and Data Extraction. Two authors will independently screen the titles and abstracts according to the inclusion and exclusion criteria to find the RCTs of nursing education. Any disagreement will be resolved by discussion [24, 30, 34, 35]. Two authors will independently extract the following items: the characteristics of the study, journal, author, and year; the characteristics of the intervention; and the outcomes. Any disagreements will be resolved by discussion. All outcomes will be included.

2.3.2. Semistructured Interviews of Stakeholders

(1) Participant Selection. The outcomes generated by systematic reviews only reflect outcomes from research; the opinion of the nurse students, nursing teachers, and nursing education managers should also be considered. Thus, nurse students, nursing teachers, and nursing education managers will be invited to participate in the semistructured interviews. The inclusion criteria are as follows: (a) nursing students: undergraduate nursing students in school for at least one year, willing to participate in the study; (b) nursing

FIGURE 1: The development process for nursing education-COS.

teacher: at least five years of nursing education or clinical nursing work, had ever participated in nursing education research, bachelor's degree or above, willing to participate in the study; (c) nursing education manager: at least five years of nursing education managing work, had ever participated in nursing education research, bachelor's degree or above, willing to participate in the study.

(2) Recruitment and Data Collection. The authors will invite nurse students, nursing teachers, and nursing education managers from the West China Hospital of Sichuan University. The author will also invite nurse students, nursing teachers, and nursing education managers from other nursing schools to participate. As shown in previous studies [24, 30, 34, 35], when the sample size is 30, it will achieve data saturation; therefore, the author will include 30 nurse students, 30 nursing teachers, and 30 nursing education managers. If new information is generated in the interview,

the sample size will be expanded as previously suggested [24, 30, 34, 35].

The authors, who have been trained in qualitative research methods, will conduct the interview and introduce the purpose and content of the interview to the participants. All participants will receive and read separate written information. The participants who agree to participate in the interview will provide their signed informed consent. After obtaining the participants' consent, the interview's content will be recorded in audio. The information on demographic characteristics will also be recorded. The interview will be mainly performed in China. Face-to-face interviews or online interviews will be used when it is possible.

The outline of the semistructured interviews for nursing teachers and nursing education managers: How long have you been a nursing teacher or a nursing education manager? What intervention will you give to nursing education? Which outcome do you think is the best intervention to

improve nursing education? Please write down at most five outcomes that you think are important for nursing education.

The outline of the semistructured interviews for nursing students is as follows: What is your grade? What intervention have you received because of nursing education from your nursing teacher? Which outcome of intervention do you want to improve after education? Which outcome do you want the intervention to improve most?.

(3) Data Analysis. Two authors will independently analyse the results of semistructured interviews to identify the important outcomes for RCTs of nursing education. The authors will conduct all interview transcriptions using the qualitative analysis software NVivo 12 plus. Two researchers will first read all transcripts to familiarise themselves with the data and develop a structured coding tree that starts with an inductive open coding. The transcripts and open coding will be initially coded individually by the two researchers. To ensure consistency and reliability of the process, themes will be sought, reviewed, defined, and named. Inconsistency will be discussed until reaching a consensus. After review by the steering committee, the new outcomes will be added to the list of outcomes.

2.3.3. Merging Outcomes and Grouping Outcomes into Different Domains. Based on previous COS studies [24, 30, 34, 35], the outcomes from the systematic review and the semistructured interviews will be merged and grouped into different domains. Nursing student-reported, teacher-reported, and nursing education manager-reported outcomes will be categorised [24, 30, 34, 35]. Two researchers will independently conduct this process. Any discrepancies will be resolved through discussion or by consulting the steering group.

2.4. Step 3: Delphi Survey with Different Stakeholder Groups to Prioritise the Outcomes. Delphi survey will be performed as previously reported [24, 30, 34, 35]. The Delphi manager is based on a web system to build and administer the Delphi surveys [24, 30, 34, 35].

2.4.1. Stakeholder Selection. The researchers will invite nursing teachers, nursing students, nursing educational managers, and nursing education researchers to participate in the three rounds of the Delphi survey [24, 30, 34, 35]. Representatives of the stakeholder groups are as follows: (a) nursing students: undergraduate nursing students in school for at least one year who are willing to participate in the study; (b) nursing teacher: at least five years of nursing education or clinical nursing work, had ever participated in nursing education research, bachelor's degree or above, and willing to participate in the study; (c) nursing education manager: at least five years of nursing education managing work, had ever participated in nursing education research, bachelor's degree or above, and willing to participate in the study; and (d) nursing education researcher: first author or

contact author of publication of nursing education, at least five years of nursing education or nursing clinical research work, bachelor's degree or above, and willing to participate in the study. There is no restriction on the geographical area of participants. As there has been no standard sample size calculation method in the Delphi survey in the development of the COS study [24, 30, 34, 35], referring to the previous COS studies, the researchers plan to select 30 participants for each stakeholder group.

2.4.2. Consensus Standards. The consensus standards will be defined as previously reported: (a) ≥70% of participants scored the outcomes as 7 to 9, and <15% of the participants scored the outcomes as 1 to 3, and the outcomes will be included; (b) ≤50% participants scored the outcome as 7–9, and the outcomes will be excluded [24, 30, 34, 35].

2.4.3. Three Rounds of Delphi Survey and Data Analysis. All candidate outcomes of nursing education will be included in the questionnaire [24, 30, 34, 35]. The questionnaire will be in two versions: for nursing teachers, nursing education managers, and researchers, and for nursing students. All participants will register in the Delphi manager and sign the informed consent [24, 30, 34, 35]. All participants will score the candidate items via the online survey and can add new outcomes that are not included in the outcome list [24, 30, 34, 35]. Additional materials will also be sent to them for reference. They can also contact the authors for further details if they have any questions. Each round of the Delphi survey will be planned in three weeks, and the author will send two emails at the end of the first and second weeks to remind the participants. If the response rate is <80% at the end of the third week, the time will be prolonged.

Descriptive analysis will be applied to analyse the results of the Delphi survey of different stakeholders. An outcome is scored as ≥4 by ≥70% of the participants in any stakeholder group who complete the questionnaire in round 1 will be included in round 2. In round 2, the participants will need to re-score the outcomes, the outcomes that agree with the consensus standards will be directly included in the consensus meeting, and the rest of the outcomes will be surveyed in round 3.

2.5. Step 4: Expert Consultation and form the Outcome Pool for the Expert Consensus Meeting. Expert consultation will be performed after analysing the results of the Delphi survey. The research team will invite one nursing teacher, one nursing education manager, one nursing education researcher to work with the steering committee to discuss the results of Delphi and determine the outcome pool for an expert consensus meeting.

2.6. Step 5: Consensus Meeting. After the development of the outcome pool, a face-to-face consensus meeting will be held with key stakeholders to finalise the COS. The consensus meeting will be held in Chengdu in China.

2.6.1. Participants of the Consensus Meeting. As reported in previous studies, there is no standard method to calculate the sample size for the consensus meeting in the development of COS studies [30]. Therefore, the researchers will invite 20 to 25 stakeholders to participate in the consensus meeting, including (a) nursing teachers who have more than ten years of teaching experience; (b) nursing education managers who have more than ten years of nursing education managing work; (c) evidence-based medicine methodologists; (d) nursing education researchers with a master's degree or above; (e) journal editors; and (f) nursing students.

2.6.2. Process of the Consensus Meeting. First, the potential outcomes from the survey will be reported to the stakeholders, and the stakeholders will decide whether the outcomes meet the consensus criteria [24, 30, 34, 35]. In addition, the less consistent outcomes will be discussed [24, 30, 34, 35]. Finally, the stakeholders will vote for each outcome. The detailed information of the consensus definition will be based on the previously mentioned [24, 30, 34, 35]. The nursing education COS will finally be formed.

3. Discussion

Nursing education research is important for developing nursing discipline and has significance for nursing management [4, 5]. However, the results have been very heterogeneous due to the heterogeneous outcomes of previous RCTs in nursing education. Many results cannot be included in a systematic review to produce evidence. Therefore, it is necessary to carry out the study of COS for nursing education.

At present, COS studies have been published in several disciplines, promoting the standardisation of outcomes in trials and reducing research waste [24, 30, 34, 35]. However, there is a need for COS in nursing education. Due to the wide range of nursing disciplines, the COS in nursing education will promote nursing education to a certain extent and improve the results of nursing education.

The current study reports a comprehensive methodological framework for COS of RCTs of nursing education by conducting a systematic review, semistructured interview, Delphi survey, expert consultation, and consensus meeting [24], which can ensure the feasibility and promotion of COS in future RCTs for nursing education. The development of COS will help the consistency of reporting study outcomes of RCTs for nursing education and reduce reporting bias [30]; then, the results of different RCTs can be compared and merged to improve the value of interventions and reduce waste resources for nursing education.

4. Implications for Nursing Management

Standardisation of the outcomes and establishing a COS will be helpful to reduce reporting bias, reduce resource waste, and help the management of nursing education research. The current methodological framework will be helpful to develop a COS for RCTs in nursing education; thus, it will help the management of nursing research and nursing education.

Data Availability

No underlying data was collected or produced in this study.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Introduction. This study introduces the Portuguese Transcultural Nursing Leadership Questionnaire (QLTE-PT), a pioneering instrument designed to assess leadership behaviours in multicultural nursing work environments, addressing gaps in current leadership assessment tools. *Aim.* This study aimed to develop and validate the Portuguese Transcultural Nursing Leadership Questionnaire (QLTE-PT). *Methods.* It was conducted as a sequential exploratory mixed-method study, integrating DeVellis's steps for instrument development. Items were formulated based on a literature review and a focus group study, and the content validity was evaluated by a panel of experts. A methodological approach involving nurses registered in the Portuguese Order of Nurses with leadership experience in multicultural nursing work environments was employed to further conduct an exploratory and a confirmatory factor analysis to assess the instrument's structure and psychometric properties. *Results.* One hundred forty-five items were initially generated, of which 39 were included in the QLTE-PT following content validity assessment by a panel of experts. EFA revealed a factor structure of 25 items loading on six factors, explaining 64% of the total variance. The overall Cronbach's α coefficient of the questionnaire was 0.90. This six-factor structure was tested by CFA, revealing a final model of 23 items and six factors, with a good quality of adjustment (CFI = 0.980, TLI = 0.976, SRMR = 0.078, and RMSEA = 0.070). Both convergent and discriminant validity were confirmed. *Conclusions.* The QLTE-PT demonstrates good psychometric properties and is suitable for assessing transcultural leadership behaviours of nurse managers and leaders in multicultural nursing work environments. *Implications for Nursing Management.* The QLTE-PT can assist nurse managers to improve their leadership behaviours, promote supportive working environments for their multicultural nursing staff, and improve the quality of care provided to patients from different cultural backgrounds.

1. Introduction

The interconnectedness and interdependence between nations, along with the exchange of people, goods, services, and information, have contributed to cultural diversity in workplaces, communities, and globally. This requires leaders who can guide multinational projects and lead people or groups from different cultural backgrounds in organizations, producing appropriate responses to their customers' needs with different cultures and expectations [1, 2]. Against this backdrop, the concept of transcultural leadership has gained prominence, advocating for the development of people and organizations equipped to address the challenges that arise from globalization, increased competition, and power asymmetries [3].

Defined as the process of articulating, implementing, and nurturing a global cultural vision and creating multicultural synergy [4], transcultural leadership is pivotal in various sectors, including healthcare. Within the nursing discipline, transcultural nursing leadership focuses on the culturally sensitive transformation journey. This involves tailoring behaviours, processes, and products to meet the cultural needs of both nurses and patients, challenging traditional paradigms, and guiding the delivery of culturally congruent care [5]. Such leadership is essential not only for delivering culturally congruent care to patients and achieving optimal health outcomes for all populations [6, 7] but also for effectively managing the challenges of culturally diverse nursing teams [5].

Cultural diversity among patients and healthcare professionals is a current scenario in Portuguese healthcare organizations [8]. Portugal hosts more than half a million of immigrants [9], who face several difficulties when accessing health services, such as discrimination, lack of information and knowledge on how the Portuguese healthcare system works, administrative barriers, and cultural and linguistic barriers that hinder communication with the employees and healthcare professionals of the National Health Service [10]. According to a study developed by Dias et al. [11], a majority of immigrants consider that having been in Portugal for a short time (85.1%), lacking knowledge about legal rights to health access (78.9%), being alone in Portugal (76.9%), having insufficient financial resources (75.6%), existence of complex bureaucratic procedures for health services access (75.2%), language differences (59.8%), absence of interpreters (49.5%), challenges in expressing symptoms and recognizing illness (46.9%), distrust towards health professionals (45.7%), and beliefs, religious, and cultural traditions (27.7%) are factors that condition their access and utilization of health services in Portugal.

In addition, recent data from the Portuguese Order of Nurses Ordem dos Enfermeiros [12] reveal that 1348 nurses registered in 2022 were from foreign countries. According to Silva and Fernandes [13], despite the reports of a good welcome, immigrant nurses report challenges and difficulties during their integration in Portugal. These difficulties and challenges are related to the recognition of academic degrees and the differences in roles, skills, autonomy, and hierarchy in professional relationships, working conditions/resources, and language, particularly differences in technical nursing terms between Portugal and their home countries. Foreign nurses in Portugal also identify experiences of discrimination from patients and colleagues and unequal treatment by their managers, such as discrediting their knowledge, exclusion from training, unbalanced work distribution, abuse of power, and no opportunities for professional development, specifically being a team leader or mentoring nursing students [13]. According to Primeau et al. [14], it is important that organizations ensure healthy work environments free of discrimination and with opportunities for this particular group of nurses to achieve their career goals.

The diversity and related challenges in Portuguese healthcare settings highlight the need for a nuanced understanding and effective management of cross-cultural dynamics, accentuating the importance of transcultural nursing leadership. Nurse managers are pivotal in this context, as they are responsible for promoting culturally congruent care to patients from different cultural backgrounds and developing favorable work environments for multicultural nursing teams [15]. The challenges they face in providing better support to their teams and developing effective leadership styles [16], especially when managing nurses from different cultures, are significant. This complexity is a growing concern in Portugal [17–21] and the complexity that cultural diversity adds to these environments must be recognized.

There are no studies or instruments to assess transcultural nursing leadership. The most commonly used tools to assess nursing leadership competencies are the Ambulance Nurse Competence scale, Leadership Practices Inventory, Clinical Leadership Needs Analysis Instrument, Cotter Preceptor Selection Instrument, Performance Evaluation Tool, Leadership and Management Inventory, Advanced Practice Nursing Competency Assessment Instrument, and Kuopio University Hospital Transformational Leadership Scale [22]. Given the absence of instruments assessing transcultural nursing leadership in multicultural settings, i.e., in healthcare settings where nurses from different cultural backgrounds work and where care is provided to culturally and linguistically diverse patients, this study aimed to do the following:

(1) Develop the Portuguese Transcultural Nursing Leadership Questionnaire (QLTE-PT) specifically tailored to assess nurse leaders and managers' leadership behaviours in multicultural nursing environments in Portugal

(2) Validate the QLTE-PT by assessing its internal consistency, confirming its construct validity through exploratory and confirmatory factor analyses, and establishing both its convergent and discriminant validity

2. Materials and Methods

A sequential exploratory mixed-method study was conducted in two stages [23]. The first stage aimed to develop the questionnaire. The second stage followed a quantitative study to analyze its psychometric properties.

The questionnaire development and validation process were based on DeVellis's [24] steps for instrument development which are as follows: (a) determine what is intended to be measured; (b) generate a set of items; (c) determine the measurement format of the instrument; (d) review the set of items formulated from a panel of experts; (e) consider the inclusion of validation items; (f) apply the items to a sample; (g) evaluate the items; and (h) optimize the dimensionality of the instrument.

2.1. Generate a Set of Items. Items were generated based on a scoping review and a focus group, which are both strategies to generate a pool of items for new instruments [25, 26].

2.1.1. Scoping Review. The scoping review was conducted in accordance with JBI guidelines [27], aiming to map the personality traits, competencies, behaviours, and leadership styles of nurse leaders and managers impacting the outcomes of multicultural nursing teams. Papers published in English, Portuguese, and Spanish languages were searched through electronic databases, such as CINAHL, MEDLINE, Nursing & Allied Health Collection, MedicLatina, Psychology and Behavioural Sciences Collection, Wiley Online Library, and Scopus. We did not restrict the publication dates in our scoping review due to the lack of previous literature reviews on this topic. This approach enabled us to

comprehensively access the best available evidence without temporal constraints. The search strategy comprised the following keywords: nursing leadership, leadership traits, competencies, behaviours, skills, and styles; multicultural nursing teams, and nurses' outcomes.

2.1.2. Focus Group.

A qualitative, exploratory focus group study was conducted to explore the strategies used by nurse managers in creating favorable work environments for multicultural teams and delivering culturally congruent care to diverse patients [28]. A convenience sample of five Portuguese nurses with experience leading multicultural nursing teams was recruited to participate in the study. A semistructured interview was performed with questions aimed at eliciting participants' insights on transcultural nursing leadership, effective management interventions for multicultural nursing teams, and strategies to improve culturally congruent care. Qualitative data were recorded and transcribed for content analysis.

Based on the results of both studies, a list of the most relevant nurse leaders and managers' behaviours in multicultural nursing work environments was produced. The items were revised to ensure appropriate wording and to remove duplicates. A first draft of the questionnaire was prepared.

2.2. Determine the Measurement Format of the Instrument.

All items of the questionnaire were scored based on a 5-point Likert scale ((1) "never," (2) "rarely," (3) "sometimes," (4) "frequently," and (5) "always"), representing a continuum of the frequency of nurse leaders or managers' behaviours in multicultural nursing work environments. This choice is based on Boateng et al.'s [25] guidelines, which advocate that response scales with five to seven points have higher reliability than Likert-type response scales with less than five points.

2.3. Reviewing the Set of Items Formulated from a Panel of Experts.

Once the items had been formulated, an assessment of the questionnaire's psychometric properties was conducted to analyze whether it was adequate and accurate in assessing transcultural nursing leadership, as well as to evaluate its validity and reliability [29]. This stage comprised two phases: content validity and construct validity.

Content validity is invaluable for the quality of a newly developed instrument [29]. Since there is no specific statistical test for this purpose, it is common to use a panel of experts to assess the set of items formulated and validate whether they accurately represent the construct measured by the new instrument [30].

The experts were recruited by convenience in a Portuguese association of nurse managers and leadership. Following the recommendations of Polit and Beck [26], it was defined that at least two rounds would be performed to determine the content validity of the items and the questionnaire as a whole. In the first round, each item was assessed regarding its degree of relevance, clarity, simplicity

and ambiguity, on a scale of 1 (not relevant) to 4 (very relevant), according to the criteria described by Yaghmale [31]. Once assessed in each criterion, the content validity index of each item (I-CVI) was calculated based on the ratings assigned by the experts regarding its degree of relevance [26, 29].

Following the authors' recommendations, it was determined that items with a I-CVI of <0.78 would be excluded from the questionnaire [26, 29]. The items with a I-CVI of ≥0.78 but with values of <1 in the criteria of clarity, simplicity, and ambiguity, estimated according to the previous formula were reformulated. After this process of item deletion and reformulation, a second round of relevance assessment of the remaining and reformulated items was carried out. The I-CVI of each item was calculated and the overall content validity index of the questionnaire (Ave-CVI) was estimated from the average of the I-CVIs [29]. It was considered that a I-CVI ≥0.78 on each item and an Ave-CVI of ≥0.90 would be indicative of an excellent content validity [26]. The estimated value of Ave-CVI in the second round would determine the need for questionnaire reformulation and additional rounds.

2.4. Consider the Inclusion of Validation Items.

Although it is possible to include additional scales that may provide information about the validity of the final questionnaire [24], it is recommended that researchers limit these efforts at this stage of developing a new instrument. According to Worthington and Whittaker [32], it is advisable to keep the overall length of the questionnaire as short as possible and directly related to the central aim of the study. Worthington and Whittaker [32] also argue that there is a potential risk that items from other scales may interact with the items designed for the new instrument, interfering with its development process. Therefore, it is important to avoid influencing the items' responses during the initial phase of instrument development, thus limiting the use of additional measures [32]. Understanding the risks highlighted by Worthington and Whittaker [32], it was decided to not include validation items as recommended by DeVellis [24].

2.5. Evaluating and Refining the Instrument.

Following the establishment of content validity, a quantitative and cross-sectional study was conducted to identify the core dimensions of transcultural nursing leadership and to confirm the reliability of the instrument. For this purpose, an exploratory factor analysis (EFA) was performed followed by a confirmatory factor analysis (CFA).

Nurses registered in the Portuguese Order of Nurses in the categories of nurse manager, nurse specialist, or nurse, with current or past leadership experience in multicultural nursing work environments were invited to participate in this study. Nurses without leadership experience in multicultural nursing work environments were excluded. The sample size was based on guidelines recommending five to ten participants for each questionnaire item to ensure a robust analysis in EFA and CFA [33].

During EFA, the correlations between items were assessed using the Kaiser–Meyer–Olkin (KMO) measure to ensure that they were suitable for factor analysis. The analysis was then performed using an appropriate estimator for ordinal data (WLSMV), robust to deviations from normal distribution [34]. For the extraction of factors in our EFA, we employed the principal component as the method to identify the initial structure of latent factors, followed by an oblique rotation to explore the relationships between these factors. The number of latent factors identified considered both the eigenvalues greater than 1 and the scree plot. We then retained factors explaining a significant portion of the total variance and removed individual items with factor loadings below 0.50.

The instrument was refined by repeating EFA, ensuring that each factor was reliable and represented by at least two items. The quality of the factor structure was assessed using the root mean square residual (RMSR) index.

Confirmatory factor analysis was performed to assess the validity of the factor structure identified in EFA. It analyzed the existence of outliers by analyzing the square distance of Mahalanobis (D^2). The normality of the variables was assessed by the uni- and multivariate asymmetry ($|Sk| < 3$) and kurtosis ($|Ku| < 10$) coefficients [35]. The quality of the model was assessed through the indices proposed by Brown [36] and Marôco [35]: CFI (<0.8: bad fit), TLI ((0.9; 0.95): good fit), SRMR (≤0.08: good fit), and RMSEA (>0.08–0.10: unacceptable; (0.05; 0.08): acceptable; and ≤0.05: very good). Necessary adjustments were made based on modification indices greater than 11 and theoretical justification, as recommended by Marôco [35].

Finally, item reliability was assessed based on the proportion of variance accounted for by the latent factor, with a target value of 0.25 or higher [35]. The overall instrument's reliability, as well as that of individual factors, was determined using Cronbach's alpha, setting a minimum acceptable level of 0.70 [37]. Construct validity was established through analyses of convergent and discriminant validity [30, 35]. Missing values were handled with the pairwise method in both EFA and CFA.

All statistical analyses were conducted in RStudio (© 2009–2022 RStudio, PBC) using packages "polycor," "psych," "lavaan," and "lavaanPlot."

2.6. Ethical Considerations. This study was first approved by the Ethics Committee of the Nursing School of Lisbon (approval no. 216/2022/CE), as part of the doctoral research project. Authorization and support were requested from a Portuguese association of nurse managers and leadership to recruit nurses to integrate the panel of experts to perform the content validity of the questionnaire. Once the content validity phase was completed, authorization and support were also requested from the Portuguese Order of Nurses to disseminate the study to its members and invite those with the experience of leadership in multicultural nursing work environments to complete the questionnaire online. All participants approved their participation through an electronic consent form, without which they could not proceed to data collection. All participants were informed that they could withdraw from the study at any moment. Anonymity and data confidentiality were guaranteed.

3. Results

3.1. Generation of Items. A total of 115 and 63 items were formulated from the scoping review and the focus group study, respectively. After removing duplicates and similar items, 145 items composed the initial version of the QLTE-PT.

3.2. Content Validity. A total of six members of the Portuguese association of nurse leaders and managers participated in the panel of experts, meeting the minimum number of experts recommended to assess the content validity of an instrument [29]. Half of the participants were female, with a mean age of 53.8 years (SD = 7.7) and 31.7 years of professional experience (SD = 7.4). More than 50% held a master's degree or PhD degree, 16.7% were nurse specialists, and 16.7% had a bachelor's degree. About 67% were nurse managers. All experts of the panel stated that they worked or had worked with professionals from different cultural backgrounds, but none of them were or had been emigrants. None of the participants had education in multiculturalism.

Of the 145 items rated by the experts regarding their degree of relevance, 98.6% ($n = 143$) had a I-CVI ≥ of 0.78. Two items were excluded from the questionnaire due to I-CVI = 0.67. Only two participants wrote comments/suggestions for improvement, which were "simplify some items." In some cases, it may even be necessary to "split one item into two" and "some questions were too long, which makes it difficult to answer them." However, these two participants did not specify items for these actions. Due to the lack of specific guidance on which items to modify, a conservative approach proceeded in the revision process. The original structure of the items was maintained, focusing instead on improving items' clarity, simplicity, and reducing ambiguity. Fifty-one items, which had clarity, simplicity, or ambiguity indices below 1, were rephrased. These revised items, along with the others, constituted a set of 143 items that underwent a second round of evaluation. Five of the six experts from the previous round participated in the second round. Of the 143 items, 94.4% ($n = 135$) obtained a I-CVI of ≥0.78 and eight were eliminated due to a I-CVI of <0.78. No comments or suggestions for improvement were made in the second round. The questionnaire showed an Ave-CVI of 0.96. As a strategy to obtain a more parsimonious set of items, it was decided to consider the items' Content Validity Ratios (CVRs).

Twenty-nine items were identified as essential/very relevant with CVR = 1. It was decided to retain 10 additional items, despite having a CVR of <1, given their relevance highlighted in the literature. For instance, item "I adapt my leadership style according to the expectations, values, habits, beliefs, and cultures of the members of the nursing team member" was aligned with established theoretical

frameworks [3, 38] and empirical studies [5, 28] within the field that underscore their significance in assessing transcultural leadership. These decisions resulted in a total of 39 items included in the QLTE-PT, categorized into seven hypothetical dimensions: impartiality and nurse manager's ability to adapt, understand, accept, and respond to cultural differences; professional and sociocultural integration of immigrant nurses; standardization of nursing practice; supporting professional development; managing problems in multicultural teams; intercultural communication; and culturally congruent services and care. Figure 1 summarizes the process of item generation, inclusion, and exclusion from the QLTE-PT.

3.3. Reliability of QLTE-PT

3.3.1. Sample Characteristics. Four hundred and sixty-three nurses answered the questionnaire between November 2022 and March 2023, among whom 79.3% were female and 21.7% were male. The average age of the participants was 41.3 years (SD = 10.6), and the mean length of professional nursing experience was 18.2 years (SD = 10.6). More than 20% reported working or having worked abroad, namely, in Belgium, Brazil, Cape Verde, France, Germany, Guinea-Bissau, Indonesia, Oman, São Tomé and Príncipe, Saudi Arabia, Switzerland, Timor-Leste, and the United Kingdom. Data about education level, professional category, work unit, exposure to other cultures and in which context, training in multiculturalism, and international professional experience are comprehensively presented in Table 1.

3.3.2. Exploratory Factor Analysis. EFA was performed to identify the relational structure among the 39 items of the QLTE-PT. The findings of the preliminary factor analysis showed a KMO value of 0.85, which indicates the adequacy of the instrument's items for factor analysis. The factorability was confirmed for the 39 items by Bartlett's test of sphericity ($X^2 = 1370.5$; $p < 0.001$).

According to the criterion of eigenvalue greater than 1 and in line with the scree plot, the relational structure of the QLTE-PT would be explained by the nine latent factors explaining 73.2% of the variance. This initial factor structure of the questionnaire resulted in a problematic factor with only one item (item A32). Subsequent attempts to refine the structure by extracting eight factors still yielded another one-item factor (item A17). Even when reducing the factors to seven, the internal consistency of the two factors fell below the recommended threshold of 0.70 ($\alpha = 0.62$ and $\alpha = 0.66$). To improve the questionnaire's psychometric properties, we conducted further analyses, ultimately settling on a factor structure with six factors, which provided a more coherent and interpretable model. The factor structure comprising six factors was successfully derived, explaining a total variance of 64%. Fourteen items were removed due to factor loadings below 0.50. The six retained factors were found to aptly describe the correlational structure between the items, and the factor structure exhibited a good quality of adjustment

(RMSR = 0.059). The overall internal consistency of the questionnaire was demonstrated to be robust ($\alpha = 0.90$). In addition, each of the six factors retained in the factor analysis also showed a good internal consistency ($\alpha \geq 0.69$). These results affirm the reliability of the instrument both as a whole and in its individual factors. Table 2 provides a comprehensive summary of the factor loadings, communalities, percentage of explained variance, overall internal consistency, and individual factors' internal consistency.

3.3.3. Confirmatory Factor Analysis. The first CFA revealed an initial poor quality of adjustment (CFI = 0.961, TLI = 0.955, SRMR = 0.089, and RMSEA = 0.091). To enhance the model, outlier observations were removed. Items A24 and A25, which exhibited modification indices suggesting saturation in at least two other factors, were also removed from the model. Furthermore, we correlated the measurement errors of items with higher modification indices (A34-A35, A3-A4, A35-A6, A5-A6, A35-A31, and A15-A8) to improve the model quality. Following these refinements, the model demonstrated good fit indices (CFI = 0.980, TLI = 0.976, SRMR = 0.078, and RMSEA = 0.070) and good internal consistency, providing robust support for the factor validity of the QLTE-PT.

All items had standardized factor loadings greater than 0.50 and individual reliability ($\lambda_{ij} \geq 0.25$). It was observed that the average variance extracted (AVE) supported all factors' convergent validity. The discriminant validity of the factors was evaluated by comparing the AVE with the squared correlations between the factors (Table 3). It was found that each of the factors had an AVE greater than the square of its correlation with the other factors, which supported that all factors had a discriminant validity.

The first factor was designated as "supporting culturally congruent care" (CCC), the second as "managing intercultural issues" (MII), the third as "inclusive and unbiased management" (IUM), the fourth as "cultural sensitivity and adaptation" (CSA), the fifth factor as "integration in the nursing work environment" (INWE), and the last factor was designated as "adjusting care to cultural expectations" (ACCE). Figure 2 provides a visual representation of the final six-factor model of QLTE-PT.

4. Discussion

The development and validation of the Portuguese Transcultural Nursing Leadership Questionnaire (QLTE-PT) fills the gap in assessment tools for transcultural nursing leadership. It revealed a six-factor structure and 23 items that robustly encapsulate essential aspects of transcultural nursing leadership. These factors include supporting culturally congruent care, managing intercultural issues, inclusive and unbiased management, cultural sensitivity and adaptation, integration in the nursing work environment, and adjusting care to cultural expectations. The instrument demonstrates strong internal consistency, with an overall Cronbach's alpha value of 0.90, which is higher than the expected α and equal or higher than 0.70 for new instruments [37]. It explains a total

excellent content validity were assured, the high dimensionality of the questionnaire in its initial development phase raised concerns. In the early stages of questionnaire design, it should not be so long that it reduces the likelihood of potential participants answering or completing all the items, nor too short that it fails to cover all aspects of the construct it is intended to measure [32]. Such imbalances pose risks to the internal consistency of the construct and can affect the relationships and correlations among items within specific factors or domains [29]. As a strategy to obtain a more parsimonious set of items, it was decided to consider also the items' CVR as proposed by Lawshe, cited

by Almanasreh et al. [29], which reduced the number of items from 135 to 29.

The inclusion of 10 additional items with a CVR of <1 proved to be a significant step in the development of the QLTE-PT. Only two of these items were dropped during the EFA due to factor loadings below 0.50, which underscores the importance and relevance of the remaining eight items, as they contribute meaningful dimensions to the overall construct despite their initial lower CVR scores.

The first factor, "supporting culturally congruent care," showed good internal consistency, as evidenced by a high Cronbach's alpha value ($\alpha = 0.81$). This indicates that the
FIGURE 2: Six-factor model of QLTE-PT (CFI = 0.980, TLI = 0.976, SRMR = 0.078, and RMSEA = 0.070). Standardized loads and covariances.

items within this factor reliably measure the intended construct. The factor accounted for a significant portion of the total variance (13.9%), demonstrating its substantial contribution to the overall model. This factor comprises five items that encapsulate the actions taken by nurse leaders and managers to assist nurses in enhancing the quality of care they provide to patients from different cultural backgrounds. Examples of such actions include "I encourage immigrant nurses to take a course on the local language and facilitate their schedules to be able to attend it," "I conduct trainings that enable nurses to provide culturally congruent nursing care," and "I provide nurses with pamphlets and handbooks related to the delivery of culturally congruent nursing care." These items align closely with the established strategies to improve culturally congruent care in nursing literature, which supports the convergent validity of this factor. According to Russell [7], a transcultural nurse leader engages nurses, nursing students, and other healthcare professionals in a learning process of what it means to deliver culturally congruent care to culturally diverse populations. Providing written documentation on culturally congruent care [39], introducing transcultural education in services [40] and encouraging nurses to attend culture-related training sessions and activities, and ensuring their coverage during their absence from the shift [41] are a few examples of how this learning process may be conducted that support this factor. This factor includes also an item related to the nurse leader or manager's improvement to

communicate effectively with nurses of different nationalities and cultures, which is supported by the literature about the importance of engaging in ongoing training that enhances the skills related to culture and diversity in the workplace [41]. The discriminant validity of this factor is supported by its distinctiveness from other factors in the model. The relatively low correlations with other factors indicate that it measures a unique aspect of transcultural nursing leadership, separate from other leadership dimensions captured in the QLTE-PT.

The second factor "managing intercultural issues" contains four items, for instance, "I investigate events related to verbal or physical abuse, discriminatory behaviour, and harassment, and implement measures that reduce the risk of occurrence." It comprises nurse leaders and managers' attitudes and actions to prevent, resolve, and mitigate problems arising from cultural differences between nurses. This factor demonstrated a good internal consistency ($\alpha = 0.79$), reflecting the coherence of its four items in assessing leadership approaches to intercultural challenges. The factor's significant contribution to the total variance (13.6%) underscores its importance in the overall construct of transcultural nursing leadership. Convergent validity for this factor is supported by literature emphasizing the critical role of nurse leaders in addressing and resolving cultural conflicts and fostering a harmonious work environment. For instance, Munkejord [42] argues that healthcare managers can contribute to challenging the ethnic pyramid often

identified in culturally diverse institutions by implementing diversity-sensitive measures. Encouraging and arranging dialogue and collaboration among staff are one of those measures that lead to better relationships and reduce ethically based discrimination [42]. Nurses from ethnic minorities need to feel supported in the nonthreatening work environment. They also need to know that corrective actions will be implemented if the behaviour of an employee or group of employees is considered harmful [43]. The distinctiveness of this factor from others in the questionnaire, as shown by its discriminant validity, highlights its unique role in transcultural nursing leadership.

Factor 3 was labelled as "inclusive and unbiased management" as it concerns the degree to which the decision-making process of the nurse leader or manager deviates from favoring some nurses. It demonstrated a significant internal consistency ($\alpha = 0.76$), which suggests that the item effectively captures the essence of unbiased and inclusive decision-making in transcultural nursing leadership. Factor 3 is composed offour items, including "I have a transparent policy in the unit regarding the method of organizing nursing care, schedules, holidays, annual appraisal, and promotions." Convergent validity for this factor is evident in its alignment with existing literature on the importance of equity and impartiality in leadership, particularly within culturally diverse healthcare settings. Studies have highlighted that nurse managers who show favoritism, plan schedules, and vacations unequally among nurses of different cultural backgrounds, and promote nurses based on cultural criteria over merit, impact negatively on migrant nurses' job satisfaction, retention, and professional development [44, 45]. Discriminant validity is also well-established, with this factor distinctly measuring characteristics of leadership that are separate from others, as suggested by its low correlations with other factors in the QLTE-PT. This uniqueness is crucial in a transcultural context where unbiased and inclusive management is key to harmonizing a diverse workforce.

The fourth factor "cultural sensitivity and adaptation" is composed of four items aiming to describe nurse leaders and managers' sensitivity to cultural differences and how this sensitivity is reflected in their attitudes and behaviours towards nurses. The internal consistency of this factor ($\alpha = 0.76$) confirms the reliability of the items in measuring cultural sensitivity and adaptation in nursing leadership. This factor's convergent validity is supported by the existing research, such as studies by Sharifi et al. [46], which emphasize cultural sensitivity as an attribute of cultural competence in nursing, translating into valuing, respecting, and admiring cultural diversity and helping nurses to understand how people's attitudes and views affect their behaviours and care-seeking patterns. Examples of such nurse manager's sensitivity and adaptation included in the QLTE-PT are "I am open to realities that are different from mine" and "I adapt my leadership style according to the expectations, values, habits, beliefs, and cultures of the nursing team members." The distinctiveness of this factor from other factors in the QLTE-PT is evident in its unique focus on leaders' ability to respect, understand, and adapt to

cultural differences, as outlined by Matveev [47]. Transcultural leaders must demonstrate the ability to adapt to the distinct expectations of their organization, community, competitors, and clients [3]. This supports the factor's discriminant validity, as it captures unique aspects of transcultural leadership not covered by other factors.

Factor 5 "integration in the nursing work environment" comprises three items which highlight interventions targeted at the professional integration of immigrant nurses into the specificities of the nursing practice in the host unit, for example, "I implement a clinical orientation program specific to my unit to develop competencies of immigrant nurses with different levels of knowledge and professional experience" and "I recourse to international protocols to guide and standardise nursing practice in the team." This factor demonstrated a good internal consistency ($\alpha = 0.76$), indicating that the items are cohesively capturing the essence of immigrant nurses' integration in the work environment. Convergent validity is reinforced through literature emphasizing the need for supportive nursing work environments for diverse nursing staff. Integration in multicultural nursing work environments is a bidirectional process that involves efforts not only by the immigrant nurses but also by the host organization [48]. Rovito et al. [49] warn that sometimes nurses need to "unlearn" practices of nursing care that were common in their home country, since they are not a part of the nursing practice in the culture of the host country. According to Safari et al. [50], several strategies are needed to guide immigrant healthcare professionals in the culture of the host country before starting their clinical practice. A clinical orientation program is an example of a strategy that minimizes the impact of the challenges and difficulties migrant nurses experience, improves their well-being, the quality of care, and mitigates the risks to patient safety [51]. It is the nurse manager's responsibility to provide guidance, invest in multicultural education and mentoring for these nurses, guide their practice to provide safe and culturally congruent care, and ensure competence development and efficient use of their expertise [52]. Discriminant validity is evident, as this factor uniquely addresses the integration of immigrant nurses in the work environment, distinct from other transcultural nursing leadership characteristics evidenced in the other factors.

The last factor was labelled as "adjusting care to cultural expectations." It demonstrated an acceptable internal consistency ($\alpha = 0.69$), indicating that the items are able to capture nurse managers and leaders' interventions to meet patients' cultural expectations regarding nursing care. This factor is composed of three items such as "I request religious support congruent with patients' beliefs (e.g., Chaplain, Imam, Brahmin, Lama, and other spiritual leaders)." According to Leininger and McFarland [38], if patients receive nursing care that is not compatible and respectful with patients' ways of life, beliefs, and values, they will demonstrate signs of stress, nonadherence, cultural conflict, and ethical or moral concerns. This factor is in line with the guidelines for the implementation of culturally congruent nursing care in organizations, namely, the provision of structures and resources needed to meet patients' cultural

needs [53]. It is also supported by existing literature on the responsibility of nurse managers to provide culturally and linguistically appropriate services to diverse populations [28, 54]. This literature supports the convergent validity of this factor. Furthermore, the distinctiveness of the factor, evident through discriminant validity, confirms its unique role in the QLTE-PT, differentiating it from other factors.

Although there is an overall agreement about the scenario of cultural diversity among patients and healthcare workers in Portugal, no studies have attempted to describe the leadership behaviours of nurse leaders and managers in multicultural nursing work environments in this country. Therefore, this paper is innovative and grants a questionnaire that addresses nurse leaders and managers' leadership behaviours in multicultural nursing work environments with applicability in Portugal.

4.1. Study Limitations. The findings of this study contribute to the field by providing a reliable and valid instrument for assessing transcultural nursing leadership. However, it is important to consider the limitations of this study and the implications they have for the generalizability and interpretation of the results.

First, self-report measures were utilized in this study, which are subject to potential biases. Participants may have provided socially desirable responses regarding their leadership behaviours in multicultural nursing work environments, leading to response bias. Efforts were made to minimize these biases through clear instructions to participants and ensuring data anonymity. However, it is important to acknowledge this limitation probability.

In addition, despite QLTE-PT having good internal consistency and construct validity, further validation in different cultural contexts is necessary. The current study focused on nurses registered with the Portuguese Order of Nurses and with experience of leadership in multicultural nursing work environments. Future research should aim to conduct cross-cultural validation to ensure the questionnaire's robustness across diverse cultural contexts. Future research should also include a criterion measure to provide a more comprehensive assessment of the questionnaire's validity.

5. Conclusions

This study successfully developed and validated the Portuguese Transcultural Nursing Leadership Questionnaire (QLTE-PT). The final instrument, comprising 23 items across six factors, demonstrates robust psychometric properties, including good internal consistency and construct validity. The QLTE-PT captures essential aspects of transcultural nursing leadership, making it a valuable tool for evaluating nurse managers and leaders' behaviours in multicultural nursing work environments. While acknowledging the study's limitations, the QLTE-PT represents a significant contribution to nursing management, offering insights into leadership behaviours in diverse healthcare settings. Due to its potential interest of use in other countries with multicultural healthcare settings, we recommend the

development of guidelines with comprehensive information about different methodological approaches to support the decision-making and the quality of the cross-cultural adaptation process [55].

6. Implications for Nursing Management

The development and validation of the QLTE-PT hold important implications for nursing management and leadership. By providing a reliable and valid instrument to assess transcultural nursing leadership, the QLTE-PT offers nurse managers a valuable tool to gain insights into their own leadership behaviours in their multicultural units or organizations and acknowledges the needs of their nursing staff and patients from different cultural backgrounds. The questionnaire can assist nurse managers in identifying areas for improvement in their leadership and promotes a supportive work environment for their multicultural nursing staff, conducive to the well-being and engagement of nurses. It can also contribute to improving the quality of care provided to patients from different cultural backgrounds, ensuring patients' safety, satisfaction with nursing care, and higher levels of adherence to treatments.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Aim. To develop a set of infectious disease emergency response competencies specific to frontline nurses in China. *Background*. Nurses play an important role in the infectious disease emergency response. Competency-based training is the cornerstone of the professionalization of disaster rescue, including the infectious disease emergency response. Accordingly, reaching a consensus on a set of core competencies is essential. However, information regarding the competencies needed for nurses in the infectious disease emergency response is limited. *Methods*. A literature review and in-depth expert interviews were conducted to establish a draft of competencies, which consisted of 53 items, including 3 first-level index items, 12 second-level index items, and 38 third-level index items. Eighteen experts with the knowledge of infectious disease management and experience with infectious disease emergency rescue from different regions in China were recruited for Delphi consultation. A two-round Delphi survey was conducted via email. Consensus was defined as a mean importance value >4.5 and the coefficient of variation <0.25 among the experts. Finally, the analytic hierarchy process was used to determine the weight of each index on which consensus had been reached. *Results*. An index system of infectious disease emergency response competencies for nurses was constructed, including 3 first-level indices (knowledge, attitudes, and skills), 10 second-level indices, and 32 third-level indices. The response rates of the two rounds of the Delphi survey were both 100%, and the authority coefficient of the 18 experts was 0.903. The weighted value of each index was established with a consistency ratio <0.1, demonstrating that skill (0.5396) ranked first among the three first-level indices, followed by knowledge (0.2970) and attitudes (0.1634). *Conclusion*. The study developed a consensus on infectious disease emergency response competencies required for nurses in China, which provides guidance for the assessment and training of nurses on infectious disease emergency response. *Implications for Nursing Management*. According to the competency index system, nursing managers could develop effective training programs of infectious disease emergency response competency for nurses and select competent nurses for emergency response to infectious diseases.

1. Introduction

In recent decades, emerging infectious diseases have increased due to socioeconomic, environmental, and ecological factors [1, 2]. In general, humans lack natural immunity to emerging infectious diseases; therefore, they may spread rapidly and cause devastating consequences [3]. Correspondingly, the risk of unpredictable infectious disease

pandemics is increasing and has become a potential threat to global security. Currently, the entire world is encountering the largest infectious disease emergency, the coronavirus disease 2019 (COVID-19) pandemic. As of November 27, 2022, 637 million cases of COVID-19 and 6.6 million deaths have been reported worldwide [4]. Global health, economies, and social development have been significantly affected.

Although a clear definition of an infectious disease emergency is lacking, it involves two characteristics: infectious disease-related and public health events [5]. Therefore, in this study, we regarded infectious disease emergencies as public health emergencies caused by epidemics or pandemics of infectious diseases, such as severe acute respiratory syndrome (SARS), H1N1, Middle East respiratory syndrome (MERS), Ebola virus disease, and COVID-19. Medical rescue is an essential part of the infectious disease emergency response. Nurses have always played an important role in the response to infectious disease emergencies, including infection prevention, infection control, isolation, containment, and public health [6]. Especially in the absence of effective medical interventions for an emerging infectious disease, nurses play a vital role in caring for patients with fatal infectious diseases [7–9]. For example, during the COVID-19 pandemic in China, approximately 42,000 health care workers nationwide, more than 68% of whom were nurses, were sent to support Hubei Province [10].

Nurses' knowledge and experience are the key to controlling infectious disease pandemics [11]. A group of skilled and competent nurses is essential to adapt to a rapidly changing work environment and provide high-quality care, especially in response to infectious disease emergencies [12]. However, due to the shortage of specialty nurses for infectious disease, most nurses who participate in infectious disease emergency rescue are from noninfectious departments with no prior experience caring for patients with infectious diseases [13]. For example, Labrague and Santos [14] found that 91.4% of the frontline nurses reported that they were not completely prepared to care for COVID-19 patients and highlighted the need to improve nurses' core competencies to better handle infectious disease emergencies. Moreover, frontline nurses are repeatedly exposed to the virus, and providing sufficient training and equipment to protect them is consequently essential [15].

Competence-based emergency nursing staff deployment and training are the cornerstones of the professionalization of disaster rescue, including the infectious disease emergency response [16–18]. Accordingly, reaching a consensus on a set of core competencies is essential. Competence is a complex concept and has been defined as the ability to perform a task with desirable outcomes [19], "functional adequacy and the capacity to integrate knowledge and skills with attitudes and values into the specific contexts of practice" [20], or "the effective application of a combination of knowledge, skill, and judgment demonstrated by an individual in daily practice or job performance" [21]. In this study, the framework of the Chinese registered nurse's competency [22] is adopted for the term nursing competence. According to this framework, nursing competence

refers to the integration of knowledge, skills, and attitudes in clinical nursing practice [22]. Therefore, in this study, we define infectious disease emergency response competencies as the integration of knowledge, skills, and attitudes in effective response to an infectious disease emergency for nurses.

To our knowledge, very few studies have demonstrated the specific competencies that are required for nurses in the infectious disease emergency response. Kan et al. [5] developed a competency index system for medical staff in response to infectious disease emergencies. In the index system, only the competencies shared by physicians and nurses were included. However, in the actual situation of infectious disease emergency response, the specific tasks and abilities required for physicians and nurses are quite different. Physicians are mainly responsible for diagnosis and treatment decisions, whereas nurses need to provide specific care activities. Medical diagnosis and treatments are lifesaving but temporary. In contrast, nurses remain at the patient's bedside for long periods and provide the necessary labor-intensive and time-consuming care for the patient's recovery and rehabilitation [23]. Therefore, a scientific and comprehensive competency index system of infectious disease emergency responses for the nurses needs to be developed to guide high-quality training and effective nursing staff deployment during an epidemic. Thus, this study presents the following guiding question: what knowledge, skills, and attitudes are needed by frontline nurses in response to infectious disease emergencies? This study aims to develop a set of infectious disease emergency response competencies specific to frontline nurses in China.

2. Methods

This study took place from July 2020 to January 2021. We conducted a modified Delphi consultation to construct the index system and then used the analytic hierarchy process to determine the weight of each index.

2.1. Establishment of the Research Team. We established a research team that included 2 nursing education experts, 1 nursing management expert, 1 clinical nursing expert, and 1 nursing graduate student. The responsibility of the research team included developing expert consultation questionnaires, recruiting and contacting experts, and summarizing and analyzing expert opinions.

2.2. Construction of the Index System

2.2.1. Construction of the Index Draft and Consultation Questionnaire. In this modified Delphi consultation, we used an initial draft of the index system to replace the traditional first-round Delphi survey. The index draft was constructed through theory analysis, literature review, and a face-to-face in-depth expert interview. First, we adopted the framework of the Chinese registered nurse's competency [22] as the theoretical framework and divided "competencies" into three first-level elements: knowledge, attitudes,

and skills. Second, a literature review and expert interviews were conducted, and the data were classified into any dimension of knowledge, attitude, and skills. Eight experts with infectious disease rescue experience participated in 30–60 minutes of one-on-one interviews. In the interviews, the participants were asked approximately 6 questions as follows: According to your experiences and opinions, (1) What roles are played by frontline nurses in response to infectious disease emergencies? (2) What tasks should be undertaken by frontline nurses in response to infectious disease emergencies? (3) What knowledge is needed for frontline nurses in response to infectious disease emergencies? why? (4) What skills are needed for frontline nurses in response to infectious disease emergencies? why? (5) What attitudes and personal attributes are needed for frontline nurses in response to infectious disease emergencies? why? and (6) Is there anything else you would like to share with me? Subsequently, based on the literature [5, 22, 24, 25] and the results of expert interviews, we listed the second-level index and the third-level index related to knowledge, attitudes, and skills. Furthermore, each item was discussed by the research team, and modifications were made where necessary. Finally, an initial draft of 53 indices, including 3 first-level indices, 12 second-level indices, and 38 third-level index items, was developed. The consultation questionnaire consisted of four parts: (1) questionnaire introduction, including the research background, consultation purpose, completion instructions, and contact information for the research team; (2) main body of the questionnaire, including a five-point Likert scale with 53 items with scores ranging from 1 (completely unimportant) to 5 (very important) to represent the importance of each index (each item had an open-ended question to collect the expert's free-text comments); (3) basic characteristics of the experts, including their sex, age, education level, work experience, mentor status, professional title, academic qualifications, and current professional area; and (4) experts' familiarity level and judgment basis relating to the consultation questions.

2.2.2. Recruitment of the Expert Panel. Purposive sampling was used for expert recruitment. Additionally, expert heterogeneity was also considered to obtain a variety of perspectives and achieve more accurate judgments [26], such as different professions (nursing, public health, and hospital infection management), regions, and positions (frontline staff, managers). The selection criteria were as follows: (1) previously participated in the rescue of infectious disease emergencies; (2) ≥10 years of experience in clinical nursing, nursing management, nursing education, public health, or hospital infection management; (3) a bachelor's or higher degree; and (4) willingness to participate in this study. There is no consensus on the necessary number of experts. Belton et al. [26] recommended that 5–20 experts were sufficient; therefore, 18 experts were selected in this study.

2.2.3. Consultation Procedure. The members of the research team contacted the experts, explained the purpose of the research to them, and obtained their consent. The questionnaires were sent to the experts via email. The experts were required to fill out the questionnaires independently and send them back in two weeks. A brief reminder was sent to the nonresponders one day after the deadline.

2.2.4. Data Analysis and Selection of the Index. We used Microsoft Excel 2010 and IBM SPSS Statistics 21.0 to analyze all quantitative data. Frequencies, proportions, and means were used for data descriptions. The authority coefficient of experts was calculated to represent the reliability of the consultation results [27]. The coefficient of variation (CV) was used to judge the coordination and concentration of expert opinions. Kendall's W was used to test the consistency of experts' opinions [28]. The qualitative data of experts' free-text comments were analyzed by content analysis [29]. The research team carefully reviewed and discussed the comments from the experts and then modified, excluded, or added items based on the study aims and literature.

After round 1 consultation, the items with a mean importance value <4.5 were deleted. Additionally, the researchers carefully reviewed the experts' comments, categorized the content, integrated similar opinions, and then discussed the research team to modify, exclude, or add items based on the study aims, literature, and theoretical framework of this study. For example, three experts suggested adding items that reflect the "overall view," "obedient organization arrangements," and "team spirit" of nurses. Therefore, a related third-level item was added. Two experts suggested changing the second-level index of "communication and management abilities" into "communication abilities." Through discussion and a literature review, the research team agreed that the comment was reasonable and thus modified the item according to the expert opinion. Finally, several items were modified, and new items were added following analysis of the experts' comments. All the retained items and the new items were entered into the second-round questionnaire. After round 2 of consultation, the items with a mean importance value >4.5 and CV < 0.25 were considered to have reached a consensus [30].

2.3. Weight of the Index. We used the analytic hierarchy process to determine the weight of each index. The analytic hierarchy process was completed by Yaahp V10.3 (Meta Decision Software Technology Co., Ltd., Nanjing, China).

2.3.1. Build the Hierarchical Structure Model. In this study, the hierarchical structure model of the index was established according to the result of round 2 of the Delphi consultation, which consisted of four layers: the target layer, the criteria layer, the subcriteria layer, and the scheme layer. In this study, the target layer was the competency assessment index system for nurses responding to infectious disease emergencies, the criteria layer included the 3 first-level indices, the subcriteria layer included the 10 second-level indices, and the scheme layer included the 32 third-level indices.

2.3.2. Construction of the Judgment Matrix. The mean importance value of each index determined by the experts in

the round 2 consultation was used to calculate the difference between pairwise indices. Then, the importance degree between pairwise indices was compared, and the pairwise comparison judgment matrix was constructed based on Saaty's fundamental 9-point scale [31]. In this study, we formed a total of 14 judgment matrices.

2.3.3. Test Consistency and Weight Calculation.

For consistency testing, a consistency ratio (CR) of the judgment matrix <0.10 indicates that the judgment matrix has satisfactory consistency; in contrast, CR > 0.10 indicates that the judgment matrix needs to be adjusted [30]. In Yaahp V10.3 software, the power method was used to calculate weights.

2.4. Ethical Considerations.

This study was approved by the Biomedical Research Ethical Committee of West China Hospital, Sichuan University (No. 2020312), and was conducted in accordance with the principles of the Declaration of Helsinki. The study objectives and participant rights were explained to the experts via an electronic document. Consent was implied after the participant completed the survey.

3. Results

3.1. Characteristics of the Experts.

In this study, we conducted two rounds of expert consultation. A total of 18 experts were enrolled from 11 hospitals and universities, covering 7 provinces, autonomous regions, or municipalities, including Hubei, Beijing, Sichuan, Anhui, Gansu, Yunnan, and Xinjiang. The experts' characteristics are shown in Table 1. The response rates of the two rounds of consultations were both 100%. Fifteen (83.33%) and five (27.78%) experts also provided free-text comments in the two rounds. The authority coefficient of the 18 experts was 0.903, indicating that the experts were highly authoritative, and the consultation results were reliable. The concentration and coordination of expert opinions are listed in Table 2. The CVs were 0–0.23 (median 0.13) and 0–0.17 (median 0.09) in the first and second rounds, respectively. Kendall's W was 0.170 and 0.139 in the two rounds, with statistically significant differences, indicating a high level of synergy among experts.

3.2. Nursing Response Competency Index System of Infectious Disease Emergency.

The process of index construction is shown in Figure 1. In the first round, the importance value was 4.11–5.00, with an average of 4.69, and 9 items scored <4.5. In the first round, 62 comments were provided by 15 experts regarding adjusting the wording, merging or splitting some items, and deleting or adding new items. Two second-level indices and 7 third-level indices were deleted, 3 new third-level indices were added, 2 second-level indices, and 17 third-level index statements were revised, and 1 third-level index was reclassified through data analysis. Therefore, a five-point Likert scale with 47 items (3 first-level indices, 10 second-level indices, and 34 third-level indices) was sent to 18 experts for the second round of consultation.

In the second round, the importance value was 4.28–5.00, with an average of 4.78; 2 items scored <4.5, and all CVs were <0.25. The second round also included 13 comments from 5 experts. Two third-level indices were deleted, and 3 third-level index statements were revised. After the second round, the experts' opinions tended to be consistent, and the nursing response competency index system of infectious disease emergencies was confirmed, including 3 first-level indices, 10 second-level indices, and 32 third-level indices (Table 3).

3.3. Weight of the Competency Assessment Index.

The results showed that the first-level CR was 0.0088, the second-level CR was 0.0825, 0.0000, and 0.0314, and the third-level CR was 0.0266, 0.0000, 0.0000, 0.0000, 0.0000, 0.0192, 0.0172, 0.0000, 0.0000, and 0.0707. All the CRs were <0.1, indicating that each judgment matrix had satisfactory consistency. The weight coefficients of each index are listed in Table 4.

4. Discussion

In this study, we developed a competence index system of infectious disease emergency response for nurses in China through a Delphi survey and determined the weight of each index with an analytic hierarchy process. The consensus-based competence index system represents the general expectations of the Chinese health care team for the nurses in response to infectious disease emergencies.

The competence index system established in this study is scientific, reliable, and representative with the following characteristics. First, the response rate of experts indicates their concern for the research, and a response rate >70% is necessary to ensure the rigor of the Delphi technique [32]. The response rate of the two rounds of consultation in this study was 100%, indicating that the experts had high enthusiasm for consultation. Second, a higher degree of expert authority generally indicates better accuracy of prediction, and an authority coefficient ≥0.7 specifies that the consultation results are reliable [27]. In this study, the authority coefficient exceeds 0.9, showing excellent reliability of the experts' opinions. Third, Kendall's W in the two rounds was significantly different, indicating good coordination among experts and acceptability of the study results. Additionally, the items' CVs decreased from round 1 to round 2, showing that the experts' opinions tended to be stable and that the consensus was meaningful. Furthermore, the selection of experts is crucial for success in a Delphi study [33]. Purposive sampling was used to improve representativeness, rather than random sampling. In this study, 18 experts were well-known experts in infectious disease nursing, education, or management, and all of them had frontline work experience in infectious disease emergency rescue, such as SARS or COVID-19. They originated from 11 institutions, covering 7 geographic regions, which decreased the regional distribution bias. In summary, the Delphi technique and qualified experts ensure the reliability of this competence

Round1	4.11–5.00	44.00–100	0.00–0.23	0.170	147.565	<0.001
Round2	4.28–5.00	39.00–100	0.00–0.17	0.139	114.780	<0.001

index system. Moreover, the combination of the Delphi technique and the analytic hierarchy process method in this study integrates the wisdom of experts and the science of quantitative measurement.

Competency is a complex and holistic concept. Although consensus on the definition and domains of competency is lacking, it contains the integration of knowledge, skills, and attitudes required to accomplish a task effectively and efficiently [18, 20]. Therefore, in this study, the nursing competencies of the infectious disease emergency response initially consisted of 3 first-level indicators—knowledge, attitudes, and skills—and the experts also reached a high consensus. The weights of knowledge, attitudes, and skills were 0.2970, 0.1634, and 0.5396, respectively, reflecting the priority of nursing skills in responding to infectious disease emergencies. Nursing practice is highly technical; therefore, excellent skills are essential for completing basic nursing tasks. In the context of infectious disease emergencies, nurses usually must address many clinical nursing tasks [34]. In this circumstance, nursing skills should be prioritized both in nurse training and in staff deployment. The weight of knowledge ranked second, and most abilities can reasonably be acquired based on knowledge. Finally, although the weight was relatively low, the experts still highly agreed that attitude was indispensable (mean importance value 4.83, CV 0.10). In general, attitude can predict behavior to some extent. The professional attitudes of nurses are essential to enhancing the quality of health care [35]. Professional attitudes are particularly important in response to an infectious disease emergency. Because nurses may be at risk of being infected, stigmatized, isolated, and even sacrificing their lives [36, 37], only nurses with a firm professional attitude and good mental health are suited for frontline nursing work in an infectious disease emergency.

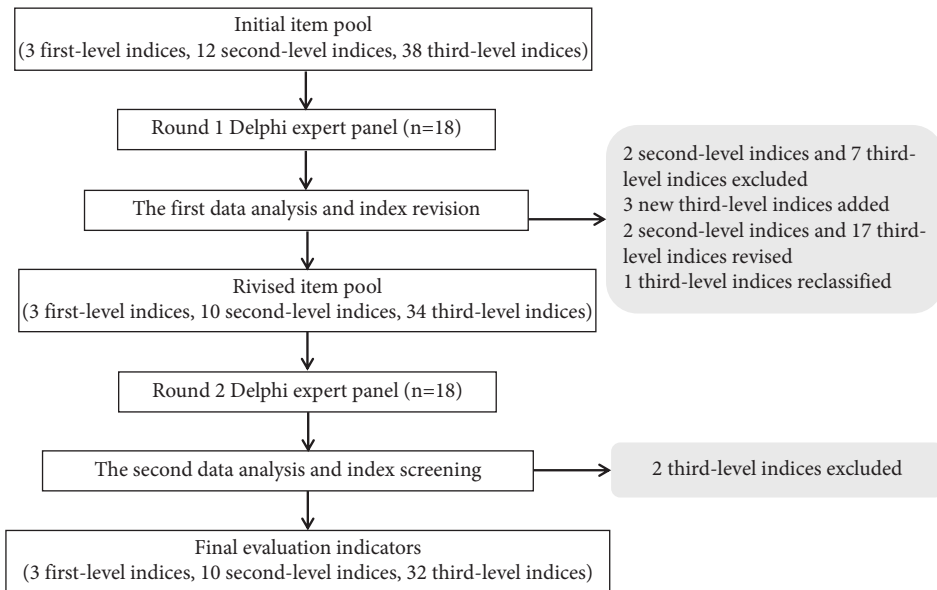
Finally, we confirmed 32 third-level indicators and identified their weight coefficients. These third-level


FIGURE 1: Flowchart of the index construction process. Two rounds of expert consultation were conducted to construct the index system. Through the first round data analysis, 2 second-level indices and 7 third-level indices were deleted, 3 new third-level indices were added, 2 second-level index and 17 third-level index statements were revised, and 1 third-level index was reclassified. Through the second round data analysis, 2 third-level indices were deleted, and 3 third-level indices statements were revised. Finally, the nursing response competency index system of infectious disease emergencies was confirmed, including 3 first-level indices, 10 second-level indices, and 32 third-level indices.

indicators provide evidence for developing training curricula and identifying prioritized training topics in future education. For example, "understand the disinfection and isolation of infectious diseases" (portfolio weight 0.1241) and "correctly perform specimen collection for infectious disease patients" (portfolio weight 0.1245) are the most important knowledge and skills and need to be trained preferentially. Notably, two third-level indicators were also very important. The first indicator was "effectively adjust one's own psychology and behavior to quickly meet the work requirements under the pressure caused by the infectious disease emergency." The outbreak of an infectious disease and subsequent pandemic exert considerable psychological pressure on health care workers who directly provide care to patients [38]. Studies have demonstrated that nurses who can recover quickly from a stressful event may cope effectively and overcome the pressure imposed by an infectious disease emergency [14]. The second indicator was "follow organization arrangements and collaborate effectively with other team members in an infectious disease emergency." Good cooperation within a health care team is crucial for providing high-quality care to patients and ensuring the safety and health of staff [34, 39]. In the rescue of an infectious disease emergency, health care workers from various

departments, multiple professions, and even different hospitals or institutions may be integrated as a temporary medical aid team to participate in the frontline care work [40]. Team members may not be familiar with each other or with the workflow and the environment in a new workplace; therefore, cooperation on the team is full of challenges. Accordingly, the nurse's team spirit and effective collaboration should be emphasized in this context.

5. Limitations

This study was also subjected to limitations. Although the 18 experts recruited nationwide in this study are sufficient for a Delphi study, they may not fully represent all stakeholders. Although purposive sampling was essential to reach the target experts, it may also have introduced bias in the sampling process [30]. Furthermore, the infectious disease emergency response competencies constructed in this study have not yet been tested in a clinical setting. Therefore, the study results should be generalized with caution and limited to a similar context. Future studies need to collect more opinions from various stakeholders to improve the competency index system and test the index system in a real clinical context.

TABLE 4: Continued.

First-level indicators	Weights	Second-level indicators	Weights	Third-level indicators	Weights	Portfolio weights
(C) Skills	0.5396	(C1) Specialty in nursing practice	0.5352	(C1.1) Properly perform respiratory care techniques for patients with infectious disease, e.g., oxygen therapy, atomization inhalation, sputum suction care, endotracheal intubation care, tracheostomy care, and ventilator care	0.0773	0.0223
				(C1.2) Properly perform circulatory care techniques for patients with infectious disease, e.g., electrocardiographic monitoring and cardiopulmonary resuscitation	0.2224	0.0642
				(C1.3) Identify anticipated condition changes and provide effective care for patients with infectious disease	0.1330	0.0384
				(C1.4) Identify the psychological needs of infectious disease patients and their families and give appropriate support	0.1330	0.0384
				(C1.5) Correctly perform specimens collection for infectious disease patients	0.4343	0.1254
		(C2) Hospital infection management	0.1163	(C2.1) Comply with the quarantine requirements of different areas (clean, potential contamination, and/or contamination area) and channels	0.3772	0.0237
				(C2.2) Correctly classify and provide quarantine measures for infectious disease patients, e.g., placement of patients, selection of medical protective products, and management of visiting and accompanying	0.1570	0.0099
				(C2.3) Correctly perform disinfection and dispose of the environment, belongings, cadavers, medical waste, and medical reusable materials of infectious disease patients	0.1570	0.0099
				(C2.4) Put on and take off personal protective equipment according to the quarantine type and the protection level (level 1 protection, level 2 protection, and level 3 protection)	0.1570	0.0099
				(C2.5) Properly perform hand hygiene	0.0936	0.0059
				(C2.6) Manage the personnel and environment in the ward to reduce the risk of infectious diseases spread	0.0583	0.0037
		(C3) Education and consulting	0.0547	(C3.1) Effectively teach the prevention, containment, and rehabilitation measures about infectious disease to patients and their families	0.5000	0.0148
				(C3.2) Guide other health team members in caring for patients with infectious diseases	0.5000	0.0148
		(C4) Communication abilities	0.1697	(C4.1) Effectively communicate with infectious disease patients and their families	0.2500	0.0229
				(C4.2) Effectively communicate and coordinate with health team members during infectious disease emergencies	0.7500	0.0687
		(C5) Thinking and learning abilities	0.1240	(C5.1) Under the pressure of infectious disease emergency, remain critical thinking and make correct decisions to solve difficulties in work	0.1172	0.0078
				(C5.2) Identify and deal with potential risks related to infectious disease emergency response	0.2684	0.0180
				(C5.3) Actively and effectively learn new knowledge and skills to improve the required abilities for infectious diseases patient care	0.6144	0.0411

Note. The first-level consistency ratio (CR) was 0.0088; the second-level CR was 0.0825, 0.0000, and 0.0314, respectively; and the third-level CR was 0.0266, 0.0000, 0.0000, 0.0000, 0.0000, 0.0192, 0.0172, 0.0000, 0.0000, and 0.0707, respectively.

6. Conclusion

This study is the first to develop a consensus on infectious disease emergency response competencies needed for nurses in China. A Delphi survey based on a literature review and in-depth expert interviews were used to establish the competency index system, and eventually, 3 first-level indices, 10 second-level indices, and 32 third-level indices were agreed upon. Additionally, the weighted coefficients of each index were determined using the analytic hierarchy process. The competency index system is scientific and reliable, revealing clear expectations and performance standards for nurses in response to an infectious disease emergency and providing guidance for nursing educators to develop effective infectious disease emergency response competency training programs.

7. Implications for Nursing Management

The competency index system reveals clear expectations and performance standards for nurses in response to an infectious disease emergency. The findings specifically apply to situations where emergency rescue is required in an infectious disease epidemic or pandemic and the frontline nurses who are deployed to undertake rescue tasks in such an infectious disease emergency. Nursing managers could develop effective training programs for infectious disease emergency response competency for the nurses based on the competency index system and select competent nurses for medical rescue in infectious disease emergencies.

Data Availability

The data analyzed during the current study are not publicly available due to privacy restrictions but are available from the corresponding authors on reasonable request.

Aim. The present study aimed to evaluate the effect of 3D animation combined with teach-back health education on the recovery of low anterior resection syndrome (LARS) patients. *Background*. LARS is the most common problem after anus-preserving surgery in rectal cancer. Pelvic floor muscle training can promote the recovery of recto-anal function. *Methods*. Ninety-nine patients with LARS were randomly divided into control group, experiment group I, and experiment group II. The control group was guided by one-to-one verbal pelvic floor muscle training. The experiment group I was given self-made 3D animation along with one-to-one pelvic floor muscle guidance. The 3D animation and teach-back methods were used for training and guidance in the experiment group II. The outcome measures were scores of low anterior resection syndrome scale items, as well as the completion of training content. *Results*. The degree of completion of training content in the experiment group II was higher than that of the control group and experiment group I. The total score of LARSS in the experiment group II was significantly lower than in the control group and experiment group I. In particular, scores of loose stool incontinence, defecation frequency level, tenesmus, and defecation urgency in experiment group II were better than those in the control group. *Conclusion*. 3D animation combined with teach-back health education improved the mastery of pelvic floor muscle training theory and practice in LARS patients, and effectively reduced the symptoms. *Implications for Nursing Management*. This intervention promoted the recovery of pelvic floor muscle function in LARS patients and can be regarded as an effective measure to improve quality of life and provide better clinical care for patients.

1. Background

According to pertinent statistical reports, the incidence and mortality of colorectal cancer rank third and second in the world, respectively, and it has become the most prevalent malignant tumor of the digestive system in China, among which rectal cancer accounts for about 60%–75% [1, 2]. At present, the treatment methods for rectal cancer mainly include combined abdominoperineal resection (Miles) and transabdominal resection and anastomosis (Dixon), also known as anal preserving surgery, accounting for 70% of the surgical methods [3]. Following anus-preserving surgery,

90% of patients show a series of defecation-related bowel function changes such as increased defecation frequency, difficulty in excretion, and incontinence, a phenomenon referred to as low anterior resection syndrome (LARS) [4, 5].

At present, the treatment for LARS consists of drug therapy (tryptamine agonists and antagonists), anal lavage and anterograde enema, sacral nerve stimulation and percutaneous tibial nerve stimulation, pelvic floor rehabilitation training (pelvic floor muscle exercise, rectal balloon training, and biofeedback training), and other methods [6, 7]. Pelvic floor muscle training refers to the voluntary contraction of pelvic floor muscles, dominated by the levator ani muscle, in

a conscious and rhythmic way to strengthen defecation control ability, and is simple and easy to learn, while not being restricted by external objective conditions [8]. At present, pelvic floor muscle training is widely used in the treatment of stress urinary incontinence, postpartum urinary retention, postpartum pelvic floor function, and sexual dysfunction [9, 10], and the effects are significant.

The vivid image characteristics of 3D animation creates a rich color saturation viewing experience, increasing and improving learners' perceptual understanding [11]. Teachback is a communication method that allows information recipients to repeat or demonstrate the information provided to them using their own language and actions to confirm their understanding. The technique comprises four steps: explanation, evaluation, clarification, and understanding [12]. Studies have shown that this feedback method has significant effects in reducing the readmission rate of patients, improving diet compliance, and reducing surgical complications and medication error rates [13]. At present, the study of feedback methods in Chinese health education focuses only on chronic diseases, and there are no reports of its impact on intestinal function and quality of life in patients with rectal cancer LARS.

Therefore, this study proposes a training program for LARS patients to quickly recover pelvic floor muscle function, which can improve their quality of life, and also provide a reference for medical staff to provide them with appropriate care.

2. Methods

2.1. Program Development. This study used a randomized controlled trial to evaluate the effectiveness of the developed program. In the control group, the responsible nurse selected a one-to-one verbal health education method to provide patients with pelvic floor muscle knowledge and guidance on training the muscles. Group I conducted one-to-one education with the vivid, three-dimensional 3D animation, and training measures the same as those in the control group. In group II, the patients were trained with 3D animation and teach-back (pelvic floor muscle training method guidance, assessment of mastery, repeat of guidance deficits, confirmation of mastery, and continuous exercise).

2.2. Design and Study Protocol. Patients enrolled in the study were randomly divided into three groups using SPSS Statistics for Windows, version 18.0 random number generator program. The results of randomization were 33 cases in the control group, 33 cases in the experiment group I, and 33 cases in the experiment group II. To ensure validity, this study was designed as a single-blind trial.

2.3. Outcome Measures. All the patients in the three groups started training on the 7th day after surgery which lasted till 3 months after. Training took place daily at 8 AM, 2 PM, and 6 PM. The baseline data recorded comprised the low anterior resection syndrome score (LARSS) and the training content completion evaluation.

2.4. Participants and Setting. Participants were LARS patients from the gastrointestinal surgery department of Guizhou Provincial Class A Hospital. The age range included in this study was 45 to 75 years. They were diagnosed with rectal cancer and first treated with anus-preserving surgery. The LARSS scale at baseline was scored at ≥21, with the rating level indicating above mild severity of LARS [14]. Participants chosen had constant access to their mobile phone during hospitalization and discharge and had a long-term primary caregiver (care time of no less than 4 h/d; if there were many caregivers, the longest care time was considered; caregivers included family members who were ≥18 years of age and were fluent in the language) [15].

2.5. Procedures

2.5.1. The Control Group. The responsible nurse engaged the patient in one-to-one verbal health education to provide them with relevant, pelvic floor muscle knowledge and guidance on training the muscles before surgery, after surgery, on the day of discharge, and when returning to the hospital for chemotherapy [16]. The muscles of pelvic floor muscle training mainly include the levator anal muscle, the internal and external anal sphincter, the transverse and transverse anal canal muscle, and the coccygeal muscle.

2.5.2. Experiment Group I. 3D animation was used to enhance their knowledge of pelvic floor muscles and guide them in performing pelvic floor muscle training. The content and duration of the training were the same as in the control group.

A 3D motion capture camera was used to capture and save videos of the standardized patients. In the first part of the animation, Autodesk-Maya modeling software was used to recreate the pelvic floor muscle and bone model on the computer. In the second part, the muscle and bone model was superimposed on the corresponding anatomical position in the human body captured on video and presented with perspective three-dimensional effects. Finally, a complete 3D animation was made using the post-effect editing function of Adobe After Effects.

2.5.3. Experiment Group II. The patients were trained using the 3D animation combined with teach-back. The training content and duration were the same as the control group. The intervention involved the following steps:

(1) The teach-back health education team was established. The head nurse of the department coordinated and managed the team, 2 responsible nurses were mentors of the education team, 1 subject researcher, and 1 gastrointestinal surgeon and 1 rehabilitation training instructor in the department served as health consultants.

(2) The 3D animation was played for the patients and their families to enhance the guidance and explanation.

(3) On a postoperative day 7: the teach-back procedures were used to continue the pelvic floor muscle training

    (a) Guidance on pelvic floor muscle training methods: the researchers watched the 3D animation again with the patients and reviewed the information and functional training methods shared before surgery.

    (b) Assessment of mastery: The patient was asked to repeat the procedure for pelvic floor muscle training in their own words and demonstrate it. The method explanation and the completion degree of the exercises by the patient was evaluated by the trainer, who maintained detailed records.

    (c) Repeated guidance for deficiencies: further guidance for deficiencies of the patient was given according to the records.

    (d) Mastery and continued use of the exercise are confirmed: mastery of the exercises was evaluated, and video playback and one-on-one education applied until the patient fully grasped the entire information and procedure.

(4) After discharge: every Monday, Wednesday, and Friday, mobile phone communication was used to remind patients to train, to understand their training situation, and give guidance.

(5) Returning to hospital for chemotherapy: patient's understanding and accuracy of practice was recorded and guidance was provided if necessary.

2.6. Ethical Considerations. This study was approved by the Medical Ethics Committee of the Affiliated Hospital of Guizhou Zunyi Medical University (review approval document no.KLLY-2020-143). During the intervention, the researcher strictly followed the bioethical principles of benefit and no harm, informed consent, confidentiality, ethics, and fairness.

2.7. Statistical Analysis. SPSS Statistics for Windows, version 18.0 was used to sort and analyze the data, and the level of significance was set at 5%. Unpaired F tests and the χ^2 test were used to compare the participants' baseline data. The measurement data were presented by $\overline{x} \pm s$, and the three groups of data, with normal distribution and homogeneity of variance, were tested by repeated measurement ANOVA. Before the analysis of variance, the sphericity test was performed for all of them, and if the results were not satisfactory, multivariate tests were conducted. After repeated measures of ANOVA, if there was an overall interaction, comparisons between groups and within groups were carried out. One-way ANOVA test was used for comparison, and the least significant difference (LSD) method was used for post-hoc multiple comparisons when significant differences were found. The Kruskal–Wallis H rank sum test was used in non-normal

measurement data, and in the nonparametric test was used for rank data.

3. Results

3.1. Patients Baseline Data. A total of 99 patients with LARS were enrolled in this study, assigned as 33 patients each were to the control group, experimental group I, and experimental group II. In the course of the study, one case in the control group was discharged automatically in advance and one case could not be contacted after discharge. One case in experimental group I had poor compliance, one case in experimental group II had poor compliance, as well and one other case was transferred to another department for treatment. Finally, a total of 94 patients completed the program and data collection phase of the study. There were no significant differences in baseline data such as gender, age, height, weight, and BMI among the three groups ($P > 0.05$), indicating comparability. Specific comparison results are shown in Table 1.

3.2. Pelvic Floor Muscle Training Content Completion. When comparing the degree of completion of the training content, experiment group I and experiment group II were better than the control group before the surgery, and 7 days, 14 days, 1 month, and 3 months post-operation ($P < 0.05$). The details are shown in Table 2.

3.3. LARSS Total Score. The total score of LARSS for the three groups was analyzed and that of the experiment group II was significantly lower than that of the control group one month after the operation ($P < 0.05$). The total score of LARSS in the experiment II group was lower than that in the experiment I group and the control group at 3 months after the operation. There were statistically significant differences in the total score of LARSS between the control group and the experiment II group before and after intervention ($P < 0.05$). Specific comparison results are shown in Table 3.

3.4. Comparison of Scoring on Individual LARSS Items. The time effect of LARSS items was statistically significant ($P < 0.05$). The treatment effects of loose stool incontinence, frequency of defecation, and urgency of defecation were also statistically significant ($P < 0.05$). The interaction effects of loose stool incontinence, frequency of defecation, tenesmus-related weight loss, and urgency of defecation scores were statistically significant ($P < 0.05$). One-way analysis of variance was used to compare the three groups at different time points. The results showed that the defecation urgency score of group II was better than that of the control group on the 14th day after the operation; defecation frequency, 1 month after operation; loose stool incontinence, 3 months after operation; defecation frequency level, tenesmus, defecation urgency score in the experiment group II were consistently better than those in the experiment group I and control group. The scores of loose stool incontinence in experiment

group II were better than those in the control group. Detailed results comparison are shown in Table 4.

4. Discussion

4.1. Effectiveness of Training. Pelvic floor muscle training has been proven to be effective in improving LARS symptoms. The results indicated that the degree of completion of training in experiment groups I and II at each time point was higher than that in the control group. Experiment group II combined the stereo-realistic characteristics of 3D animation with the four steps of teach-back (pelvic floor muscle training, method guidance, assessment of mastery, repeated guidance of deficits, confirmation of mastery, and continued exercise), and fully mobilized patients' vision, hearing, and motion perception. Regular health education gives priority to the verbal method of information transmission, usually one way [17, 18]. Teach-back adopts a two-way information transmission mode, to help medical staff to assess patients' understanding of the health education content, through real-time testing of mastery, receiving feedback from the patient, correcting errors, and providing missing information to strengthen and consolidate repeatedly. Its effect was found to be significantly higher than that of conventional health education, and its connotation of health education was quite consistent with the concept of "knowledge-belief-behavior" [19, 20].

LARSS is the most commonly used assessment tool for LARS patients that can evaluate the symptoms of anal exhaust, defecation, tenesmus, and so on. If the score of LARSS is lower, the recovery of anal exhaust and defecation function is better. At 1 month and 3 months after the operation, the total score of LARSS in experiment group II was lower than that in the control group and experiment group I, and the effect at 3 months was better than that at 1 month, indicating that the intervention method in experiment group II obtained stronger results than that in the control group. Realistic 3D animation of the characteristics of pelvic floor muscles provided a visual impact that was memorable and patients could view it in privacy. In combination with the teach-back method, the aim was to emphasis the training content and deepen, preoperative knowledge about pelvic floor muscles, and strengthen this during the postoperative review. It can effectively promote patients to form a deep

memory and develop the habit of persistent exercise [21]. Related studies had reported that patients may have temporary uncontrolled defecation in the early stage due to the disorder of normal functioning after anal preservation surgery. However, long-term uninterrupted pelvic floor muscle training of patients was not only conducive to the recovery of normal anal defecation function but also the success rate of treatment of short-term or long-term treatment can reach 50%–92% [22].

The normal rectal and anal sphincter, intact rectal nerve reflex arc, and sound fecal storage mechanism together maintain the normal function of the anus, and the failure of any one of these links leads to various problems [23]. After training, the level of loose stool incontinence and defecation frequency at 1 and 3 months after surgery in group II was better than that of the control group and group I. The reason was that the combination of 3D animation and teach-back on pelvic floor muscle functional exercise made a deep impression in the memory of the patients motivating them to continue exercising for a long time. Abdominal breathing can regulate gastrointestinal peristalsis and intra-abdominal pressure, and the up- and down-training of the muscle can also effectively drive the operation of the levator ani muscle [24]. Kegel exercise can improve the muscle contraction ability of the levator ani muscle and promote the recovery of its innervated nerve function [25]. Fork leg anal levator exercises can further strengthen the intensity of anal levator exercises with the help of hip muscles and thigh strength, inducing effective training of the levator ANI muscle, improving the patient's ability to control stool, and reducing the frequency of defecation [16]. Through perineal four-dimensional pelvic floor ultrasound examination, Yao found that pelvic floor muscle exercise could strengthen the thickness of the levator ani muscle itself and reduce its hiatus, thereby providing strong objective evidence for pelvic floor muscle training to improve the ability of defecation control [26]. In the LARSS items, tenesmus and defecation urgency items in the experiment group II were better than those in the control group and the experiment group I on the 14th day, 1 month, and 3 months after the surgery, and with the increase of time, there were more and more differences between items, indicating that the intervention of the experiment group II was effective. With training through repeated pelvic

1: comparison between groups: ▲compared with the control group, ◆compared with the experiment group I, ◇compared with before intervention, ○compared with 14 days after the operation, and ◇compared with 1 month after the operation, all $P > 0.05$. 2: intra-group comparison: ^Δcompared with before intervention: ^△compared with 14 days after the operation, all $P < 0.05$. 3: *indicates that there were statistically significant differences between the experiment group I and experiment group II and the control group ($P < 0.05$).

floor muscle exercises, muscle strength and tension in the region are enhanced along with functioning, promoting the recovery of the sensory nerve endings on the intestinal wall, stimulating and strengthening the excitability of the cerebral cortex which controls defecation, and adding elasticity to the rectum, thereby increasing the storage capacity for excrement and urine and alleviating rectum edema and fibrosis in the surrounding tissue. Thus, the symptoms of tenesmus and urgency of defecation can be improved [27], so as to improve the life comfort of patients.

4.2. Limitations and Future Challenges. This study has some limitations. First, limited research time and manpower led to the restriction of the sample to only 94 patients. Furthermore, as it was mainly a hospital intervention, and the follow-up duration was only up to 3 months after the surgery, and there was a lack of continuous nursing guidance for the patients. Moreover, the limitation of research funds, equipment, and other conditions meant that this study did not use an anorectal manometer to measure rectal contraction force and lacked objective evaluation indicators. In the future, we will expand the sample size and the intervention time, study the deficits in patients' home exercise from the perspective of quantitative research, analyze the causes, and add objective indicators involving continuous detection of pelvic floor muscle function.

5. Conclusion

This study demonstrated that 3D animation combined with teach-back health education improved the mastery of pelvic floor muscle training and exercise in LARS patients, thereby effectively reducing their symptoms of loose stool incontinence, defecation frequency, tenesmus, and urgency of defecation.

6. Implications for Nursing Management

In this study, the combination of 3D animation and teach-back with real-time feedback advantages were applied to the pelvic floor muscle training of LARS patients, which not only promoted the early and rapid recovery of patients but also significantly improved their quality of life, and symptoms of loose stool incontinence, defecation frequency, tenesmus, and urgency of defecation. The results prove that it is worth adopting as a regular course of treatment.

Data Availability

The data that support the findings of this study are available from the corresponding author upon reasonable request.

Ethical Approval

This study was conducted after obtaining the approval of the Medical Ethics Committee of the Affiliated Hospital of Guizhou Zunyi Medical University (approval: KLLY-2020-143).

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Background. Few studies have analyzed the negative outcomes of disruptive behaviors in the nurse-physician relationship in patient care and their impact on patient safety. These multicausal studies significantly relate to organizational, institutional, and professional attitudinal risk factors. *Aim.* Analyze healthcare professionals' perceptions of disruptive behavior and factors associated with patient safety climate in the nurse-physician relationship at the hospital level. *Methods.* A multicenter cross-sectional study was conducted with a sample of 370 nurses and physicians assigned to different public hospitals in the Murcia/Spain region, applying the adapted and validated Spanish version of the Nurse-Physician Relationship Scale: Impact of Disruptive Behavior on Patient Care. The analysis used proportions or means (standard deviation (SD)), univariate and multivariate linear regression models, and the chi-square test. *Results.* Disruptive behavior was more prevalent in the ICU (81.6%) and the emergency department (67.8%). Professionals indicate that fear of reprisals is the main barrier to the reporting system. Likewise, stress and frustration are more associated with disruptive behavior and influence the safety climate. *Conclusion.* Professionals indicate that disruptive behaviors can have a negative impact on clinical outcomes. Age and type of service were identified as the most relevant socio-occupational factors. Stress, frustration, and communication problems are the factors that most influence the safety climate.

1. Introduction

The healthcare industry is considered one of the most complex sectors in the world, alongside aviation and nuclear energy. Labor relations within healthcare systems are especially noteworthy, as they contribute to an environment that is more susceptible to risks and failures. Furthermore, the likelihood of failures increases with the complexity of a system [1]. Interprofessional relationships between healthcare professionals are crucial in developing strategies to reduce disruptive behaviors and improve patient safety. Before this investigation, we conducted a systematic review to identify disruptive behaviors in nurse-physician

relationships and their impact on patient care [2]. However, we found limited international studies and none conducted within Spain's healthcare domain. This indicates a significant gap in the literature on disruptive behaviors in nurse-physician dynamics. Therefore, further research is necessary to understand healthcare personnel's perceptions of the factors contributing to disruptive behavior and areas that require improvement to prevent such behavior.

There is no consensus on the definition of disruptive behavior and safety climate. Nevertheless, this study aims to contribute to resolving this issue or advancing current knowledge. Concerning disruptive behaviors, we define them as actions that impede interpersonal communication,

strain work relationships, and hinder the sharing of crucial information among professionals, thereby directly impacting the quality of the care process [3, 4]. According to the patient safety culture [5], disruptive behaviors can lead to errors in the care process. Our study defines safety climate as how organizational factors influence the safety culture perceived by professionals and institutions [6, 7]. Specifically, patient safety culture is a strategic focal point to encourage healthcare professionals to adopt attitudes and behaviors that encourage patient safety [8]. Moreover, it fosters a nonpunitive environment in which individuals at all levels of an institution or organization (including caregivers, managers, and administrators) pledge to improve patient safety by promoting error reporting as a source of learning rather than blame [9, 10]. Cooper et al. stress the significance of fostering an organizational culture that esteems professionals, caregivers, managers, and administrators who adeptly navigate ethical conflicts impacting the quality of the care process. This culture encompasses effective communication (encompassing behavior management, staff safety status, and attitudes) and procedures (encompassing participation in decision-making, adherence to protocols, and task allocation) [11]. The perception of an unfavorable environment can lead to behaviors associated with horizontal violence, which negatively impacts patient safety [5]. On the other hand, creating a safe environment that promotes an improved safety climate can positively influence professionals' perceptions of workplace safety, leading to more favorable attitudes and behaviors toward patient safety. Research indicates a notable reduction (76%) in adverse event rates associated with such improvements [9, 12].

Many factors that cause disruptive behaviors are closely related to patient safety culture, particularly communication and teamwork. These factors significantly influence compliance with safe work practices [13] and healthcare professionals' perception of a safe environment [14]. Disruptive behaviors may be linked to low job satisfaction due to poor work relationships and co-worker communication [15]. Organizational risk factors at work [16], which include various aspects such as strategies, behavior, and attitudes adopted by healthcare centers to improve the safety environment, can influence professionals' perceptions. The attitudes and approaches of institutional managers and professional burnout can significantly affect emergency nurses' satisfaction and quality of work life.

For a long time, healthcare professionals and institutions did not openly acknowledge disruptive behaviors or measure their impact. In 2001 and 2002, the American Association of Critical Care Nurses (AACN) recognized the need to address the working relationships between nurses and management physicians. They emphasized the importance of establishing a reporting system for disruptive behaviors in healthcare facilities. They stated that such behaviors could not be ignored because they disrupt the workplace and can lead to unpleasant incidents and possible workplace accidents [17, 18]. In 2005, disruptive behaviors were observed to affect patient care and attention [19, 20]. In 2004, the Institute for Safe Medication Practices highlighted potential risks to patient safety due to the approach to medications. They stated that the disruptive behavior of some physicians inhibits nurses from asking questions or providing information about the use of drugs. This behavior is labeled "dangerous silence" and can be interpreted as abusive behavior by some physicians that prevents nurses from answering questions or seeking clarification [21]. In 2008, Rosenstein et al. [22] found that healthcare professionals identified disruptive behaviors as a cause of adverse events that disrupt the chain of patient safety. In 2012, the same author emphasized the connection between disruptive behavior and patient safety. The study revealed that nearly 33% of physicians and nurses believed that these behaviors could lead to adverse events, and, more alarmingly, 12.3% of them were associated with an increased risk of patient mortality [23].

Disruptive behaviors generate vertical workplace violence and are considered a public health problem with global repercussions, affecting the entire healthcare system in its multiple spheres and levels [24]. As part of its healthcare quality accreditation process for healthcare institutions, the Joint Commission has made it mandatory for institutions to implement policies that address disruptive behavior. These policies should be based on human capital prepared to handle the complexity of the healthcare environment. The aim is to prevent and control factors associated with disruptive behavior while ensuring patients' safety and protecting healthcare professionals' occupational health (physical, mental, and emotional) [25]. This study aims to analyze healthcare professionals' perceptions of disruptive behavior and factors associated with patient safety climate in the nurse-physician relationship at the hospital level.

2. Materials and Methods

2.1. Study Design. A multicenter cross-sectional study was conducted to assess the perceptions of healthcare professionals at the hospital level about disruptive behaviors and factors associated with the patient's safety environment. The research was conducted at the hospital level within the network of public hospitals in the Murcia region. This region encompasses nine referral hospitals, each corresponding to one of the nine Health Area Managements of the Murcian Health Service. Specifically, this study was conducted in five of the nine referral hospitals.

2.2. Participants. The sample consisted of nurses (direct care), administrative nurses (indirect care/management), physicians (direct care/management), and administrative physicians (indirect care/management) assigned to different clinical and surgical services.

The study included all physicians and nurses working in public hospitals in the Murcia region, Spain, who met the following criteria: (a) had a contractual relationship (permanent/interim) with any of the hospital services, (b) had worked for more than a year in the service/unit and job position, (c) were Spanish or naturalized citizens and belonged to different work shifts, and (d) agreed to

participate in the study. We excluded professionals with temporary contracts or on standby (holidays or temporary leave) because these contracts were subject to short periods in the same department/unit/plant and high staff turnover, which could bias the perception of the safety climate and work relationships.

The professionals were identified based on the hospital's human resources lists.

2.3. Procedure. During the study period, from January to July 20, 2022, a researcher was responsible for providing and collecting evaluation instruments. The researcher personally delivered each instrument to participants and explained the importance of their participation in the study. No personal data were included in the instrument to ensure anonymity and confidentiality. Participants were instructed to complete the scales and group them by units/services. The completed scales were collected and sealed in an envelope. In April 2022, a reminder intervention was conducted to increase the response rate.

2.4. Measurements. The instrument used was the Spanish version of the original "Survey on the nurse-physician relationship: The impact of disruptive behavior on patient care" [25]. This scale was cross-culturally adapted and validated for use at the hospital care level in Spain. [26]. In this study, the scale obtained a Relevance Index (RI) of 0.89 and a Pertinence Index (PI) of 0.94. The RI and PI values were both below 8, which was considered acceptable for each item and for the scale as a whole. Most of the items in the scale showed a moderate to almost perfect level of concordance between responses (16 items). The Intraclass Correlation Coefficient (ICC) values for these items were equal to or greater than 0.75, indicating excellent reproducibility. Additionally, all items in the scale showed a general agreement index of 100%. The scale is made up of 21 items. In the first part of the scale, the socio-occupational variables are presented: age, sex, service, and position (nurse and clinician or administrative physician). The latter was identified as nurse and clinician, which defines professionals who spend 50% or more of their working day in clinical tasks/direct patient care, and nurse and administrative/managerial physician, which represents professionals who spend 50% or more of their working day in administrative tasks/indirect management. Items 1 to 9 assess the perception of the environment, specifically the safety climate, in the relationship between nurses and physicians, addressing the presence and frequency of disruptive behaviors in different services and specialties. However, items 10 to 17 focuses on assessing the perception of the impact of disruptive behaviors on patient safety, considering various psychosocial aspects, adverse events, and dimensions such as communication and information. Items 18 to 21 focus on assessing the reporting system for disruptive behaviors and barriers that may hinder its effectiveness (Supplementary Table S1). This scale provides a comprehensive measure of the perception of disruptive behaviors in the relationship between physicians and nurses and their impact on patient care.

2.5. Data Analysis. Each item on the scale was used as a variable to assess healthcare professionals' experiences of disruptive behavior in the physician-nurse relationship and its impact on patient care. No missing data was present as we discarded incomplete questionnaires. This upheld data integrity for accurate analysis.

Proportions or means (standard deviation (SD)) were used to describe the participants' characteristics and the questionnaire's items. Univariate and multivariate linear regression models were used to analyze the perception of the environment of the physician-nurse relationship and the severity of problems caused by disruptive behavior. The chi-square test was used to compare the proportion of physicians and nurses who had witnessed disruptive behavior. We also used this test to examine the frequency with which physicians and nurses believe disruptive behavior negatively affects the team and patients. P values <0.05 were considered significant. All analyses were performed using SPSS software version 22.0 (IBM, Armonk, NY, USA).

2.6. Ethical Considerations. Approval was obtained from the Ethics Committee of the Catholic University of Murcia (Code No. CE041825) and from all participating hospitals to conduct the study. Furthermore, confidentiality and data protection are guaranteed by Organic Law 3/2018, of 5 December, on the Protection of Personal Data and the Guarantee of Digital Rights [27].

The Materials and Methods section should contain sufficient detail to repeat all procedures. It may be divided into headings if several methods are described.

3. Results

Of the 500 nursing and medical professionals from public hospitals in the Murcia region invited to participate in this study, 370 responded to the scale/instrument (74%). Most of the sample consisted of men (53%) between 20 and 29 years old (42.7%). 41.1% belonged to the emergency department. Regarding position/category, there were few differences in the frequency of participation, except for the low participation of administrative physicians (indirect assistance/management) (18.4%) in the other categories (Table 1).

The average perception of the nurse-physician relationship environment among the 370 participants was 8.05 (SD = 1.59).

Table 2 details the mean values for each variable studied and the results of the univariate and multivariate linear regression analyzes that identify the sociodemographic and occupational determinants of the environment of the nurse-physician relationship. The findings revealed a statistically significant association between the variable age range 30–49 years, both in the univariate (0.487, $p < 0.05$) and multivariate (0.566, $p < 0.05$) models, compared to the reference group (20–29 years). A significant association was also found with the administrative group (indirect care/management) of physicians in the univariate (0.975, $p < 0.05$) and multivariate (0.625, $p < 0.05$) models compared to physicians (direct care). The intensive care unit

Physician (administrative)	68 (18.4)
Nurse (clinical)	101 (27.3)
Nurse (administrative)	104 (28.1)
Unit	
Emergency department	152 (41.1)
Intensive care unit (ICU)	137 (37.0)
Surgery	81 (21.9)

(ICU) (univariate −0.453, $p < 0.05$; multivariate −0.505, $p < 0.05$) and surgery (univariate −1.090, $p < 0.001$; multivariate −1.078, $p < 0.001$) also showed significant associations compared to the emergency department. Nagelkerke's square R indicated that the independent variables used in the multivariate linear regression model explained 11.5% of the variance of the dependent variable.

According to the perception of nurses and physicians ($n = 370$), a higher prevalence of disruptive behaviors was observed in specific areas, the most affected being the intensive care unit (ICU) with 81.6% ($n = 302$), followed by the emergency department with 67.8% ($n = 251$) and general medicine with 58.6% ($n = 217$). Regarding the frequency of such behaviors according to specialty, respondents reported a higher incidence in general surgery with 83.0% ($n = 307$), followed by obstetric/gynecology with 45.9% ($n = 170$), and cardiology with 40.8% ($n = 151$). On the other hand, the specialty with the lowest frequency of disruptive behavior was anesthesia, with 13.2% ($n = 49$) of affirmative responses.

Table 3 shows that physicians (clinical) (87.6%) and administration/management nurses (81.2%) were the most frequent witnesses of disruptive behavior by a physician. When asked, have you ever witnessed disruptive behavior by a nurse at your hospital? A positive response from clinicians was observed (96.6%). Furthermore, compared to nurses, a significant difference was found and nurse clinicians (76.9%, $p < 0.001$) reporting more disruptive behavior from another nurse clinician.

In the multivariate model, the perception of the severity of disruptive behavior problems was primarily influenced by age and the care service. Table 4 shows that physicians and nurses in the age range between 30 and 49 years and those older than 50 years have a more marked perception compared to other age groups. Furthermore, the surgical service showed a significant influence on this perception in both professional categories, with coefficients of 0.911 ($p < 0.001$) for physicians and 0.674 ($p < 0.001$) for nurses.

When analyzing the impact of the results of disruptive behaviors in the nurse-physician relationship on the patient safety climate, the following factors were identified: stress and frustration (219, 59.2%), loss of concentration (207, 55.9%), reduced teamwork (161, 43.5%), reduced information sharing (214, 57.8%), reduced communication (269, 80.0%), and problems in the nurse-physician relationship (256, 69.2%). When analyzing the differences between physicians and nurses in these factors, it was found that loss of concentration, reduction in transmitted information, and problems in the nurse-physician relationship have a significant implication ($p < 0.001$) on the patient's safety environment according to nurses compared to physicians (see Table 5).

When asked about the relationship of disruptive behavior with aspects or indicators related to patient safety, the following percentages were identified: adverse events (25.4%), patient safety errors (13.0%), quality of care (20.8%), patient mortality (14.9%), nurse satisfaction (33.2%), physician satisfaction (43.2%), and patient satisfaction (39.2%). When analyzing the differences between physicians and nurses, it was found that physicians have a significantly more negative perception of quality of care ($p < 0.001$) and patient mortality ($p < 0.001$) than nurses.

Most professionals, 83.8% ($n = 310$), indicated that they were aware of a possible adverse event that could have occurred as a result of disruptive behavior. Furthermore, 29.0% ($n = 90$) stated that such events could be severe. Some 47.3% ($n = 175$) indicated that they were aware of the following adverse events that had occurred as a result of disruptive behavior: lack of information (8.6%), delays in care (28.0%), misunderstandings between staff (26.9%), and misinformation provided to relatives (36.6%).

Four questions were asked about the system to prevent and report patient safety incidents. When asked whether incidents could have been prevented, 94.9% ($n = 166$) answered yes. Regarding the conduct procedure, 99.7% ($n = 369$) indicated that a code of conduct or protocol is in place to address disruptive behavior in their hospital. Of these, 27.8% ($n = 103$) stated that a protocol was followed, while 71.9% ($n = 266$) mentioned a code of conduct. Virtually all professionals (99.7%) stated that a nonpunitive recording system was in place for those who witnessed or experienced disruptive behavior. In terms of barriers or obstacles to reporting disruptive behavior, practitioners noted fear of reprisals (82.4%), lack of confidentiality (19.7%), feeling that nothing would change (31.6%), and no response or outcome (10.0%).

4. Discussion

Overall, professionals assessed the nurse-physician relationship environment positively, though disruptive behaviors were noted in clinical practice, potentially impacting safety climate and clinical outcomes. Age and service type emerged as key variables affecting perceptions of disruptive behavior impact. Stress, communication barriers, and nurse-physician relationship issues were linked to disruptive behavior. Nurses reported more negatively affected concentration and information transmission. Due to disruptive behavior, physicians perceived lower care quality, safety, and

higher mortality rates. Such behaviors also diminished satisfaction among patients, physicians, and nurses. Professionals recognized patient safety incidents associated with disruptive behaviors but did not understand safety incident taxonomy. A cultural perception hindered trust in reporting systems for learning and improvement, indicating a need for cultural change as a priority in improvement strategies.

Although disruptive behaviors are not uncommon [28, 29] and should be of concern for healthcare institutions to improve patient safety and foster a working environment conducive to positive outcomes [7, 30], few studies have been published on this problem in the healthcare setting. This is the first study in Spain, to our knowledge, that explicitly addresses disruptive behaviors in the healthcare setting. The first published studies correspond to Rosenstein

et al., the authors of the instrument used in our research. In 2002, they analyzed 1,200 questionnaires on the United States West Coast [25]; in 2005, there were 244 participants [31].

In recent years, studies like ours have obtained a lower response rate than ours (74%). For example, a study in Singapore had a response rate of almost 40% (39.9%), and most of the respondents were physicians (64.2%) [32]. This contrasts with our results. In the context of Iranian healthcare care, we found two relevant studies. One of them, carried out in health centers affiliated with the University of Isfahan, involved 248 professionals, most of them nurses [33]. The other study was carried out in four emergency departments, with 45 physicians and 110 nurses responding [34]. Considering cultural and social differences, the professionals participating in our study may have a greater postpandemic awareness, leading them to participate in studies to improve the psychosocial aspects associated with the care process.

According to our 10-point maximum rating scale, our professionals reveal a moderate-high degree (with an average of 8.05 points). Being between 30 and 49 years old and working in the surgery and ICU departments are the sociodemographic and occupational factors most influencing this perception. Regarding age, these results were expected, as it is likely that, with increasing age, professionals acquire more experience and a more critical view of their working environment, identifying aspects that may go unnoticed by their younger colleagues.

Regarding the type of service, several studies have found that emergency and operating room areas are the most significant in the manifestation of disruptive behavior [22, 23, 25, 33, 35]. These two environments are high-stress environments characterized by high communication flow and remarkable concentration. Surprisingly, our findings, in agreement with those of Rosenstein and O'Daniel [35], indicate that the emergency department is not significant in

overall perception; on the contrary, the intensive care unit (ICU) and the operating theatre are. The Nagelkerke R square coefficient of determination value of 11.5% highlights the importance of interpreting this result with caution and assessing the linear relationship with other socio-occupational variables in future research.

In terms of the type of department and specialty, there are different perceptions. When asked about the prevalence of disruptive behaviors by department type, the emergency department and the ICU are the most relevant in our study. However, in terms of specialty, they are more frequent in general surgery, which coincides with the study by Saghaei et al. [33]. This reflects that these services have a context characterized by high demand and a high level of technology where life and death are separated by an instant or an error in care. It is understood that these characteristics can contribute to the perception of disruptive behaviors in these environments.

Our results reveal a significant discrepancy with the existing literature on the observation of disruptive behaviors. Previous research has indicated that clinicians and nurse clinicians frequently witness such behaviors in their work environments, primarily by clinicians. However, in our study, clinicians reported seeing disruptive behavior from other physicians and nurses with greater frequency than that reported by nurses, in line with the results of Lim et al. This finding is remarkable and contradicts the prevailing conception, suggesting that direct care nurses, who work in

contexts characterized by hierarchies, manifestations of authority, and negotiation of responsibilities, especially in emergency and operating rooms, are more susceptible to abusive behaviors from physicians.

Both older physicians and nurses show a higher perception of the severity associated with disruptive behaviors, with significant negative implications in the context of the surgical service. This phenomenon suggests that these factors are relevant in the professional assessment of the seriousness of disruptive behaviors. This finding indicates that more experienced practitioners may be more willing to express their views on disruptive behaviors' possible complications and effects.

According to the perspective of professionals and according to the existing literature, the main factors linked to disruptive behaviors that impact the safety climate include stress and frustration [32–39], poor communication [32], and problems in the nurse-physician relationship [33]. However, nurses report a more negative perception of lost concentration and reduced information transmission than their medical colleagues. This insight underscores the importance of communication and information for safer care [40, 41]. Professionals recognize the relevance of all aspects of communication for continuity of care and to promote a positive working relationship between nurses and physicians [42]. Both healthcare bodies and international organizations recognize that deficiencies in patient information transmission can cause substantial safety problems [42, 43]. Effective communication is a global goal to improve patient safety [44], as reflected in Strategic Objective 6: Information, research, and risk management of the World Patient Safety Action Plan 2021–2030 [45]. According to Astier-Peña et al. [46], this goal aims to ensure a better flow of information and knowledge to promote risk management and ensure more respectful care at all levels of care.

Regarding the undesirable clinical outcomes associated with disruptive behaviors, professionals point out that these directly impact the satisfaction levels of patients and professionals themselves, according to previous research [32–34, 47]. There is also evidence of their relationship with adverse events in clinical practice. Given the consequences and impact of disruptive behaviors, these results were predictable. The degree of satisfaction is not always determined solely by the structure or level of knowledge; it can be related to a culture of attitudes and behaviors that have a negative impact on working relationships [48, 49], compromising the safety climate, weakening teamwork, and affecting job satisfaction. Furthermore, our findings highlight that physicians are the ones who most strongly perceive the relationship between disruptive behaviors and poor quality of care and patient mortality, in agreement with another research [32, 34]. However, these cause-effect results must be assessed with caution, as other factors that have not been studied or may be intrinsically or hidden in negative behaviors and attitudes can be involved, which can be detrimental to the care process.

Although unwanted events due to disruptive behavior were not unexpected, as identified in other studies [20, 22, 25, 32, 34, 41, 45], we were surprised by the high percentage observed in the investigated context. Professionals reported adverse events such as "misinformation to relatives," "delay in care," and "misunderstandings between staff." We recognize that disruptive behaviors affect the safety climate and can have severe consequences on the job, compromising the nurse-physician relationship and creating obstacles to improving the quality of care. However, when examined from the perspective of the taxonomy of safety incidents proposed by the Heinrich Pyramid, we observe that, rather than events, they constitute patient safety incidents with the potential to cause patient harm [50]. These incidents are classified as near misses, indicating the possibility of having caused harm to the patient [50], and physicians indicated that these risk circumstances for patient safety could have been avoided. Furthermore, they noted clear guidelines in their centers on addressing disruptive behaviors, through protocols or codes of conduct. We believe that this aspect is relevant and should be integrated into the healthcare management strategies of each center and institution.

In examining the question related to the reporting system for disruptive behaviors witnessed or experienced, almost all practitioners indicated that it was a nonpunitive system. However, a significant proportion of them expressed that fear of reprisals was a major concern, acting as a substantial barrier to reporting such behavior. Furthermore, they reported a perceived lack of feedback or positive response as a consequence of the report. They noted that there was no change in practice, findings that are consistent with previous research [31, 33, 34, 47]. Against this backdrop, several questions arise. Is there truly a nonpunitive system, or does fear persist among professionals to speak openly and honestly about the reporting system? Do professionals understand the inherent meaning and function of a reporting system? Have health institutions succeeded in effectively implementing a reporting system? These questions raise fundamental questions about the culture of patient safety. Despite more than two decades since the publication of the report To Err Is Human [51], it remains imperative to address these issues to drive continuous improvement in quality and safety in healthcare. The foundation of all healthcare systems is an awakening towards improving patient safety, evidenced by joint efforts and focused attention on this crucial aspect. Despite two decades since the National Quality Forum's recommendation to implement safety culture as the first of its "30 safe practices," there is still a way to go towards fully realizing this goal [52]. From our perspective, the "tip of the iceberg" represents only a visible fraction of a broader set of factors influencing or determining safe practice. We recognize that visible and invisible aspects intrinsically relate to patient safety culture. This culture, characterized by its nonpunitive nature and its focus on learning from mistakes, is a fundamental element in promoting safety and improving the quality of care [8].

This study is not without limitations. First, the sample used. Our study focused on five hospitals of the 9 Health Departments of Murcia Healthcare, Spain. This selection can restrict the interpretation of the results, as it is described as a global perception of professionals only in hospitals in

a specific region of Spain. Although it was not our main objective, it is important to note that including other professional categories could enrich the understanding of the general importance of disruptive behaviors. This aspect should be addressed in future studies. It is essential to remember that the subjects in our study represent only a sample of the total population, which also implies certain limitations regarding the generalizability of the findings.

The second aspect refers to the "Nurse Physician Relationship Survey: Impact of Disruptive Behavior on Patient Care." Although the results of the previous study of adaptation and validation [24] in Spanish were satisfactory, certain important aspects must be considered. Not many questionnaires or scales have been found that specifically address disruptive behavior in the hospital setting. Although this scale covers all the issues relevant to our research objectives, few studies are available to compare the results obtained. In the Spanish context, none have been identified to date. More research is needed to assess the perception of disruptive behaviors in the hospital setting and their impact on patient safety using this national and international instrument to establish meaningful comparisons between different countries.

Finally, another study limitation is the lack of consideration for potential confounding variables. While efforts were made to control for known factors, variables beyond the scope of this research could influence outcomes. Future studies should address these variables to provide a more comprehensive understanding of the phenomena under investigation.

5. Conclusions

Professionals have assessed that the nurse-physician relationship environment is relatively good overall. However, disruptive behaviors have been observed in clinical practice, which can have a negative impact on the safety climate and clinical outcomes.

Age and type of service were the most relevant socio-occupational variables for the perception of the impact of disruptive behavior in the nurse-physician relationship. The factors most associated with disruptive behavior and influencing the safety environment included stress and frustration, reduced communication, and problems in the nurse-physician relationship. Nurses expressed significantly more negative perceptions of losing concentration and reducing information transmission.

Regarding the impact of disruptive behaviors on the nurse-physician relationship and clinical outcomes, physicians have a more unfavorable perception of quality of care, patient safety, and even mortality rate. In addition, disruptive behaviors negatively influence patient, physician, and nurse satisfaction.

We have observed that professionals do not yet understand the taxonomy of patient safety incidents, but they have a relatively high perception of incidents associated with disruptive behaviors. In addition, a cultural perception persists that generates fear and "low credibility" with respect to the reporting system as a tool for learning and improvement. Changing culture is not an easy challenge, but it significantly impacts other countries and remains a priority in improvement strategies.

The bullying of nurses by patients, doctors, and employees is common in the healthcare industry. Nurses who are bullied are more likely to experience burnout, and nurses who experience burnout are more likely to intend to quit. However, few studies investigate how leadership can mitigate workplace incivility and nurse bullying as a way to improve nurse retention. A cross-sectional study was conducted using a sample of 216 nurses recruited from various regions across the United States from different specialties. A moderated mediation model using path analysis was used to examine the relationships between bullying, burnout, and ethical leadership in predicting intentions to stay. Bullying significantly and positively related to burnout ($\beta = 0.22$, $p = 0.02$), and burnout significantly and negatively related to intent to stay ($\beta = -0.18, p = 0.01$). Perceived ethical leadership predicted intentions to stay ($\beta = 0.62$, $p = 0.00$), and ethical leadership moderated the effect of bullying on burnout ($\beta = 0.20$, $p = 0.03$). The results of our study also suggest that nurses are less likely to quit when ethical leadership is present, and ethical leadership weakens the effect of bullying on burnout.

1. Introduction

Nurses are a key part of the healthcare system; they have the majority of direct interactions with patients, and it is estimated that by the next decade over 13 million nurses will be needed worldwide [1]. In the United States, there will be a national shortage of 63,720 full-time registered nurses for nursing roles by the year 2030 [2]. Additionally, the health systems of all 63 countries of the World Health Organization European Region have been adversely affected [3], and a shortage of more than 100,000 nurses is expected in Australia by the year 2025 [4]. This shortage is, in part, due to a variety of factors including a decline in nursing faculty, an aging population, an aging nursing workforce, burnout, staffing ratios, and verbal abuse in healthcare settings [4]. Many new nurses graduating and beginning their careers are not staying in the profession as a whole for long [5]; in

addition, fewer nurses are becoming certified [6–8]. Additional factors contributing to this shortage include workplace environment, team dynamics, leadership style, organizational commitment, and turnover [7]. As this historical shortage persists in the United States [9, 10], patient care suffers, and the remaining nurses tend to be overworked, which leads to more negative experiences for those remaining.

In recent years, events such as the introduction of the Affordable Health Care Act in the U.S. have resulted in a substantial increase in potential patients testing the capacity of healthcare providers [11]. Coupled with global health pandemics such as SARS, Ebola, and Covid-19 over the past few decades, first responders in healthcare have encountered additional strain that leads to burnout [12] and lower job engagement worldwide [13, 14]. For example, during the time of the COVID-19 pandemic, nurses in

Australia and New Zealand experienced more stress and greater workloads [15, 16]. More than half of the 351 nurses in a study conducted in Oman during the pandemic reported high levels of job burnout [13]. This resulting burnout among nurses is high [17, 18], and it is an important variable that affects employee turnover intentions [19]. Therefore, it is critically important to assess the level of burnout among nurses and identify factors that can reduce it.

Turnover can be costly for organizations monetarily [20], but turnover among nurses has even greater implications for healthcare organizations because it negatively impacts patient outcomes [21] and healthcare resources [22]. Nursing shortages lead to negative outcomes including an increase in mortality, staff violence, accidents, and injuries [8], rates of nosocomial infections, patient mortality, patient falls, pressure ulcers, prolonged average hospital stay lengths, and additional healthcare costs [23], further validating the need for solutions to ameliorate it.

Prior research has shown that some main psychological predictors of turnover include job satisfaction [24, 25], organizational commitment, and intent to stay [24, 26], value attainment, and mood [25]. Being bullied at work [27], burnout [19, 28], and leadership style [29] have also been shown to influence employees' turnover intentions. In the context of nursing, inadequate staffing is another important predictor of turnover because it leads to greater physical exhaustion by nurses managing heavy workloads [28].

Bullying is one way in which experienced nurses control new nurses to meet objectives, but verbal abuse can be traumatic for new nurses [30] and lead to outcomes that are psychologically, physically, and emotionally harmful [31]. In prior research, bullying is "considered as the most chronic issue in the health-care sector" [32]: 2, and being placed in stressful and unethical situations such as this can lead to job burnout [33]. Moreover, nurses who experience bullying at work may leave the nursing profession altogether [34–36]. Although bullying and burnout can negatively affect outcomes for nurses and their patients, scant research addresses strategies to reduce bullying incidents, especially related to nursing [37].

Some research results suggest that leadership styles of nursing managers can impact nurse behavior [29]. Unfavorable leadership styles, such as toxic leadership, are positively related to turnover intentions [29] while favorable leadership styles, such as transformational leadership, are negatively related to turnover intentions [38]. Despite the call from scholars to redirect attention to ethical leadership to improve nursing and patient outcomes [39], empirical investigations on how it can impact a culture of workplace incivility and burnout are limited. Because ethical leadership can model ethical performance [37], we propose that ethical leadership will ameliorate workplace incivility, and possess a buffering effect on burnout that stems from bullying behavior.

In this study, we examined perceived ethical leadership among nurses working for various types of healthcare provider institutions, and the consequences of bullying and burnout on intentions to stay. Our aim is to understand some understudied causes of turnover intentions in nursing.

Our study makes a significant contribution to the literature in the following ways. First, given the turnover crisis in the nursing profession [4, 8], we fill a void in the turnover intentions literature by investigating how an ethical leadership style can mitigate the effect of bullying on burnout. Furthermore, because ethical leadership is understudied in the nursing literature [32, 37], and bullying is prevalent among new nurses [40], we examine its effect on intentions to stay among nurses who experience burnout as a result of experiencing or observing bullying in the workplace. In line with prior research, we contend that bullying and burnout have negative effects on intentions to stay, and further the literature by proposing that perceptions of ethical leadership influence this relationship.

As shown in Figure 1, we hypothesize that bullying is directly related to job burnout of nurses. Further, we propose that job burnout is negatively related to intentions to stay. Also depicted by our model, we contend that leadership perceived to be ethical by nurses ameliorates the effect that bullying has on job burnout. Lastly, we propose the interaction effect between perceived ethical leadership and bullying on job burnout is indirectly related to intentions to stay resulting in a moderated mediation model.

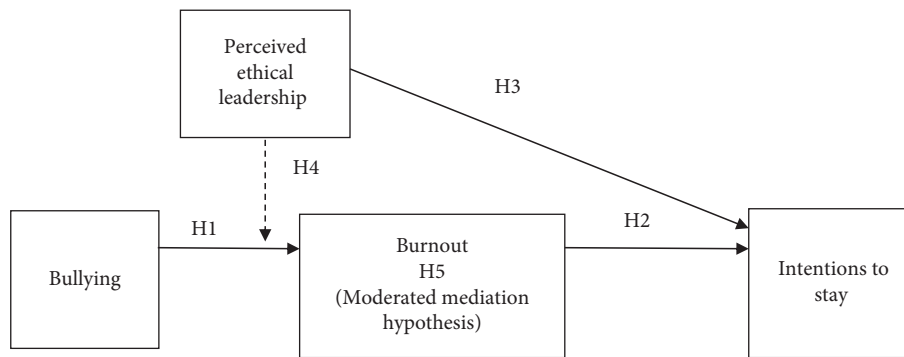
1.1. Predictors of Turnover Intentions. Turnover intention refers to when an employee's motive is to leave a specific organization [41] and is a predictor of the actual act of turnover [42]. Job turnover among nurses has been an ongoing concern for many years [43] with the national average total hospital turnover rate being 19.5% as of 2022 [44]. In general, four types of variables have been studied extensively as predictors of turnover which include job training, job involvement, positive affectivity, and negative affectivity [45]. Positive and negative affectivity refer to dispositional states of pleasurable or unpleasurable engagement, respectively [46]. Justice, stress, and social support are variables associated with positive and negative affectivity used to research determinants of turnover [45], which include, but are not limited to, dimensions of supervisory support, role overload, role conflict, and perceptions of fairness [45]. Specific to the field of nursing, job turnover is exacerbated when nurses' have negative experiences in their work environment [47]. For example, other factors contributing to turnover include pandemic-related pressures [48], inadequate nurse staffing [49, 50], dealing with toxic leadership [29], and workplace violence [51]. In line with research on perceptions of fairness, bullying in the workplace is associated with high turnover intentions [52–54]. Viewed as a form of stress, burnout is also linked to intentions to quit and actual turnover [33]. As of recent, nurses specifically are leaving the nursing field due to emotional exhaustion brought on by high job demands, low job control, and role overload due to caring for COVID-19 patients [55], that also contributes to lower overall psychological well-being among nurses [48]. Besides dispositional effects on turnover intentions, perceptions regarding the nursing profession and the negative public image of their organization also affects nurses' job satisfaction which in


FIGURE 1: Conceptual model.

turn influences their decision to quit their job or the profession entirely [51, 56].

1.2. Nursing Context. For our study, we focus on bullying and how it leads to both burnout and nurse intentions to stay because healthcare organizations are especially susceptible to bullying behaviors [30, 57]. There is evidence to suggest this may be because nurses are taught to bully others as an organizational cultural norm [58], and that healthcare systems traditionally operate using paternalistic styles of leadership that can lead to the oppression of nurses [58], exacerbated by authoritarian management practices [59]. Bullying is the act of aggressive behavior toward an individual repeatedly over time [60] which may also violate employees' civil rights [61]. Due to both the nature of their work environments and hospital group dynamics, nurses work under unique conditions that can be tied to turnover, including the experience of both physical and psychological effects. Physical conditions experienced by nurses from doctors, patients, and co-workers include "invasion of personal space, shoving and blocking the way, threat of violence, physical abuse, or actual abuse" [57]: 140. Patients in facilities where nurses are bullied can also receive poor nursing care or experience adverse events [62, 63]. We suggest that the nurse manager can play a key role in mitigating these bullying behaviors as a way to increase nurse retention and improve patient outcomes. Specifically, we study the effect that the ethical leadership of the nurse manager has on these scenarios.

1.3. Bullying and Job Burnout. Job burnout occurs when employees experience chronic stress resulting from their job [64] and is caused by various stressors which may include a number of physical or psychological issues nurses experience in their workplaces [65]. A key dimension of burnout is exhaustion [33], which is defined in the nursing literature as a common feeling of physical and emotional overload experienced by nurses stemming from interactions with co-workers and patients [66]. A work environment where bullying occurs is a stressful environment where employees feel intimidated, abused, or insulted, resulting in a stressful work experience [32]. Workplace bullying among nurses can lead to a number of psychological and mental health

outcomes and work behaviors such as quiet quitting [67], depression, suicidal ideation, post-traumatic stress disorder, deterioration in the quality of their work life [68], job dissatisfaction [51], and burnout [69]. Physical health symptoms experienced by bullied nurses include headaches, eating disorders, onset of chronic diseases, and sleep disturbances [40].

Emotional exhaustion, a dimension of burnout [33], can be exacerbated by bullying, which could have a greater effect on intent to leave than any other factor [35]. Bullying can manifest itself in unfair treatment or any sort of verbal or physical harassment and may greatly influence whether or not nurses stay with an organization [61]. Examples of bullying include, but are not limited to, verbal attacks, intimidations, and withholding support [70] and its effect on employees shares similar characteristics to symptoms of burnout including anxiety and depression symptoms [33, 71, 72]. Further, prior research has shown that nurses experience burnout in climates where workplace bullying occurs [73]. In line with prior research, we contend that bullying is another prevalent factor that explains intentions to quit as it influences feelings of burnout.

Hypothesis 1. Bullying is positively related to burnout.

1.4. The Effect of Burnout on Intentions to Stay. Some of the global nursing shortage can be attributed to burnout, as increasingly more countries report how it has directly impacted turnover across their health systems [50]. Since nurses are likely to experience job burnout [74], the relationship between burnout and turnover must be further explored, especially since nurses have ongoing interaction with patients and their visitors, and frequent encounters with work stressors [75]. Burnout is considered a stress phenomenon, linked to lower job performance and poor health outcomes [33, 76], physical and mental health outcomes including psychological and physiological fatigue [75], impaired short-term memory and cognitive decline [77], alcohol and drug use [76], and disintegration of family and social relationships [74, 78, 79]. Under stressful circumstances associated with burnout, employees are less committed to the organization [80], become exhausted, and struggle to continue working. Some recent examples of stressful circumstances that relate to burnout and turnover

among nurses include, but are not limited to, inadequate staffing [50], anxiety, and fear stemming from caring for patients during the COVID-19 pandemic [81]. Consequently, nurses experiencing burnout seek other jobs [82] and are more inclined to quit [75]. Not only is nurse burnout related to greater turnover [51, 83], burned-out nurses may no longer communicate effectively with others, engage in behaviors of workplace incivility [83], and experience physical and mental health challenges. Burned-out nurses will also express indifference toward patients [84] which can jeopardize their safety [21].

Hypothesis 2. Burnout is negatively related to intentions to stay.

1.5. The Effect of Ethical Leadership on Employees and Organizations. The type of leadership employees receive can greatly influence performance, especially in an environment like that of nursing. Ethical leadership is an observable expression from leaders of support for behavior deemed appropriate for followers that may be enacted through relationship building [85], communication, decision-making, and reinforcement [86]. Various studies have shown that ethical leadership creates an ethical environment conducive for reducing moral distress, thereby improving job satisfaction and absenteeism [87]. However, among the few studies on ethical leadership in the nursing literature that do exist, the number of quantitative studies is lacking [88].

Leaders in an organization set the tone for employees in terms of establishing a support system, the work environment, and acceptable behaviors. In fact, one of the most powerful methods to promote ethics in healthcare and the nursing practice is to role model ethical performance on the managerial level [37]. Leaders, through displaying and modeling ethical leadership, foment an ethical environment for nurses. Working in an ethical environment is especially important in a healthcare environment; especially at the nurse level, given that they interact the most frequently with patients.

1.6. Ethical Leadership and Turnover Intentions. In environments where nurses are "faced with obstacles that force them to act against their ethical beliefs, they feel discomfort, dissatisfaction, and frustration" [89]: 5, which can increase intentions to quit. An ethical environment allows nurses to feel supported and operate in an environment that is conducive to a higher quality of patient care. Moreover, ethical leadership influences the behavior of employees through its influence on the work climate [90]. However, many nurses report that they feel unsupported by their leaders [37] and some nurse leaders admit that ethical practice should be emphasized more as a part of organizational support [39]. However, the literature regarding the role of ethical leadership in nursing has recently been sparse [37]. For these reasons, we expect ethical leadership to be immensely important in the nursing field, which can prove beneficial for healthcare systems via increased job satisfaction for nurses and better patient outcomes [39]. Medical practices may

receive outsized gains for attracting and developing ethical leaders throughout their organization due to the difficult work climate that nurses face on a day-to-day basis [91]. Furthermore, results from prior research suggest that a climate perceived as ethical helps prevent burnout [92] and strengthens organizational commitment [92–94], and job satisfaction [95–97], both predictors of turnover intentions [56]. For this reason, we expect to find that strong ethical leadership has a direct relationship with intention to stay.

Hypothesis 3. Perceived ethical leadership is positively related to intentions to stay.

1.7. The Interaction Between Perceived Ethical Leadership and Bullying. While we suggest that bullying [27] and burnout [98] will increase employees' intentions to leave an organization, we propose that the employment and development of ethical leaders in the organization can mitigate those intentions. Ethical leadership in place decreases employee anxiety about their job and increases employee behavior aligned with ethical principles [99]. Ethical leaders are both moral persons and moral managers [100]. Not only do they need to be moral individuals, but also they must apply that morality in the workplace. Brown and colleagues [86] define ethical leadership as "the demonstration of normatively appropriate behavior through personal actions and interpersonal relationships, and the promotion of such conduct to followers through two-way communication, reinforcement, and decision-making (p. 120)." Prior research has utilized social learning theory to explain how ethical leadership can mitigate negative workplace environments [101, 102]. This is welcome news for healthcare providers and nurses in particular because work environments in healthcare organizations have been shown to create a climate that leads to burnout [103].

Ethical leaders set a standard for what moral behavior is like in the workplace [104]. Employees with ethical leaders learn what is and what is not appropriate behavior in the organization through their leaders. In addition to the likelihood that bullying would decrease under ethical leaders due to an increased ethical climate [105], employees reporting to ethical leaders will be much less likely to assume bullying behavior is normal and appropriate workplace behavior. Evidence suggests that employees with ethical leaders will develop the ability and willingness to confront and address the conflict behavior [106] rather than assuming that exiting the organization is their only way out. For example, Islam and colleagues [32] found that the presence of ethical leadership positively influenced employee voice behavior and negatively affected bullying. In addition to the ethical role modeling and increased psychological safety that employees feel when working for ethical leaders, these ethical leaders have also been found to increase employees ability to deal with relationship conflict situations in the workplace by increasing employees' ability to create resolution [101]. In addition to social learning, the way that leaders design the work environment has been found to be a key mechanism for ethical leaders to decrease workplace

bullying [107]. Prior research indicates that ethical leaders influence both the work climate that an employee works in and influences the behaviors and abilities of employees directly. For these reasons, we expect ethical leadership to moderate the effect that bullying has on employee burnout.

Hypothesis 4. Perceived ethical leadership moderates the effect of bullying on burnout such that nurses will experience less burnout from bullying when ethical leadership is high compared to when it is low.

Thus far we have proposed that bullying is positively related job burnout (i.e., Hypothesis 1 above), and that this relationship is moderated by perceived ethical leadership (i.e., Hypothesis 4 above). We also proposed that perceived ethical leadership is positively related to intentions to stay (i.e., Hypothesis 3 above). As prior research suggests that job burnout predicts turnover intentions, we contend that perceived ethical leadership signals to nurses messages of support regarding bullying prevention which, in turn, improve their feelings of job burnout, and ultimately intentions to stay. Thus not only do we propose that job burnout is related to intentions to stay (i.e., Hypothesis 2 above), we also propose that a conditional indirect effect exists for bullying and perceived ethical leadership on intentions to stay through job burnout. Based on prior research regarding the mediating role of burnout [79], this type of model is a moderated-mediation model [108, 109] resulting in our final hypothesis (full model shown in Figure 1).

Hypothesis 5. Bullying is related to intentions to stay via conditional indirect effects, such that its relationship with intentions to stay is moderated by perceived ethical leadership and mediated by job burnout.

2. Materials and Methods

2.1. Participants. A total of 216 nurses from various regions across the Unites States were recruited from different specialties to participate in the current research study in exchange for modest compensation. One hundred were identified through an email listserv managed by the Association of Women's Health, Obstetric, and Neonatal Nurses (AWHONN) and followed by nurses in obstetrics and women's health as their primary field. The remaining 116 were recruited using an online surveying agency (Turk-Prime's Prime Panels platform: https://www.turkprime.com/LaunchedSurvey/PrimePanels) that commissions large-scale stratified samples. By recruiting participants from a wide array of online sources, this service allows researchers to set a priori demographic quotas for sampling. The panel was set to ensure the recruitment of participants from the nursing field.

2.2. Measures. All of the scales of measurement used for the current study were adapted from those published in peer-reviewed journals and have a reliability Cronbach's alpha coefficient greater than 0.80.

2.2.1. Intentions to Stay. The dependent variable intentions to stay were measured using a four-item five-point Likert scale [110] used to measure intent to stay. For the current study $\alpha = 0.89$. Sample items include "I would like to leave my present employer" and, "I plan to stay with my present employer as long as possible."

2.2.2. Bullying. The workplace incivility/bullying culture scale [111] was adapted to measure the independent variable bullying. It includes 12 items and uses a five-point Likert scale. The scale yielded a coefficient $\alpha = 0.96$ for the current study. The survey begins with the following incomplete question to be completed by the 12 listed items to total 12 questions: "During the past year were you ever in a situation in which any of your supervisors or coworkers..." Sample items used to complete the question asked of participants include "Gave you hostile looks, stares, or sneers" and, "Made jokes at your expense."

2.2.3. Burnout. Malach-Pines' [112] short version of burnout measure was used to measure the mediating variable job burnout of participants in the current study. It includes 10 items using a seven-point Likert scale and yielded a coefficient $\alpha = 0.92$. Participants are asked an introductory question "When you think about your work overall, how often do you feel the following?" Sample items that follow the introductory question for participants to answer include "Hopeless", and "Difficulties sleeping."

2.2.4. Perceived Ethical Leadership. We measured perceptions of ethical leadership using the 10 item five-point Ethical Leadership Scale that Brown and colleagues [86] developed. For the current study $\alpha = 0.96$. Sample items include, "Conducts his/her personal life in an ethical manner," and "Sets an example of how to do things the right way in terms of ethics."

2.2.5. Controls. Age, race and organizational tenure were originally entered as control variables, and because they significantly did not have an effect on the primary variables of interest we removed them from the main statistical analysis.

2.3. Procedures. Online surveys were used to collect the data for this study. Participants replied to a link sent to their email address after having signed up to be a part of the research study either through their listserv announcement or as part of the Prime Panels platform. Upon clicking on the link, participants were redirected to an introductory web page where they provided consent before completing a battery of questions including surveys that measured the primary variables of interest in the current study dispersed among other surveys that measured various work attitudes, perceptions, beliefs, and basic demographic information.

2.4. Statistical Analysis. A moderated mediation model using path analysis in Mplus v.8 was conducted to examine proposed relationships [113] as seen in Figure 2. A moderated mediation path model is a statistical technique used to
FIGURE 2: Graphed interaction effect between bullying and perceived ethical leadership on burnout.

TABLE 1: Descriptive statistics and bivariate correlations.

	Variable	Mean	SD	1	2	3
1	Bullying	1.58	0.79			
2	Burnout	3.10	1.17	0.30**		
3	Ethical leadership	0.13	1.10	−0.39**	−0.42**	
4	Intentions to stay	3.60	1.10	−0.36**	−0.46**	−0.61**

Note: $N = 184$.

Abbreviation: SD, standard deviation.

**$p < 0.01$.

Hypothesis 3 which proposed that perceived ethical leadership predicts intentions to stay was also supported with significance ($\beta = 0.62$, $p = 0.00$), and our fourth hypothesis proposing that ethical leadership moderates the effect of bullying on burnout was supported ($\beta = 0.20$, $p = 0.03$). The graph of the interaction in Figure 2 indicates the direction hypothesized with perceived ethical leadership mollifying the effect of bullying on burnout. Our fifth and final hypothesis proposed a moderated mediation model. Although there were significant paths from bullying to burnout and from burnout to intent to stay, and the interaction term was significant, the indirect effect of bullying on intentions to stay was not significant; hence Hypothesis 5 was not supported ($\beta = -0.04$, $p = 0.08$). Table 2 presents the results and coefficients for the observed variables.

examine how the relationship between two variables (independent and dependent variable) is influenced by a third variable (moderator) through a mediating variable [114, 115]. In this model, the mediator (burnout) lies between the independent and dependent variables and explains part of the effect of the independent variable on the dependent variable. The moderating variable (ethical leadership) influences the strength or direction of the relationship between the independent variable and the mediator, ultimately affecting the indirect effect on the dependent variable. The current model examined the interaction between bullying, burnout, and ethical leadership in predicting intentions to stay. The primary purpose of the model was to examine how job burnout mediated the relationship between bullying and intentions to stay. In addition, the interaction effect between bullying and perceived ethical leadership on job burnout was tested to examine the mediation effect further.

3. Results and Discussion

3.1. Results. Participants with missing data related to the variables being investigated were removed resulting in 184 valid responses ($N = 184$); a response rate of 85.2%. Respondents were 92% female with an average age of 40.2 years (SD = 11.95), and most were White (84%), followed by Black (7.4%), Hispanic/Latinx (6.8%), and American Indian (1.9%).

Table 1 shows the means, standard deviations and bivariate correlations for all study variables. It should be noted that the path model was just-identified, thus, model fit indices were not useful (i.e., RMSEA = 0.00, CFI and TLI = 1.00). Our first and second hypotheses were supported as expected indicating that bullying significantly and positively relates to burnout ($\beta = 0.22$, $p = 0.02$), and burnout significantly and negatively relates to intent to stay (i.e., intentions to quit) ($\beta = -0.18$, $p = 0.01$), respectively.

3.2. Discussion. There is an ongoing shortage of skilled nurses across many high income countries. The key components of nursing work of providing care are challenging and emotionally trying, which have an impact on the shortage and the ability of the industry to attract and retain nurses [116], and the resulting quality of patient care [28]. Prior research has established that bullying relates to burnout [23, 69, 116–118], yet there is limited research that examines solutions to mitigate this relationship, and how nurse leaders, specifically, can address this cultural phenomenon. There is limited research that investigates the effect of ethical leadership on nursing outcomes [37], and scant research in the nursing literature addresses how various styles of leadership can mitigate the effect of bullying on burnout and turnover intentions, specifically. The results of the current study contribute to the literature and to solutions for mitigating burnout and turnover among nurses in a number of ways.

The results of the current study align with prior research suggesting that bullying relates to burnout, and that burnout relates to turnover intentions [23, 118]. The results also suggest that bullying has a main effect on turnover intentions. However, we found no indirect effect for bullying on turnover intentions through burnout in the present study, compared to prior studies with nurses working in Taiwan [23] or Korea [118]. This could be due to cultural differences and how workplace culture is perceived differently by nurses in the United States compared to nurses from other countries. For example, based on Hofstede's dimension of national cultures [119], the United States ranks lower than Taiwan and Korea on the dimensions of power distance and higher on the dimension of individualism. Power distance is defined as the

TABLE 2: Summary of path analysis predicting intentions to stay.

Path	R^2	β	SE
Burnout on	0.23*		
Perceived ethical leadership		0.39***	0.09
Bullying		0.22*	0.09
Perceived ethical leadership X			
Bullying		0.20*	0.09
Intentions to stay on	0.52***		
Perceived ethical leadership		0.62***	0.06
Burnout		−0.18*	0.07

Note: $N = 184$.
Abbreviation: SE, standard error.
* $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$.

degree to which employees prefer a consultative or participative style of leadership (i.e., low ranking) versus an autocratic style of leadership (i.e., high ranking) [119]. Individualism refers to the degree in which a person views their connection to their society on a spectrum of either having loose ties to others and looking after one's self (i.e., high ranking), or valuing strong bonds with their community and having a great sense of loyalty to their society (i.e., low ranking) [119]. Employees in the U.S. who prefer a consultative style of leadership (i.e., low power distance) may be less apprehensive about expressing their opinions, attitudes, and beliefs with leadership compared to employees in other countries where a more autocratic style of leadership is preferred (i.e., high power distance). Also, employees in the U.S. who are more likely to hold individualistic ideals (i.e., high individualism) may be more likely to challenge the "status quo" compared to employees from countries where collectivism ideals (i.e., low individualism) are the norm. We posit that this perspective may weaken or eliminate the indirect effect that bullying has on turnover intentions. This is because their perceived ability to express concern about bullying may serve as a coping mechanism for reducing burnout, thereby weakening the relationship. More research about the relationship between bullying, burnout, and turnover intentions among nurses in the U.S., and its comparison across multiple countries may offer a more comprehensive understanding of this phenomenon.

Suggestions for mitigating the effects of bullying and burnout on turnover have been proposed in prior research [23, 118], but there is limited empirical evidence that these solutions work. Although prior research has investigated the relationship between leadership, bullying, burnout, and turnover intentions, not all leadership styles have been empirically examined as a means to mitigate the negative effects of this relationship. Laschinger and colleagues [120] conducted a study with results to suggest that authentic leadership negatively affects workplace bullying. Another study, qualitative in nature, suggested that transformational leadership attributes are important for establishing a positive hospital work environment [121]. We responded to the call for a greater examination of ethical leadership as an effective tool to manage nursing outcomes in healthcare [37, 118], and specifically the call to propose interventions to mitigate the effect of bullying on burnout [69]. Not only did the current study results suggest that ethical leadership has

a positive main effect on intentions to stay, the results also show that ethical leadership ameliorates the effect of bullying on burnout. Providing ethical leadership training and employing nurses who demonstrate ethical leadership may be a useful strategy for mitigating the effect of bullying on burnout, two important predictors of turnover.

4. Limitations and Future Research

It is important to note a few limitations of this study. The current study used self-report measures where social desirability may have affected the results of the data in addition to mono-method bias as a result of common method variance [122]. Cross-sectional designs such as the kind used for our study also poses limitations on causal inferences regarding the relationships between the observed variables. Online data collection also can pose limitations for controlling environmental factors. However, prior research has established there is equivalence between the results of online survey methods and results produced using paper-and-pencil formats [123].

Although our study yielded significant findings, qualitative studies may offer additional explanations to why ethical leadership mitigates the effect of bullying on burnout and increases intentions to stay in the nursing field. The current study used the survey method to measure participants' perception about the ethical leadership of their nurse manager, which can limit the richness of the data collected. Research questions that address how followers identify ethical leadership in healthcare settings are warranted. For example, does it matter if perceived ethical leadership communication is verbal instead of written? Are there any effects for gender based on the identity of leaders or nurse managers? Building on prior research [124], should we investigate whether any effects exist for race based on the identity of leaders or nurse managers perceived as ethical? Future researchers should address these questions to explain the effect of different circumstances under which ethical leadership influences the behavior and attitudes of nurses.

5. Conclusions

The aim of the current study was to investigate the relationships between perceived bullying, burnout, perceived ethical leadership, and turnover intentions. In line with prior research, the results suggest that nurses who get bullied are more likely to experience burnout, and nurses who experience burnout are more likely to intend to quit. Furthering this line of research, the results of our study also suggest that ethical leadership weakens the effect of bullying on burnout, and nurses are less likely to quit when ethical leadership is present [125–130].

5.1. Implications for Nursing Management Research. Our path analysis findings align with and extend previous research on workplace mental health outcomes in nursing. The significant relationship we found between bullying and burnout ($\beta = 0.22$, $p = 0.02$) supports prior studies showing that workplace incivility and bullying contribute to emotional exhaustion and burnout among nurses [73, 116]. The moderating effect of

ethical leadership on this relationship ($\beta = 0.20$, $p = 0.03$) builds on work by Laschinger et al. [130] on authentic leadership, suggesting that multiple positive leadership styles may help buffer against the negative effects of bullying.

Furthermore, our results highlighting the importance of ethical leadership in predicting intentions to stay ($\beta = 0.62$, $p = 0.00$) complement research on the nursing work environment. Studies have shown that supportive practice environments and ethical climates are associated with lower turnover intentions among nurses [96, 131]. Our findings suggest that ethical leadership may be a key factor in creating such positive work environments.

5.2. Implications for Nursing Management Practice. Developing a better understanding of ethical leadership's role in nursing has major implications for strategies to increase retention. There are instances when organizations go through periods of rough transitions when trying to improve their climate or culture. As leaders remove bully employees from their organization, ensuring there is ethical leadership in place may mitigate the degree of burnout experienced by nurses who are bullied. The first implication of our study is for healthcare administrators to recognize the importance of training nurse managers about ethical leadership principles and strategies. The study results suggest that this will help improve nurses' intentions to stay, and thereby reduce turnover in the field of nursing. Second, nurse managers who are perceived as ethical leaders have the effect of weakening the impact of workplace incivility on burnout. This should translate into better work outcomes for nurses and, in turn, improve health outcomes for patients. In line with prior recommendations for improving the nursing work environment [132], our results suggest that healthcare organizations should prioritize developing ethical leadership skills among nurse managers. This aligns with calls for creating positive practice environments to enhance nurse retention [133].

Aim. To assess the efficacy of a low-cost haemorrhage-control task simulator integrated in a high-fidelity simulation scenario to facilitate knowledge and practical skills acquisition, as well as self-efficacy in haemorrhage control among nursing students. *Design*. A quasiexperimental before-after design was conducted at the University of Almeria. *Methods*. A one-group preintervention, immediate postintervention, and a third assessment at three months were performed, with the Stop the Bleed Education Assessment Tool used to evaluate knowledge of haemorrhage control, as well as a 5-point Likert scale used to evaluate perceived self-efficacy. The success of controlling exsanguinating bleeding was determined by quantifying the millilitres lost during the intervention and calculating the time required to control the haemorrhaging. The data were reported using the TREND guidelines. *Results*. One hundred and three final-year nursing students participated in this study. Significant improvements ($p < 0.001$) were observed in pre- and posttest total scores on knowledge of bleeding control, self-efficacy, as well as time is taken and volume loss to control the haemorrhage. Similar results were observed between preassessment and three months postassessment with significant improvements ($p < 0.001$) in all measures. *Conclusions*. The use of a haemorrhage-control task simulator within a high-fidelity simulation scenario resulted in noteworthy improvements in nursing students' practical skills, knowledge retention, and self-efficacy. After three months, performance decreased but remained greater than pretraining levels. Thus, broadening the use of this task-training simulator would be of great value to further develop a first responder training approach with healthcare professionals and other laypersons, allowing for greater knowledge distribution and reaching a larger audience. *Implications for Nursing Management*. The findings underscore the potential efficacy of this simulator as a valuable resource for nursing educators and supervisors to train nursing students and professionals in terms of practical skills, knowledge retention, and self-efficacy in haemorrhage control, fostering a train-the-trainer cascade approach to reach a wider audience and enhance bleeding control proficiency among professionals.

1. Introduction

Haemorrhagic shock is a severe form of hypovolemic shock that occurs when significant blood loss leads to insufficient oxygen delivery at the cellular level and, if ignored, may culminate in death within minutes [1]. Indeed, only haemorrhage is the cause of death in 55.1% of patients aged 1 to 46 [2], thereby being the primary cause of intrahospital mortality within 48 hours after admission and the second highest cause of prehospital death in both military and

civilian trauma patients, accounting for 40–45% of all fatalities [3–6]. In this context, managing patients with haemorrhagic shock remains difficult and complex, with a high mortality rate [7–9]; hence, early recognition and prompt action to halt bleeding are critical, as the condition is time-dependent [4, 10].

Moreover, 34.5% of traumatic accident patients die from preventable bleeding-related causes, either in the prehospital setting or within an hour of being admitted to the hospital [11, 12]. While strengthening hospital and prehospital care seems to be essential for reducing trauma-related mortality, further bleeding control training needs to be provided to ensure such successful interventions [13–15]. The World Health Organisation and numerous consensus groups recommend first responder training programmes, for instance, as the first step in formalising emergency medical services in areas where no prehospital services have yet been created [16–18]. In this vein, one of the most effective and well-established training programmes for adequate bleeding control worldwide is the Stop the Bleed (STB) campaign, a basic short educational programme for both laypeople and healthcare professionals, that aims to provide education on wound compression, wound packing, and the use of emergency tourniquets [19]. According to certain research, even a single 2-hour STB training course could significantly increase self-confidence and competence among healthcare students instructed in bleeding control measures [20, 21].

Aside from the STB programme, there are a number of additional training programmes available that have similar objectives, which include Haemorrhage Control Course [22], Tactical Combat Casualty Care, and Advanced Trauma Life Support [23]. These programmes all share an agreed-upon aim of providing individuals with the knowledge and skills to effectively manage haemorrhage, with tourniquets standing as the primary device used to control time in exsanguinating haemorrhage in extremities [24, 25]. Although different methods can be employed for this training, simulation-based education, ranging from low-fidelity simulation (LFS) to high-fidelity simulation (HFS), has been shown as one of the most successful teaching-learning approaches for these scenarios [26–28]. In this manner, high-fidelity simulation (HFS) stands as the most popular and effective approach for incorporating realism and authenticity into the educational experience for demanding scenarios [29]. Notably, nursing students demonstrate superior outcomes in both technical and nontechnical skills when employing HFS during their emergency environment training [30]. This may not only foster self-confidence but also help in lowering anxiety levels among students [29, 31]. However, recent evidence suggests that its use in haemorrhage control training programmes such as STB appears to be currently limited and costly due to the nature of the specialist simulators and personnel skillset required [32].

Notwithstanding self-efficacy in bleeding control is paramount in successfully performing the intervention, and specialised training for first responders and healthcare professionals has shown improvement in confidence across all domains, thereby increasing the ability to manage severe active bleeding and pack a bleeding wound, and there is still

scant evidence regarding the use of cost-effective HFS for haemorrhage education. For these reasons, the aim of this study was to assess the efficacy of a low-cost haemorrhage-control task simulator, recently patented by our research team (ES-1294309_U [33]) and integrated into an HFS scenario to facilitate knowledge and practical skills acquisition, as well as self-efficacy in haemorrhage control among nursing students.

2. Material and Methods

2.1. Design and Participants. A quasiexperimental one-group before-after design was conducted at the University of Almeria from February to July 2022, following the recommendations of the Transparent Reporting of Evaluations with Nonrandomized Designs statement (TREND) guidelines [34]. The study participants were selected through purposive sampling from final-year nursing students who met the following inclusion criteria: (1) were enrolled in clinical placement 6 and 7 modules, (2) attended the bleeding control training, and (3) signed the required informed consent forms prior to participation.

2.2. Clinical Simulation. An HFS scenario was designed using a low-cost haemorrhage-control task simulator developed by our research team (ES-1294309_U) and based on the INACSL of Best Practise Standards: SM Simulation Design framework [35]. This simulator comprises a first container, means for pressurizing the infusing liquid, a venepuncture member with a flexible conduit leading to a second collecting container, and pressure control means for the user to regulate the pressure on the venepuncture member. The simulator is calibrated to measure the millilitres exsanguinated and includes a timer to record the time taken to control the haemorrhage. Specifically, the device replicates a haemorrhage in a limb within a closed circuit, using a fluid simulating blood, pressurized at a constant pressure chosen by the user-trainer, optionally through a manual or automatic sphygmomanometer. Proper and effective tourniquet placement is essential for haemorrhage control, requiring the application of the appropriate pressure.

The clinical setting was intended to simulate an exsanguinating haemorrhage scenario in which the participant was only able to control the condition using a tourniquet, without prior training (PRE). The exsanguinating haemorrhage was caused by a 6-millimetre incised wound on the anterior surface of the simulator's forearm. Table 1 summarises the required elements used to lead the simulation-based experience.

Following the collection of PRE data, the clinical simulation started with an initial 90-minute briefing in which participants were presented with the purpose of the intervention and the scenario they were facing. The nursing students received training on the proper management of exsanguinating haemorrhages using a tourniquet. This training was provided by experienced military nurses in the field and was based on the first-care provider model. After

TABLE 1: Simulation training session of bleeding control.

	Prebriefing	HFS components	Simulated scenario	Debriefing	IPA	3M
Knowledge questionnaire (SBEAT) Self-efficacy questionnaire (5-point Likert scale) Practical skills (time, exsanguinated volume)	Military nurses provide 90-minute specialised training based on the first-care provider model	Modality (exsanguinating haemorrhage simulator) Fidelity (realism through simulation equipment, setting, and scenario)	Haemorrhage-control task simulator integrated into a traumatic multiple-incident scenario (including an exsanguinating haemorrhage) Standardised emergency equipment (including tourniquet) Practical skills (time, exsanguinated volume)	Plus-delta approach using double-barrelled questioning (problem-solving and critical thinking through informed learner self-assessment, and managing perception mismatches)	Knowledge questionnaire (SBEAT) Self-efficacy questionnaire (5-point Likert scale)	Knowledge questionnaire (SBEAT) Self-efficacy questionnaire (5-point Likert scale) Practical skills (time, exsanguinated volume)

3M: 3-month assessment; HFS: high-fidelity simulation; IPA: postassessment; PRE: preassessment; POST: postassessment; SBEAT: Bleed Education Assessment Tool.

the initial briefing, the simulation stage began, in which the students attempted to control the haemorrhage with the tourniquet (POST), applying the training received during the clinical simulation by the military. This was followed by a 30-minute debriefing stage in which critical thinking and perceptions were shared collectively. Additionally, three months (3M) later, a third assessment of each study parameter was performed to assess the short- to medium-term retention of knowledge and practical skills for bleeding control.

2.3. Instruments.

The sociodemographic data were collected using an ad hoc questionnaire created expressly for this purpose. The gender, age, and total amount of previous training in bleeding control were all questions on this questionnaire. The level of knowledge in bleeding control, success in haemorrhage control with tourniquet application, and students' training self-efficacy were measured as outcome variables pre- and postintervention.

Pre- and postintervention student knowledge was assessed using a nonvalidated modified version of the Stop the Bleed Education Assessment Tool (SBEAT) [36], a standardised assessment instrument for evaluating cognitive components of first aid for potentially life-threatening haemorrhages. The tool used incorporates 34 items into 20 survey questions. The questionnaire score ranged from 0 to 100, with a higher score indicating more knowledge in the field. In a Rasch model, the mean infit statistics were 1.00 and the outfit was 0.99, showing a reasonable level of fit [37].

Conversely, student self-efficacy was measured using a 5-point Likert scale, which was applied to 23 questions in the developed questionnaire. The responses to each of the questions were totalled up at the end of the questionnaire and shifted so that the maximum score was 100 points; a higher score on the questionnaire was interpreted as a greater perceived self-efficacy by the student. Cronbach's alpha reliability levels for this instrument were 0.99 (PRE), 0.99 (POST), and 0.98 (3M).

Lastly, the success of controlling exsanguinating bleeding was determined by quantifying the millilitres lost during the intervention and calculating the time required to control the haemorrhaging. The blood lost quantification was carried out by instructors directly observing the simulator's collection bag, which was graduated in 20-millilitre increments. When the amount of exsanguinated blood did not exceed 800 millilitres and the time did not exceed 120 seconds, the intervention was deemed successful.

2.4. Data Analysis.

All statistical analyses of the data were conducted using the IBM SPSS Statistics v.27.0 software. A significant value of $p < 0.05$ was considered for all statistical tests performed. First, a descriptive analysis was performed on sociodemographic variables. The frequencies and percentages of qualitative variables, and the mean and standard deviation of quantitative variables were calculated. The Kolmogorov–Smirnov test was used to determine the normal distribution of the data. The chi-square test was then used to analyse the differences between qualitative variables. The Student's t-test or Mann–Whitney U test, ANOVA, or Kruskal–Wallis test were used for quantitative variables, depending on whether the variables matched normality conditions or not. Depending on the distribution, Pearson's or Spearman's correlation was used to relate quantitative variables.

2.5. Ethical Considerations.

The study proposal was approved and authorised by the Ethics Committee of the Department of Nursing, Physiotherapy andMedicine at the University of Almería (EFM 99/2021) and in accordance with all of the ethical aspects of the Declaration of Helsinki. All participants were informed and signed informed consent forms prior to participating in the study, as well as had the option to withdraw at any time. Added to that, participants were advised that their participation in the clinical simulation training would have no influence on their grades.

3. Results

One hundred and three final-year nursing students participated in the study, with women accounting for 78.64% ($n = 81$) and men for 21.36% ($n = 22$). In terms of age, the mean age was 23.34 years (5.81), with a range of 21 to 56 years. Baseline characteristics are summarised in Table 2.

Table 3 and Figure 1 provide a comparison of the variables knowledge, self-efficacy, time, and volume pre- and postintervention. These phases correspond to the initial evaluation (PRE), the immediate evaluation after the intervention (POST), and the three-month (3M) late evaluation.

In terms of participant knowledge, statistically significant differences were found between the PRE and POST findings ($Z = -5.84$; $p < 0.01$), as well as at 3M when compared to the PRE phase ($Z = -4.82$; $p < 0.01$). The mean questionnaire score in the PRE phase was 70.58 (10.24), increasing to 79.51 (8.53) in the POST phase and 76.70 (8.95) at 3M (Figure 1(a)).

PRE-intervention self-efficacy was significantly different from POST self-efficacy ($Z = -8.53$; $p < 0.01$) and self-efficacy findings at 3M ($Z = -8.23$; $p < 0.01$). The mean score in the PRE phase was 45.83 (21.69), 77.50 (15.24) in the POST phase, and 68.50 (15.19) at 3M (Figure 1(b)).

The time required for controlling bleeding differed statistically between the three phases: PRE-POST ($Z = -6.65$; $p < 0.01$), PRE-3M ($Z = -5$; $p < 0.01$), and POST-3M ($Z = -2.48$; $p < 0.05$). Prior to training, the mean time (s) to stop simulated haemorrhaging was 76.38 (41.28), which was reduced to an average of 41.69 (27.13) following the intervention and 47.13 (28.88) after three months (Figure 1(c)).

The difference in the amount of exsanguination (mL) in the simulator between the PRE and POST phases was statistically significant ($Z = -6.98$; $p < 0.01$) as was the difference between the PRE and 3M ($Z = -5.23$; $p < 0.01$) and between the POST and 3M ($Z = -2.84$; $p < 0.01$). The mean loss was 573.30 (246.01) in the PRE phase, 325.15 (179.83) in the POST phase, and 387.38 (199.10) at 3M (Figure 1(d)).

TABLE 2: Baseline demographic characteristics of participants.

Variable	N/M	%/SD
Gender		
Male	22	21.36
Female	81	78.64
Age (years)	23.34	5.83
Knowledge (0–100)	70.58	10.24
Self-efficacy (0–100)	45.83	21.69
Time (s)	76.38	41.28
Volume (mL)	573.30	246.10

4. Discussion

The aim of our study was to assess the efficacy of a low-cost haemorrhage-control task simulator integrated into an HFS scenario to facilitate knowledge and practical skills acquisition, as well as self-efficacy in haemorrhage control among nursing students. While there have been a few studies in this field to date, the current study emphasises training utilising a low-cost simulator to improve clinical skills and knowledge retention in the nursing student training process, which is created from generally available materials, requiring a minimal economic investment.

According to the findings of our study, final-year nursing students had a very poor success rate in haemorrhage management. At baseline, only half of the study participants demonstrated effective control prior to the intervention using a tourniquet. Likewise, the time required and the number of millilitres of blood lost during the pre-intervention phase were inadequate. This supports previous findings employing certified training manikins as simulators [38, 39]. They found that the success rate in haemorrhage control among healthcare students was less than 66% and less than 24%, respectively, and the mean time taken was more than 75 seconds, and the amount of blood lost was more than 500 mL. Following the educational intervention, however, significant improvements in the level of knowledge, self-efficacy, and bleeding control skills among nursing students were observed, suggesting that the intervention was effective in improving the students' abilities to manage haemorrhages using a tourniquet. The present findings seem to be consistent with other research. Goralnick et al. [40] found that laypersons can successfully apply tourniquets following a one-hour course. Their study utilised various training methods, including an audio kit with visual aids on the device (audio kit) and instructional flashcards. Similarly, Stadeli et al. [41] reported improvements in knowledge and self-efficacy after participants received theoretical exposure with English slides followed by practical interpretation

without an apparent simulator. Furthermore, Muret-Wagstaff et al. [42] observed that participants achieved a proficiency level in controlling bleeding after four sessions. Their training consisted of in-person instruction following the Peyton 4-stage model and simulation-based mastery learning with deliberate practice on certified simulators of amputated limbs [42]. While earlier research has noted the importance of educational interventions in the domain of self-efficacy in bleeding control training [43, 44], our findings have important implications for developing similar results in self-confidence and self-efficacy among nursing students utilising a low-cost simulator. In this vein and as mentioned in the literature, participants are able to attain nearly flawless competency scores and appropriately assist a bleeding victim by applying direct pressure [45], particularly when HFS or more realistic models are being used, with no major financial expenditure [46]. The study by Orlas et al. [45] was conducted through a master class followed by a practical component, employing Z-Medica's training kits, which include certified manikins. Additionally, the study by Villegas et al. [46] also employed manikins as simulators.

Regarding the limitations of the study, it should be noted that the intervention was a pre-post design with expected improvements after the training and a late assessment at three months. Nonetheless, this is the first study to incorporate a low-cost simulator with regular nursing faculty materials in an HFS scenario, which demonstrated reliability and validity in evaluating advancement in knowledge level, self-efficacy, and haemorrhage control. Although our results demonstrate reliability and validity, it is important to note that the study design has several limitations and is not adequate for establishing causality. Therefore, in future studies, it would be desirable to perform a randomised trial that measures the retention of this training for a longer period than three months and expand the sample to other populations such as medical students, other healthcare professionals, civilian populations, or laypeople. Finally, another limitation of this study to consider was the use of tourniquets solely as haemorrhage control methods; hence, it might be worthwhile paying attention to other approaches such as pressure, wound packing, and others.

5. Implications for Nursing Management

In general, it seems that educating and training healthcare professionals and students is effective in promoting self-efficacy, knowledge retention, and ensuring patient survival while controlling and managing haemorrhages [47–51]. However, both laypeople and healthcare professionals continue to lack the necessary knowledge and expertise to utilise tourniquets properly [52], and thus, our findings may help healthcare educators and supervisors to find a suitable approach to foster training among their professionals and students in effective bleeding control. As previously stated in the literature, it may be worth noting that this basic training could serve as the initial step in a train-the-trainer cascade, allowing for more knowledge distribution and reaching a broader audience [20, 53].

6. Conclusion

The effectiveness of a low-cost task simulator within an HFS scenario for haemorrhage control training in nursing students was evaluated in this study, which revealed a significant improvement in the practical skills and knowledge retention of the students who used the simulator. This was evidenced by a reduction in the time required to apply a tourniquet and the millilitres of blood lost in the simulator, whereas knowledge and perceived self-efficacy were increased. Although a decrease in the performance of the students was observed after three months, they still maintained higher results than those obtained before the training and close to those obtained immediately after the high-fidelity clinical simulator training. Overall, these findings indicate that using a low-cost task simulator within an HFS can be a valuable resource for training nursing students in haemorrhage control, with effects that are comparable to additional simulators and persist over time, though reinforcement of its application may be required in the future.

Objectives. To examine the effectiveness of a patient-family (carer) partnership intervention on the BP control, self-care and self-efficacy for hypertensive people, and dyadic-relationship quality, depressive and anxiety symptoms, and health-related quality of life for the family dyads (hypertensive people and family carers) in rural communities of mainland China. *Design.* A randomised controlled trial. *Methods.* A total of 110 family dyads were randomly recruited from village clinics and randomly allocated to the intervention group ($n = 55$) or control group ($n = 55$). Family dyads in the control group received usual care. In addition to the usual care, family dyads in the intervention group received the individual-based, five-session patient-family (carer) partnership intervention. The primary outcomes included SBP, DBP, and the proportion of people with normal controlled BP. EuroQol five-dimensional-five-level (EQ-5D-5L) was adopted to evaluate participants' health-related quality of life. Data were collected at the baseline (T0), one-month (T1), and three-month postintervention (T2). Generalised estimating equation model was adopted to test the study hypotheses on all study outcomes. *Results.* Compared with the control group, hypertensive people in the intervention group had a greater reduction in SBP by 10.10 mmHg and DBP by 4.66 mmHg and a larger proportion of people with normal BP at T2, as well as statistically significant improvements at T1 and T2 in dyadic relationship, self-care, antihypertensive drug-titration rate, anxiety symptoms, and health-related quality of life. The intervention also had statistically significant positive effects on family carer's dyadic relationship and health-related quality of life at T1 and T2. *Conclusion.* The patient-family (carer) partnership intervention has the potential to improve hypertensive people's BP control and family dyad's dyadic-relationship quality and mental health at short-to-medium term follow-ups. *Implications for the Profession and/or Patient Care.* This study provided evidence and direction to support healthcare providers in developing and implementing patient-family (carer) partnership intervention for hypertension care in rural areas. This trial is registered with ChiCTR1900027087.

1. Background

Cardio-cerebrovascular disease is the leading cause of death and disability-adjusted life-year worldwide [1]. Hypertension is a major risk factor for cardio-cerebrovascular disease, and it is a major challenge for chronic illness management, with high prevalence and poorly controlled blood pressure

(BP) [2]. Hypertension prevalence in rural and urban areas could be similar, but the control rates were statistically significant lower in rural areas in China and worldwide, that was, about 9.8% versus 14.5% worldwide [3] and 9.5% versus 14.0% in China [4].

The health disparities in rural areas can contribute to the lower treatment and control rates of hypertension [5]. In

rural areas, the health disparities are considerably related to the healthcare system, socioeconomic condition, geographical distance of seeking healthcare services, strength and competence of healthcare providers, and individual characteristics such as education level and physical activity pattern, as well as the differences in cultural practices and living habits [6]. One of the largest health disparities presented in China is the inequality of resources and accessibility to healthcare services between rural and urban areas [7]. The percentages of hypertensive people receiving treatment provided by physicians in the recent two weeks are 11.29% in urban areas and 6.77% in rural areas [8].

Hypertension management interventions for populations in rural areas should consider specific sets of important sociodemographic characteristics of hypertensive people, the healthcare service/system, and their living districts/areas as needed. Families serving as an important source of social support for people with hypertension in rural areas can facilitate their compliance with the recommended treatment regimen [9]. Notably, Chinese family culture and values place high emphasis on the responsibilities and obligations of family members in caring for sick family members, considering them to be moral obligations and norms of Chinese societies [10]. These cultural specificities can influence family members' and carers' responses to the needs of their patients, the self-efficacy of an ill relative, and the relationship of the family dyad in daily care [11, 12].

Establishing a positive family-dyad (patient and the family carer) partnership is essential in family-oriented care at home [13]. Family care intrinsically involves the patients and their family carers (i.e., the family dyad) in close interactions and relationships. Family-dyad partnership is the supportive and collaborative relationship in illness management. A review of systematic reviews demonstrated that involving family members in chronic illness care can benefit patients and families [14]. However, there were research results showed that family care can be stressful for the patients and family carers during the caregiving process because of criticisms [15], family conflicts [16, 17], and overcontrolling or protective behaviours [18, 19], which can negatively affect the relationship between family dyad, as well as their physical and psychological health. Most family carers especially those living in rural areas often have lower levels of education and health literacy and may not be equipped or prepared for engagement and facilitated hypertension management. Interventions directed at improving family carers' ability and confidence and family-dyad partnership in providing care for hypertensive people are needed [20, 21]. Therefore, this study aimed to test a family-dyad partnership programme on BP control for people with hypertension in rural communities of mainland China.

1.1. Intervention Development. The development of the patient-family (carer) partnership intervention (PFPI) for people with hypertension and their family carers living in the rural areas of mainland China was (1) based on the findings of a systematic review and (2) guided by a theoretical framework-shared care model (SCM).

We conducted a systematic review to evaluate the effects of different approaches to psychoeducational intervention for family dyads in hypertension care and to examine the optimal structure, format, and components of effective interventions [22]. Synthesised evidence of the 15 (RCTs and quasiexperimental) studies demonstrated a small to medium effect of family dyad-oriented psychoeducational intervention on BP control. Several main intervention components among the effective psychoeducational interventions were identified, including education for lifestyle modification and medication adherence, home BP monitoring, and group education for family carers. In addition, interventions using a mixed-teaching approach (a combination of didactic and participatory learning) can be more effective for these family dyads than other methods. Also, several research gaps have been identified. First, very few interventions were developed to improve patient-family (carer) communication and cooperation in daily hypertension care. In addition, only two of the 15 studies adopted a theoretical framework to guide the intervention. Second, none of the included studies reported the effects of psychoeducational interventions for family dyads/family carers focused on health outcomes of family carers. Third, RCTs with high-quality methodology on psychosocial intervention for hypertension care are lacking. Well-designed RCTs of family-oriented psychoeducational intervention with commonly accepted health outcomes for the Chinese hypertension population are recommended. Finally, only two studies on hypertension care were conducted in rural areas; thus, the effects of psychoeducational intervention for hypertensive patients residing in rural areas are uncertain and inconclusive. Considering the low percentage of well-controlled hypertension and health disparities (e.g., lack of healthcare providers) in rural communities such as remote districts or villages in mainland China, there is a strong need or demand for a well-prepared family carer to facilitate and support daily care, lifestyle change, and health management for their hypertensive relatives. Therefore, a family-dyad psychoeducational intervention with didactic and participatory learning strategies (e.g., family dyadic communication, decision-making, and action planning) for hypertension care in rural communities can be designed for further testing among the population of family dyads of people with hypertension.

SCM was adopted to guide the intervention used in this study. SCM provides a structure on how to involve a family carer in caring for a patient with chronic illness. Figure 1 presents the theoretical framework of the current study. In the SCM, shared care is defined as an interpersonal process used by patients and family carers (family dyad) in home care to exchange support and manage a chronic illness [23]. Shared care is a dyadic process in which each participant affects and is affected by the other(s) [24]. The SCM hypothesises and anticipates that shared care can improve the effects of providing and receiving a family member's (carer's) assistance on improving the quality of the dyad's relationship and therefore positively affects the self-care and promotes the physical and mental health of the family dyads [23, 25]. Shared care elements (communication, decision-
FIGURE 1: Theoretical framework of this study.

making, and reciprocity) have substantial positive associations with the self-care, depressive symptoms, dyadic-relationship quality, and health-related quality of life of patients with heart diseases and their family carers [26–28]. The elements or components of shared care also have inverse relationships with the strain and depressive symptoms of patients and their family carers (family dyads) [25]. Therefore, the SCM provided a practical and structured framework for developing the patient-family carer partnership intervention for the current study. The three main elements of shared care (communication, decision-making, and reciprocity) were used to guide intervention development.

2. Method

2.1. Study Design. This study adopted a single-blinded RCT with a parallel control (usual care) group and repeated measurements at one- and three-month postintervention. The study is reported in line with the Consolidated Standards of Reporting Trials 2010 Statement. We registered the study in the Chinese Clinical Trial Registry (registration number: ChiCTR1900027087) in October of 2019.

This study hypothesised that the participants in the intervention group would show statistically significant greater improvements at one-month and three-month postintervention, when compared with those in the control (usual care) group, on the followings:

(1) The patients' SBP and DBP levels and proportion of patients with normal controlled BP (primary outcomes), self-care, self-efficacy, antihypertensive drug-treatment rate, antihypertensive drug-titration rate, dyadic-relationship quality, depressive and anxiety symptoms, and health-related quality of life

(2) Family carers' dyadic-relationship quality, depressive and anxiety symptoms, and health-related quality of life

2.2. Participants and Setting. Hypertensive patients receiving home visits and care at two village clinics in Liuyang City, Hunan Province, China, were the potential eligible participants of this study. The eligibility of participants was identified according to the study criteria by the researcher in home visit. People with hypertension and their family carers (dyads) were randomly enrolled in this study.

These two adjacent rural villages are located in Liuyang City, which is the most populous county-level division in the easternmost part of Hunan Province of mainland China. Meanwhile, Hunan Province is located in the south-central part of China, with over 69 million population. Liuyang city (covering an area of around $5,000 \, \text{km}^2$) comprises 1.5 million residents. The villages under study are Gaoping and Longquan villages in Gaoping county, which are remote villages on the east side of Liuyang, being 20–30 km distance from Liuyang City. Each village has over 2,000 residents. Owing to the distance from the city, the village residents usually receive healthcare services provided by doctors at the village clinics. The public village clinics have only one medical staff (village doctor) in each clinic who provides primary health care to all residents there, such as home visits and medical consultations for people with hypertension, diabetes, and other chronic illnesses in the village(s).

Random sampling was used to recruit the eligible participants. The researcher reviewed the hypertensive people's medical records in the two village clinics under study and created a list of potential participants in alphabetical order of their family names after screening. The people on the list were randomly selected using a random number table and approached by the researcher during home visits to confirm the study eligibility and ask for consent for participation. The block randomisation with a block size of four or six and sealed opaque envelopes labelled with group (number) were adopted to ensure the randomisation and allocation concealment, respectively. An independent research assistant prepared the randomisation schedule and sealed opaque

envelopes. The randomisation sequence was generated from an online randomisation programme (https://www.sealedenvelope.com). After baseline measurement, participants opened the sealed envelope and were allocated to either the intervention or the control group, which was concealed from the outcome assessors, as well as the clinic staff. The inclusion criteria for people with hypertension were as follows:

(1) Those aged 18 years or above.

(2) Having essential hypertension without adequate BP control (SBP ≥140 mmHg and/or DBP ≥90 mmHg). Essential hypertension was confirmed by examining the patient's medical records in the village clinics. When "essential" was not clearly marked, the village doctor would check against the patient' medical information in the clinic for interpretation and confirmation.

(3) Living with one or more family members.

(4) Speaking Mandarin or local dialect.

People were excluded if they were as follows:

(1) Diagnosed with a terminal illness (e.g., cancer, end-stage renal disease, and severe heart failure)

(2) Diagnosed with a mental disorder, including dementia, schizophrenia, etc.

(3) Diagnosed with stroke or COPD

(4) Having physical disability, which was defined as needing assistance with or inability in any of the six activities of daily living (e.g., toilet, feeding, dressing, grooming, physical ambulation, or bathing) in the Physical Self-maintenance Scale [29]

(5) Living alone

(6) Participating or having participated recently in a structured hypertension management programme in the last six months

A family carer is a member of a family with a kinship, marital, or coresidence relationship involved in a patient's daily health care [30]. Each person nominated one family carer for participation by asking two questions in the sociodemographic datasheet: (1) "Do you have family member(s) who get involved with your health care in helping with medications, blood pressure monitoring, clinic visits, smoking cessation, alcohol control, weight loss, healthy diet, sodium restriction, or physical activity?"; and (2) "How long do you two spend together every day on average"? The family member who provided more assistance and stayed longer time was selected as the family carer to be enrolled in this study.

The family carers were included if they were as follows:

(1) Aged 18 years or above

(2) Blood, by-marriage, or coresidence relatives of the patient

(3) Contactable by phone or WeChat

Conversely, the carers were excluded if they were as follows:

(1) Having a severe mental disorder such as dementia, schizophrenia, acute or severe depression/anxiety disorders, and/or learning disorder

(2) Taking care of two or more patients in the family

(3) Diagnosed with hypertension

2.3. Sample Size. The sample size was estimated with reference to the effect sizes on the primary outcomes (change in SBP, DBP, and proportion of normal controlled BP) in similar studies. In our previous systematic review [22], the Cohen's effect size (d) of family dyad-oriented psycho-educational intervention for hypertensive people on changes in SBP and DBP was 0.59 and 0.57, respectively, at short-term (immediately to three months) postintervention. From the results, the sample size could be 94 and 100, respectively, with a two-group comparison test such as t-test (two-tailed) with 80% power at the statistically significant level of 5%, by using G∗Power [31]. Moreover, the results of our previous systematic review reported attrition rates between 0% and 19.77%, and most studies had an attrition rate below 10% (13 out of the 15 included studies) [22]. Furthermore, the pilot study of this RCT indicated an attrition rate of 4.55% [32]. Therefore, an attrition rate of 10% was used, and the final sample size was 110 family dyads (i.e., 55 for each group).

2.4. Intervention Group. The people with hypertension and their family carers received the patient-family (carer) partnership intervention (PFPI), which were five individual-based, biweekly face-to-face training sessions. We conducted a pilot study to test the feasibility, acceptability, and preliminary effect of the patient-family (carer) partnership intervention for people with hypertension in a Chinese rural community. The findings of this pilot study indicated that the PFPI was a feasible and acceptable programme, as reflected by its high recruitment and intervention and study-completion rates, as well as positive feedback and perceived benefits from the participants. The results of the pilot study and the structure, content, format, and components of the PFPI have been published somewhere [32]. Improvements in the intervention in current RCT were made based on the findings of pilot study. Table 1 outlines the protocol of the PFPI.

In this study, the PFPI was delivered by the first author, who is a registered nurse and has research experience in chronic disease management (e.g., cardiovascular disease, stroke, and diabetes) in rural communities. Moreover, the researcher could speak the local language of the participants and was familiar with their local culture. This familiarity could facilitate the researcher-participant communication in the delivery of the intervention and in sample recruitment.

2.5. Control Group. Participants in the control and intervention groups received usual care delivered by a village doctor during home visits every three months following government regulations: the village doctor monitored BP, provided advice on hypertension self-care, and responded to people's questions about hypertension management during

TABLE 1: Protocol of the patient-family carer partnership intervention (PFPI).

Session no. and name	Week no.	Time (min)	Main contents
Session 1 information giving	Week 1	30	(i) Measure BP (ii) Inform dyad about the pharmacological therapy (iii) Inform dyad about criteria of healthy behaviours regarding hypertension management (iv) Guide the dyad to identify the patient's problem behaviours *Tool*: Hypertension management booklet (see supplementary file 2)
Session 2 communication skills training	Week 3	30	(i) Measure BP (ii) Dyad reports the progress of behaviour modification (iii) Discuss with the family carer about issues in caring for and living with a family member with hypertension and his/her role as a family carer in hypertension management (iv) Communication skills training (1) Encourage the patient to share his/her symptoms and feelings (2) Use didactic teaching and role-playing with case scenario to train dyad's communication skills in behaviour change, including listening fully and actively, reducing controlling, criticizing, or guilt provoking language, providing the rationale for self-management behaviours, expressing empathy and concern, enhancing choice, and expressing appreciation (v) Encourage the family carer (using the learned communication skills) to help patient implement behaviour change in daily life *Tool*: Case scenarios
Session 3 decision-making techniques training	Week 5	30	(i) Measure BP (ii) Dyad reports the progress of behaviour modification (iii) Assess dyad's implementation of learned communication techniques in daily hypertension care and session (1) Ask the family carer to provide examples of using the learned communication techniques in hypertension care (2) Observe the dyad's communication in session to confirm their communication issues (3) Discuss the issues of using communication techniques in hypertension care in the recent two weeks (4) Further training of communication techniques is provided with additional case scenarios and by further discussion (5) The identified communication issues are recorded in the "checklist of partnership skills implementation in sessions and daily life" (iv) Decision-making techniques training (1) Identify problem behaviours and set goals (2) Discuss the influence of behaviour change (3) Discuss the difficulties of behaviour change and identify the coping strategy (4) Discuss ways to seek information and help when needed (5) Identify an action plan. The dyad is guided by an "action plan for behaviour change worksheet" to develop the plan for actions (v) Encourage the dyad to implement the decision-making techniques and the action plan in daily life *Tools*: An action plan for behaviour change worksheet; checklist of partnership skills implementation in sessions and daily life

Table 1: Continued.

Session no. and name	Week no.	Time (min)	Main contents
Session 4 reciprocity techniques training	Week 7	30	(i) Measure BP (ii) Dyad reports the progress of behaviour modification (iii) Reciprocity techniques training (1) Discuss the existing and potential assistance provided by the family carer and received by the patient in behaviour change (2) Discuss issues of giving and receiving assistance and explore the strategies (3) Express gratitude. Dyad is asked to present his/her obtained achievements and to express their congratulations and gratitude to each other for their achievements (iv) Assess dyad's implementation of learned decision-making techniques in hypertension care (v) Encourage dyad to implement reciprocity techniques in hypertension care *Tools*: An action plan for behaviour change worksheet; checklist of partnership skills implementation in sessions and daily life
Session 5 review	Week 9-10	30	(i) Measure BP (ii) Dyad reports the progress of behaviour modification (iii) Assess the implementation of learned reciprocity techniques in daily life (iv) Review (1) Review the contents of the last four sessions (2) Review the issues of building a positive partnership that arose in previous sessions *Tools*: Hypertension management booklet; an action plan for behaviour change worksheet; checklist of partnership skills implementation in sessions and daily life

home visits. The BP values collected were uploaded to the hypertension follow-up system managed by the Health Bureau of Liuyang City. The village doctors did not prescribe antihypertensive drugs during home follow-up. Patients who needed prescriptions were referred to visit the village clinic or other regional clinics/hospitals for medical care.

2.6. Instruments

2.6.1. Demographic Data Form. The demographic data form was developed and used to collect the sociodemographic and clinical characteristics of people with hypertension and their family carers. The sociodemographic and clinical information of people with hypertension included age, gender, marital status, employment status, education level, body mass index (BMI), smoking status, alcohol status, physical exercise, medical insurance, annual family income, family structure/unit, duration of hypertension, and comorbidities. The family carers' age, gender, marital status, employment status, education level, BMI, smoking status, alcohol status, medical diseases, and the relationship with patient were also collected.

2.6.2. Measure for Outcomes Variables

(1) BP Measurement. The method and procedure for measuring BP followed the Chinese hypertension management guideline [33]. Before starting to measure BP, the patients sat quietly in a chair, feet on the floor, and back supported, for at least 5 minutes; exercise and smoking were avoided for at least 30 minutes before measurement; the bladder was emptied; and the patient's arm was supported (resting on a desk). The middle of the cuff was placed on the patient's upper arm in the same horizontal position as the right atrium which is at the midpoint of the sternum. The correct cuff size adhering to Whelton et al. [34] recommendation was used. An electronic upper-arm sphygmomanometer (OMRON HEM-752) with a validated measurement protocol and the results have been published in a peer-reviewed journal was used to measure BP [35]. BP was measured in both arms, and the arm with a higher BP reading was used for all subsequent BP measurements. BP measurement was repeated at an interval of 1 min, and the mean value of two readings was recorded. If the difference between two readings of SBP or DBP was more than 5 mmHg, it was measured again, and the average value of three readings was recorded [33].

(2) Proportion of People with Normal BP. The number of hypertensive people with normal BP at each assessment divided by the total number of hypertensive people enrolled in the group resulted in the proportion of people with well-controlled or normal BP at that time of measurement. According to the Chinese hypertension management guideline [33], the normal BP level of Chinese adults was below 140/90 mmHg (i.e., both SBP and DBP should achieve this norm-based standard); for patients aged 65 years or above, a normal BP should be less than 150/90 mmHg; and for patients with diabetes, it should be less than 130/80 mmHg. The determination of normal BP control was based on the current BP reading taken by the researcher/data collector in T0, T1, and T2.

(3) Antihypertensive Drug-Treatment Rate. The assessor asked participants a single question (e.g., "Have you taken any antihypertensive drugs prescribed by your doctor in the past two weeks?") to collect data about the antihypertensive drug usage in the past two weeks. The antihypertensive drug-treatment rate refers to the percentage of total number of patients took antihypertensive drugs (in the past two weeks) among the hypertensive patients who participated in this study.

(4) Antihypertensive Drug-Titration Rate. The assessor asked participants the question "Have your antihypertensive drugs prescription been adjusted by your doctor in the past two months?" to collect data about the titration of the antihypertensive drug. The antihypertensive drug-titration rate refers to the percentage of the total number of patients who had drug titration (in the past two months) among the hypertensive patients who participated in this study.

(5) Hypertension Self-Care Profile (HBP SCP). Three scales are included in HBP SCP (behaviour, motivation, and self-efficacy), which can be used together or independently. In this study, the Behaviour and Self-efficacy subscales in the HBP SCP were used to measure hypertensive people's self-care behaviour and self-efficacy, respectively. Each subscale contains 20 items rated on a four-point scale; a higher score indicates a high level of self-care behaviour or self-efficacy. The Chinese version of HBP SCP revealed good psychometric properties in the Chinese hypertensive population. Cronbach's alpha coefficients of the Behaviour and Self-efficacy subscale were 0.86 and 0.93, respectively. Moderate correlations were identified between HBP SCP subscales and Treatment Adherence Questionnaire for Hypertension (TAQPH) scales ($r = 0.45, 0.61, 0.65$, all $p < 0.001$) [36].

(6) Dyadic Relationship Scale (DRS). A Chinese version of the DRS was used to measure the family dyad's partnership quality. It comprised two separate versions, namely, the Patient and the Caregiver version, to evaluate both the patients' and caregivers' perceptions towards the impacts of family care on positive and negative (dyadic strain) interactions [37]. The Patient and Caregiver versions of the DRS were rated on a four-point Likert scale, from 0 (strongly agree) to 3 (strongly disagree). A lower score of the two versions indicated better perceived dyadic relationships by patients and their family carers, respectively. The Chinese versions were tested with 132 hypertensive people and their family carers in China, with good internal consistency (Cronbach's alphas = 0.82 and 0.83 for the Patient and Caregiver version, respectively), positive correlations with the self-efficacy subscale of the Hypertension Self-Care Profile and Zarit Burden Interview schedule (Pearson's $r = 0.70$ and 0.79, respectively; both $p < 0.001$), and test-

retest reliability (ICC = 0.97 and 0.96, both $p < 0.01$) (Zeng, Yang, and Chien, 2022).

(7) Patient Health Questionnaire-9 (PHQ-9) and Generalised Anxiety Disorder Scale-7 (GAD-7). The PHQ-9 and GAD-7 are efficient tools for measuring perceived depressive and anxiety symptoms, respectively. Items in PHP-9 and GAD-7 are rated on a four-point Likert scale from 0 "never" to 3 "almost every day;" and the higher scores of both scales indicated more severe symptoms of depression and anxiety, respectively. Cronbach's alpha coefficient of the Chinese version of PHQ-9 was 0.82 in Chinese rural elderly [38]. The GAD-7 has been translated into a Chinese version and validated in general hospital outpatients, with a Cronbach's alpha coefficient of 0.90 and test-retest reliability of 0.86 [39].

(8) EuroQol Five-Dimensional-Five-Level (EQ-5D-5L). EQ-5D-5L, including the descriptive system and the EQ visual analogue scale (EQ-VAS), was adopted to evaluate participants' HRQoL. Five dimensions of individual health condition (e.g., mobility, self-care, usual activities, pain/discomfort, and anxiety/depression) were measured by the descriptive system using five items with a five-point Likert scale from 0—"No" to 5—"Extreme". The mainland China set value of EQ-5D-5L was used to convert the ratings on five dimensions into a single value, in which a higher score represented poorer HRQoL [40]. The EQ-VAS was a 20 cm vertical, visual analogue scale rating on one's overall health, with an endpoint between 0 (worst imaginable health state) and 100 (best imaginable health state). In Chinese patients with chronic illnesses, Cohen's kappa for the test-retest reliability of the self-classifier ranged from 0.41 to 1.00. Validity was demonstrated using known-group construct validity: seven of 10 priori hypotheses relating the EQ-5D dimensions to SF-36 dimensions were fulfilled [41].

2.7. Process Evaluation.

A checklist of all items of the intervention protocol to check/monitor the intervention fidelity was used by the researcher during each session to monitor the intervention implementation (see supplementary file 1). The family dyads' adherence to the partnership techniques in daily hypertension care is difficult to assess. In this study, strategies, such as behaviour observation during sessions and reporting and the feedback sought from the participants (dyads), were used to assess the family dyad's adherence to the learned partnership and related techniques in daily hypertension care. For example, the researcher asked the family dyad to provide examples of the communication, decision-making, and reciprocity used in hypertension care [28] and observed the dyad' s communication styles and patterns during the training sessions. The identified partnership issues were recorded in the "checklist of partnership skills implementation during training sessions and daily life." Each identified partnership issue was listed and marked as "implemented" or "non-implemented/inappropriately implemented" by the researcher. Further training was implemented in the next or subsequent sessions to address the "non-implemented/inappropriately implemented" skills.

2.8. Data Collection.

The researcher reviewed a total of 702 patients' medical records in two village clinics (387 and 315 records per clinic) under study at Liuyang City, Hunan Province, China, between July and August 2020 and created a list of 530 potential participants in alphabetical order of their family names. There were 180 (33.96%) patients on the list, who were randomly selected and approached during home visits to confirm the study eligibility and ask for consent for participation. After visiting 137 patients, 110 eligible family dyads (patients and their family carers) agreed to participate in the study. The 110 dyads were randomly assigned to either the intervention or control group in equal total numbers in each group, that is, with 55 dyads per group. The recruitment was conducted by the researcher.

Written informed consent was obtained from the participants who agreed to participate in this study. Then, the researcher collected the baseline data (T0). For the participants who could not read and understand the items/contents in instruments, the researcher/assessors read and explained the items and recorded participants' responses to each item.

The researcher delivered the ten-week PFPI from August to October 2020. Postintervention data collection was conducted through home visits at 1-month (T1, November 2020) and 3-month (T2, January 2021) postintervention by a retired village doctor who was blinded to the group allocation. The retired village doctor was trained (in the village clinic) by the researcher to develop skills in data collection. Five hypertensive people were invited to participate in the training session. Peer assessments were performed on these five people with hypertension to ensure BP measurement consistency between the researcher and the assessor. An explanation of the instruments was provided during the assessor training. Considering some of the participants in the rural communities were illiterate, the accessor practiced reading and interpreting each item in the instruments to the participants. The practices for data collection were conducted in the training session until the assessor was competent to collect the data independently.

2.9. Data Analysis.

IBM SPSS version 25.0 (IBM Corp. Armonk, NY, USA) was used for data analysis. Data cleaning was adopted to ensure data quality and study validity. All statistic tests involved were two-sided with the statistically significant level set at 0.05. Descriptive statistics were used to summarise the participants' demographic and clinical characteristics and outcome variables. The assessment of normality for the continuous variables was conducted using Q-Q plot, skewness, and kurtosis statistics.

Chi-square tests and independent t-tests were adopted to test the homogeneity of the sample at baseline measurement. Chi-square test or Fisher's exact test was used for categorical variables. Independent t-tests were applied for the continuous variables that followed a normal distribution.

Intention-to-treat (ITT) analysis was used for data or outcome analysis. ITT analysis method could preserve the sample size and statistical power, thereby resulting in a more accurate, unbiased estimation of the effectiveness of an

intervention [42]. The generalised estimating equation (GEE) model was adopted to analyse the group and time differences of individual outcome variables. In the current study, the data collected at three different time points within the same subject were usually auto-correlated. Therefore, the AR(1) model was selected as working matrices in GEE analyses. The GEE model can be applied when the data missing completely at random (MCAR) [43]. In this study, the results of Little's MCAR test ($\chi^2 = 108.949$, DF = 148, $p = 0.993$) supports the MCAR and GEE can be used.

In the GEE analyses, the interaction (group × time) treatment effects were included in the GEE model to examine the changes in each outcome between the intervention and control groups across the three time points. When the interaction treatment effect was statistically significant in the GEE analysis, pairwise contrast tests were used to identify any statistically significant mean score differences in each outcome measure between groups at postintervention time points (T1 and T2).

Incorporating covariates into the GEE model could minimise the bias of confounding variables and safeguard the statistical power of the intervention effects [44]. In this study, potential covariates were identified based on the results of comparisons for sociodemographic and clinical characteristics and outcome variable scores at baseline between the intervention and control groups. Variables with $p < 0.1$ were considered as potential covariates and adjusted in the GEE model [45].

2.10. Ethical Considerations.

This study was conducted in compliance with the principles outlined in the Declaration of Helsinki. Approvals for this study were obtained from the University Cluster Clinical Research Ethics Committee (CREC Ref. No.: 2019.375). Access permission for this study from the village clinic under study was also obtained. Participant recruitment was followed the voluntary principle. Each potential participant (hypertensive people and their family carers) received a detailed introduction about the study. Informed written consent was obtained from all individual participants before collecting any data. All participants had the right to refuse to participate or withdraw from the study without any influence on usual care services provided by clinical doctors. All data collected were anonymous, kept confidential, and used for research purposes only. The participants were not in any way identifiable in the research reports.

3. Results

110 eligible family dyads (patients and their family carers) participated in the study. Within one month after the intervention (T1), one person with hypertension in the intervention group died after baseline data collection; one family dyad from the control group moved to the city to live with their son. Therefore, the two groups shared the same attrition rate of 1.82% at T1. At three months postintervention (T2), one person with hypertension died after T1 in both groups; one dyad in the intervention group and

two dyads in the control group were out of villages at the time-point of T2. Therefore, the attrition rates at T2 were 5.45% ($n = 3$) for the intervention group and 7.27% ($n = 4$) for the control group; hence, the attrition rate of the study was 6.36% ($n = 7$) at T2. Figure 2 illustrates the flowchart of participants' recruitment, group allocation, and number and reasons for withdrawals.

3.1. Demographic and Clinical Characteristics.

Table 2 presents the demographic and clinical characteristics of people with hypertension. The mean age was 67.65 years (SD = 11.53). The majority of them were female (60.91%, $n = 67$), married (72.73%, $n = 80$), and farmers (93.36%, $n = 106$). 30.00% of the people with hypertension were illiterates ($n = 33$). The mean BMI was 23.52 kg/m^2 (SD = 3.61). About 15% ($n = 17$) and 35% ($n = 39$) were currently drinking and smoking, respectively. More than half of the people with hypertension (54.55%, $n = 60$) took part in farm work. Their average duration of hypertension was 6.25 years (SD = 3.64). About two-thirds of people with hypertension had at least one comorbidity (60.91%, $n = 67$), from whom one-third of them were diagnosed with diabetes (29.09%, $n = 32$). No statistically significant differences were observed in the demographic and clinical characteristics of people with hypertension between the two groups (p values ranged from 0.06 to 1.00).

The demographic characteristics of family carers are summarised in Table 3. About two-thirds of the family carers were spouses of people with hypertension (67.27%, $n = 74$). The average age of family carers was 59.51 years (SD = 9.53), and nearly two-thirds of them (61.82%, $n = 68$) were male. The majority of them completed at least primary school education (66.36%, $n = 73$) and farmers (89.09%, $n = 98$). Their average BMI was 24.91 kg/m^2 (SD = 2.78). About half of them (49.09%, $n = 54$) had one or more medical illnesses. Neither the Chi-square tests nor t-tests identified statistically significant differences in the demographic and clinical characteristics of family carers between the two groups.

3.2. Outcome Variables at Baseline.

The mean scores or frequencies/percentages of the outcome variables are summarised in Table 4. At baseline (T0), the mean SBP values for both study groups were above the normal level of SBP (90–140 mmHg), and the mean DBP values were normal (60–90 mmHg). People with hypertension in the two groups had similar mean score of DRS-C-PT, 12.60 (SD = 3.45) for the intervention group and 12.22 (SD = 3.90) for the control group. The results of independent t-tests showed no statistically significant differences between groups in the outcome variables of people with hypertension, including SBP, DBP, dyadic-relationship quality, self-care, self-efficacy, depressive symptoms, anxiety symptoms, and health-related quality of life at T0, with p values ranging from 0.29 to 0.89; the Chi-square tests did not identify any statistically significant differences in antihypertensive drug-treatment rate ($p = 0.70$) and the rate of hypertensive drugs titration ($p = 0.54$) at T0.

All the outcome variables of family carers were computed using independent t-tests. There were no statistically significant differences between groups in family carers' dyadic-relationship quality, depressive symptoms, anxiety symptoms, and health-related quality of life at T0, with p values ranging from 0.44 to 0.98.

3.3. Effects of PFPI on People with Hypertension. The results of outcome variables for people with hypertension and family carers at T0, T1, and T2 are presented in Table 4. Most of the outcome variables were normally distributed with standard skewness and kurtosis scores between −1.96 and +1.96 and the data points were approximately located on the diagonal line of the Q-Q plot. However, the scores of PHQ-9 and GAD-7 for patients were not normally distributed. The normality of the PHQ-9 and GAD-7 scores across the three data collection time points was met with logarithm transformation. The effect sizes for patients' continuous outcome variables at T1 were small to medium, with Cohen's d values ranging from 0.33 to 0.77; at T2, Cohen's d values ranged from 0.31 to 0.92. Regarding the

categorical outcome variables of patients, the odds ratio ranged from 1.49 to 11.81 at T1 and 1.51 to 9.91 at T2. For the outcome variables of family carers, the effect sizes were small, with Cohen's d values ranging from 0.18 to 0.44 at T1 and 0.20 to 0.44 at T2.

The results of GEE test (Table 5) indicated statistically significant interaction (group × time) treatment effects on the study outcomes, including SBP, DBP, proportion of people with normal BP, DRS-C-PT, HBP SCP-Behaviour, HBP SCP-Self-efficacy, PHQ-9, GAD-7, EQ-5D-5L index score and EQ-VAS of people with hypertension with p values ranged from <0.001 to 0.04, between the two groups over three-month follow-up. Regarding the effects of PFPI on family carers, the results of the GEE test (Table 5) indicated statistically significant interaction treatment effects on GRS-C-CG, GAD-7, EQ-5D-5L index score, and EQ-VAS between groups over the three-month follow-up, with the p values ranged from <0.001 to 0.03.

Pairwise contrast tests in the GEE (Table 5) indicated that, compared with the control group, the people with hypertension in the intervention group reported statistically significant greater improvements in SBP, DBP, DRS-C-PT, HBP SCP-Behaviour, hypertension drug-titration rate, GAD-7, EQ-5D-5L index score, and EQ-VAS at T1 and T2; and in the proportion of people with normal BP, HBP SCP-Self-efficacy at T2. When compared with the control group, the family carers had statistically significant greater improvements in GRS-C-CG and EQ-5D-5L index score at T1 and T2, and in GAD-7 and EQ-VAS at T1.

4. Discussion

4.1. Effects on the Outcomes of People with Hypertension. We supported the study hypotheses that people with hypertension in the intervention group would show statistically significant greater improvements in SBP and DBP values, dyadic relationship, self-care, hypertensive drug-titration rate, anxiety symptoms, and HRQoL at both T1 and T2 and on the proportion of patients with normal BP and self-efficacy at T2, when compared with those in the control (usual care) group. However, the hypotheses concerned with statistically significant greater improvements on the proportion of people with normal BP and self-efficacy at T1 and on antihypertensive drug-treatment rate and depressive symptoms at both T1 and T2 were not supported.

4.1.1. SBP and DBP Values and the Proportion of People with Normal BP. The effect sizes of PFPI on SBP were medium (Cohen's $d = 0.77$) at T1 and large (Cohen's $d = 0.92$) at T2, whereas those on DBP were small at T1 and T2, with Cohen's $d = 0.44$ and 0.47, respectively. The findings of BP control are consistent with and more effective (in SBP and DBP reduction) than the results of our previous systematic review in which eight included RCTs of family dyad-oriented psychoeducational interventions reported that the SBP and/or DBP of people with hypertension statistically significant decreased at less than three months postintervention (medium pooled effect sizes of 0.59 and 0.57, respectively)

[22]. Furthermore, PFPI significantly improved the proportion of people with normal BP across the study period, from zero at baseline to 23.64% at T1 and 41.82% at T2. Among the studies included in our previous systematic review [22], four reported the effects of family support interventions on the proportion of people with normal BP. The improvements in the proportions of people with normal BP in these studies (15.8%–44.90%) were similar to those in the current study (23.64% at T1 and 41.82% at T2). The overall rate of well-controlled hypertension (SBP <130 mmHg and DBP <80 mmHg) in the USA in 2017–2018 was 39.64% [46]. Therefore, PFPI could be useful in improving the proportion of people with normal BP across rural areas, bringing it to the same level in developed countries.

People with hypertension in rural communities could not receive adequate healthcare services [7, 8]. In the current study, the clinic doctor (the only staff in the clinic) needs to provide nearly 300 home visits each month to all patients with hypertension and/or diabetes in the village. The large workload is not conducive to providing complete and effective hypertension care services. The family carers in the PFPI group were trained to supervise and assist in patients' medication intake, BP monitoring, and problem behaviour change and to record BP values and medication adherence in the booklet provided for reference to healthcare providers. Therefore, they were employed as surrogates for formal healthcare providers [47]. This assistance in hypertension care could alleviate the effect of the shortage of healthcare providers on hypertension management in rural areas [48]. Moreover, compared with the previous studies on family-oriented or family support intervention [48, 49], PFPI was delivered in face-to-face individual (for family dyad) sessions during home visits. The scattered living status and underdeveloped transportation in rural areas could prevent patients from actively seeking healthcare services. The healthcare service (e.g., PFPI) delivery format of home visits addresses the health disparities in seeking healthcare service for rural community residents due to long geographical distance.

The construct of SCM, which was adopted for PFPI development in this study, could interpret the statistically significant effect of PFPI in BP control. The three main components (communication, decision-making, and reciprocity with family dyad) in SCM were committed to building an effective patient-family carer (dyadic) partnership in daily hypertension care. The conflicting beliefs, difficulty in talking about an emotional topic, and lack of skills in handling conflict negatively affected the care partnership [15, 16]. PFPI provided dyadic communication skill training improving dyadic communication led to reductions in depressive symptoms for the patients and/or family carers and a positive value for the family. Systematic reviews demonstrated that family-dyadic partnership-/relationship-focused interventions were more likely to lead to reductions in depressive symptoms for patients with chronic illness and their family carers than the family interventions only directed at increasing knowledge and skills for managing the disease [47]. The exchange of values and prefers about self-management strategies between the dyad

members is the basis of decision-making and action in hypertension care; it could improve the self-care (e.g., medication intake and problem behaviour change) of patients with hypertension [50]. Implementing the action plan with mutual support is highly emphasised in the SCM and PFPI [28]. In the PFPI sessions, the family dyad was guided to identify problem behaviour and set goals; discuss the influence of behaviour change; discuss difficulties in behaviour changes and effective coping strategies; identify ways to seek information, professional help, and community support whenever needed; and formulate an action plan. The family dyad applied these decision-making techniques in daily hypertension care situations when needed to make decisions. Research has demonstrated that the improved decision-making skill of stroke survivor-caregiver dyad was positively associated with survivors' depressive symptoms, dyadic relationship, and survivor coping skills [51]. Dyadic partnership is also a process of giving and accepting physical and emotional help with appreciation [52]. For example, in the PFPI sessions, the family dyads discussed the assistance provided by the family carer and received by the patient in behaviour modification. They also discussed the difficulties and challenges throughout the process of giving and receiving assistance and the strategies to overcome them and express gratitude and appreciation. These reciprocity skills facilitate the family dyad's mutual cooperation in BP monitoring, medication adherence, and behaviour change at home.

Another feature of PFPI is cultural sensitivity. Interventions taking the culture into account are more likely to lead to more positive behavioural changes [53]. In the rural areas of China, family culture and values highly emphasise the responsibilities and obligations of family members in caring for sick family members [10]. Therefore, in PFPI, the family carer was treated as a partner in hypertension care. Each family dyad worked together to promote treatment adherence and lifestyle modification through effective dyadic communication (to avoid conflicts and over-protection) and decision-making in health care.

4.1.2. Dyadic-Relationship Quality.

In this study, the dyadic relationship significantly improved for the intervention group at T1 ($p = 0.004$) and T2 ($p < 0.001$) with medium effect sizes (Cohen's $d = 0.52$ and 0.65, respectively). As the dyadic relationship quality was seldom measured as an outcome in previous studies [47], limited information about the effect of interventions on dyadic relationship quality among people with hypertension could be found. Seber and Woda [28] developed a shared care dyadic intervention based on SCM for patients with heart failure and used a dyadic relationship measure as one of the patient outcomes in their pilot study. However, noticeable differences were found in the participants, sample size, study design, and times of outcome measurements between two studies, which may have led to the difference in their effect sizes on the dyadic relationship quality, with a Cohen's d of 0.65 at three-month postintervention in the current study and 0.25 immediately postintervention in Sebern and Woda's study [28].

In an RCT study, a family partnership intervention was effective in improving perceived confidence and motivation for self-care and reducing dietary sodium among heart failure patients. Other RCT study also demonstrated the effectiveness of family-focused dyadic psychoeducational intervention on the dyadic relationship of stroke survivors and their family caregivers [51]. Therefore, family-dyad partnership intervention may be feasible and effective in improving self-care and self-efficacy for patients with chronic illnesses.

4.1.3. Self-Care and Self-Efficacy.

PFPI significantly improved hypertensive people's self-care and self-efficacy in hypertension management with medium and small effects, respectively (Cohen's $d = 0.65$ and 0.31, respectively). In our previous systematic review [22], three studies reported the results of self-care, all of which revealed statistically significant improvements. Similar to this study, educating family dyad jointly in the educational sessions on knowledge and skills of lifestyle modifications through discussion and goal setting and encouraging family carers to supervise patients' behavioural changes were used in previous studies. These intervention components/contents were also demonstrated (in a systematic review) to be effective in improving self-management for patients with uncontrolled type II diabetes mellitus [54]. PFPI also adopted participatory learning strategies to improve the family dyads' skill in identifying the problem behaviour and making decisions and action plans for behaviour change. The participatory learning strategies encourage more active involvement of participants in the learning process, improve the dyadic communication and cooperative techniques of family dyad in health care, and facilitate changes in their lifestyle behaviour [55].

4.1.4. Antihypertensive Drug-Treatment Rate and Antihypertensive Drug-Titration Rate.

In the current study, the hypertensive people in the intervention and control groups had improved antihypertensive drug-treatment rates. However, the difference between groups was nonsignificant ($p = 0.17$ and 0.18, respectively) at T1 and T2. In the home visit service (usual care), the village doctor monitored the BP of people with hypertension (every three months) and encouraged them to intake hypertensive drugs for those who had uncontrolled BP, which may lead to an improvement in antihypertensive drug treatment [56]. On the other hand, people with hypertension in the intervention group had significantly improved antihypertensive drug-titration rate at T1 and T2 ($p = 0.01$ and <0.001, respectively). Although usual care (with or without PFPI) revealed effect on improving antihypertensive drug-treatment rate, the PFPI together with usual care for the intervention group had a much better effect on the antihypertensive drug-titration rate.

Evaluating the efficacy of antihypertensive drugs in BP control (e.g., BP monitoring) promptly is a prerequisite for drug titration [34]. However, only 24.5% to 34.3% of people with hypertension living in China rural communities

conducted weekly BP measurements [57]. People with hypertension receiving the PFPI had more frequent BP monitoring (e.g., measured BP at each session) than those in the usual care group, which may lead to a higher antihypertensive drug-titration rate. A recent systematic review examined the effects of family involvement in hypertension care on managing medications of older patients with chronic illnesses [56]. The findings indicated that family carers' participation in conveying information about patients' medication adherence and BP values to healthcare providers and receiving feedback and decision-making in managing medications could lead to drug titration more effectively. The intervention combining BP self-monitoring and self-titration to adjust antihypertensive medication could lead to the reduction of 9.2 mmHg in SBP and 3.4 mmHg in DBP for people with hypertension compared with the usual care group [58]. In the current study, we did not collect the data on dose and types of antihypertensive drugs, and the BP values changed after the drug titration. Therefore, the effect of drug titration on BP change remains unknown. Further studies should collect the data of doses and types of antihypertensive drugs used and changed over time, and the BP values changed after the drug titration, to identify the trajectory of BP change.

4.1.5. Depression and Anxiety Symptoms. The findings of this study revealed that PFPI reduced depressive symptoms, but the effect was nonsignificant between groups. However, anxiety symptoms were significantly reduced at T1 and T2 compared with the control group, with medium and small effect sizes (Cohen's $d = 0.52$ and 0.48, respectively). Inconsistent with the findings on depressive symptoms of hypertensive people in the current study, systematic reviews in chronic illness care have provided evidence of the positive effects of family involvement in illness management programs for adults with different chronic illnesses (e.g., stroke survivors and patients with cancer) [59, 60]. The inconsistency may be due to the low level of people's depression at baseline (mean PHQ-9 score was 4.00), where a PHQ-9 score below 10 is considered to be mild in depression symptoms. Such flooring effect of low depressive symptoms at baseline might cause difficulty in showing treatment effects by making statistically significant changes or improvements in their scores. Patients with serious illnesses (e.g., stroke and cancer) often experience more depressive symptoms [47]. The effect of PFPI on reducing hypertensive people' s depressive symptoms should be further studied.

Increasing evidence of the association between anxiety and hypertension exists [61, 62], and anxiety could negatively affect medication adherence [63]. A significant correlation between anxiety, family function, and QoL was found, and anxiety had a partial mediating effect on the relationship between family function and QoL of older adults with hypertension in low-income communities [64]. The effects of family involvement in hypertension care on anxiety could not be found in previous studies. In other chronic illnesses, such as heart diseases, the effect of family dyad intervention on anxiety in patients with coronary heart

disease and family partners was evaluated in a systematic review; the authors could not find significantly lower anxiety levels for patients who received interventions focusing on disease counselling and improving social support than the control group [65]. By contrast, another systematic review demonstrated that interventions targeting the relationship between patients with cancer and their family carers could significantly improve anxiety, depression, and/or distress in both [59]. The potentially effective components of these included studies were education and training about disease knowledge, problem-solving skills, and counselling and discussions in a dyadic manner, similar to the PFPI in the current study. Therefore, even though the evidence of family-dyadic partnership interventions on anxiety symptoms of hypertension and other chronic illnesses (e.g., hypertension, diabetes, and stroke) was limited, the findings of this study supported that family-dyadic partnership intervention could be a promising intervention in improving the anxiety symptoms of people with chronic illness.

4.1.6. Health-Related Quality of Life, HRQoL. PFPI significantly improved the HRQoL of people with hypertension at T1 and T2, with medium and small effects (measured by EQ-5D-5L index: Cohen's $d = 0.66$ and 0.49, respectively; measured by EQ-VAS: Cohen's $d = 0.61$ and 0.51, respectively). An effective family-dyadic partnership was beneficial for QoL of people with hypertension in low-income communities [64]. The structure of SCM also supports a positive relationship between self-care, dyadic relationship, and HRQoL [24]. Similarly, Reid et al. reviewed [63] psychological interventions for patients with coronary heart disease, and their partners demonstrated improvements in the HRQoL of patients at 6 to 13 months post-intervention. The main components of the interventions in the reviewed studies were similar to those in this study, including information giving and counselling in 2 to 8 dyadic sessions within 1.5 to 4 months.

4.2. Effects on the Outcomes of Family Carers

4.2.1. Dyadic Relationship Quality. With no available evidence for the family's perceived dyadic relationship in hypertension care, the GEE test identified statistically significant interaction effects of PFPI on the family carers' perceived dyadic relationship at T1 ($p = 0.04$) and T2 ($p = 0.049$) with small effect sizes (Cohen's $d = 0.36$ and 0.31, respectively). In two pilot studies (with small sample sizes of four and 10 only), shared care interventions developed based on SCM were tested among patients with heart failure and their family carers. These studies reported improvements in the quality of dyadic relationship (also measured by DRS-CG) immediately post-intervention [27, 28]. Dyadic communication and reciprocity in healthcare were the main contents of PFPI in the current study, leading to significant improvements in dyadic relationship. Family-dyadic partnership-focused intervention had positive effects on improving the dyadic relationships in their verbal feedback, such as knowing each other better, expressing suggestions and assistance positively, exchanging

views on illness experiences, and clarifying perceptions [50]. The findings could support further research to employ the patient-family (carer) partnership model of intervention to improve the dyadic relationship of family carers and patients with hypertension.

4.2.2. Depressive and Anxiety Symptoms. The PFPI has positively improved the family carers' depressive symptoms, but the GEE test results did not indicate statistically significant effect between groups. None of the studies reviewed in our previous systematic review provided evidence about the family carers' depressive symptoms in hypertension care. The result of a systematic review and meta-analysis demonstrated that a stronger perception of filial obligation was associated with increased depressive symptoms among family carers, especially in Chinese culture [66]. Family dyadic relationship-focused interventions can significantly improve family carers' depression of patients with stroke, cancer, and arthritis [59]. Since patient and family carer depression influences patient self-care and family carer's contribution to self-care, healthcare providers should assess and treat depression in both members of the dyad to improve self-care [67]. However, caring for seriously ill patients (e.g., stroke and cancer) can bring more caregiving burden and pressure to family care. As discussed above, the low level of family carers' depression at baseline might cause difficulty in showing treatment effects by making statistically significant changes or improvements.

In the current study, family carers' anxiety symptoms were significantly improved at T2, with a small effect size (Cohen's $d = 0.28$). The improved dyadic partnership is conducive to lowering anxiety symptoms, as declared in SCM [24]. No information on anxiety symptoms of family carers for people with hypertension could be obtained from previous studies. The positive effect of interventions involving the family in treatment of the anxiety of family carers has been demonstrated in systematic reviews of patients with other chronic physical diseases, such as cardiovascular disease, arthritis, and diabetes [68]. An "umbrella" review also found that dyadic relationship-focused family interventions could improve the mental health of adult patients with chronic illness and their family carers [47]. Therefore, family-dyadic partnership/relationship intervention may positively affect the family carers' anxiety symptoms, and further research is needed to support the positive effect of PFPI in improving the anxiety symptoms of family carers in hypertension care.

4.2.3. Health-Related Quality of Life (HRQoL). PFPI significantly improved the HRQoL of family carers at T1 and T2 ($p = 0.03$ and 0.02, respectively), with small effects when measured using EQ-5D-5L index (both Cohen's $d = 0.44$). However, the difference in HRQoL measured using EQ-VAS was statistically significant at T1 only ($p = 0.04$) with a small effect size (Cohen's $d = 0.33$). The symptoms, mood, knowledge, and behaviour of people with hypertension towards hypertension management and the family carers' caregiving burden were significantly related to the HRQoL

of the family carer [69]. The results of a systematic review and meta-analysis that showed lower poststroke cognitive performance were associated with poorer caregivers' quality of life [68]. In the current study, with the positive effects of PFPI in improving patients' self-care, anxiety symptoms, and family carers' perceived dyadic relationship, the improvement of HRQoL could also be statistically significant and positive. Similar to other family outcomes used in this study, limited evidence was available in previous hypertension care studies. Further research is suggested to confirm the effect of PFPI on improving the carer's HRQoL.

4.3. Limitations. Several limitations should be acknowledged. First, the participants in this study were recruited in only two villages in Hunan Province in Southern China, thus limiting the representativeness of the participants and the generalisability of this study to other rural areas in China. Second, this study examined the short-term (one- and three-month postintervention) effects of PFPI on the outcome variables of people with hypertension and their family carers. The longer-term (e.g., six months or above) effects of PFPI on these outcomes remain unknown, and they need to be tested in further studies. Third, although a checklist of all items of the intervention protocol was used to monitor the intervention fidelity by the researcher during each session, this study lacked sufficient process evaluation. Future studies are recommended to adopt a process evaluation to thoroughly understand the intervention implementation, compliance of participants, and successful features of the programme [70]. An independent observer or audio and video recording could be used to measure implementation fidelity. Lastly, as an individual's BP values could fluctuate throughout the day, the BP values obtained from measuring at a one time point on the data collection day may not comprehensively reflect the patient's BP controls. A 24-hour ambulatory blood pressure monitoring could be adopted in future research to obtain more accurate BP values.

4.4. Implications. This study provides evidence on integrating the PFPI into hypertension management programmes for rural communities in China. This study also reveals its potential application to a wider hypertensive population in the rural and urban areas of China. Several suggestions were provided to facilitate the implementation of PFPI in practice. First, the study findings could help health policymakers and government administrators realise the importance of patient-family (carer) partnership as the model of intervention in hypertension management in communities, particularly in rural areas with very limited healthcare service. They could also promote the related health regulations or policies to emphasise the adoption of patient-family partnership models of care in community-based hypertension management or services. Second, hypertension care stakeholders need to discuss the barriers and facilitators of integrating PFPI into the current hypertension management service. Third, the village doctors and/or social workers, who are the common healthcare workers in rural areas, should be trained to conduct PFPI.

5. Conclusion

We evaluated the effectiveness of PFPI on people with hypertension and their family carers in rural communities in China. The findings demonstrated statistically significant positive effects of PFPI on the majority of the outcomes of participants. These findings supported integrating PFPI into the current hypertension care programmes/services as it could be a more feasible and effective approach to hypertension management in rural areas of China. Further studies are recommended to apply a mixed-method research design and recruit participants with diverse clinical, sociodemographic, and ethnic backgrounds to evaluate the longer-term effects of PFPI in different China regions.

Data Availability

The datasets used to support the findings of this study are available from the corresponding author upon request.

Additional Points

Reporting Method. The study is reported in line with the Consolidated Standards of Reporting Trials 2010 Statement. Patient or Public Contribution. Eligible hypertensive people receiving home visits and care at two village clinics and their family carers were randomly enrolled in this study. The researcher reviewed the hypertensive people's medical records in the two village clinics under study and created a list of potential participants (those aged 18 years or above and having essential hypertension without adequate BP control) in alphabetical order of their family names after screening. The people on the list were randomly selected using a random number table and approached by the researcher during home visits to further confirm the study eligibility (living with one or more adult family members, speaking Mandarin or local dialect, and without terminal and mental illness, etc.). The researcher introduced the study to the participants and the benefits, risks, participants' rights, and confidentiality when participating in this study. Written informed consent was obtained from the participants who agreed to participate in this study. The researcher delivered the intervention to participants in the intervention group. A retired village doctor was trained to collect data. What Does this Paper Contribute to the Wider Global Clinical Community? (i) The patient-family (carer) partnership intervention has the potential to improve hypertensive people's BP control in rural areas. (ii) The intervention also helps to improve hypertensive people's and family carer's dyadic-relationship quality and mental health at short-to-medium-term follow-ups. (iii) This study provides evidence on integrating the patient-family (carer) partnership intervention into hypertension management programmes for rural communities worldwide. Trial Registration. This study was registered in the Chinese Clinical Trial Registry https://www.chictr.org.cn (registration number: ChiCTR1900027087) in October 2019, and the first participant was recruited in July 2020.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

Supplementary Materials

Supplementary material 1: a checklist of intervention fidelity. The checklist consisted of all items of the intervention protocol. It was used by the researcher during each intervention session to monitor the intervention fidelity. At the end of each session, the researcher checked the completion of each item on the list with family dyad and marked as "completed" or "uncompleted." The "uncompleted" intervention item was made up in time. Supplementary material 2: hypertension management booklet. The booklet comprised four sections, including the goal of BP control, risk assessment for cardiovascular disease, criteria of healthy behaviours and worksheets for identifying behavioural problems, and hypertension self-care. Background. Most frontline nurses lack sufficient readiness for effective disaster response. Therefore, designing a disaster management training program (DMTP) to promote nurses' readiness for disaster response is imperative. *Aim.* This study aimed to evaluate the effectiveness of a structured DMTP on nurses' readiness for response to disasters. *Methods.* A randomized controlled trial was conducted. One hundred eligible nurses, recruited using convenience sampling from a medical centre in northern Taiwan, were randomly assigned to either the experimental (EG, $n = 50$) or control (CG, $n = 50$) group. Both groups received regular continuous nursing education. The EG received an extra two-day (16 h) structured DMTP delivered by transdisciplinary collaborations through multiple teaching strategies (lectures, simulations, problem-solving lessons, demonstrations, tabletop exercises, discussions, group presentations, and reflections). Readiness for disaster response, consisting of four subscales (emergency response, clinical management, self-protection, and personal preparation), was assessed at baseline and 12 weeks after the intervention. Generalized estimating equations were used as the primary method of data analyses to evaluate the intervention effects. *Results.* Ninety-four nurses (94%) completed the study, and 100 nurses were included in the intention-to-treat analysis. While participants in the EG had increased readiness for disaster response after training and at the 12-week follow-up, those in the CG exhibited no differences between baseline and 12-week follow-up. When the group × time interaction was examined, the EG had a greater increase in readiness for disaster response and its four domains, including emergency response, clinical management, self-protection, and personal preparedness after 12 weeks, than the CG. *Conclusion.* A two-day structured DMTP utilizing multiple teaching strategies through transdisciplinary collaborations is recommended to enhance hospital nurses' readiness for disaster response. *Implications for Nursing Management.* Nursing leaders should consider incorporating such a structured DMTP into ongoing nursing training as a critical component of professional development programs, thereby strengthening nurses' disaster readiness in hospital settings.

1. Introduction

Disasters have engendered significant repercussions characterized by extensive damage, destruction, and loss of life, property, or livelihoods in communities and societies [1]. Worldwide, nations face potential threats from a wide array of disasters, including natural disasters such as earthquakes, hurricanes, floods, landslides, and wildfires, and anthropogenic catastrophes such as terrorist attacks and warfare. These disasters have profound impacts on both individuals and nations, leading to severe consequences [2, 3].

Taiwan, situated in a geographically vulnerable region, faces a wide spectrum of natural disasters and associated hazards. Among these, earthquakes, typhoons, landslides,

floods, and industrial accidents have historically affected island nations. Over the past few decades, earthquakes have been one of the most devastating events in Taiwan. Previous disaster epidemiology studies related to the 1999 Chi-Chi earthquake in Taiwan, which claimed 2,415 lives and caused injuries to 11,305 people, revealed that the demand for medical care peaked 12 hours after the earthquake and remained elevated for up to three days [4]. These findings highlight the critical significance of timely disaster response for healthcare in Taiwan.

Disasters can result in a range of adverse outcomes, including infrastructure damage, economic consequences, physical injuries, psychosocial impacts, environmental ramifications, and deprivation of essential services such as water, sanitation, and healthcare, forcing people to leave their homes and communities temporarily or permanently and even lose their lives [3, 5]. Therefore, efforts to decrease the unexpected consequences of disasters and develop strategies to mitigate their impacts remain an imperative research focus. However, to minimize the impact of a disaster and ensure timely and effective responses, a robust frontline medical workforce, particularly nurses, is crucial in disaster areas and local hospitals near the affected sites [6, 7]. Frontline nurses must efficiently assess the severity of patients' injuries and prioritize care based on the level of urgency during a disaster when there may be a high volume of patients in need of care. In addition, nurses are responsible for stabilizing patients experiencing a medical emergency with initial treatment, transferring patients to hospitals or medical facilities, offering coordinated care to patients with other healthcare professionals, and providing emotional and psychological support to patients and their families during disasters [8].

Considering the continuous occurrence of disasters and the negative impacts they entail, nurses' readiness to respond is crucial for mitigating the adverse consequences on affected individuals. Recently, the COVID-19 pandemic has highlighted the necessity of having a national nursing workforce prepared with the knowledge, skills, and abilities to respond [9]. Disaster management is the effort to reduce unexpected consequences and disaster risks [10]. Therefore, to ensure effective and efficient disaster management, it is crucial to enhance frontline nurses' readiness for disaster response, thereby saving lives and mitigating adverse health impacts on affected populations [10, 11].

According to the World Health Organization, most disaster-related deaths occur in healthcare facilities that are unprepared for emergency situations [12]. Adequate preparation and disaster readiness of healthcare personnel, especially nurses who often serve as first responders, can significantly reduce fatalities [8, 13]. Moreover, building resilient health systems through better-prepared medical staff is fundamental [8, 11]. The readiness of nurses not only impacts the immediate effectiveness of disaster response but also significantly affects the overall resilience of health systems and predicts the nurses' willingness to engage in these situations [7] and their capacity to deliver adequate care within a disaster environment [14]. Comprising the largest segment of the healthcare workforce, nurses play

a pivotal role in shaping community health outcomes during disasters [15] and managing emergency or disaster medical situations, thereby forming the backbone of the health system. Therefore, it is crucial that nurses possess the requisite knowledge, skills, and competencies, especially readiness, to respond effectively to disasters [16].

However, a significant concern is that many hospital nurses report a lack of readiness for disaster response [15, 17]. Disaster readiness varies significantly across countries, influenced by factors such as economic status, governance, infrastructure, and historical disaster experience [18–21]. For instance, high-income countries like Finland exhibit a proactive approach by incorporating a disaster readiness mindset into governmental strategies [21]. This approach involves identifying potential disaster risks and implementing measures to mitigate them effectively, ensuring a well-coordinated response when disasters occur [21]. In contrast, many countries face challenges in disaster preparedness due to limited resources and infrastructure. Previous studies have highlighted that nurses, especially undergraduate nursing students in these regions, often lack sufficient training and education in disaster management, which is crucial for effective emergency response and clinical management [18, 20, 22]. This gap is evident in regions such as Southeast Asia and parts of Africa, where the frequency of natural disasters like floods and cyclones is high, yet preparedness levels remain inadequate [20, 22]. In Taiwan, a cross-sectional study involving 311 registered nurses at a military hospital found that the majority of nurses demonstrated poor readiness and lacked adequate preparation for disaster situations [11]. Studies have also highlighted that nurses and nursing students with prior disaster-related training and experience in disaster response demonstrate higher readiness and competencies [11, 18]. In India, nurses display moderate levels of preparedness, influenced by various factors such as education, prior disaster experience, mental health, and especially disaster self-efficacy, a vital factor that determines an individual's behavior and performance during disaster situations [23]. In Japan, nurses' disaster readiness has been significantly shaped by the country's frequent exposure to natural disasters. A study examining the disaster preparedness of nurses following the Great East Japan Earthquake found that while they demonstrated moderate levels of overall preparedness, there were notable deficiencies in handling specialized scenarios, such as chemical or biological incidents, and in their psychological preparedness [14]. Thus, the availability and quality of emergency and disaster management training for health professionals vary widely, with many countries offering little to no formal training [14]. Therefore, it is essential to develop structured and effective educational programs to enhance hospital nurses' readiness for disaster response [17].

Disasters also have significant adverse effects on the mental well-being of frontline nurses, who are a high-risk and vulnerable group of medical responders to adverse psychological outcomes [13]. In the context of surging demand, providing high-quality care during disasters is a daunting task. Such situations detrimentally affect the

health of healthcare professionals, especially their psychological well-being, owing to the repetitive exposure to traumatic events inherent in their work. Adapting preventive interventions and mitigation strategies targeted specifically at high-risk hospital nurses would be beneficial in decreasing negative outcomes [13]. The lack of adequate training for healthcare providers is a risk factor for adverse psychological health outcomes after disasters [24]. Therefore, designing and incorporating a well-structured disaster management training program into continuous clinical nursing education can mitigate the negative impacts on the mental well-being of hospital nurses who experience disaster events.

Curricula related to disaster training using multidisciplinary methods of simulation and human factor training have been proposed for implementation by organizations such as the Association of American Medical Colleges in the USA, the Government of the Federal Republic of Germany, and the Research Centre in Emergency and Disaster Medicine and Computer Science Applied to Medical Practice in Italy [17]. However, it is currently recognized that there is brief or nonexistent exposure to disaster training within current clinical training curricula worldwide, which may leave hospital nurses unprepared for an intimidating and unfamiliar setting if assisted in the healthcare workforce. Given that various nursing programs have provided education and training in disaster management in recent decades [17, 25–27], most research has focused on nursing students, and most frontline nurses have also reported insufficient readiness or preparedness in responding effectively to disasters [15, 28]. According to a recent study conducted in Greece that evaluated the effects of disaster education on hospital nurses' knowledge, skills, and expertise through evidence-based interventions, the educational intervention resulted in improved knowledge and self-confidence levels among nurses but did not lead to changes in their behavioral intentions [27]. In addition, most existing disaster programs focus on triage skills during disaster response instead of addressing the full spectrum of disaster management, including preparedness, clinical management, emergency response, and self-protection [11, 17]. Tzeng et al. delineated four critical domains of nurses' readiness for disaster response: emergency response, self-protection, clinical management, and personal preparation [11]. These domains align with the International Council of Nurses (ICN) Core Competencies in Disaster Nursing, outlined in 2019, which emphasizes the necessity for nurses to possess both theoretical and practical understanding of disaster preparedness to respond effectively to emergencies [29]. Emergency response entails managing large-scale emergencies through triage, initial stabilization of patients, incident management, medical evacuation, and transportation [8, 11, 19]. Self-protection focuses on the use of protective clothing; handling chemical, biological, radiological, and nuclear decontamination; infection control; and ensuring safety of both patients and nurses [8, 11, 17, 19]. Clinical management involves performing physical assessments, operating equipment in austere environments, and providing specific medical care such as trauma care, management of burn or

explosion injuries, first aid, and handling toxic substance injuries [8, 11, 19]. Personal preparation includes acquiring basic survival skills; making physical, psychological, and social plans (law/ethics) prior to engaging in disaster response; communication; recovery; and fostering confidence in collaboration with multidisciplinary teams or peer care [8, 11, 19].

Designing educational programs to enhance frontline nurses' disaster readiness without considering the above key domains of disaster management may not only result in the depletion of manpower and material resources but also fail to achieve the expected outcomes. Given that the ICN's core competencies in disaster nursing and the disaster readiness for response to emergencies and disasters are diverse and extensive, enhancing these competencies and readiness inevitably relies on a variety of teaching strategies. In addition, improving learning effectiveness requires the development of skills across different learning dimensions [30]. Therefore, designing disaster curricula or training programs may require multidisciplinary methods and innovative strategies. However, the development of comprehensive disaster management training programs remains limited, particularly in Taiwan, a region that urgently requires a well-prepared disaster nursing workforce.

This study examined the effectiveness of a two-day structured disaster management training program with multiple teaching strategies to promote hospital nurses' readiness for disaster response. We assume that providing such a well-organized disaster management training program delivered by transdisciplinary collaboration through multiple teaching strategies may enhance nurses' readiness for disaster response, possibly increasing their willingness to respond to disasters and mitigating the negative impacts on hospital nurses' mental well-being in the face of future disaster events. Therefore, the practical purpose of this study was to achieve two outcomes: (1) to improve nurses' readiness for disaster response, enabling them to provide timely and efficient care during disasters and (2) to strengthen nurses' resilience, helping them cope with the trauma associated with disaster response, and empowering them with the skills to take on key roles in disaster management teams.

2. Materials and Methods

2.1. Study Design. A two-parallel, randomized controlled trial was conducted at a medical centre in northern Taiwan. Eligible hospital nurses were randomly assigned to either a control group (CG), which received regular continuous nursing education, or an experimental group (EG), which participated in an additional two-day (16-hour) structured disaster management training program (DMTP). The readiness for disaster response including four domains (emergency response, clinical management, self-protection, and personal preparedness) was assessed as outcome measures.

2.2. Participants. Initially, potential participants from a military medical centre in northern Taiwan, affiliated with the national government and responsible for dispatching personnel to disaster-affected areas in Taiwan or overseas,

were recruited by a research assistant. Inclusion criteria were (1) hospital nurses with at least three months' work experience at the local medical centre; (2) aged 20–65 years; (3) full-time employees; (4) able to speak and understand Mandarin; and (5) agreed to participate in the research and to be randomized to one of the two groups. The exclusion criteria were (1) trainee nurses without nursing licenses; (2) new nurses lacking signed contracts because of their inability to work independently; (3) individuals not providing direct care; and (4) those unable to complete the intervention.

Sample size estimation using G* Power (Germany, version 3.1.9) software was based on previous studies with a medium-to-small effect size of 0.15 for the outcome of the expected increase in readiness for disaster response [19, 31, 32], an alpha set at 0.05, number of measurements 2, and a power of 0.80, and each group required 45 hospital nurses [33]. Fifty estimated participants from each group were recruited to account for a 10% loss to follow-up.

2.3. Study Cohorts and Interventions.
Eligible hospital nurses were randomly assigned to the EG or CG using sealed opaque envelopes following computer-generated random serial numbers by the project investigator. All recruited participants underwent monthly continuous nursing education sessions (30–60 minutes/session) in their workplace units/wards. The participants in the EG received an extra two-day structured DMTP through multiple teaching strategies, such as lectures, simulations, problem-solving lessons, demonstrations, tabletop exercises, discussions, and reflections.

Before implementing the DMTP, we assembled a team of 17 transdisciplinary professionals, including a wilderness survival expert with over 10 years of experience, three nursing specialists in disaster nursing education with more than 10 years of experience, an emergency physician with over 20 years of experience, and 12 clinical practice experts. Among the 12 clinical practice experts, six had experience as nurses supporting disaster events, while the other six were nurse leaders with expertise in emergency/critical care, involving the project investigator/corresponding author. This team held consensus meetings to discuss program content and determine effective teaching strategies for a total of 16 hours, with 2 hours/session weekly for eight weeks. The DMTP, implemented following the consensus protocol developed by the consensus/research team, was structured based on four major domains/themes—emergency response, clinical management, self-protection, and personal preparation [11]—to ensure the validity and veracity of the delivered DMTP.

The outline of the two-day (16-hour) DMTP, as presented in Table 1, included a 2-hour lecture and a 14-hour workshop. The 2-hour lecture covered the concepts of disaster nursing, special concepts of disaster, effects of disasters on health, disaster management and its stages, assessment of possible hazards and vulnerabilities, and stages of planning in disasters. The 14-hour workshop consisted of (a) emergency response: mass casualty and triage, medical evacuation, and delivery; (b) clinical

management: trauma care, burn/explosion injury management, first aid treatment, and toxic substance injury management; (c) self-protection: nuclear and biochemical pollution disposal, protective equipment—wear and remove skills—and infection control; and (d) personal preparation: water survival training and rappelling training. In addition, disaster situational responses involve determining the magnitude of a disaster event, planning disaster response, evaluating the health needs of the affected groups, establishing priorities, identifying actual and potential public health problems, determining the resources needed to respond to the needs identified, and collaborating with other professional disciplines and governmental and nongovernmental agencies. Additionally, communication skills were incorporated into the workshop to achieve goals such that the participants could better understand the challenges and complexities of responding to disasters through engagement in hands-on training exercises, role-playing scenarios, and simulations [8, 11, 17].

2.4. Measures.
Sociodemographic characteristics and readiness for disaster response were collected by a separate research nurse who was blinded to the group assignments. Data on sociodemographic characteristics (age, sex, marital status, and educational level), length of nursing work, position (military or civilian nurse), nursing leader (yes or no), work unit/specialty (critical care units/emergency, general/medical-surgical ward, or others such as outpatient department and operation room), previous disaster training (yes or no), and previous disaster nursing experience (yes, no, or not yet but on list) were collected using self-administered questionnaires. Participants, including head and assistant head nurses of hospitals responsible for overseeing nursing staff, coordinating patient care, and managing resources, were categorized as nursing leaders. The EG was invited to assess their readiness for disaster response at the end of the training program. Both the EG and CG completed the evaluation of readiness for disaster response at 12 weeks. Prior to the study, the tool was reviewed by a panel of experts in disaster management, including five disaster-related experts (content validity index: 0.91), to ensure content validity. A pilot test was also conducted with 10 nurses (2 males and 8 females) to assess the tool's clarity, relevance, and ease of use. Furthermore, quality checks were conducted regularly to ensure the integrity and reliability of the data throughout the study period.

2.5. Readiness for Disaster Response.
Nurses' readiness for disaster response was assessed using a 40-item self-administered scale with well-established reliability and validity (acceptable convergent validity with 0.84–0.97), including four domains: emergency response (6 items), clinical management (7 items), self-protection (11 items), and personal preparedness (16 items) [11]. The internal consistency reliabilities of the entire questionnaire and its four subscales (emergency response, clinical management, self-protection, and personal preparedness) were 0.96, 0.86, 0.85, 0.88, and 0.97, respectively. Each item was scored from

TABLE 1: The disaster management training program content in the experimental group.

Content	Teaching strategy	Domain	Time
(1) Concept of disaster nursing, special concepts of disaster, and effects of disaster on health (2) Disaster management and its stages (3) Assessment of possible hazards and vulnerabilities (4) Stages of planning in disasters	Lecture	—	2 hr
(1) Mass casualty and triage (2) First aid treatment, bone injury, and wound care (3) Medical evacuation and delivery/transport (4) Childbirth care at disaster sites (5) Burn/explosion injury management and fluid infusion (6) Management of multiple trauma care	1st-day workshop, six concurrent sessions: lectures, simulations, and problem-solving lessons	a, b	3 hr. (30 min/each topic or session)
Emphasizing personal safety and protection measures for responders and affected individuals during disasters (1) Water survival training (2) Rappelling training	Lectures and demonstrations	c, d	4 hr. (2 hr./each topic or session)
(1) Detection/triage and treatment of nuclear, biological, and chemical contamination/pollution (2) Decontamination practice and treatment for nuclear, biological, and chemical substances (3) Protective equipment—wear and remove skills (4) Infection control in the disaster environment (5) Toxic substance injury management (6) Management of nuclear, biological, and chemical pollution disposal	2nd-day workshop: lectures, simulations, problem-solving lessons, demonstrations, discussions, and reflections	a, b, c	3 hr. (30 min/each session)
Scenario simulation exercises: Conducting simulated emergency scenarios to provide hands-on experience in managing crises, determining the magnitude of the disaster event, planning disaster response, evaluating health needs of the affected groups, establishing priorities, identifying actual and potential public health problems, determining resources needed to respond to the needs identified, and collaborating with other professional disciplines, governmental and nongovernmental agencies, and communication skills	Tabletop exercises, simulations, problem-solving skills, group presentations, group discussions, and debriefing	a, b, c, d	3 hr
Comprehensive discussions	Group discussions and reflections	—	1 hr

Note. [a]Emergency response, [b]clinical management, [c]self-protection, and [d]personal preparation.

1 (strongly disagree or very low readiness), 2 (disagree or low readiness), 3 (neutral or average readiness), 4 (agree or high readiness), to 5 (strongly agree or very high readiness) on a five-point Likert scale, with scores ranging from 40 to 200. Each subscale score ranged from 6 to 30, 7 to 35, 11 to 55, and 16 to 80, in emergency response, clinical management, self-protection, and personal preparedness, respectively. Higher scores represented greater readiness for disaster response. The percentage of total scores was categorized into readiness levels: a score percentage above 75% indicated "highly competent or very good," 50% to 75% indicated "moderately competent or good," 25% to 50% indicated "low competent or fair," and below 25% indicated "incompetent or poor." In addition, the Cronbach's alpha for the scale and its four subscales (personal preparedness, self-protection, emergency response, and clinical management) in this study were 0.92, 0.94, 0.90, 0.82, and 0.76, respectively.

2.6. Ethical Consideration. Approval from the institutional review board was obtained (Reference number: 2-103-05-018) from a local medical centre in Taiwan. Participation in the study was entirely voluntary, and the participants could withdraw from the study at any time.

2.7. Data Analysis. The study employed SPSS version 16.0 (SPSS Corp., Armonk, NY, USA) for all statistical analyses. Descriptive statistics including means with standard deviations (SDs) and numbers with percentages (%) were utilized to present the characteristics of the study participants. The last observation-carried-forward method of data imputation was used for the intent-to-treat analysis. Baseline characteristic comparisons between groups were conducted using the independent t-test or chi-square test. Differences between the groups, both pre- and postintervention, as well as the mean difference between pre- and postintervention within the two groups, were compared using independent t-tests. To assess the intervention effects over time, the generalized estimating equations (GEEs) analysis for longitudinal data was applied, considering the significant interaction of group and time (group × time) [34]. All statistical analyses were two-tailed, and significance was set at $p < 0.05$.

3. Results

3.1. Baseline Characteristics of Participants. Initially, 399 hospital nurses were screened. Of these, 264 nurses declined to participate, and 35 nurses did not meet the inclusion criteria (six had not yet signed contracts with the hospital, four were trainee nurses without nursing licenses, two did not provide direct care, and 23 reported not being able to complete the study intervention). The remaining 100 participants who met the inclusion criteria were randomly assigned: 50 (50%) to the EG and 50 (50%) to the CG.

Of the 100 eligible hospital nurses, 94 (94%) completed the study. The reasons for missed visits, including withdrawal from the study due to absence on the second day of the training program ($n = 4$) and loss in follow-up due to leaving the nursing job at the hospital ($n = 2$) at the 12-week assessment, are presented in the flow diagram (Figure 1). However, 100 participants were included in the data analysis.

The sociodemographic characteristics, working units, experience of previously received disaster training, and personal participation experience in disaster events of the EG and CG are presented in Table 2. The baseline scores of readiness for disaster response and its four subscales (emergency response, clinical management, self-protection, and personal preparedness) for the two groups are shown in Table 3.

3.2. Outcome Evaluation. Table 3 presents the descriptive and univariate analyses of the outcome evaluations. Nurses in the EG had increased readiness for disaster response and its three subscales—emergency response, self-protection, and personal preparedness—immediately after the program and at the 12-week follow-up. However, there were no significant changes in the readiness or its four subscales in the CG. The EG had a remarkably greater increase in the mean differences between pre- and postintervention in readiness for disaster response and its four subscales than the CG.

The effectiveness of the two-day DMTP on readiness for disaster response and its four subscales, including emergency response, clinical management, self-protection, and personal preparedness, assessed through GEE analyses, is shown in Table 4. The analysis revealed a significant interaction between group and time (group × time) regarding readiness for disaster response, indicating that the EG experienced a greater increase at 12 weeks than the CG ($\beta = 27.3$, $p < 0.001$). Specifically, the EG demonstrated significant improvements in emergency response ($\beta = 3.7$, $p = 0.002$), clinical management ($\beta = 3.7$, $p = 0.012$), self-protection ($\beta = 8.4$, $p < 0.001$), and preparedness ($\beta = 10.5$, $p = 0.003$), compared to the CG.

4. Discussion

4.1. Summary of Findings. Our study demonstrates the effectiveness of a two-day, structured disaster management training program provided by transdisciplinary professionals via multiple teaching strategies in improving hospital nurses' readiness for disaster response, including four domains: emergency response, clinical management, self-protection, and personal preparedness. The program significantly enhanced hospital nurses' disaster management readiness. These findings contribute substantively to the existing literature by confirming that active participation in a structured and comprehensive disaster management training initiative can substantially bolster hospital nurses' preparedness, increasing their confidence and willingness to engage in effective disaster response [17, 35]. Moreover, our results align with previous research, emphasizing the importance of a well-structured training program delivered through collaborative efforts across disciplines and employing varied

teaching strategies, ultimately improving response readiness in complex disaster scenarios [17].

The effectiveness of this disaster management training program offers compelling evidence for an optimal educational approach geared towards improving nurses' readiness for disaster response, encompassing emergency response, clinical management, self-protection, and personal preparedness. In light of the steady rise in the availability of disaster training programs over the past two decades, our hypothesis was that creating a structured disaster management training program, delivered by transdisciplinary professionals utilizing multiple teaching strategies, would enhance individuals' knowledge and skills. Furthermore, as previously reported, we believe that it can also enhance their motivation to overcome perceived barriers and indecisive thinking and, most importantly, strengthen their willingness to actively participate in complex disaster situations [17, 35]. The primary focus of the program was to promote readiness for disaster response through a transdisciplinary professional-delivered approach. In addition, the utilization of diverse teaching strategies in the program served as a valuable model for evidence-based nursing education in clinical settings, specifically for hospital nurses.

4.2. Comparison with Previous Research. Our study findings highlight that transdisciplinary collaboration brings together experts from various professional fields, such as emergency management, public health, education sciences, and nursing, and ensures a holistic understanding of disasters and their impacts. This collaborative approach allows the design of a comprehensive educational training program for disaster response [17, 36]. Diverse experts foster innovative thinking and problem solving by providing various perspectives, ideas, and solutions, leading to more effective and well-rounded disaster preparedness, response, and management plans [17]. For example, during a consensus meeting before the training program, the invited experts shared diverse perspectives on the program's design. Transdisciplinary professionals collectively identified the vulnerabilities and risks associated with various types of disasters, aiding the development of targeted mitigation strategies and risk reduction measures [17]. In addition, our transdisciplinary teams analyzed resource requirements across multiple sectors and identified efficient allocation strategies, optimizing the use of limited resources and prioritizing critical needs during disasters to simulate real-world scenarios. A recent report stated that the emerging trends in disaster research

over the past 20 years, marked by increased international cooperation and the transdisciplinary nature of disaster science, have gained popularity [36]. This demonstrates that valuable lessons can be learned from catastrophes and that these emerging trends serve as a scientific foundation for a clearer understanding of progress in disaster science, providing a reference for rapidly identifying frontier issues in disaster science.

Adopting various teaching approaches such as competency-based, all-hazard, and interprofessional approaches, flipped classrooms, simulations, tabletop exercises, virtual reality, and telenursing care in simulated conditions is the current trend in the design of disaster training programs [17, 37]. Therefore, our study employed multiple teaching strategies, including lectures, simulations, problem-solving lessons, demonstrations, tabletop exercises, discussions, group presentations, and reflections, through transdisciplinary collaborations in designing the disaster management training program for hospital nurses. This program aimed to enhance learning outcomes because individuals have different learning styles and preferences. In addition, participants accommodated various learning styles and engaged in training more effectively, increasing their chances of understanding and retaining information and enhancing learning outcomes. Different teaching strategies promoted active participation and engagement among the participants. Instead of passive learning, participants were actively involved in the learning process through discussions, group activities, and practical exercises. This active engagement facilitates better comprehension, critical thinking, and knowledge application, making training more effective and impactful. In addition, given the rapidly changing nature of disasters, the effectiveness of disaster response remains uncertain, particularly due to the challenges in ensuring the timely arrival of professional rescuers. Therefore, telehealth will play an important role in disaster management. A recent study demonstrated that the quality of telenursing care under simulated conditions was satisfactory during the response phase to disasters at Kerman [37]. Therefore, implementation of telenursing care would be helpful in future disasters; however, more evidence is recommended to support the use of telenursing care training under simulated conditions as an alternative teaching strategy.

Disaster management training requires the development of practical skills such as emergency response procedures, risk assessment, communication protocols, and coordination techniques. Therefore, incorporating hands-on

TABLE 3: Comparison of readiness for disaster response between groups at baseline and 12 weeks.

	Baseline				12 weeks				M.D. between pre- and post-test

exercises, simulations, and real-life case studies provides opportunities for participants to apply their knowledge and practical skills to make decisions in realistic scenarios. This practical approach helps bridge the gap between theory and practice, building competence and confidence in hospital nurses, thus ensuring their readiness for disaster response. Therefore, using multiple teaching strategies in a disaster management training program not only enhances learning outcomes but also promotes active participation and engagement, facilitates varied perspectives, develops practical skills, improves knowledge retention, fosters collaboration, encourages adaptability, and provides a holistic understanding of the field [17, 36]. These benefits contribute to the overall effectiveness of the training program and equip hospital nurses with effective disaster management strategies.

A recent systematic review reported that, among 23 studies, the majority assessed knowledge (78.3%), attitude (60.9%), or skills (43.5%) following disaster training [35]. This highlights the need for further research on the assessment of readiness for disaster response after such training. Most of the reported disaster programs focused on triage skills during disaster response instead of addressing the full spectrum of disaster management [11, 17]. In addition, the length of disaster training programs ranged from 1 to 28 days, with a median duration of two days [35]. Therefore, we developed and evaluated the effectiveness of a two-day structured DMTP covering the full spectrum of disaster management, including emergency response, clinical management, self-protection, and personal preparedness. Overall, our study found that the DMTP improved hospital nurses' readiness for disaster response, which could be attributed to the enhancement of participants' attitudes, knowledge, and skills in disaster response [35]. In addition, most studies investigating the effectiveness of disaster training programs have used pre- and posttest measures [17]. Therefore, the strength of our study lies in the fact that we conducted a randomized controlled trial to prove the effectiveness of DMTP.

Medical responders are at a high risk of experiencing a wide range of negative psychological health conditions following a disaster. Notably, depression and posttraumatic stress disorder are the most commonly diagnosed conditions among medical responders. A recent report documented that the prevalence of posttraumatic stress disorder among medical workers involved in the earthquake response was 16.4%, highlighting that medical workers involved in responding during disasters should undergo screening for mental health disorders before and after disasters and receive the necessary training regarding stress management and psychological resilience [38]. Particularly, nurses have higher levels of adverse outcomes than physicians and other medical professionals [13]. In addition, when organizations are exposed to disasters, staff members are often unprepared for the potential psychological impacts that can negatively affect their well-being. Fortunately, predisaster training can improve employees' confidence in their ability to cope with disasters [28, 39] and contribute to improving their psychological health [40]. Furthermore, combining reinforcement of emotional intelligence with predisaster training can also facilitate learning outcomes, since emotional intelligence has a significant positive relationship with various components of learning strategies, namely, self-efficacy, rehearsal, critical thinking, cognitive self-regulation, time and study environment management, peer learning, and help seeking [40]. Therefore, lack of structured and comprehensive training is an important risk factor for negative psychological outcomes across all types of disasters [13].

Personal preparedness and self-protection are critical for disaster response management. In challenging disaster environments, emergency services may not be readily available or may become overwhelmed. Individuals who are self-prepared and have basic self-reliance skills are more likely to survive, recover quickly, and be in a position to help others, reducing the risks of injury or death. Therefore, preparedness for self-rescue or self-protection is one of the most important elements of organized and timely emergency response to disaster events [41]. Personal preparedness and self-protection also enable swift responses in the immediate aftermath of a disaster, which is crucial for survival. Additionally, having individuals well-prepared for self-protection during a disaster can alleviate the burden on emergency services, allowing first responders to prioritize those in greatest need [11]. Therefore, personal preparedness and self-protection not only increase individuals' chances of survival and recovery but also contribute to an effective disaster response.

Readiness for disaster response, an important component of disaster management, encompasses the capacity to manage disaster impact quickly and efficiently. Therefore, responding quickly and appropriately to disasters is crucial and depends on frontline nurses' preparedness. Nurses' readiness for disaster response and competencies can vary depending on factors such as their specialty or work area of practice, individual interests, prior experience in in-service training programs, and exposure to deployments in disaster sites [18]. For example, nurses working in emergency departments or critical care settings may have more training and experience in disaster response than those working in other areas of healthcare [28]. However, nurses' readiness for disaster response includes not only clinical management and emergency response but also personal preparedness and self-protection ability [11]. During a disaster event, nurses not only provide first aid and advanced clinical care, monitor physical and mental health needs, allocate resources, conduct efficient communication, and provide crisis leadership [17] but also oversee the use of personal protective equipment, maintain personal emergency supply, prioritize their own safety, utilize appropriate personal protective equipment, and practice infection control measures to minimize exposure to hazards. In addition, according to our previous findings, nurses with prior disaster training were associated with greater readiness for disaster response, including its four major domains: emergency response, clinical management, self-protection, and personal preparedness, after adjusting for potential covariates such as sociodemographics (marital status and educational level), length of nursing

work, nursing position, nursing leaders, work unit/specialty, and previous disaster nursing experience [28]. Therefore, the current study aimed to develop a two-day structured disaster management training program that addresses the full spectrum of disaster management, including preparedness, clinical management, emergency response, and self-protection. Fortunately, we discovered the effectiveness of the training program in increasing hospital nurses' readiness for disaster response, both immediately after the program and at the 12-week follow-up.

4.3. Limitations and Strengths. There are some limitations in this study that should be considered. First, the geographic region in which this study was conducted may limit its generalizability to other cultural groups. Therefore, the current research findings must be interpreted with caution; more rigorous sampling strategies from multiple sites or hospitals are recommended. Second, although the 12-week follow-up effects after intervention are important, evaluation of long-term follow-up might be necessary. While acknowledging these limitations, it is crucial to recognize the strengths of our study as well. These strengths include the random allocation design, provision of a well-structured disaster management training program with multiple teaching strategies, and a high rate of study completion by the participants (94%).

4.4. Contributions and Future Directions. Notably, our study is the first trial to test the effectiveness of a two-day (16-hour) structured disaster management training program that includes four major domains/themes (emergency response, clinical management, self-protection, and personal preparation) through multiple teaching strategies (i.e., lectures, simulations, problem-solving lessons, demonstrations, tabletop exercises, discussions, group presentations, and reflections by transdisciplinary collaborations on readiness for disaster response among hospital nurses). Future studies could apply this training program to confirm its effectiveness across different cultures and focus on investigating competencies, combining knowledge, attitude, skills, readiness, and self-efficacy. This might help to elucidate how the training program improves readiness for disaster response in this population. Moreover, further more studies can (1) conduct longitudinal studies to provide insights into the long-term retention of disaster response skills and identify necessary intervals for refresher training; (2) integrate modern technologies like virtual simulation to potentially elevate training efficacy; (3) explore whether the program not only increases readiness for disaster response but also empowers hospital nurses; and (4) employ focus groups or qualitative methods to examine hospital nurses' perceptions regarding the most helpful aspects of the training. In addition, the feasibility of implementing the intervention in hospitals, educational institutions, and schools is an important next step.

4.5. Implications for Nursing Management. In light of our study findings, which reveal that structured disaster management training programs (DMTPs) utilizing multiple teaching strategies and transdisciplinary collaborations significantly enhance nurses' readiness for emergency and disaster response, nursing leaders or managers should actively integrate such DMTPs into ongoing professional development curricula to fortify hospital response readiness and capabilities. Specifically, nursing leaders are encouraged to prioritize these training modules, ensuring they are recurrent and updated regularly to reflect the latest in disaster response protocols and technology. Moreover, it is recommended that these programs be tailored to the specific needs and challenges of the nursing staff within individual healthcare facilities, considering factors such as existing skill levels and potential disaster risks pertinent to geographical locations. Nursing management could also benefit from establishing a feedback loop where participants in these programs contribute insights and suggestions for improvements. This approach fosters a culture of continuous learning and adaptation, thereby improving individual nurse preparedness and enhancing the overall institutional resilience to disasters.

5. Conclusions

A two-day structured disaster management training program, delivered by transdisciplinary professionals using multiple teaching strategies, can serve as an effective approach to improve hospital nurses' readiness for disaster response. Such disaster training programs might include innovative methods such as virtual reality and be integrated into ongoing nursing education and future curricula to strengthen disaster readiness across healthcare settings. In addition, continuous educational efforts and periodic refresher training are recommended to maintain and update these critical skills. Nursing leaders or managers should consider incorporating such a structured disaster management training program as a critical component of professional development programs, thereby strengthening nurses' disaster readiness in hospital settings, fostering a culture of continuous learning and adaptation, and enhancing overall institutional resilience to disasters.

Aims. This umbrella review aims to comprehensively synthesize and analyze the findings of available systematic reviews on the effectiveness of individual-based strategies for reducing nurse burnout occurring in hospital-based settings. *Methods*. Following JBI guidelines, an umbrella review was conducted to integrate the effectiveness of various strategies to reduce burnout. Systematic reviews were searched in the Embase, MEDLINE (Ovid), Cochrane Library, CINAHL (EBSCO), Scopus, and WOS databases. Inclusion criteria included studies published in any language from database inception to April 2023. Eligibility assessment involved two independent reviewers who evaluated titles, abstracts, and full texts. The systematic reviews were critically evaluated using JBI SUMARI. The results were narratively synthesized and grouped by strategy. *Results*. Eleven systematic reviews were included, covering the years 2012 to 2021. The appraisal tools varied, though all included reviews were of high quality. The strategies were categorized into three domains: mental health (51%), physical activities (26%), and professional competence (13%). The interventions most identified were mindfulness-based stress reduction for mental health, yoga for physical activities, and professional competence education. These individual-based strategies were shown to effectively eliminate emotional exhaustion (72.7%), depersonalization (44%), and occupational stress (78%) among nurses in hospital-based settings. *Conclusion*. Mental health, physical activities, and professional competence are strategies to reduce nurse burnout. Implementing these approaches in healthcare settings can improve emotional exhaustion, depersonalization, and occupational stress of nurses.

1. Introduction

Globally, nurse burnout is a critical issue impacting on the healthcare workforce which is reported as 11.23% of burnout symptoms [1] and continuously spreading out within the healthcare sector [2].

Indeed, nurse burnout is amplified during the COVID-19 pandemic, given their increased vulnerability to the virus and the multifaceted challenges encountered in providing care [3, 4]. Nurses constitute a large proportion about 60% in hospitals, and an increasing number of nurses are required to assist critical and general patient care during the COVID-19 pandemic [5].

Burnout in nurses has numerous detrimental effects on individuals, organizations, and patient care. It significantly affects the health and well-being of nurses by emotional exhaustion, depersonalization, and low personal accomplishment. These symptoms can have adverse consequences for nurses, including the development of physical and mental health problems such as depression and anxiety [6, 7]. Nurse burnout is linked to poor outcomes such as quality of care and patient satisfaction [6]. Burnout can be detrimental to patient care quality, leading to an increase in medical errors that compromise patient safety [8]. Addressing nurse burnout becomes imperative to uphold quality patient care and sustaining the healthcare system. Improving nursing burnout requires interventions at various levels, including national and organizational policy such as creating a positive work environment and healthy workforce strategies, as well as individual-based approaches. While national and organizational strategies to reduce burnout are generally directed towards the majority, individual-based strategies are needed to be designed for nurses to choose according to their preference.

Numerous interventions have been suggested to assist nurses in practicing self-care with the aim of mitigating or preventing burnout and various individual health-related outcomes [9–13]. For example, physical activities such as yoga, Qigong, and Tai Chi have been proposed to improve sleep quality and alleviate post-shift stress [10]. Emotion-focused tactics and psychosocial programs have been implemented to enhance mental health and prevent burnout [12]. A variety of mindfulness-based interventions (MBSR) have been advocated to enhance nurse well-being. These interventions have shown positive impacts on sleep quality, anxiety, depression, and overall resilience [13–15]. Interventions such as team-based training, communication skills enhancement, cognitive coping mechanisms, and problem-solving techniques have demonstrated efficacy in reducing nurse burnout and maintaining effectiveness [9, 11]. Multicomponent interventions have also positively affected physical and mental health and job satisfaction [12].

Recent research on nursing burnout has increasingly focused on multifaceted interventions with promising potential. These interventions often combined physical or psychological methods, yet researchers are interested in wide range of outcome indicators [16, 17]. Numerous original studies employing different approaches to reduce burnout have yielded varying results due to differences in study design and implementation [17, 18]. Systemic review and meta-analysis on the topic of burnout have emerged prominently since the 1990s and have been essential to integrate the best evidence while evaluating research biases [19]. However, differing criteria for research inclusion and exclusion, search terms, timeframes, language, and type of article have contributed to varied outcomes and interpretations on the efficacy of nurse burnout strategies. The increasing number of such reviews can be overwhelming for those seeking clinical application. Furthermore, while numerous interventions are frequently used, their comprehensive evaluation in many meta-analyses remains lacking [20].

An umbrella review, alternatively known as an overview of reviews, represents a unique literature review format that aggregates findings from multiple systematic reviews or meta-analyses on a specific subject [21]. Unlike traditional systematic reviews that examine primary studies, an umbrella review analyzes evidence from existing reviews to provide a more comprehensive overview of the research area. This method is particularly apt for a comprehensive synthesis of varied strategies and outcomes across a multitude of reviews, providing a more integrated understanding of effective interventions in a thoroughly researched domain [20, 21]. By compiling data from various reviews, an umbrella review yields clearer, more substantial, and elevated insights into the efficacy of individual-based strategies for mitigating burnout among nurses. This type of review facilitates a thorough assessment of current evidence, pinpointing both consistencies and discrepancies in the findings [22]. Therefore, the objective of this umbrella review is to comprehensively synthesize and analyze selected systematic reviews which have evaluated the effectiveness of individual strategies implemented to reduce burnout among nurses.

2. Methods

This umbrella review aims to synthesize the impact of individual-based strategies on reducing nurse burnout within hospital-based settings. The methodology adhered to the guidelines developed by the Joanna Briggs Institute [23] and the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) reporting standards. The umbrella review was registered in the PROSPERO system (Number: CRD42022330618).

2.1. Search Strategy. Six databases, from inception to April 2023 were searched: Embase, MEDLINE (Ovid), Cochrane Library, CINAHL (EBSCO), Scopus, and WOS. The PICO framework guided this umbrella review with the question: Are individual-based strategies effective in reducing burnout among front-line nurses in hospital settings? Language was not restricted. The MeSH and free-text terms related to individual-related strategies for burnout in nurses were searched. The syntax was listed as [(nurse* OR (staff* OR employee* OR officer* OR personnel* OR practitioner* OR profess* OR provider* OR specialist* OR worker*) NEAR/6 (nurs* OR health* OR hospital* OR medical))] AND

[(burnout* OR "burn out*" OR exhaustion* OR (extreme* ADJ 4 fatigue*))]. The SR filter formula used the BMJ Best Practice syntax (https://bestpractice.bmj.com/info/toolkit/learn-ebm/study-design-search-filters/).

2.1.1. Inclusion and Exclusion Criteria.
The selection process applied the following inclusion criteria: (1) studies specifically targeting nurses, (2) interventions that were individual-based and aimed at reducing burnout, (3) primary outcomes related to burnout and their dimensions, such as emotional exhaustion, depersonalization, and reduced personal accomplishment, (4) the context as hospital-based setting, and (5) type of systematic reviews was intervention-based. Studies were excluded if (1) participant data were combined with other healthcare disciplines, (2) no provided data to address the effectiveness in the systematic reviews, and (3) insufficient information to appraising methodologic quality.

2.1.2. Selection of Articles.
Articles meeting the inclusion criteria were uploaded to EndNote X9 (Clarivate Analytics, PA, USA) for article screening. Two independent reviewers assessed eligibility by titles and abstracts followed by full text review of eligible studies. Reasons for the exclusion of papers that did not meet the inclusion criteria were recorded. Any disagreements between the two reviewers were resolved through discussion with a third reviewer. After relevant studies were retrieved, the JBI system for the unified management, assessment, and review of information (JBI SUMARI) (JBI, Adelaide, Australia) was applied to integrate findings.

2.2. Quality Appraisal.
The methodology's quality was evaluated using the JBI SUMARI's systematic review instruments, consisting of the JBI Critical Appraisal Checklist for Systematic Reviews and Research Syntheses (JBI CACSRRS) [24]. The appraisal of systematic reviews or meta-analyses is guided by 11 questions. The answers are rated as "yes," "no," "unclear," "or not applicable." Two independent reviewers used the instruments to appraise eligible studies. A third reviewer was consulted to facilitate discussion and resolve any issues.

2.3. Data Extraction.
The JBI SUMARI was used to extract data from the included reviews. The information extracted included first author's name and country, published year, and review objectives. The details of included studies in each review were extracted and included the number of studies, number of included participants, country, study design, strategies, outcome measurement, and conclusions.

3. Results

3.1. Search Process.
A total of 2424 articles were retrieved from six databases. After removing duplicate records ($n = 1130$) and screening by title and abstract, 52 full-text articles were reviewed. Articles were excluded due to the following: the outcome did not include burnout ($n = 10$), subjects included non-nursing staff ($n = 25$), and the article did not present a systematic review ($n = 8$). Nine articles from six databases were retained. Two additional articles were obtained using a citation search. Eleven articles were included in the analysis (Figure 1).

3.2. Characteristics of Included Articles.
The articles were published between 2012 and 2021, with two of the eleven systematic reviews including meta-analyses (Table 1). The number of studies synthesized with the systematic review ranged from 6 to 25, encompassing a total of 467 to 6,055 subjects. Researchers were represented from Germany ($n = 4$), Canada ($n = 2$), and one each from Taiwan, Korea, Australia, Malaysia, and Iran. The included studies in the review encompassed a global perspective, covering Europe (with countries such as the Netherlands, Spain, Italy, Germany, Ireland, the UK, Portugal, Denmark, Sweden, Norway, Greece, and France), the Americas (the USA, Canada, and Brazil), the Middle East (Iran and Israel), Asia (India, Japan, Turkey, China, Taiwan, Malaysia, Hong Kong, and Korea), and Oceania (Australia). The RCT was the most researched design within the reviews. The outcome indicators represented three categories: mental perception (e.g., stress, burnout, depression, and life satisfaction), physical symptoms (e.g., muscle pain and insomnia), and work-related (e.g., patient care and job satisfaction).

3.3. Quality Appraisal.
The quality of the eleven included articles was evaluated using the JBI CACSRRS. In the eleven systematic reviews, 10 (90.9%) achieved a yes score on 8 of the 11 questions (Table 2). All articles met of 100% for questions 1, 7, 8, 10, and 11. Four questions (Q2, Q3, Q4, Q5, and Q6) were met between 64% and 91%. Question 9, "the likelihood of publication bias," was answered for only one review due to the low number of studies in the other reviews. All eleven systematic reviews were included for qualitative integration.

3.4. Effectiveness of Strategies and Interventions

3.4.1. Strategies and Interventions for Reducing Burnout.
Among the 11 selected systematic reviews, a total of 145 studies were included. After removing duplicates, 131 remained, of which 64 studies discussed the three strategies for the outcome indicators of burnout or occupational stress. Within these 64 studies, the strategies employed included combinations in 6 studies (four mental health + physical activities and two mental health + professional education) and single strategies in 59 studies (25 for mental health, 24 for physical activities, 9 on professional education).

Among the 64 studies, the distribution of strategies applied was as follows: mental health ($n = 31$, 44%), physical activities ($n = 28$, 40%), and professional competences ($n = 11$, 16%). In the 31 studies focused on mental health strategies, three types of interventions were included: mindfulness-based stress reduction (MBSR), stress and relaxation management, and resilience and cognition training. Two studies combined two approaches (stress and relaxation management + resilience and cognition training; MBSR + resilience and cognition training). Thus, in these 31
Figure 1: Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow diagram. From: Page MJ, McKenzie JE, Bossuyt PM, Boutron I, Hoffmann TC, Mulrow CD, et al. The PRISMA 2020 statement: an updated guideline for reporting systematic reviews. BMJ 2021; 372: n71. doi: 10.1136/bmj. n71.

mental health strategy studies, the distribution of the interventions was MBSR (48%), stress and relaxation management (27%), and resilience and cognition training (24%). In the 28 studies related to the strategies of physical activities, two types of interventions were yoga and general physical exercise, with their distribution being yoga (71%) and general physical exercise (29%). Among the 11 studies on professional competences strategies, two types of interventions were competence education (73%) and coworker supervision (27%) (Figure 2).

3.4.2. Effectiveness of Interventions for Reducing Burnout. Among the 64 studies reviewed, 23 mentioned the effectiveness of interventions on emotional exhaustion (EE), with 17 (74%) reporting a significant reduction in EE. Among these 17 studies, the interventions most frequently effective in reducing EE included MBSR mentioned 5 times, competence education 4 times, resilience and cognition training 3 times, stress and relaxation management 2 times, coworker supervision 2 times, and yoga once. 19 studies addressed the impact of interventions on depersonalization (DP), with 11 (58%) reporting effective reductions. The most frequently effective measures for reducing DP included MBSR 4 times, resilience and cognition training 3 times, competence education 2 times, stress and relaxation management once, coworker supervision once, and yoga once. 20 studies discussed intervention effects on low personal accomplishment (LPA), with 10 (50%) achieving significant reductions. The interventions most effective in reducing LPA were MBSR, resilience and cognition training, and competence education, each mentioned 3 times, followed by coworker supervision 2 times, stress and relaxation management once,

and yoga once. 42 studies examined the effectiveness of interventions on work stress, with 32 (76%) noting substantial stress reductions. The most frequently effective strategies to reduce work stress were yoga 17 times, MBSR 6 times, stress and relaxation management 5 times, competence education twice, and general physical activities twice (Figure 3).

4. Discussion

An umbrella review included a comprehensive evaluation of evidence derived from eleven systematic reviews of 131 different research studies focused on reducing nurse burnout. Strategies formed three main categories: mental health, physical activity, and professional competence. The interventions which positively contributed on burnout were MBSR, resilience and cognition training, and stress and relaxation as well as yoga in occupational stress.

4.1. Enhancing Mental Health. MBSR is the most frequent mental health strategy applied to reduce burnout based on the study findings. Nurses face a high workload and poor working conditions [29] and are at risk of developing psychological distress [30]. Many studies have documented the effectiveness of MBSR in reducing stress [13, 14]. For physical mechanism, MBSR practices can be crucial for the body's defense against infections and improving health [31, 32]. MBSR practices cultivate self-compassion, helping individuals to face adversity without succumbing to self-criticism or negative self-evaluation, which are key factors in burnout [33]. When conducted in group settings, mindfulness practices strengthen interpersonal connections

(5) Were the criteria for appraising studies appropriate? (6) Was critical appraisal conducted by two or more reviewers independently? (7) Were there methods to minimize errors in data extraction? (8) Were the methods used to combine studies appropriate? (9) Was the likelihood of publication bias assessed? (10) Were recommendations for policy and/or practice supported by the reported data? (11) Were the specific directives for new research appropriate?
Figure 2: The strategies and interventions for reducing nurse burnout.

among nurses, providing a network of emotional support that is vital for managing work-related stress and reducing the risk of burnout [34].

A typical MBSR program consists of two to three hours of instruction per week for eight weeks and requires regular practice to reap its full benefits. However, some factors should be considered for the individuals [35, 36]. (1) Time commitment: a typical MBSR program consists of two to three hours of instruction per week for eight weeks; it may be challenging for some individuals to commit this amount of time. (2) Requires practice: MBSR requires regular practice to reap its full benefits; a busy schedule may make this difficult for some individuals. (3) Not a substitute for professional help: the MBSR program should not be regarded as a substitute for professional medical or psychological care. In cases involving mental or physical illness, it is essential to seek professional assistance.

4.2. Increasing Physical Activity. Increasing physical activity was the second most frequently strategy for mediating nursing burnout, with yoga being the most common activity. Physical activity influences hormone levels, including the stress hormones. Maintaining physical activity provides a positive contribution to human psychoneuroimmunology and improved mental health [37]. The systematic review of Dutta et al. [38] described the physical and psychological benefits of yoga. However, yoga practitioners must be cautious of (1) musculoskeletal injuries: injuries to the musculoskeletal system are caused by the improper position,
FIGURE 3: The effectiveness of interventions for reducing emotional exhaustion, depersonalization, low personal accomplishment, and occupational stress.

which can lead to muscle, bone, and joint problems [39]; (2) overstretching: an individual who overstretches their body or pushes it beyond its limits can lead to both pulled muscles and torn ligaments as a result of overstretching or pushing the body beyond its maximum ability [40]; and (3) physical exhaustion: for beginners or individuals with underlying health conditions, intense yoga sessions can sometimes result in physical exhaustion [41].

4.3. Improving Professional Competence. Professional competence was the third strategy, and professional competence education and coworker supervision were the important interventions in the current systematic reviews. The nurses' professional competence is reflected in their attitudes, knowledge, and psychosocial and psychomotor skills [42]. Nursing professional competence refers to the ability of nurses to demonstrate various abilities such as personal characteristics, professional attitudes, values, knowledge, and skills as they carry out their professional responsibilities [43]. Some researchers emphasized the significance of professional values on nursing competence and found the negative relationship between professional values and burnout [44, 45]. On the other hand, work-related stress occurs when people are expected to perform tasks beyond their abilities which requires coping mechanisms. Improving professional competence can provide confidence which can lead to a sense of mastery and control. Situational control reduces the stress associated with uncertainty and ambiguity for a decrease in burnout [45, 46]. Nurses possessing high levels of professional competence are typically well-equipped with the necessary knowledge, skills, and experience to adeptly handle challenging situations and workloads [47].

Additionally, nurses with higher levels of professional competence reported stronger relationships with their colleagues, likely because they are more likely to be seen as competent and trustworthy [48]. Many research studies have indicated that good interpersonal relationships are an important factor in combating burnout [49, 50]. Therefore, higher professional competence can positively contribute to good interpersonal relationships and self-confidence at work, which can then reduce stress and burnout.

4.4. Implications for Managers. The umbrella review highlighted the importance of manager facilitation in addressing nursing burnout through individual-based strategies. Key recommendations include routine assessment of burnout level, offering MBSR and yoga programs, fostering workplace social support networks, and organizing professional competence development programs.

First, regular assessment of the burnout level is necessary because the effectiveness of interventions would be ineffective after 6 months [11]. Managers can tailor the schedule for burnout assessments to align with the organization's culture and the individual characteristics of employees. This approach allows for a thorough evaluation of burnout levels, taking into account differences across various professional nursing tiers and considering significant occurrences like hospital accreditation or personal milestones. Second, managers can arrange the MBSR and physical activities such as yoga or general physical exercise training for nurses. Before the nurses practice the MBSR or yoga activities by themselves, well-trained instructors can provide comprehensive training and prevent the adverse events of MBSR and yoga. On the other hand, the instructors can suggest the appropriate period of MBSR or skill of yoga according to individual

characteristics. Third, resilience improvement is also an important factor. Studies indicate that resilience can combat burnout [15, 26]. Health organizations need to improve the well-being of nurses and the managers can implement training courses such as resilience training to prevent the incidence of cumulative burnout [51]. Fourth, nurse leaders can mitigate the negative impact of burnout on their professional values by strengthening and improving their professional value education through seminars and nursing in-service education programs [52]. In addition, nurse managers can provide continuing education opportunities based on the working unit or level of professional capacity to enhance professional competence among nurses [53]. The competence improvement education can teach nurses to determine for themselves how to handle their problems and how to improve their situation through meaningful dialog and engagement with nurse leaders concerning their work-life issues. Finally, the peer support and supervision system is necessary. A network fosters a sense of belonging and security, enhancing individuals' ability to cope with stress and burnout. Designing leisure activities for nurses can contribute to interpersonal relationships and decrease stress [54].

5. Strengths and Limitations

An umbrella review systematically compiled and synthesized evidence on individual-based strategies for reducing stress and burnout among nurses in hospital-based settings. The review marks a significant step in collating evidence and identifying the research on the most frequently used strategies. The review was limited by only including published systematic reviews and omitted grey literature or unpublished studies. Overlapping sources across the systematic reviews led to inconsistent outcomes and may have rendered burnout metrics inaccurate. Additional mental health indicators, such as anxiety or depression, may have confounded burnout findings. The umbrella review revealed that while numerous interventions are commonly used, many have not been thoroughly tested. More research is needed for in-depth analysis of these interventions.

6. Conclusion

Strategies for reducing nurse burnout are focused on mental health, physical activity, and professional competence. Nurses can adopt personal preference strategies and self-help interventions to reduce burnout.

Data Availability

Data are available upon request.

Additional Points

What Is Already Known about the Topic? (1) Nurse burnout is a widespread and global problem. (2) Nurse burnout has been associated with negative individual and work-related outcomes. (3) Various strategies have been implemented to reduce nurse burnout. *What This Paper Adds.* (1) Strategies to reduce burnout can be categorized into three domains:

mental health, physical activities, and professional competence. (2) The interventions most applied were mindfulness-based stress reduction, yoga, and competence education. (3) Individual-based strategies were shown to effectively eliminate emotional exhaustion, depersonalization, and occupational stress.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Aim. To explore the status of job crafting, leisure crafting, and burnout among nurses and to examine the impact of job crafting and leisure crafting variations on burnout using machine learning-based models. *Background.* The prevalence of burnout among nurses poses a severe risk to their job performance, quality of healthcare, and the cohesiveness of nurse teams. Numerous studies have explored factors influencing nurse burnout; however, few involved job crafting and leisure crafting synchronously and elucidated the effect differences of the two crafting behaviors on nurse burnout. *Methods.* Multicentre cross-sectional survey study. Nurses ($n = 1235$) from four Chinese tertiary hospitals were included. The Maslach Burnout Inventory-General Survey, the Job Crafting Scale, and the Leisure Crafting Scale were employed for data collection. Four machine learning algorithms (logistic regression model, support vector machine, random forest, and gradient boosting tree) were used to analyze the data. *Results.* Nurses experienced mild to moderate levels of burnout and moderate to high levels of job crafting and leisure crafting. The AUC (in full) for the four models was from 0.809 to 0.821, among which the gradient boosting tree performed best, with 0.821 AUC, 0.739 accuracy, 0.470 sensitivity, 0.919 specificity, and 0.161 Brier. All models showed that job crafting was the most important predictor for burnout, while leisure crafting was identified as the second important predictor for burnout in the random forest model and gradient boosting tree model. *Conclusion.* Even if nurses experienced mild to moderate burnout, nurse managers should develop efficient interventions to reduce nurse burnout. Job crafting and leisure crafting may be beneficial preventative strategies against burnout among nurses at present. *Implications for Nursing Management.* Job and leisure crafting were identified as effective methods to reduce nurse burnout. Nurse managers should provide more opportunities for nurses' job crafting and encourage nurses crafting at their leisure time.

1. Background

Nurses constitute the largest proportion of the healthcare workforce worldwide and play an essential role in clinical treatment, illness prevention, and health promotion. However, because of extensive job demands, scarce resources, work-family conflicts, and complex clinical work environments, nurses experience several burnout symptoms, such as emotional exhaustion, cynicism, and reduced professional efficacy [1, 2]. These phenomena adversely affect the quality of care, patient safety and satisfaction, job performance, turnover rate, and the physical and mental health of nurses [3, 4]. According to a nationwide survey conducted in the United States of America, 16.6%–30.0% of nurses (3,957,661 samples) reported experiencing burnout and 31.5% of them listed burnout as a contributing factor to their decision to leave their positions [5]. A cross-sectional survey in 12 European countries showed that 10%–78% of nurses had burnout symptoms [6]. In the mainland China, the burnout rate is also high; for example, in Shanghai, it is 45.1% [7], and in Hunan, it is at 34.9% [8]. Given the current high levels of burnout among nurses worldwide, it has

become critical for hospital administrators, nurse managers, and nurses themselves to gain a deeper understanding of the factors that contribute to burnout to enhance the quality of clinical care, stabilize nurse retention, and improve the physical and mental health of nurses.

Job crafting is defined as the actions employees take in modifying their tasks and work relationships to promote their cognitive understanding of the job meaning and attain a greater person-job fit [9]. Previous studies have highlighted that job crafting is not only beneficial to employees' health (e.g., well-being and general health) [10, 11], work attitude (e.g., job satisfaction and organizational commitment) [12], and behavior (e.g., work engagement and creativity) [13] but is also conducive to organizational performance (e.g., quality of care and group innovation) [14, 15]. Literature review shows that increasing research had investigated the relationship between job crafting and burnout in nurses. Cumulative evidence has shown that job crafting can maintain a proactive balance between job demands and resources by fostering self-driven work behavior, consequently alleviating nurse burnout [16]. Several studies have found a moderate-to-high influence of job crafting on burnout [16, 17], whereas others have reported a rather small effect of job crafting on burnout [18]. Because the effect sizes of these studies were inconsistent, further investigation is required to provide new evidence.

Leisure crafting is a novel strategy for dealing with depleted resources and was firstly defined by Petrou and Bakker [19]. This strategy refers to individuals' proactive and self-initiated pursuit of off-job life to fulfill their goals, interpersonal connections, learning, and personal growth. Unlike job crafting, leisure crafting motivates individuals' passions and satisfies their psychological requirements by shaping their leisure activities in a proactive, deliberate, and serious manner [20, 21]. Existing studies indicated that leisure crafting can reshape the task and relational bounds of individuals' leisure, improve their sense of mastery, and help them acquire resources [22, 23]. Leisure crafting is believed to address individuals' needs and values and improve their ability to handle workplace stressors, thereby averting the negative effects of job demands [24]. Few studies have explored the effects of leisure crafting on work-related attitudes and behaviors, particularly burnout issues. Moreover, little is known about whether job crafting and leisure crafting have similar effects on burnout.

Conservation of resources' theory assumes that individuals have the motivation to invest their resources for accumulating additional resources to protect their health and well-being [25]. Based on the conservation of resources' theory, an excessive workload is a persistent threat to nurses' valued resources, which results in burnout [26]. While nurses' accumulation of resources can sustain and protect additional resources, which greatly alleviate burnout among nurses, several studies supported that both job crafting and leisure crafting play vital roles in acquiring and adjusting resources [10, 27]. Job crafting and leisure crafting represent resource gain processes as nurses cope with stressful job demands and enrich their leisure time that motivate them and enhance their ability to perform well [28]. Resources gained from job crafting can improve nurses' ability to better fulfill their work obligations, which is conducive to reduce burnout [29]. Resources activated and replenished from leisure crafting can spill over to the work domain to improve nurses' work engagement and hence lighten nurse burnout [27]. Therefore, based on theoretical basis and the empirical studies, the study puts forward hypothesis 1: job crafting and leisure crafting are negatively influencing nurse burnout.

At present, most studies have investigated the factors influencing burnout using multiple linear regression models, which have high requirements for data features (including normal distribution and homoscedasticity). Machine learning, a common artificial intelligence-driven technology, has been successfully integrated into the field of health risk assessment. Unlike traditional statistics, machine learning models do not have any rules for data distribution and learn from provided samples to explore the complex and nonlinear relations among measured variables [30]. Several studies have applied machine learning to test predictors of burnout and achieved good findings. However, most of them only used one type of machine learning model (e.g., convolutional neural network, multitask learning technique, and decision tree) [31, 32], which does not avoid bias caused by the model and confirms the most significant predictors of burnout.

The main objectives of this study were to provide a comprehensive description of job crafting, leisure crafting, and burnout among nurses from Chinese tertiary hospitals. We also aimed to evaluate the effects of job crafting and leisure crafting on burnout by developing and validating four machine learning-based models.

2. Methods

2.1. Study Design. The cross-sectional multicenter study design was employed to describe the status of job crafting, leisure crafting, and burnout among nurses and explore the associations among these variables.

2.2. Participants. There are 107 tertiary hospitals in Shandong Province, China (https://www.doc88.com/p-11461558491027.html). A convenience sampling method was used to recruit hospitals from the 107 tertiary hospitals. Nurses from the included hospitals, who met the inclusion and exclusion criteria, were required to participate in the online survey. The inclusion criteria included registered and licensed practical nurses who directly cared for patients. Nurses on sick leave or those in the process of turnover were excluded from the study.

A total of 1,754 nurses from the four tertiary hospitals were invited to complete the online questionnaires, and 1,235 responses were included in the final analysis (Supplementary file "Participation rate and sample size").

2.3. Measures. A personal demographic form, the Maslach Burnout Inventory-General Survey (MBI-GS), the Job Crafting Scale (JCS), and the Leisure Crafting Scale (LCS) were used for the online survey.

The personal demographic form included 10 questions to investigate nurses' sociodemographic information, such as sex, age, years of service, academic degree, marital status, do they have a child/children, professional qualifications, specialty area, monthly income, and shift work.

The MBI-GS was used to assess the nurses' burnout status. This 16-item seven-Likert scale was developed by Maslach and Jackson [33]. The Chinese version was translated by Li and Shi [34]. Three dimensions of the MBI-GS are "emotional exhaustion," "cynicism," and "reduced professional efficacy." A seven-point Likert scale (0 = never, 6 = every day) was used to score the items. The following equation, developed by Kalimo et al. [35], was used to calculate the total MBI-GS score. Total score for burnout = score for "emotional exhaustion" × 0.3 + score for "cynicism" × 0.3 + score for "reduced professional efficacy" × 0.4. The minimum and maximum scores for burnout range from zero to six, with higher scores indicating severe levels of burnout. Cronbach's alpha coefficients for the MBI-GS were 0.88 in the study.

The JCS used to measure job crafting was developed by Tims et al. [36]. The Chinese version's validity and reliability were tested by Liao [37]. This 21-item scale has four dimensions (increasing structural job resources, increasing social job resources, increasing challenging job demands, and reducing obstructive job demands) and scores on a five-point Likert scale. The score for job crafting is the average score of the total items. Higher scores indicated greater job crafting experienced by nurses. In this study, Cronbach's alpha coefficients for the JCS were 0.95.

The nine-item LCS, developed by Petrou and Bakker [19], measured nurses' crafting during their leisure time. The validity and reliability of the Chinese version were examined by Guo et al. [38]. A five-point Likert scale (1 = not at all, 5 = very many) was used to score each item. The LCS score is the average of nine items. The LCS had good validity and reliability, with Cronbach's alpha coefficients of 0.95 in the current study.

2.4. Data Collection. This study was conducted at four tertiary hospitals between June 3 and October 31, 2022. The Wenjuanxing-Enterprise edition (Changsha Ranxing Information Technology Co., Ltd., Changsha, China) was used to develop the online survey. Two research assistants were recruited from each hospital. All research assistants were given a three-hour investigation training session before conducting the survey. Research assistants delivered an online questionnaire link and explanatory statements to the nurses via e-mail, WeChat, and other communication apps. Nurses who met the inclusion criteria were asked to complete the survey. Two push notifications (Dear participants, please remember to complete the online survey. Thank you.) were sent to nurses. The survey took 10–15 minutes to complete.

2.5. Ethical Considerations. Ethical approval (Human Sciences Ethics Committee of School of **, one University No. 2020-R-030) and hospital permissions were obtained for this study. Nurses who submitted the online survey were considered to have provided informed consent.

2.6. Data Analyses. Data were analyzed using SPSS 24.0, with descriptive analysis, *t*-tests (to compare burnout scores between two groups), ANOVA (to compare burnout scores' differences among three or more groups), and correlation tests (to evaluate the correlations among the measured variables). Kurtosis and skewness were used to describe the normal distribution of measured variables. Values for kurtosis were from −0.237 to 1.002, and values for skewness were between −0.724 and 0.392, indicating that, generally, the data were normally distributed. According to the Harman single-factor analysis, 36.7% of the variance could be explained by one factor, which suggests that no significant common method variance was found in the study. K-means clustering analysis was used to divide burnout into a low burnout group and a high burnout group.

A computer-generated random number sequence divided the data into training (70%) and validation (30%) cohorts. Python 3.9 was employed to conduct four machine learning algorithms (logistic regression model, support vector machine, random forest, and gradient boosting tree) to obtain models for predicting nurse burnout. The logistic regression model is one kind of generalized linear regression categories. Support vector machine employs kernel functions to map linearly indivisible data to a multidimensional feature space, which could deal with complex data such as high dimensional, nonlinear, and small sample size. Random forest is an integrated algorithm which uses decision trees as the main classifier. Random forest is applied to issues of classification and regression. Gradient boosting tree includes decision tree and gradient boosting. It can deal with tasks of classification and regression via additive model and forward distribution algorithms.

The burnout prediction models included 16 variables (independent variables: job crafting and leisure crafting; covariates: significant demographic characteristics; dummy variables: eight variables). Five repetitions of the 10-fold cross-validation were conducted to optimize the model parameters. The area under the receiver operating characteristic curve (AUC), accuracy, sensitivity, specificity, and Brier were calculated to compare the predictive performance of the models. Brier represents the average-squared distance from the predicted probability of the model to the actual probability. The lower the Brier scores, the better the model performance. A two-sided *p* value ≤0.05 was considered statistically significant.

3. Results

3.1. Demographic Characteristics and Burnout of Nurses. Most nurses were women (95.8%), married (80.9%), held bachelor's degrees (85%), and had a child/children (76.2%). Over half were 30–39 years old, had temporary employment, had worked less than 11 years in medical and surgical departments, and had shift work more than four times per month. Of these, 46.4% were lead nurses, and only 23.3% of the nurses' income was higher than 9000 Yuan (1,231 $ USD) (Table 1).

The results of the bivariate statistical analysis showed that nurse burnout levels were significantly different according to age, years of service, marital status, child/children status, professional qualifications, specialty area, and shift work (each $p < 0.01$).

3.2. Descriptive and Correlation Analyses among Burnout, Job Crafting, and Leisure Crafting. The burnout level for nurses was 2.02 ± 1.05, indicating that nurses experienced mild-to-moderate levels of burnout. The average score for job crafting was 4.05 ± 0.56. The average score for leisure crafting was 3.84 ± 0.78, suggesting that nurses had moderate-to-high levels of job and leisure crafting (Table 2).

The correlation analysis showed that burnout was significantly negatively correlated with job and leisure crafting (each $p < 0.01$) (Table 2). Nurses who experienced high burnout generally engaged in less job and leisure crafting.

3.3. K-Means Clustering Analysis for Burnout. According to the K-means clustering analysis, two clusters for burnout were found: the low-burnout group (final cluster center 1.24, $n = 678$) and the high-burnout group (final cluster center 2.97, $n = 557$) (Table 3).

3.4. Model Performance. The binary logistic regression analysis showed that job crafting, age, medical department, paediatric department, and shift work significantly influenced nurse burnout. Nurses who had lower job crafting, were younger in age, worked in medical and paediatric departments, and shifted work had a higher risk of experiencing severe burnout. Supplementary Files eTable 1 and eFigure 1 present the regression model results.

Support vector machine (SVM), random forest, and gradient boosting tree were employed to evaluate significant factors influencing burnout. The importance of the permutation features was calculated using the three machine learning algorithms. In the SVM model, the top five predictors were job crafting, age, child/children status, years of service, and leisure crafting (Supplementary file eFigure 2). In the random forest and gradient boosting tree models, the top five predictors were job crafting, leisure crafting, age, years of service, and professional qualifications (Supplementary file eFigures 3 and 4).

The performance of each model is summarized in Table 4. The receiver operating characteristic (ROC) curves for the validation cohort are shown in Figures 1(a) and 1(b). The gradient boosting tree model performed the best, with an AUC of 0.821, accuracy of 0.739, sensitivity of 0.470, and specificity of 0.919. The Brier score for the gradient boosting tree was the lowest (0.161), indicating that the model was reliable.

4. Discussion

This study aimed to explore the status of job crafting, leisure crafting, and burnout among Chinese nurses and exam the effects of job crafting and leisure crafting on burnout using four machine learning algorithms. This study is one of the first investigations on this topic. We found that nurses experienced mild-to-moderate levels of burnout and moderate-to-high levels of job and leisure crafting. Furthermore, compared with leisure crafting, job crafting played a greater role in predicting burnout in SVM, random forest, and gradient boosting tree models. These important findings suggest that nurses plan their efforts to promote their job and leisure crafting and that nurse managers should adopt effective strategies to reduce burnout symptoms among nurses.

In the current study, nurses had mild-to-moderate levels of burnout. These results are supported by previous studies conducted in other countries [39, 40]. As nurses experience mild-to-moderate burnout, both nurse managers and nurses pay less attention to this chronic, persistent syndrome, which leads to severe outcomes in nurses' physical and mental health, job performance, and organizational commitment [41, 42]. Accordingly, raising managers' and nurses' concerns about burnout is vital, especially in mainland China. Furthermore, effective personal-oriented, organizational-oriented, and personal-organizational combined interventions should be implemented to reduce burnout among nurses.

In this study, the nurses experienced moderate-to-high levels of job crafting. This finding is consistent with the studies of Alharthi et al. [43] and Harbridge et al. [44]. A qualitative study revealed that nurses had passion and strengths in job crafting. They were actively job crafting in all aspects via activities, such as techniques' training, participating in working teams and committees, and being involved in programs [45]. Nurses proactively initiated and altered clinical tasks to address the requirements of their vulnerable patients, which could promote the quality of care and achieve more meaning in their jobs [46].

We found, quite interestingly, that nurses experienced moderate-to-high levels of leisure crafting. Studies have indicated that leisure crafting is an individual's adaptive behavior in leisure life, which can positively benefit work engagement, personal achievement, and organizational performance [47, 48]. Several leisure activities were believed to enhance individuals' leisure crafting, such as hobby participation, enjoying activities, and seeking a sense of purpose during leisure time [49]. Therefore, nurses are encouraged to pursue their hobbies and engage in leisure activities to produce crafting behaviors outside their work.

In the present study, four machine learning models were used to evaluate the effects of differences in job and leisure crafting on burnout among nurses. Although the predictive

Table 3: K-means clustering analysis for burnout.

Groups	n	Final cluster centers	Scores
Low burnout group	678	1.24	0.00–2.10
High burnout group	557	2.97	2.11–5.85

Table 4: Model performance in predicting burnout in the validation cohort.

	AUC	Accuracy	Sensitivity	Specificity	Brier
Logistic	0.809	0.647	0.128	0.995	0.253
SVM	0.803	0.720	0.409	0.928	0.180
Random forest	0.820	0.733	0.443	0.928	0.167
Gradient boosting tree	0.821	0.739	0.470	0.919	0.161
Figure 1: ROC curves of different machine learning models in (a) the training cohort and (b) the validation cohort.

capacity of the models was less satisfactory (AUCs ranged from 0.803 to 0.821), they can help nurse burnout management and their prediction can be improved by including more influencing variables. The sensitivity of the four models ranged from 0.128 to 0.470, indicating a low capacity to target nurses at a high risk of burnout. A possible reason is that some important predictors were not included in the models; as a result, the models could not sensitively include nurses with burnout. The specificity of the four models (ranging from 0.919 to 0.995) was good in the study,

indicating that the models specifically distinguished burnout from similar syndromes. Among the four models, the gradient boosting tree exhibited the best performance, with good sensitivity and calibration efficacy. The performance of the SVM model was similar to that of the random forest model, whereas that of the logistic model was far from satisfactory.

In this study, job crafting was the most important predictor of burnout in the four models. In contrast, the effect size of job crafting on burnout was small in the logistic

regression analysis (odds ratio = 0.123). Martinez et al. [50] reported that job crafting can explain 15.7%–19.7% of the variance in burnout in four dimensions (personal impact dimension, job dissatisfaction, motivational abandonment, and social climate dimension) among male nurses. Roskova and Faragova [18] reported that job crafting combined with age and position explained 14% of the variability in burnout among full-time employees. According to the Job Demands-Resources model, overwhelming job demands and limited job resources lead to burnout and job crafting is one of the mediating factors in this relationship. High job crafting encourages individuals to reframe their perceptions of work, engage in more workplace relationships, and change the nature of their tasks, which could decrease burnout and increase job satisfaction and well-being [51]. Considering the mild but significant effect of job crafting on nurse burnout, nurse managers and nurses must foster nurses' crafting behaviors in their clinical work through several typical interventions (e.g., job crafting workshops and job crafting exercises) [52, 53].

In the study, we creatively revealed the predictive value of leisure crafting on burnout using four machine learning models. Leisure crafting was the second or fifth most important feature for burnout in the SVM, random forest, and gradient boosting tree models. However, leisure crafting was not included in the final logistic regression model. Studies have reported that off-job crafting enables individuals to learn new things, expand existing hobbies, and have new personal connections, which can help them overcome severe challenges, promote personal growth, and achieve a good balance between job and leisure [54, 55]. Ugwu [56] demonstrated that leisure crafting alleviates the negative effects of counterproductive work behaviors caused by high job demands. Therefore, nurse manager and nurses should be aware of the importance of leisure crafting in burnout. Various leisure activities should be organized in establishing new interpersonal relationships, developing new skills, and learning new meanings in work and life [57].

Despite the fact the correlations between job crafting, leisure crafting, and burnout had been tested in the study, several limitations in this present study need to be considered. First, data were collected from four Chinese tertiary hospitals. Data from other hospital levels were lacking, which might have influenced the performance of the model in the external dataset. We suggest collecting sufficient data from different hospitals to validate the model. Second, regarding the cross-sectional study design, the effects of job and leisure crafting on burnout did not present a cause-and-effect relationship. Therefore, a longitudinal study is needed to better understand the predictions of job and leisure crafting on nurse burnout. Third, the study focused only on limited characteristics of nurses, such as demographic, job crafting, and leisure crafting. This might be the primary reason for the low sensitivity of the models. Therefore, several significant factors influencing burnout (e.g., job stress, job resources, work-family conflict, collegial support, and leadership) should be investigated and analyzed in future studies. Fourth, 52 male nurses were included in the study. Generalization of the model for male nurses should be

done with caution, and further surveys of this demographic are needed to clarify the model found in the study. Finally, nurses who were on sick leave and in the process of turnover were excluded from the study. Nurses in these conditions may experience high levels of burnout. Therefore, further studies could recruit nurses in these conditions to promote the generalization of the studies.

5. Conclusions

Burnout is a serious issue among nurses worldwide, raising great concerns among hospital administrators and nurse managers. In this study, nurses experienced mild-to-moderate levels of burnout; moreover, they had moderate-to-high levels of job and leisure crafting. These findings indicate that despite nurses having some burnout symptoms, they tend to apply crafting activities to increase their clinical skills and confidence and promote their interpersonal relationships and self-development. According to the machine learning-based predictive models, job crafting and leisure crafting were significant predictors of burnout, and job crafting was the most important predictor of burnout in the four models. Therefore, nurse managers are encouraged to create a casual crafting environment and take effective measures to improve nurses' crafting behaviors, ultimately reducing their burnout and promoting their clinical performance and organizational commitment.

6. Implications for Nursing Management

Burnout is a critical risk factor for the organizational health (e.g., organizational commitment and development) of hospitals and physical (e.g., inflammation, pain, and sleep disorder) and mental health (e.g., anxiety and depression) of nurses. Therefore, hospital administrators and nurse managers should pay more attention on this severe problem and take effective measures to alleviate burnout among nurses. According to the findings of this study, routine assessment of burnout among nurses should be added in health management strategies for nursing team.

In this study, job crafting was the most significant influencing factor for nurse burnout. Nurse managers should realize the positive effects of job crafting on nurse burnout. Several effective interventions (including job crafting training workshop, job crafting e-learning, and career crafting training) can be selected as training courses to meet the job crafting needs of nurses [58, 59]. Furthermore, nurse managers are encouraged to create a positive working environment and provide more organizational resources and opportunities for nurses to help them successfully deal with work challenges and achieve self-growth. In addition, several kinds of mutual-aid groups should be organized by nurse managers to support nurses find help from colleagues.

Leisure crafting is another new influencing factor for nurse burnout. According to this interesting finding, nurse managers are suggested to support nurses to cultivate personal hobbies and learn new knowledge via several group activities. Nurses are encouraged to fully use their leisure

time to keep good personal relationships, develop new skills, and obtain a different experience. Setting achievable goals and keeping active thinking in leisure activities are also beneficial to nurses work attitude and performance.

Background. According to projections based on current trends, it can be anticipated that from 2024 onward, approximately 70% of all cancer cases will be diagnosed in individuals 65 years and older. Given this complex intersection between population ageing and cancer incidence, it is of great importance to address this issue from a comprehensive care perspective. Here comes the importance of advanced practice nurse into play. However, this figure is still not sufficiently valued in many countries. Its roles are also not clearly defined at the international level. For this reason, a systematic review of the scientific literature was carried out to analyze the impact of advanced practice nurse on the quality of life of older adults with cancer. *Methods.* Searches were carried out in PubMed, Web of Science (WoS), Scopus, CINAHL, LILACS, and ScienceDirect databases. They were limited to studies conducted in the last 7 years. Only open-access articles were selected. To analyze the chosen articles and assess their quality, the criteria of the PRISMA and CASPe statements were applied. All authors participated in both the selection of the articles and their analysis. *Results.* Of the initial 58 articles selected, a total of 10 articles were finally included, as they met the eligibility criteria established after further analysis. The results show a positive relationship between the advanced practice nurse intervention and quality of life in older adults with cancer. *Conclusions.* Advanced practice nurse (APN) plays a key role in the care of older adults with cancer, significantly improving their quality of life and contributing to the comprehensive care of these patients. The findings evidenced in this work support the integration of APNs in cancer care teams to improve patient experience and overall well-being.

1. Background

A major challenge is being grappled with modern society: the intertwined issues of population growth and rising life expectancy. Life has been expanded by advances in healthcare, but a complex scenario has been created by declining fertility rates. From 1950 to 2015, the population over 60 quadrupled, and it is projected to be 2.1 billion by 2050 [1]. Public health worldwide is being transformed by demographic changes due to evolving factors, with significant impacts on both health and social aspects [2].

An important concern in this context is the growing prevalence of chronic diseases related to age, including cardiovascular problems, degenerative conditions, dementia, and notably, cancer [1]. From the analysis of the most current statistics, it can be seen that around 20 million

new cases of cancer were reported worldwide in 2020. Among these, breast, lung, colon, prostate, and stomach cancers are noted as standing out, being currently recognized as some of the diseases with the highest incidence rates on the international scene [3]. By 2024 and beyond, around 70% of cancer cases are expected to be diagnosed in people 65 years and older, driven by ageing-related biological changes and a higher likelihood of comorbidities. This poses a significant risk to the quality of life for older individuals [4, 5].

To tackle the challenges of ageing and increased cancer rates, a holistic strategy is essential. Nursing plays a crucial role by adopting a comprehensive perspective, considering individual differences, and tailoring personalized solutions for better elderly life quality [6].

Quality of life in cancer patients is a key concept in nursing, encompassing general well-being in various dimensions. Its understanding has evolved since its origin in the post-World War II in the United States [7]. Originally, quality of life in cancer patients was assessed through objective measures such as survival and physical function. However, psychologists found that these could not fully explain variations. Subjective interpretations, such as happiness and life satisfaction, became crucial. These subjective factors often have a more significant impact on the quality of life of patients than objective factors alone [7].

In this context, the concept of health-related quality of life (HRQoL) emerged to capture the interaction between health and quality of life in a more holistic way [7]. To measure the HRQoL in cancer patients effectively, it is essential to consider multiple components such as functional, cognitive, emotional, spiritual, social, and economic aspects. Assessing specific problems and symptoms, such as pain and fatigue, is crucial. This comprehensive approach not only aids in clinical decision-making but also identifies vulnerable patient groups that need personalized care. It helps to evaluate the impact of treatment on quality of life, tolerability, and adherence. Nursing plays a key role in providing complete care and improving the overall quality of life for cancer patients [4].

In January 2018, the Andalusia Health Quality Agency (Spain) presented a professional competency manual for advanced practice nurses (APNs) in cancer care that includes competence in complex care coordination, such as in the case of the elderly with cancer [8, 9]. In Spain, there is a distinction between generalist and specialist nurses. However, with the increasing demand for health services and the need for highly specialized care, the new role of APNs has arisen. This model draws inspiration from Anglo-Saxon countries such as the United Kingdom, Canada, Australia, and New Zealand, adapting to the evolving complexity of health systems [5]. In the international context, advanced practice nurse is increasingly gaining momentum in different countries. However, there is a common denominator which is the need to provide clarity about this role in the provision of health services [10].

The concept of the APN originated in the United States during the 1960s and was later adopted in other countries, including the United Kingdom, Canada, and Australia.

Following the National Cancer Act of 1971, which established a comprehensive framework for cancer prevention, diagnosis, and treatment in the U.S., APNs initially focused on cancer management and research. As treatments grew more complex, the need for improved coordination across cancer care facets became evident, leading to stronger interdisciplinary collaboration and integrated care. The United Kingdom's Calman–Hine's report recommended specialized multidisciplinary teams and oncology care networks, reflecting these needs. Similarly, in other countries such as Portugal, this role is fulfilled by specialized nurses who, although they may not carry the same title, perform comparable functions in providing expert care and coordinating healthcare services in their areas of specialization [8].

An APN is a highly skilled nursing professional who has obtained advanced educational credentials and clinical training beyond the basic nursing education and licensing required of a registered nurse (RN). APNs are prepared through a postgraduate degree, such as, a master's or doctoral program, which enables them to provide a higher level of care and take on roles that include direct patient care, consultation, education, research, and administration [8].

ICN emphasizes that APNs should conduct direct healthcare practices within their focus population. These nurses can play a crucial role in assessing and diagnosing the needs of senior oncology patients using theories such as the theory of unpleasant symptoms and the symptom management theory. Their expertise helps identify clusters of symptoms and assess their impact on patient's quality of life and functionality [11].

APNs play a multifaceted role in the care of elderly patients diagnosed with cancer, functioning across various capacities that directly impact patient outcomes. As consultants, they provide crucial guidance to healthcare professionals, patients, and families, ensuring personalized and understandable care plans. Their educational responsibilities are profound, with a focus on disseminating advanced nursing practices to clinical nurses in primary care settings and sociohealthcare residences, areas critical to the elderly population. APNs also engage in research, contributing to the development of innovative, evidence-based approaches that enhance cancer care. Furthermore, through transformational leadership, APNs implement significant changes in healthcare practices, advocating for improvements that optimize the treatment and recovery processes for senior oncology patients. These roles exemplify the APNs' integral contribution to a holistic healthcare approach, emphasizing their importance in both direct patient care and broader healthcare improvements [8].

Although the APN role is recognized globally, there is a scarcity of studies examining its impact on the quality of life of senior oncology patients. Updated information is crucial, especially postpandemic, to understand the quality of service perceived by the patient and academic variables related to proper training in this role. Older patients are a heterogeneous population ranging from those who are frail and dependent to those who are extremely active. Therefore, it is necessary to provide adequate geriatric care. Currently,

there is not enough evidence on whether nursing staff apply adequate and comprehensive care to senior oncology patients. APNs could have a relevant role in this comprehensive care, which is why it is important to know the experiences that already exist with these professionals [12].

Therefore, the objective of this research was to conduct a systematic review of the scientific literature to identify research studies that analyze the impact of APNs on the quality of life of older adults with cancer. This study further examines evidence of the effectiveness of advanced practice nurse roles in meeting the healthcare needs specifically the quality of life of senior oncology patients.

2. Materials and Methods

In this study, a systematic review of the scientific literature was carried out in which studies analyzed the relationship between APN interventions and the quality of life of older adults with cancer. PRISMA statement criteria were applied [13] for systematic reviews by comprehensively analyzing the selected articles. The study was carried out according to the guidelines of the Declaration of Helsinki. This research is registered in PROSPERO (International Prospective Register of Systematic Reviews) with the registration number 488680.

The PICO framework is a structured approach that helps in formulating precise clinical research questions. In the proposed study, the focus is on senior oncology patients (population), investigating the effects of advanced practice nurse care (intervention) in comparison to standard nursing care (comparison). The main goal is to determine the benefits of such specialized nursing interventions in terms of improved health outcomes (outcome). Accordingly, the research question formulated is as follows: "What are the benefits of advanced practice nurse care in improving health outcomes compared to standard nursing care among senior oncology patients?" This question aims to capture the specific impacts of advanced practice nurse on the care quality and health results in this vulnerable group, thereby guiding potential improvements in clinical practices.

2.1. Selection Criteria. The systematic review was carried out between February and March 2023 in PubMed, Web of Science (WoS), SCOPUS, CINAHL, LILACS, and Science-Direct databases. The investigation focused on literature published within the past seven years, specifically from January 1, 2016, to March 31, 2023, and exclusively included open-access documents. Our aim was to derive recent and well-supported findings from a range of documentary materials, leading to the decision to incorporate both research studies and reviews, whether systematic or bibliographic in nature.

2.2. Search Strategy. The search strategy was approached by selecting the following search criteria: for PubMed (("Advanced Practice Nurse" [Mesh]) AND "Aged" [Mesh]) AND "Neoplasms" [Mesh]; (("Advanced Practice Nurse" [Mesh]) AND "Neoplasms" [Mesh]) AND "Quality of Life" [Mesh]; for WOS ((ALL = (advanced practice nurse)) AND ALL = (neoplasms)) AND ALL = (quality of life); ((TS = (advanced practice nurse)) AND TS = (neoplasms)) AND TS = (quality of life); ((ALL = (advanced practice nurse)) AND ALL = (aged)) AND ALL=(neoplasms); for SCOPUS (TITLE-ABS-KEY ("advanced practice nurse") AND TITLE-ABS-KEY (neoplasms) AND TITLE-ABS-KEY (aged)) AND PUBYEAR >2016 AND PUBYEAR <2023; (TITLE-ABS-KEY ("advanced practice nurse") AND TITLE-ABS-KEY (neoplasms) AND TITLE-ABS-KEY ("quality of life")); for CINAHL advanced practice nurse AND quality of life AND older adult AND cancer; advanced practice nurse AND neoplasms AND aged AND quality of life; for LILACS (advanced practice nurse) AND (cancer) AND (older adult) AND (quality of life); (advanced practice nurse) AND (aged) AND (neoplasms) AND (quality of life); for ScienceDirect advanced practice nurse AND quality of life AND cancer AND older adult.

2.3. Inclusion and Exclusion Criteria. The following inclusion criteria were used: (a) studies in which APN was analyzed, (b) consideration of quality of life and cancer variables, (c) studies in which the sample was an adult population, and (d) articles published in scientific journals. All articles included in this review had to meet the four criteria detailed above.

Exclusions from this study encompassed various document types, such as editor letters, commentaries, opinions, perspectives, guidelines, standards, and case series. To ensure the reliability and accuracy of our process, three authors (C.U.-G., F.-J.G.-V., and E.C.) independently assessed the relevance of the selected articles to the study's objectives and adherence to the inclusion criteria. When the title, abstract, and keywords of the article were in doubt for inclusion, two other authors were included (R.C.-B.; M.-d.-l.-A.M.-G. and E.-M.B.-M.) to arbitrate the decision on their inclusion or exclusion.

The process of identifying and choosing articles, including those that were ultimately included or excluded, as well as the rationale behind their exclusion during the screening and selection stages, is depicted in the flowchart in Figure 1. This representation aligns with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, which are aimed at enhancing the thoroughness in the reporting of systematic reviews and meta-analyses [14].

2.4. Data Extraction. The data extraction process was carried out through extensive trials and postsearch proceedings. This started by reviewing, primarily and meticulously, the title, abstract, method, results, and conclusions of each article. Data were extracted as found in their respective studies at the time of review and were inserted into Table 1

In this systematic review, the selection of variables was guided by the PICOS framework [25], encompassing participants, interventions, comparisons, outcomes, and study design. With this strategy, it was possible to delimit the inclusion criteria and, based on them, carry out a qualitative analysis of the results. In addition, the research incorporated other pertinent variables such as the authors, year of publication, country, reference article, study objectives,
FIGURE 1: Flowchart of the systematic review process according to the statements of the PRISMA protocol.

participant details, variables measured, and the scales used. With data extraction, a document was created with a set of data and was hosted in the Arias Montano Institutional Repository [26].

2.5. Presentation of the Results: Adherence to Quality Initiative (PRISMA). The results of the primary studies, obtained through a systematic and reproducible methodology, were presented qualitatively and quantitatively (Figure 1).

2.6. Quality Evaluation. In selecting articles for this review, we conducted a quality analysis using the criteria of the EPHPP tool [27]. This tool assigns an overall quality rating to each study based on the assessment of six key components. Studies are rated as "strong" if they have no weak components and at least four strong ones. Those with fewer than four strong components and one weak component are deemed as "moderate." Studies receiving two or more weak component ratings are categorized as "weak" [27].

TABLE 1: Characteristics of the studies included in the systematic review.

Author (year) country (reference)	Study design	Comparisons	Objectives of the study	Participants	Measured variable and scale	Interventions	Results
Raphaelis, et al. (2018), Switzerland, Austria [15]	Longitudinal, multicentre, randomized phase 2 study	Written information group and counselling group with an advanced practice nurse	To determine whether written information and/or counselling reduces disease-related uncertainty in women with vulvar neoplasia	$N = 49$ women with vulvar neoplasia from four Swiss hospitals and one Austrian hospital	The German adult form of the Mishel uncertainty of illness scale (MUIS-A)	Written: two booklets during the time from diagnosis to surgery. Counselling: five consultations with APN for 10–50 minutes	Overall, the counselling group showed a better trend of improvement on all uncertainty scales throughout the study. Within the counselling group, uncertainty, ambiguity, inconsistency, and unpredictability decreased significantly over six months
Westman et al. (2019), Sweden [16]	Cross-sectional study including two cohorts of patients	All patients with gynecological, hematological, head and neck CA and upper GTI before and after the intervention of a new nursing figure	To compare patients' perceptions of care before and after the introduction of a new advanced nursing role, the coordinating contact nurse (CCN), in a region of Sweden	$N = 1872$ [patients with gynecological ($n = 598$), hematological ($n = 461$), upper gastrointestinal ($n = 418$) and head and neck cancers ($n = 395$)]	The validated Swedish versions of the European Organization for Research and Treatment of Cancer (EORTC) quality of life questionnaire, QLQ-C30 and QLQ-INFO25, and also a study-specific questionnaire	Interventions were carried out by the new nursing staff. Data were collected in April-May 2015 (baseline) and April-May 2017 (follow-up)	In relation to health-related patient information (overall mean EORTC QLQ-INFO25 score increased from 41.23 to 44.16, $p = 0.0006$), statistically significant improvements were found related to the availability of supportive care resources, e.g., increased informed access to the contact nurse and individual written care plans

TABLE 1: Continued.

Author (year) country (reference)	Study design	Comparisons	Objectives of the study	Participants	Measured variable and scale	Interventions	Results
Serra-barril et al. (2023), Spain [17]	Qualitative phenomenological study	A group of patients and a multidisciplinary group of professionals	To know the lived experience of cancer patients and multidisciplinary professionals in relation to the care provided by the advanced practice nurse	18 professionals and 11 patients	Experiences related to advanced practice nurse, most relevant functions/ characteristics/care offered by this figure, benefits of the care provided, and most relevant aspects of care. The instrument used was self-developed interviews	The study took place from March to December 2021 in four highly complex public university hospitals in Catalonia. Individual interviews with professionals (45–60 minutes each) were conducted online from March to May 2021, using the Microsoft teams platform. From October to December 2021, patient interviews were conducted in person, in a quiet and comfortable hospital room, and lasted approximately 30–45 min	Advanced practice nurses play a critical role in cancer care, making positive contributions to the patient experience and to the work of the multidisciplinary team
Serena et al. (2018), Switzerland [18]	Qualitative descriptive	A multidisciplinary group of professionals and a group of patients	To explore the acceptance of a new role, the advanced practice lung cancer nurse (APNLC), from the perspective of patients and healthcare professionals in a country that lacks regulatory oversight of advanced practice nurse (APN) roles	Multidisciplinary healthcare team, including physicians (n = 6), oncology nurses (n = 5), the social worker, and the APNLC. Patients (n = 4)	The measurement variables were identification of the role of the CLNPA, specific contributions of the role of the CLNPA, and flexibility of the CLNPA service. Semistructured interviews with self-developed items and a self-developed guide for conducting focus group discussions were used for this purpose	Two focus group discussions were conducted with members who had worked closely during the last 6 months with the ANPLC: G1 nurses and social workers and G2 physicians. Semistructured interviews were conducted for ANPLC and patients (lung cancer patients who had received care from ANPLC)	Three main themes were found: identification of the role of the CLNPA, specific contributions of the role of the CLNPA, and flexible service of the CLNPA. Clinicians and patients clearly recognized the role of the CLNPA, noting contributions to continuity of care, psychosocial support, and facilitation of self-management of symptoms

TABLE 1: Continued.

Author (year) country (reference)	Study design	Comparisons	Objectives of the study	Participants	Measured variable and scale	Interventions	Results
Schneider, Kempfer, and Backes (2021) Brazil [19]	Systematic review	—	Seeking evidence on the education of advanced practice nurses through clinical practice and nursing care with cancer patients	A total of 12 experimental studies were identified	The variables that the studies had to address were educational guidance, control of pain or other symptoms related to the disease and/or treatment, and satisfaction and improvement in the quality of life of cancer patients. All of them in studies in which advanced practice nurses had been involved	The searches were carried out in the following electronic data: PubMed, LILACS, Institute for Scientific Information (ISI) Web of Knowledge via Web of Science, Scopus, CINAHL-EBSCO, and Cochrane Central Register of Controlled Trials (CENTRAL). The timeframe was from 15 July 2018 to 15 December 2019	The analysis of these studies showed that advanced practice nurses were adequately trained. This fact was objectified through the conclusions of the experimental studies analyzed, since, through the good practice of advanced practice nurses, an improvement in the control of pain or other symptoms related to the disease and/or the treatment, satisfaction, and improvement in the quality of life of cancer patients was identified
Muñoz et al. (2023), Spain [20]	Cross-sectional, descriptive study with a quantitative approach	Intervention without a control group	To identify the competency profile of advanced practice nurses involved in the care process of oncology patients	$N = 35$ nurses caring for cancer patients at the Hospital del Mar, Barcelona	The variables analyzed were the educational standards required by ICN for advanced practice nurse and postgraduate academic qualifications. The instrument for defining the role of the advanced practice nurse (IDREPA) was used	The data were recorded between February and March 2021 through the completion of the instrument by the professionals	Nine (31%) nurses were identified as meeting the standard in all 6 domains on the IDREPA scale to be considered as advanced practice nurses. Of these 9, 31% met the educational standards required by ICN, 7 (24.1%) with an official master's degree and 2 (6.9%) with a doctorate

Table 1: Continued.

Author (year) country (reference)	Study design	Comparisons	Objectives of the study	Participants	Measured variable and scale	Interventions	Results
Geese et al. (2020), Switzerland [21]	Qualitative analysis study	A single experimental group with two subgroups, one of the patients and one of the relatives of patients	To explore the experience of prostate cancer patients undergoing radical prostatectomy and their partners from diagnosis through to follow-up care and the APN support program	$N = 18$ participants, patients ($n = 10$) spouses ($n = 8$)	The study variables were perceptions of empathetic, trusting, informed, open behaviours, and quality of information received in terms of diagnoses and symptoms, offered by the advanced practice nurse. A series of self-developed semistructured interviews were used as an instrument	Between September 2015 and January 2016, 10 patients with PCa and eight spouses agreed to participate in the study. A series of semistructured interviews were conducted to explore patients' and their partners' experiences from diagnosis to discharge	Patients appreciated the EPA's support program. They noted that the EPA was empathetic, trustworthy, knowledgeable, and open. Patients received specific information about PCa, including related symptoms and postoperative side effects
Alotaibi and Al anizi. (2020), Saudi Arabia [22]	Systematic review	—	To determine how advanced practice nurses (APNs) can contribute to cancer care	$N = 5$ items that met the established criteria	The variables taken into account in this work were support for elderly patients, stress relief, improvement of quality of life, and help in symptom management	A series of systematic searches of research studies conducted from 2005 to 2018 were carried out in the following databases: MEDLINE, CINAHL, PubMed, and AMED	The selected studies showed that EPAs provide support to elderly patients, which helps to relieve stress and improve the quality of life of cancer patients. In addition, it was found that EPAs can help patients with symptom management

TABLE 1: Continued.

Author (year) country (reference)	Study design	Comparisons	Objectives of the study	Participants	Measured variable and scale	Interventions	Results
Kim and Yoo (2022), South Korea [23]	Quasiexperimental study with a pretest-posttest nonequivalent control group	Experimental and control groups	To investigate the effects of an advanced practice nurse-led psychoeducational program on distress, anxiety, depression, cancer coping, health-promoting behaviour, and quality of life among colorectal cancer survivors	$N = 39$. 19 in the experimental group and 20 in the control group	Distress, anxiety, depression, cancer coping, health promotion, and QOL (quality of life) were investigated	A psychoeducational program was implemented by an advanced practice nurse. The program included interventions on anxiety, depression, distress, coping and health-promoting behaviours, and quality of life. Variables were measured before, immediately after, and 4 weeks after the intervention	The psychoeducation program had a positive effect on reducing stress and anxiety in colorectal cancer survivors, improving their coping with cancer and their quality of life
Morgan et al. (2016), USA [24]	Bibliographic review article	—	Describe how the advanced practice nurse (APN) is uniquely suited to meet the needs of older adults across the cancer continuum	$N = 82$. The information detailed in this paper is based on 82 articles found in searchable databases	Cancer care through: (1) preventive care, screening, and early diagnosis; (2) oncology and gerontology-specific care in geriatric oncology clinics and beyond; and (3) throughout survivorship	A series of searches were carried out in the following databases: Google Scholar, PubMed, and CINAHL. Search terms included the following: "Gero-oncology," "geriatric oncology," "advanced practice nurse," "nurse practitioner," "older adult," "elderly," and "cancer". The papers included in this review range from 2002 to 2015	APNs have made great strides in the care of older adults with cancer through prevention, screening and diagnosis, evidence-based geriatric oncology, and throughout the disease process and are well positioned to help understand the complex relationship between risk factors, geriatric syndromes, and frailty and translate research into practice

The findings of this analysis are shown in Table 2. Of the various articles analyzed, 14% had a strong overall score [23], 57% a moderate overall score [15, 16, 20, 21], and 29% a weak overall score [17, 18].

However, although the percentage of strong scores was the lowest proportion, all papers had strong internal components compared to the percentage of participants who made it to the end of the intervention. In addition, most studies showed strength in terms of the instruments used for data collection and the risk of bias [15, 16, 20, 23]. These internal components with a strong score are relevant and can be prioritized with respect to others, as they are more closely related to the objective of the study in this systematic review. Therefore, although the presence of other internal components with weak or moderate score is evident, since the most relevant internal components were strong, all these studies were included in this research. Another aspect to highlight is that the studies with a moderate overall score only presented one weak internal component out of the six evaluated [15, 16, 20, 21]. Similarly, those with a weak overall score had only two weak internal components [17, 18].

3. Results

3.1. Selection of Studies and the Data Extraction Process.

After conducting a comprehensive search and applying the controlled terms (DeCS and MeSH) together with Boolean operators as specified in the search strategy, a total of 1306 relevant articles were collected. The first search was conducted in Web of Science (WoS), where 74 articles were found; the second search was conducted in the Scopus database, gathering a sum of 62 articles; the third search was conducted in PubMed, obtaining a total of 10 articles; subsequently, different searches were conducted in ScienceDirect, CINAHL, and LILACS, obtaining a total of 906, 143, and 111 studies, respectively. Eight duplicate articles were eliminated, resulting in a total of 1298 papers.

The criteria detailed in the data extraction were applied. The first level of screening involved examining the titles and abstracts of articles in all databases, retaining those that looked promising for a full-text review. This stage left a pool of 58 articles for further analysis.

Subsequently, inclusion and exclusion criteria were applied to these 58 articles, resulting in the elimination of 48 of them. The reasons for excluding these 48 articles in the context of this review were based on several considerations: insufficient information ($n = 30$) and insufficient discussion of the topic of APN ($n = 18$).

Finally, after this selection process, a total of 10 articles were identified and retained that met the relevance and quality criteria established for this research. To reduce the selection bias, each article was independently reviewed by three of the researchers (C.U.-G., F.-J.G.-V., and E.C.), who decided whether each article met the criteria. If these researchers did not reach a consensus on the inclusion of a paper, the other two researchers (R.C.-B.; M.-d.-l.-A.M.-G. and E.-M.B.-M.) mediated the decision.

3.2. Characteristics of the Studies: Result Synthesis.

Table 1 provides exhaustive details of the main data related to each of the studies included in this review. These data include relevant information such as names of authors, year of publication, country of origin, type of study, comparisons examined, study objectives, participant population, variables considered, measurement instruments used, interventions, and, finally, the results obtained.

Of the ten research articles included in this review, one (10%) was a longitudinal, multicenter, randomized phase 2 study [15]; one (10%) a cross-sectional study involving two cohorts of patients [16]; three (30%) were qualitative studies [17, 18, 21]; two (20%) were systematic reviews [19, 22]; one (10%) a descriptive cross-sectional study with quantitative approach [20]; one (10%) a quasiexperimental study [23]; and one (10%) a literature review study [24].

In terms of the countries in which the work was carried out, three (30%) were carried out in Switzerland [15, 18, 21], one (10%) in Sweden [16], two (20%) in Spain [17, 20], one (10%) in Brazil [19], one (10%) in Saudi Arabia [22], one (10%) in South Korea [23], and one (10%) in the USA [24].

Concerning the area of study topic addressed by the different articles, five (50%) investigated patients' perceptions of the APN [15, 16, 22–24] two (20%) investigated perceptions of both patients and professionals of the multidisciplinary team [18, 20], two (20%) on the adequacy of APN education [19, 20], and one (10%) on perceptions of patients and family members [21].

Regarding the perceptions of APNs in relation to adult oncology patients, satisfactory results were obtained from patients and other professionals in the multidisciplinary team, with direct clinical practice, coordination, consultation, advice, and education being the most important [17]. In addition, the figure of obtaining information and applying advice on self-management of physical symptoms is positively valued [18]. Similarly, relatives of senior oncology patients also showed their appreciation for this professional, which is considered a valuable resource in the counselling about the disease [21].

From the ten studies analyzed, the following conclusions are drawn regarding the role of advanced practice nurses and the adequacy of their training: They play an essential role in assessing and diagnosing the needs of senior oncology patients by performing a comprehensive geriatric assessment. It also collaborates in the promotion of regular cancer screening and detection [24]; plays a crucial role in the early detection of complications and toxicities related to cancer treatment, contributing to a more accurate diagnosis and more effective care planning [17, 22]; contributes to the assessment and diagnosis of the needs of older patients with colorectal cancer by providing a comprehensive assessment of patients' needs, as well as continuity of care, psychosocial support, and facilitation of self-management of symptoms [18, 23]; and promotes care and facilitates the transition process from diagnosis to end of life. It also plays an important role in education and collaboration with multidisciplinary teams [19]; influences the improvement of patient variables such as uncertainty, ambiguity, inconsistency, and unpredictability, and increases the safety and confidence of

patients and relatives [15, 21]; and improves the acquisition of information related to supportive care resources [16]; their training in most cases meets the training standards required by ICN and this is evidenced by their clinical and care practice [19, 20].

3.3. Association between the Different APN Interventions with the Quality of Life of Senior Oncology Patients. APNs prioritize and effectively manage pain, providing vital emotional and psychological support during cancer treatment. Through empathetic communication and family participation, they improve both quality of life and patient ability to self-manage their health [19]. In certain cases, the APNs called patients after initial chemotherapy sessions to assess symptoms and provide advice, addressing both physical and psychological aspects of quality of life. This approach was proven to be more effective than interventions that focus solely on targeting quality of life [16]. Emotional and psychological support, with the use of active listening by APNs, also led to improvements in quality of life through reduced stress and anxiety [16]. Another key element was advance care planning in gerontological end-of-life care. People involved in this type of care are more likely to know and fulfill their wishes at the end of life, which improves patient and family satisfaction [24].

The groups with APN counselling showed a better trend of improvement on all uncertainty scales [15]. On the other hand, the reviewed studies have also shown how APNs can provide support to senior oncology patients through external means. The provision of telephone support facilitated access to the system and provided a rapid response to patients' problems and needs [16, 17]. Finally, it was also observed how APNs can make referrals to support services for patients and their families, such as support groups or counselors and mental health services, as they can identify signs of depression or emotional distress and collaborate with other mental health professionals when necessary. All of this had an impact on improving the quality of life of patients and families [15, 19, 24].

4. Discussion

The aim of this systematic review was to identify research papers that analyzed the impact of APNs on the quality of life of older adults with cancer.

Cancer care has become increasingly complex due to an ageing population and the growing need for comprehensive and personalized approaches to cancer treatment [1]. This review highlights multiple findings that underscore the essential contribution of APNs in enhancing quality of life and providing comprehensive care to senior oncology patients.

APN collaborates with the multidisciplinary team to carry out a comprehensive geriatric assessment, achieving a substantial change in treatment decisions in more than 40% of patients. With the intervention of this professional, great advances in prevention, detection, and diagnosis are achieved [24]. To grasp the significance of this finding, it is essential to appreciate the role of the global geriatric assessment in adults. Older people undergo a transformation in their health, affecting their functional, psychological, and social aspects. A dependable global geriatric assessment that is valid, feasible, and simple aids in diagnosing health problems across all dimensions. It streamlines medical care and improves the overall quality of life for the elderly [28].

Early implementation of palliative care with APN in cancer treatment significantly improves patient's quality of life, reduces depression, and minimizes the need for intensive care. This approach may also contribute to increased survival, as demonstrated in postoperative patients who received home APN intervention compared to those who did not [15, 19]. These findings emphasize the vital role of APNs in end-of-life care, where their advanced clinical decisions and specialized knowledge in cancer care directly contribute to improved quality of life. This ensures that older adults receive optimal treatment, leading to longer survival in most cases [20].

Nurses are increasingly taking on new roles in different countries. Health education is becoming one of its key functions. There is a significant improvement in patients' perception of the health-related information they receive [16]. All this makes a positive contribution to the patient's experience and to the work of the multidisciplinary team [17].

The health education provided by APNs goes beyond providing general information to senior oncology patients. It plays a crucial role in the ongoing dialogue with patients, offering guidance and education on managing reported side effects during medication treatment [18, 29–31]. Similarly, these nurses work closely with social workers, pharmacists, and physicians. This interdisciplinary and coordinated

approach can have a significant impact on the quality of life of senior oncology patients by providing a smoother and more effective transition from the hospital setting to outpatient or home care [16].

On the other hand, it has also been observed that with the intervention of APNs in psychoeducational programs for cancer survivors, their coping improves, as well as their quality of life. This is due to the positive effect on the reduction of stress and anxiety [23]. Patient-centered care, which includes both physical and psychological aspects of quality of life, produces more effective results than interventions that focus solely on quality of life. APNs, with their knowledge and experience, play a crucial role in achieving this, contributing to the reduction of chemotherapy-related symptoms [22, 23]. However, it should be kept in mind that an intervention directed only towards health education is unlikely to lead to a complete behavioural change. To improve the level of behavioural change in senior oncology patients, it is also necessary to implement regular physical activity and dietary practices [32]. Physical activity is an important factor that affects the prognosis and psychosocial adjustment of senior oncology patients [33].

One of the most distressing things for senior oncology patients is the uncertainty they experience. The disease process they are going through has many variables that are completely unknown to them [34]. Raphaelis and collaborators' [15] findings indicate that APN counselling reduces uncertainty related to vulvar neoplasia in adult women. Personalized counselling by APNs showed a significant decrease in uncertainty measures in six months, while written information did not produce significant decreases over time in another group [21]. This corroborates what has already been evidenced in other research, where participants stated that APNs were a key point of support: people who were there for any concerns that were difficult to discuss with a social network or other healthcare providers [35].

In terms of perception of the multidisciplinary team, Serena and collaborators [18] detailed promising results in their research. Physicians perceived APNs as adding value in facilitating access to care, supporting symptom management, providing psychosocial support, and improving continuity of care [18]. These results are consistent with other studies, which emphasize the concurrent empowerment of medicine and nursing. The specialization of nursing roles, such as APNs, contributes significantly to the overarching goal of healthcare, improving patient wellbeing. Medical professionals recognize and value this nursing role as a valuable complement to their clinical work [36].

Families' perceptions of the APNs were also identified in several studies as favorable [18, 21]. Families noted that, after the intervention, they and their ill relatives received targeted information about cancer, its symptoms, and side effects. In addition, APNs referred them to support services, including self-help groups, sex therapy, and psycho-oncology [18]. However, despite the results, Hart and colleagues [37] estimated in their study that only 65% of patients were willing to be seen by an APN for the first time.

All the scientific literature reviewed agrees that it is necessary to provide individualized, multidimensional and multidisciplinary care to senior oncology patients. For this, the figure of APNs is fundamental, as it is a specialization that requires formal training and education [38, 39]. Currently, there are multiple training initiatives in Spain, such as organizing symposiums, conferences, and courses, although it would still be necessary to include this training and specialization in the curricular training of both geriatric nurses and oncology specialists [9].

This study has limitations, including the heterogeneity of incorporated works due to methodological variations, participant characteristics, intervention specifics, and outcomes. It is difficult to extrapolate conclusions with qualitative studies or systematic reviews; however, in this research, there are also several studies with a control group, a cohort study, and a randomized study, which present greater control of bias [40] and therefore the possibility of extrapolating their conclusions. Despite these limitations, the research addresses a contemporary question in the context of recent global challenges, especially the pandemic. There is a scarcity of studies on the influence of APNs on the quality of life of cancer patient's postpandemic, making this investigation novel. Furthermore, it is a work in which the PRISMA declaration criteria [13] for systematic reviews have been rigorously followed through the exhaustive analysis of the selected articles. However, future research with various interventions and randomized trial designs by APNs is recommended to further advance knowledge in this area, taking into consideration a greater margin of years regarding the publication date for database searches. It would also be appropriate in future research to carry out a meta-analysis after making the systematic review.

5. Conclusions

Carrying out systematic reviews such as those in this study is a challenge due to the lack of recognition that currently exists for these professionals. However, the evidence reflected represents relevant conclusions for the profession in particular and for public health in general.

APNs play a crucial role in the care of older adults with cancer, significantly improving their quality of life and contributing to comprehensive patient care. The research conclusions in this review highlight various aspects of the work of APNs in oncological care for the elderly, including comprehensive geriatric assessment, early detection of complications, personalized care planning, emotional support, educational guidance for patients and families, and vital collaboration within multidisciplinary teams. It is evident that advanced practice nurse (APN) is an emerging practice that improves the care of older people.

In summary, the findings presented in this paper endorse the inclusion of APNs in oncology care teams for a better patient experience and overall well-being. It is crucial to acknowledge and appreciate the significant contribution of APNs in oncology. Advocacy for greater recognition and regulation of its role in the care of senior oncology patients, along with its participation in clinical trials, is essential. The

work of APNs not only enhances the quality of life of these patients but also positively influences clinical outcomes and the health workforce.

6. Implications to Nursing Management

The study highlights the critical role of advanced practice nurses (APNs) in enhancing the care of senior oncology patients, suggesting significant implications for nursing management and leadership. APNs lead multidisciplinary teams effectively, advocating for shared leadership to improve decision-making and care execution. Nursing management should leverage APN expertise in policy advocacy, particularly in expanding their roles within oncology, which is essential for enhancing patient care and operational efficiency.

APNs' ability to manage early complications and provide personalized care underscores the need for ongoing professional development and involvement in quality control measures. Nursing leaders should prioritize continuous education for APNs and empower them to initiate care plan adjustments, ensuring high standards of patient safety and care quality.

Furthermore, establishing robust feedback mechanisms for APNs can enhance the effectiveness of nursing practices. This feedback is crucial for refining patient care strategies and advancing nursing leadership, aligning with the goals of improving clinical outcomes and the overall patient experience in healthcare settings.

Data Availability

The data used to support the findings of this study are included within the article.

Aim. This study aimed to investigate the effects of intensive care unit nurses' personality traits and mentalization on workplace bullying after controlling for organizational culture. *Background.* Nurses' personality traits and mentalization may significantly influence workplace bullying. *Methods.* This cross-sectional study collected data from 416 nurses using an online survey in July 2022. Major variables were evaluated using the Pathological Narcissism Inventory, Perfectionistic Self-Presentation and Psychological Distress Scale, Short Dark Triad, Mentalization Scale, Positive Nursing Organizational Culture Measurement Tool, and the Negative Acts Questionnaire-Revised. . A multiple regression analysis was performed. *Results.* Narcissistic vulnerability, mentalization, and perfectionistic self-presentation significantly influence workplace bullying (victim aspect). Dark personality, mentalization, and perfectionistic self-presentation significantly influence workplace bullying (perpetrator aspect). *Conclusions.* Individual nurses could become either victims of bullying or perpetrators according to their personality traits. Therefore, it is necessary to determine their personality traits, so that they do not become influencing factors in workplace bullying. *Implications for Nursing Management.* Efforts at a nursing organization level are crucial to understand nurses' personality traits, enhance their mentalization, minimize the manifestations of the negative aspects of their traits, and positively affect the prevention and alleviation of workplace bullying.

1. Background

Workplace bullying causes practice errors among nurses, affects patient outcomes [1], significantly influences turnover [2], and increases workload and stress among the remaining nurses [3], resulting in a vicious cycle. Workplace bullying in nursing organizations remains an unresolved problem, and the understanding of contributing factors is still lacking [4]. In the nursing profession, research on workplace bullying has been conducted for the past 30 years, and various intervention methods have been suggested, but it is difficult to find noticeable improvements [5]. A systematic review of the literature on interventions over the past decade [6] also indicated that while it is significant that diversified antibullying interventions have been applied and evaluated, problems with conceptual clarity and effectiveness measurement still exist.

Meanwhile, the intensive care unit involves complex treatment and nursing due to higher patient severity than in other hospital departments; moreover, tasks must be performed quickly and accurately [7]. Furthermore, as most intensive care units are restricted, contact with outsiders such as patients and guardians is limited compared to general wards; however, there is much contact with medical personnel, resulting in conflicts [8]. In particular, the violence among intensive care unit nurses is mostly horizontal violence related to nursing work, that is, workplace bullying [9]. ICU nurses reported experiencing more work-related bullying than other types [10]. In a recent study of ICU nurses, the perpetrators of bullying were mainly nurses [11]. Workplace bullying among nurses is repeated, continuous, covert [4], and perpetrated by individuals [12]. Parke et al. [11] emphasized that negative behaviors such as bullying need to be recognized, reported, and effectively addressed

rather than normalized within healthcare professions and workplace environments. Thus, nurses must be aware of their personality traits [13]. Understanding the relationship between personality traits and bullying may be a way to break the vicious cycle of bullying.

Johnson [14] recommended a multifaceted ecological model approach to understand bullying and develop interventions, wherein the microsystem is the smallest of the four interrelated systems, and the individual characteristics of the bully and target constitute an approach to this microsystem [14]. Personality traits refer to the patterns of thinking, feeling, and acting that have been formed over time, become stabilized under various conditions, and are distinguished from other characteristics [15]. Particularly, self and interpersonal functioning are key components of personality traits (American Psychiatric Association [16]); evaluating these factors is crucial to understanding personality pathology [17]. However, nurses' personality traits were analyzed as predictors of engagement among nursing professionals [18] and related factors of critical care nursing competence [19]. While previous studies on the relationship between personality and bullying exist, most have focused on adolescent bullying [20, 21]. A recent study targeting nurses [22] dealt with workplace bullying and personality traits as factors influencing nurses' health status but did not deal with the detailed characteristics of personality traits. To determine the relationship between workplace bullying and personality, this study focuses on pathological narcissism, perfectionistic self-presentation, dark personality, and mentalization among personality traits.

Pathological narcissism is characterized by a marked lack of empathy, a sense of entitlement, exploitative or arrogant behaviors or attitudes (narcissistic grandiosity), a desire for admiration, and frustration at the lack of admiration from other people (narcissistic vulnerability) [16]. While nurses with narcissistic personalities work with other nurses, such personality traits are likely to manifest in the form of workplace bullying victims or perpetrators. Previous studies show that narcissistic personalities induce counterproductive work behaviors toward colleagues [23] and that narcissistic behavior among nurses might have detrimental effects on their colleagues and institutions [24].

Perfectionist self-presentation refers to the desire to be seen as perfect [25]. People with high levels of perfectionistic self-presentation tend to promote behaviors perceived as perfect and conceal behaviors that they think are perceived as imperfect [26]. This means that beyond the desire to be perfect, these people are concerned with expressive desires, such as how they behave to be seen as perfect, which is an extreme and deceptive presentation of themselves to other people [26]. According to the Perfectionism Social Disconnection Model [27], perfectionistic self-presentation represents a set of defensive interpersonal behaviors including securing other peoples' love and respect (perfectionistic self-promotion) and preventing humiliation and rejection by other people (nondisplay of imperfection and nondisclosure of imperfection). Such behaviors have reportedly contributed to or exacerbated various forms of psychological distress and maladaptation, including depression, loneliness, hopelessness, and social anxiety [25, 28].

Paulhus and Williams [29] referred to individual tendencies to commit crimes or cause social problems as the "Dark Triad of personality," which comprises three constructs: narcissism, Machiavellianism, and psychopathy; all three constructs commonly have negative characteristics such as coldness, lack of empathy, and duplicity [29]. Coldness and lack of empathy induce a tendency to manipulate other people [30]. Cold people appear attractive in short-term interactions with other people. However, this may negatively affect their relationships with others in long-term interactions owing to their low empathy and exploitative behaviors in pursuing their interests [31]. Disruptive behaviors (e.g., unproductive work behavior and abusive supervision) associated with the dark triad can adversely affect safety and productivity in organizations [32, 33]. Since a "dark" personality can be more excessively exhibited in a psychologically competitive organizational environment [34], it is important to identify the dark triad in employee selection and organizational culture improvement.

Mentalization refers to the ability to consider one's own and other people's mental states [35]. The ability to mentalize emotions is a construct of emotional competence in a broader sense and promotes an understanding of interpersonal relationship behaviors and self-regulation [36]. The deterioration of the ability to mentalize can put various psychological issues and bullies at risk. Moreover, victims are particularly vulnerable to mentalizing anger and are consequently more likely to perceive anger and happiness as behavioral conditions rather than mental states [37]. According to a previous study, the inability to mentalize can affect the ability to suppress violent behaviors [38].

A previous study on the effects of personality traits and perceived nursing organizational culture on workplace bullying among nurses [39] reported that higher perceived relationship-oriented and innovation-oriented cultures among nurses were associated with lower perceived workplace bullying, while higher nurse-perceived hierarchy-oriented and task-oriented cultures among nurses were associated with higher perceived workplace bullying. Other previous studies also reported that organizational culture was a significant influencing factor in workplace bullying [39, 40]. Therefore, this study aimed to analyze the effects of personality traits (pathological narcissism, perfectionistic self-presentation, and dark personality) and mentalization on workplace bullying among nurses after controlling for organizational culture.

2. Methods

2.1. Study Design. A cross-sectional study design was used.

2.2. Participants. The inclusion criteria were as follows: (1) nurses working in intensive care units (ICUs) at tertiary hospitals in South Korea at the start of this study and (2) nurses belonging to a nursing department. The exclusion criteria were as follows: (1) physician assistants, (2) nurses working in medical departments, (3) those not engaged in nursing-related work, and (4) those

diagnosed with mental health problems or receiving treatment for mental health problems.

2.3. Data Collection and Ethical Considerations.

An online survey was conducted in July 2022. The minimum number of samples required for multiple regression analysis was 322 with a two-tailed test, a significance level of 0.01, a power of 0.99, 16 predictors, and an effect size of $f^2 = 0.15$ (medium) using the G∗power 3.1.9.7 version program. Considering a dropout rate of approximately 20%, 400 participants were targeted, and data were collected online through a Google Forms link in the form of an open call invitation. A warning was displayed to the participants not to respond more than once. The promotional notices on the survey were posted on online communities used mainly by nurses, such as tertiary hospital groupware bulletin boards and the online platform of the Korean nursing representatives. Finally, we collected 432 completed questionnaires; 416 (except for 16 that met the exclusion criteria) were finally analyzed.

This study was approved by the institutional review board (IRB) of the university to which the authors of this study belong (No. 1041078-202203-HR-96, approved on June 7, 2022). The participants who accessed the survey through the link received information about the study's purpose, methods, and voluntary withdrawal at any time. Those who agreed to participate in this study submitted electronic informed consent by clicking an "agree" button. All participants were provided with a guarantee of anonymity throughout the process.

2.4. Measurements.

Information regarding participants' general (age, sex, marital status, religion, educational level, and subjective health status) and work-related characteristics (total working years, position, antibullying education, and experience of workplace bullying) was collected using self-report questionnaires. Specifically, regarding subjective health status, participants were asked, "How do you feel about your health condition?" Responses were provided using a 5-point Likert scale (1 = very bad, 2 = bad, 3 = moderate, 4 = good, and 5 = very good); a score of below three was considered to reflect a poor subjective health status, and a score of three or above was considered to reflect a good subjective health status. Participants were also asked to answer "yes or "no" to the question, "Do you attend religious services regularly?" to assess their religion status, referring to a previous study on nurses' workplace bullying [13]. Permissions were obtained for the original version/ Korean version of all instruments.

2.4.1. Pathological Narcissism.

Pathological narcissism was evaluated using the Pathological Narcissism Inventory Korean version (a total of 35 items), which was culturally adapted for Koreans by Yang and Kwon [41], and the Pathological Narcissism Inventory (52 items), developed by Pincus et al. [42]. Additionally, this tool can be used to evaluate two phenotypes of pathological narcissism, namely, narcissistic grandiosity and narcissistic vulnerability. This tool is rated on a 7-point Likert scale (scoring range: 0–210 points); a higher score indicates more severe pathological narcissism. Cronbach's α at the time of the development of the original inventory [42], in the Korean version in a study by Yang and Kwon [41], and in this study was 0.95 (0.78–0.93), 0.92 (0.85–0.92), and 0.96 (0.91–0.95) respectively.

2.4.2. Perfectionistic Self-Presentation.

Perfectionistic self-presentation was evaluated using the Korean version [26] of the Perfectionistic Self-presentation and Psychological Distress scale (PSPDS) [25]. The PSPDS comprises three subdomains (perfectionistic self-promotion, nondisplay of imperfection, and nondisclosure of imperfection) with 27 items and is a 7-point Likert scale (1 = strongly disagree; 7 = strongly agree). Its Korean version comprises 19 items, of which 8 were deleted in cultural adaptation from the original scale. Cronbach's α during its development [25], in its Korean version [26], and this study was 0.91~95, 0.85 (0.75~0.88), and 0.90 (0.76~0.91), respectively.

2.4.3. Dark Personality.

Dark personality was evaluated using the Korean version [43] of the Short Dark Triad (3 factors: narcissism, Machiavellianism, and psychopathy; a total of 27 items) [44]. The Korean version is a 17-item scale, in which 10 items from the original scale were deleted. Machiavellianism and psychopathy were grouped into one factor. Each item is rated on a 5-pointLikert-type scale (1 = strongly disagree; 5 = strongly agree); the total score ranges from 17 to 85 points. Cronbach's α at its development, in a Korean version in a study by [43], and in this study was 0.73~0.78, 0.85 (0.75~0.84), and 0.90 (0.80~0.87), respectively.

2.4.4. Mentalization.

Mentalization was evaluated using the Korean version [45] of the Mentalization Scale (28 items) developed by Dimitrijević et al. [46]. It is a 25-item5-pointLikert-type scale (1 = completely incorrect; 5 = completely correct) comprising three domains: self-related mentalization, other-related mentalization, and motivation to mentalize. Cronbach's α of the original scale, the Korean version, and that in this study was 0.84 (0.74–0.79), 0.88 (0.74–0.84), and 0.84, respectively.

2.4.5. Organizational Culture.

Organizational culture was evaluated using the Positive Nursing Organizational Culture Measurement Tool [47]. This tool comprises four factors (positive leadership of the nursing unit manager, the pursuit of common values, forming an organizational relationship based on trust, and the fair management system), with 26 items. Each item is rated on a 5-pointLikert-type scale (scoring range: 24–120 points). A higher score indicates stronger perceived positivity toward nursing organizational culture. Cronbach's α of the tool during its development and in this study was 0.95 (0.83~0.95) and 0.96, respectively.

2.4.6. Workplace Bullying (Victim and Perpetrator Aspects).
The workplace bullying (victim aspect) was evaluated using the Korean version [48] of the Negative Acts Questionnaire-Revised (NAQ-R) [49]. This tool is a 22-item and 5-pointLikert-type scale (scoring range: 22–110 points). Cronbach's α of the original scale during its development [49] and in a Korean version in a study by Nam et al. [48] was 0.93 and 0.96, respectively. The workplace bullying (perpetrator aspect) was evaluated using the Negative Acts Questionnaire-Perpetrator [13], which was modified for the perpetrator aspect from the Negative Acts Questionnaire-Revised (NAQ-R) [49], and tested for its reliability and validity; Cronbach's α was 0.97 both during its development and in this study.

2.5. Statistical Analysis. Data were analyzed using the SPSS Statistics program 26.0 version (IBM Corp., Armonk, NY). Differences in workplace bullying according to participants' general and work-related characteristics were analyzed using a *t*-test and a one-way ANOVA. Ad hoc testing was further performed for variables with a significant intergroup difference using the Scheffé test. The correlations between pathologic narcissism (narcissistic grandiosity and narcissistic vulnerability), perfectionistic self-presentation, dark personality, organizational culture, mentalization, workplace bullying victim, and perpetrator aspects were analyzed using Pearson's correlation coefficients. Multiple regression analysis was also performed to identify the influencing factors of workplace bullying from the victim and perpetrator perspectives. The normality of the residuals was determined using the Kolmogorov–Smirnov test.

3. Results

3.1. General and Work-Related Characteristics of the Participants. The mean age and total working experience of the participants were 30.82 years old (standard deviation: 5.47 years) and 5.96 years (standard deviation: 4.49 years), respectively. Of the 416 participants, 380 (91.3%) were female, 299 (71.9%) were unmarried, 340 (81.7%) had a bachelor's degree, and 369 (88.7%) were staff nurses (Table 1).

3.2. Comparison of Workplace Bullying according to General and Work-Related Characteristics. The score for workplace bullying (victim aspect) was statistically significantly higher among women, those who attended religious services, staff nurses, and those with poor subjective health status. The score for workplace bullying (perpetrator aspect) was high among those with a religion, 3-year nursing college graduates, poor subjective health status, and those who completed antibullying education within 1 year (Table 2).

3.3. Correlation among Major Variables. Workplace bullying (victim aspect) was positively correlated with narcissistic grandiosity, narcissistic vulnerability, perfectionistic self-presentation, and dark personality, whereas it was negatively correlated with working years, mentalization, and organizational culture. Workplace bullying (perpetrator aspect) was positively correlated with working years, narcissistic grandiosity, narcissistic vulnerability, perfectionistic self-presentation, and dark personality, whereas it was negatively correlated with mentalization and organizational culture. Additionally, workplace bullying (victim aspect) and workplace bullying (perpetrator aspect) (Table 3) were positively correlated.

3.4. Factors Affecting Workplace Bullying

3.4.1. Workplace Bullying (Victim Aspect). Variables that significantly differed in workplace bullying (victim aspect) according to participants' characteristics and those that were significantly correlated with workplace bullying (victim aspect) were input into a regression model using the enter method. There was no multicollinearity between the independent variables (variance inflation factor: 1.04–3.62). Moreover, the Durbin–Watson index was 2.03. This confirmed the independence between error terms, thereby satisfying the assumptions of the regression analysis. The normality of the residuals was also confirmed ($Z = 0.04$, $p = 0.531$). This regression model explained 36.2% of the workplace bullying variance. Narcissistic vulnerability ($\beta = 0.25$, $p < 0.001$), followed by organizational culture ($\beta = -0.23$, $p < 0.001$), mentalization ($\beta = -0.16$, $p < 0.001$), working years ($\beta = -0.14$, $p = 0.002$), subjective health status ($\beta = 0.12$, $p = 0.005$), and perfectionistic self-presentation ($\beta = 0.11$, $p = 0.019$) were found to significantly influence workplace bullying (victim aspect). In other words, the score for workplace bullying (victim aspect) was higher among those who had a more severe narcissistic vulnerability, a more negative organizational culture, a lower mentalization, fewer working years, and a more severe perfectionistic self-presentation compared with their counterparts (Table 4).

3.4.2. Workplace Bullying (Perpetrator Aspect). Variables that significantly differed in workplace bullying (perpetrator aspect) according to participants' characteristics and those that were correlated with workplace bullying (perpetrator aspect) were input into the regression model using the enter method. There was no multicollinearity between the independent variables (variance inflation factor: 1.07–3.65). Moreover, the Durbin–Watson index was 1.90. This confirmed the independence between error terms, thereby satisfying the assumptions of the regression analysis. The normality of the residuals ($Z = 0.05$, $p = 0.269$) was also confirmed. This regression model explained 41.0% of the workplace bullying (perpetrator aspect) variance. Dark personality ($\beta = 0.48$, $p < 0.001$), followed by mentalization ($\beta = -0.17$, $p < 0.001$), education level ($\beta = 0.15$, $p = 0.023$), perfectionistic self-presentation ($\beta = -0.13$, $p = 0.007$), and subjective health status ($\beta = 0.13$, $p = 0.001$) were found to significantly influence workplace bullying (perpetrator aspect). Specifically, the score for workplace bullying (perpetrator aspect) was higher among those with a darker

personality, lower mentalization, a weaker perfectionistic self-presentation, and poor health status and those who graduated from a three-year nursing college compared with their counterparts (Table 5).

4. Discussion

This study investigated the effects of personality traits and mentalization (individual factors) on workplace bullying among nurses after controlling for organizational culture (organizational factor). It demonstrated that narcissistic vulnerability had the greatest influence on workplace bullying (victim aspect) among nurses. People with more severe narcissistic vulnerability may experience more negative emotions, such as depression, owing to their unrealistic expectations; thus, they demand only positive responses from others [17] and may also feel ashamed for seeking recognition from others [50]. A previous study on the effects of personality factors on workplace bullying among nurses reported that narcissistic vulnerability was significantly positively correlated with depression, anger, and negative emotions and negatively correlated with positive emotions [41]. Therefore, nurses who exhibit narcissistic vulnerability are considered vulnerable to other peoples' negative evaluations or comments and are highly likely to perceive them as workplace bullying. Therefore, interventions such as emotion regulation and self-esteem regulation must be provided to nurses to actively regulate emotions and self-esteem according to their levels of narcissistic vulnerability [13, 41].

Another major influencing factor of workplace bullying (victim aspect) was mentalization. Mentalization is the ability to focus on and understand the mind of oneself or other people [35]. Low or impaired mentalization can cause difficulties in inferring the mental activity of oneself or other people, resulting in psychopathologies such as difficulties in

emotion regulation and interpersonal problems [45]. Conversely, high mentalization has been associated with high life satisfaction, low depression, and low anxiety [46, 51]. Mentalization is developed through individuals' attachment relationships with their primary caregivers during their growth process but is also a fragile brain function that can be easily damaged by stressful situations [52]. Therefore, nurses with this tendency may be more likely to experience workplace bullying (victim aspect). It is thus necessary to develop and provide nurses with interventions that can reduce stress, help in coping with stress appropriately, and maintain stable mentalization.

Perfectionistic self-presentation also impacted workplace bullying (victim aspect). Specifically, higher scores for workplace bullying (victim aspect) were associated with higher perfectionistic self-presentation. People with high perfectionistic self-presentation conceal their imperfections and tend to appear perfect to consequently receive and maintain a favorable reputation from others [26]. As people with severe perfectionistic self-presentation tend to avoid other peoples' negative evaluations of themselves and gracing their shortcomings [17, 26], they are presumably more vulnerable to other peoples' negative evaluations or criticisms of their shortcomings that they may receive at work.

This study also showed that dark personalities had the greatest influence on workplace bullying (perpetrator aspect). Coldness (lack of empathy), one of the common characteristics of the three constructs of dark personality, inevitably induces a tendency to manipulate other people [30]. This may result in low empathy and exploitative behavior so that one pursues their interests in long-term interactions with others [31, 43]. This characteristic may be the basis for a major factor affecting workplace bullying (perpetrator aspect).

[†]Dummy variable (reference), religious service attendance (no); education level (above bachelor's degree); subjective health status (good); antibullying education (no); SE, standard error; VIF, variance inflation factor.

Mentalization was a major influencing factor of workplace bullying (perpetrator aspect). Specifically, lower mentalization was associated with higher scores for both workplace bullying victim and workplace bullying perpetrator aspects. Previous studies showed that mentalization was negatively correlated with borderline personality traits, depression, and anxiety [45]. Bullying victims are particularly vulnerable to mentalizing anger [37], and the inability to mentalize may affect the ability to suppress violent behavior [38]. Therefore, lower mentalization is presumably associated with higher workplace bullying.

Perfectionistic self-presentation was also a factor affecting workplace bullying (perpetrator aspect). This study showed that the score for workplace bullying (perpetrator aspect) was higher among those with weaker perfectionistic self-presentation, which contradicts results showing that the score for workplace bullying (victim aspect) was higher among those with stronger perfectionistic self-presentation. As people with high levels of perfectionistic self-presentation tend to be concerned about how they appear to other people to avoid making mistakes in social situations and tend to value harmony with other people [53], they are likely to have low scores for workplace bullying (perpetrator aspect). A previous study [54] showed that other-oriented and socially prescribed perfectionism showed unique relationships indicative of social disconnection and hostility, whereas self-oriented perfectionism showed unique relationships indicative of social connection. That is, since the perfectionism social disconnection model may not be applicable to all forms of perfectionism, it is necessary to confirm the association between perfectionism and bullying (victim and perpetrator aspects) through additional research [54, 55].

4.1. Limitations. This study had some limitations. First, as this is a cross-sectional study, it was difficult to determine the causal relationship between the major variables. Second, because this study involved ICU nurses at tertiary hospitals in South Korea, the possibility of selection bias (sampling bias) cannot be eliminated. Accordingly, generalizing the results of this study is limited. Therefore, longitudinal studies are needed to determine the causal relationship between personality traits and workplace bullying. Moreover, subsequent studies including background factors such as religion, education level, and subjective health status, all of which may affect workplace bullying, are also needed to strengthen the evidence. Additionally, it is necessary to develop and implement education and intervention programs that can reduce negative personality traits among nurses and improve mentalization and conduct studies on the effects of respective programs.

5. Conclusion

This study investigated the effects of personality traits and mentalization on workplace bullying among nurses. Under tense and unique working conditions, nurses occasionally become either workplace bullying victims or perpetrators. Accordingly, there is a need for continuous efforts at a nursing organization to understand nurses' personality traits, develop the mentalization that enables them to understand their own and other peoples' thoughts, and establish a positive organizational culture so that nurses can understand and support each other.

6. Implications for Nursing Management

This study demonstrated that personality traits might influence workplace bullying among nurses. However, assuming that certain nurses may be at risk of becoming workplace bullying perpetrators or victims owing to their personality traits, such individual nurses should not be stigmatized as victims or perpetrators. Nursing managers can help ICU nurses improve their self-awareness of personality traits and recognize the relationship between personality traits and bullying to prevent workplace bullying. It is necessary to develop and implement interventions to improve and reinforce mentalization that can help one properly perceive and interpret the thoughts and situations of oneself and others. Additionally, efforts at the nursing organization level are needed so that nurses' personality traits can harmonize with the culture of nursing organizations and generate positive effects. This will contribute to improving the quality of patient care and forming a positive organizational culture. Moreover, based on the study findings, nursing managers can raise awareness of personality traits and prepare interventions at the organizational level to prevent and cope with workplace bullying of ICU nurses.

Aims. This study examined nurse managers' conflict resolution styles, tranquillity and patience levels, and their relationships. *Background.* Managers are supposed to know how to manage conflict to reduce the destructive effects of conflict and create constructive effects. *Methods.* The study was a descriptive cross-sectional study and in a city centre in Karadeniz region, in May 2022. It was aimed to reach all executive nurses but was completed with 41 executive nurses. The data were collected face to face using a Sociodemographic Questionnaire, the Rahim Organizational Conflict Inventory, the Patience Scale, and the Tranquillity Scale. *Results.* 51.2% experienced conflict with colleagues and 46.3% with other employees. In conflict management, the most commonly used style was integrating and the least was dominating, respectively. The Patience Scale score (39.15 ± 6.09) and Tranquillity Scale score (3.70 ± 0.70) were moderate. At the same time, long-term (10.19 ± 2.18), short-term (8.90 ± 2.54), and total patience scores were significantly lower in case of conflict with nurses. Interpersonal patience levels were significantly lower in case of conflict with other employees. There was a negative correlation between working as a manager and compromising style. *Conclusion.* It was concluded that executive nurses used the integrating style more, and their patience and tranquillity levels were moderate. In addition to using the integration style more, the fact that nurse managers have moderate levels of patience and calmness will reflect positively on the quality of patient care. It will also increase employee satisfaction. Increasing the level of peace in health institutions will support patience, happiness, and a sense of belonging among employees.

1. Introduction

Conflict is a disagreement or incompatibility between two or more people or groups, a clash of interest, power, and status [1] and occurs when conflicting activities happen [2]. Conflict is a contestation of interests, power, and status between two or more individuals or groups and occurs when conflicting activities occur. The differences in values, ideas, and attitudes, communication and coordination disorders, uncertainties about the management field, and sometimes the poor functioning of the management process can be considered the root causes of conflict in hospitals [1, 3, 4]. Conflict is not always positive or negative; it can signify danger or a harbinger of new opportunities. Whether

conflict outcomes are positive or negative is related to how it is managed [1]. Constructively worked conflict is said to bring about healthy competition, strengthen team participation, and bridge the communication gap [5]. Therefore, conflict management is one of the skills managers require [6].

Conflict resolution is the method used to resolve conflicts in social situations [7]. Different strategies such as integration, obliging, dominating, compromising, and avoiding are used in conflict management. The "integration" strategy adds up to a high interest for self and others, plus involves preciseness, information exchange, and questioning. As for the strategy of "compromising," the individual neglects his self-interest to satisfy the other party's anxiety,

resulting in the situation's characterisation as obedience and compliance with the requests of the opposite party. In addition, it is used when the protection of relations with the other party is more important than the satisfaction of needs. Contrary to the strategy of "integration," "domination" adds up to a high interest for oneself and a low interest for others. The dominant person will do anything to win, resulting in their ignorance of the other party's needs and expectations. Conflict is viable unless it is between the superior and the subordinate, but it can lead to a stalemate when both sides are on equal footing. The "avoiding" strategy involves low interest, both for oneself and others. In other words, an avoidant cannot satisfy both his anxiety and others. Instead of resolving the conflict, postponement can be used to gain time for one of the parties. The "obliging" strategy involves both parties giving up on something to reconcile mutually. Therefore, it is unsuitable for dealing with complex problems requiring a problem-solving approach. However, it is useful when building a consensus is impossible and both parties need a temporary solution to a complex issue [1, 8, 9].

Nurse managers experience conflict daily and are central to conflict management [10]. A study revealed that 61.4% of the nurses in charge of the service had conflicts with the nurses they worked with, most of which were caused by organisational reasons (61.5%) [11]. The leading causes of conflict between physicians and nurses are ambiguity in job descriptions, communication problems, rude and destructive behaviours of physicians, perception of the profession [12], and differences in doctors' demand for power and nurses' demand for influence [13]. In addition, other studies have found moderate to high levels of stress [14–16], job burnout [17], low job satisfaction [15, 18–21], and occupational fatigue [22] in nurses. Factors affecting stress and job satisfaction, such as high workload, shift work and overtime, staff shortage, job uncertainty, workplace violence, and managers' attitude [15, 16, 22–24] can also be considered as factors that cause conflict.

The reasons for the conflict among the executive nurses were affected by variables such as the hospital, age, and professional experience. In addition, the job description and workload caused the conflict [25]. Regarding conflict management, it was determined that the service managers used the integration strategy the most and avoidance the least [11]. Accordingly, nursing students mostly used the strategy of obliging and least domination [26]; in addition, the conflict strategies of university students did not differ according to gender [27]. Different strategies were used to resolve the conflict between doctors and nurses; the most used strategies were integration, compromising, and avoidance, whereas the least used one was dominating [12]. While determining the appropriate strategy in a conflict, considering its contribution to organisational effectiveness, satisfying social needs, and meeting members' ethical and moral needs are crucial. However, excessive integration and obliging strategies help solve strategic problems [1].

Patience, which is among the characteristics expected in managers [28, 29], is defined as a person's tendency to stand calmly in the face of disappointment, distress, or suffering [30]. The concept of patience gives the manager purpose, tolerance,

openness to change, and empathy. It is expected by employees to be more compassionate, open-minded, and willing to manage any situation [29]. Patience has long been recognised as a human strength and a critical component of moral excellence [31]. Its structure saves the individual from negative emotions and increases life satisfaction [32]. The demonstration of true patience depends on both behavioural and emotional components [30]. Patience is positively related to subjective well-being, positive coping, and success [31]. It also includes powerful virtues, such as balance and justice. Patients have less negative affect, lower depression, fewer health problems, and increased life satisfaction [32]. Nurses' patience levels were above the average [33], and it was determined to be a component that affects nurses' resilience in Iran [34].

On the other hand, tranquillity reflects feelings such as comfort, calmness, and serenity, expressed by the characteristics of [35] individuals, such as harmony, balance, comfort, confidence, and inner peace [36]. When there is no threat in daily life, feelings of satisfaction, tranquillity, and well-being emerge, and people generally express their expectations from life in two different ways: tranquillity and happiness [35]. Although studies on patience and tranquillity in the healthcare field are limited, tranquillity and employee performance are positively associated [37]. In this respect, it is thought to be a pioneering study.

Conflicts can frequently emerge due to the complex structure of health services, which are also areas where different disciplines work together. They can happen between health personnel, resulting in medical errors with severe consequences if they are not resolved [38, 39]. Since all conflicts in health institutions will affect cooperation and the delivery of quality health services, managing the conflict with a positive outcome is crucial. Therefore, it is necessary to determine the use of conflict resolution strategies by executive nurses. In addition, nurses work in extraordinary situations such as pandemics. Also, these processes cause nurses to experience depression, stress, and anxiety [40]. These negative emotions can affect the level of patience and peace of mind of nurses. Patience and peace levels of nurse managers will be reflected on the working environment and nurses and will affect the quality of service. The level of patience and peace affected may also influence the choice of conflict resolution strategy. Therefore, this study aims to determine executive nurses' conflict resolution strategies, tranquillity, and patience levels and examine their relationship.

Research Questions.

(1) Which conflict resolution strategies is the most used by nurse managers in conflict resolution?

(2) Which levels of tranquillity and patience the nurse managers need?

(3) Is there a relationship among conflict resolution strategies, tranquillity, and patience levels?

The hypotheses of this study are formulated as follows.

Hypothesis 1. There is a relationship between the patience levels of nurse managers and their conflict resolution styles.

Hypothesis 2. There is a relationship between the serenity levels of nurse managers and their conflict resolution styles.

Hypothesis 3. Patience level and serenity level are related to each other.

2. Methods

2.1. Population and Sample of the Study. This study was conducted as a descriptive cross-sectional study. The study population comprised 60 executive nurses working in the Education and Research Hospital and the State Hospital in a city centre in Karadeniz region. It was aimed to reach all administrative nurses without dealing with the sample determination process. The study was completed with 41 executive nurses who agreed to participate and obtained consent in May 2022. 68% of the research population has been reached.

Inclusion criteria were as follows:

Working as an executive nurse

Volunteering to participate in the study

2.2. Sampling Strategy. The questionnaires were distributed to the executive nurse and collected after they were filled out.

2.3. Data Collection Tools. The data were collected face to face using the Sociodemographic Questionnaire, the Rahim Organizational Conflict Inventory Scale, the Patience Scale, and the Tranquillity Scale.

2.3.1. Sociodemographic Questionnaire. The questionnaire developed by the researcher consists of 11 questions, including age, gender, marital status, educational status, working time in the profession, working time in the current institution, working time as a manager, condition of a conflict with nurses, condition of a conflict with other employees, and state of finding oneself patient and peaceful.

2.3.2. Rahim Organizational Conflict Inventory (ROCI-II). This scale was developed by Rahim in 1983 to identify five different conflict management strategies. It was adapted into Turkish by Gumuseli and Taymaz and consisted of three forms. Form A includes conflict management strategies used by subordinates in conflicts with superiors. Unlike form A, form B holds strategies superiors use in conflicts with subordinates. Form C consists of strategies organisation members use in conflicts with their peers. In this study, form B, also called ROCI II, was used. The scale, which was designed in a 5-point Likert type, consists of 28 items and has options such as always (5), often (4), sometimes (3), rarely (2), and very rarely (1). It reveals individuals' use of five conflict management strategies to what extent. Also, it has the following five subdimensions: integration, compromising, dominating, avoiding, and obliging. Items "1, 5, 12, 22, 23, and 28" are related to the "integration" strategy, items "2, 11, 13, 19, and 24" to "compromising," "8, 9, 18, 21,

and 25" to "dominating," "4, 7, 10, 14, 15, and 20" to "obliging," and items "3, 6, 16, 17, 26, and 27" to the "avoiding" strategy. The score intervals of 4.20–5.00 (always), 3.40–4.19 (often), 2.60–3.39 (sometimes), 1.80–2.59 (rarely), and 1.00–1.79 (very infrequently) are used in grading and interpreting the weighted averages obtained from the scale. A high score from any subdimension indicates that that specific conflict management strategy is used more than others. In contrast, a low score from any subdimension shows that that particular strategy is used less than different strategies [8, 41]. Cronbach's α of the scale subscales was calculated as 0.81 [41]. In this study, Cronbach's α values of the scale were found in the range of 0.66–0.89.

2.3.3. Patience Scale. The Patience Scale was developed by Schnitker, and its validation study in Turkish was conducted by Dogan and Gulmez. There are three subdimensions on the scale, namely, interpersonal patience: 1, 4, 7 (r), 9, 11; long-term patience (patience in life hardships) 2, 5, 8; and short-term patience (patience in daily life) 3, 6, 10 (r). It was designed in a 5-point Likert type with 11 items and covered the options between "strongly agree" and "strongly disagree." Also, it contains nine positive and two opposing statements. Items 7 and 10 are reverse scored. The highest score on the scale is 55, and the lowest is 11 points. The highest and lowest score ranges that can be obtained from the subdimensions of the scale are interpersonal patience "5–25," long-term patience "3–15," and short-term patience "3–15." A high score obtained from the scale indicates that the patience levels of the individuals are high, whereas a lower score shows a lower level of patience [30, 42]. Cronbach's α of the scale was found to be 0.78 [42]. The Cronbach's α value was found to be 0.68 in the study.

2.3.4. Tranquillity Scale. The Tranquillity Scale developed by Demirci and Eksi is an 8-item one-dimensional scale. Items 5 and 6 are reverse scored. It was designed in a 5-point Likert type, including options such as not at all suitable for me (2), not suitable for me (3), somewhat suitable for me (4), fairly suitable for me (5), and completely suitable for me. The highest score on the scale is 40, and the lowest is 8 points. A high score obtained from the scale indicates that the tranquillity levels of the individuals are high, whereas a lower score shows a lower level of tranquillity. The Cronbach's α internal consistency coefficient of the scale was calculated as 0.78 [35]. Also, its Cronbach's α value was found to be 0.84 in the study.

2.4. Statistical Analysis. For the statistical analysis of the data, the SPSS Statistics 22 software was used. Elements such as percentage, mean, and standard deviation were used to analyse descriptive data. In addition, the Student t-test, Mann–Whitney U test, one-way ANOVA, Kruskal–Wallis test, pairwise comparisons, Tukey's HSD post hoc test, and the Pearson correlation analysis were used according to the normal distribution of quantitative data. In the correlation

analysis, 0–0.39 was considered a weak correlation, 0.40–0.69 a moderate correlation, 0.70–0.89 a strong correlation, and 0.90–1.00 a powerful correlation [43]. The level of significance was accepted as $p < 0.05$.

2.5. Ethical Considerations. The study data were collected by obtaining the Ethics Committee's permission of the university numbered 2022/89 and institutional permissions from the relevant units. Participants agreed to participate voluntarily.

3. Results

37 (90.2%) of the executive nurses participating in the study were women, 38 (92.7%) were married, and their age average was 37.90 ± 7.35. If we look at their educational status, 27 (65.9%) of them have a bachelor's degree, 8 (19.5%) have an associate's degree, 4 (9.8%) are postgraduates, and 2 (4.9%) are high school graduates. Their working hours in the profession are 14.5 ± 7.31, in the current institution 11.8 ± 7.23, and as a manager 5.69 ± 5.07. 21 (51.2%) of the participants stated that they had conflicts with their colleagues, 19 (46.3%) had conflicts with other employees, 38 (92.7%) were patient, and 29 (70.7%) were peaceful. When the reasons stated by those who have conflicts with their colleagues are classified, we develop six themes. The highest cause of conflict is due to working conditions such as lack of personnel and heavy workload, as shown in Figure 1.

When we group the themes as per the literature, 8 (44.4%) of the conflicts are happening due to individual reasons (lack of love and respect, not taking responsibility, lack of empathy, and personal problems), 10 (55.6%) of them due to organisational reasons (working conditions and health policies).

Observations revealed that executive nurses always used the integration strategy, mostly the obliging and compromising strategies and, occasionally, the avoidance and domination strategies. The average score of the Patience Scale is considered moderate with a value of 39.15 ± 6.09, and its subdimension scores were determined as 9.88 ± 2.42 for short-term patience, 18.02 ± 2.98 for interpersonal patience, and 11.24 ± 2.35 for long-term patience, respectively. Participants' level of tranquillity is considered moderate, with a score of 3.70 ± 0.70. In addition, their average scores from the scales are shown in Table 1.

Accordingly, executive nurses' long-term, short-term, and total patience levels were significantly lower in case of conflict with the nurses ($p = 0.002$, $p = 0.007$, and $p = 0.001$). Their interpersonal patience levels were also substantially lower in case of conflict with other employees ($p = 0.037$). There was no significant difference in the Patience Scale according to gender, marital status, educational status, and being patient and peaceful. No significant difference was found in the Tranquillity Scale by the independent variables. (Table 2).

According to the analysis in Table 3, there was a significant difference in terms of using the strategies of integration and obliging as conflict resolution methods as to

Distribution of Conflict Causes

- Lack of love and respect
- Not taking responsibility
- Lack of empathy
- Working conditions
- Bringing personal problems to work
- Health policies

the educational status of the executive nurses ($p = 0.040$, $p = 0.049$). While this difference was observed between postgraduates and high school and undergraduates regarding the integration strategy, it was only seen between postgraduates and undergraduates in the obliging strategy. The table also reveals that postgraduates use the integration and obliging strategies less often. There was no significant difference between conflict resolution strategies by gender, marital status, conflict with nurses and other employees, and state of being patient and peaceful variables. (Table 3).

The corelation analaysis revealed that a weak negative correlation was determined between the variable of working time in the institution and both compromising ($r = -0.34$) and obliging ($r = -0.37$). There was a weak negative ($r = -0.37$) correlation between the working time as

a manager variable and the obliging strategy. A weak positive ($r = 0.35$) correlation was determined between short-term patience and the level of tranquillity.

Then again, a moderate positive correlation was found between the strategies of integration and compromising ($r = 0.66$), a strong correlation with obliging ($r = 0.77$), and a weak positive correlation with the level of tranquillity ($r = 0.31$). The correlation analysis is shown in Table 4.

4. Discussion

This study, which investigated the strategies of nurses working in managerial positions in two different hospitals in conflict management and their levels of patience and tranquillity, revealed that 51.2% of the participants had conflict with their colleagues and 46.3% with other employees. In similar studies, 61.4% of the nurses in charge of the service stated that they had conflicts with the other nurses [11], and conflict was experienced by all critical care nurses, with 42.5% of the studied nurses having had moderate conflict [44]. This can be explained by the fact that different professional members work together in the health sector, working conditions are complex, and the workload is high. As per the study, the participants mostly used the "integration" strategy in conflict management, the second most "obliging," and the least "dominating." Similar to this study, in other relevant studies, it was stated that the strategies of integration and compromising [11, 12, 25, 45–48] were used the most, and the domination [12, 25] strategy was used the least. In addition, some studies indicate the least used strategy was avoidance [11, 45, 46]. The fact that the nursing students mainly used the compromising strategy and least the domination strategy shows similarity with our results [26]. According to the literature, strategic solutions can be solved by integrating and obliging [1]. Consistent with this information, executive nurses use the strategies desired in conflict resolution more. Although administrative nurses and nursing students use the compromising strategy more often in conflict resolution, the data show that conflict continues at high rates in hospitals. Therefore, it is crucial to attempt to solve the individual and organisational factors that are considered to be the cause of this situation. In a study, it was shown that by using tele-nursing application, it can improve the delivery of health services by increasing access to specialised services where mutual communication and interaction are well established [49]. Similarly, tele-nursing application can be tried in conflict resolution.

According to our study, postgraduate executive nurses used "integration" and "obliging" strategies less than high school and undergraduate nurses. While it was similar in one study that undergraduates used the compromising strategy less than other strategies [46], the educational status variable did not make a significant difference in conflict resolution strategies in other studies [11, 45, 47]. This difference may be due to the different grouping of the educational status variable. The fact that postgraduates are positioned in senior management is not unexpected. On the other hand, executives are more likely to resolve strategic

conflicts involving differences in planning and objectives, and the literature suggests using the strategies of integration and obliging in strategic conflict resolution. Integration and compromise styles allow all employees to adopt the organisation's goals and objectives. So, the reason for the decrease in integration and generous strategies, which were widely used by students and postgraduates, should be investigated in other studies.

As the duration of work in the profession and the hospital increases, the usage of the strategies of compromising and obliging decreases. Similarly, one study found that the compromising strategy decreased as the experience and seniority increased, which supports our study results [46]. This study has also revealed that the compromising strategy decreased as the working time as a manager increased. According to another study, while the generous strategy was used more in those who worked as a manager for 20 years or more, avoidance was used more in those who worked for 6–10 years [45]. Working as a long-term manager can increase organisational commitment and the use of a compromising strategy. The difference in this study may be that nurses have less managerial experience. Besides, there are studies in which these variables do not make a difference [47].

In this study, the age average was 37, and no significant relationship was found between age and conflict resolution strategies. There are other supporting studies with the same results [47]. However, as a result of this study, the compromising strategy was used significantly more by employees over 45 [45]. The majority of the young population in this study, which showed a positive correlation between age and experience, may explain the difference from the other research.

In the study, similar to the literature, the gender [27] and marital status [45] variables did not make a significant difference in conflict management strategies. Unlike this study, there are studies where males prefer to use the generous [46] or avoidance [47] strategies more, while females prefer to use the integration strategy more [47].

92.7% of the participants think that they are patient. When we look at the scale scores, their patience levels are above average in total and subdimensions, similar to a study [33]. Also, it was observed that although executive nurses' long-term, short-term, and total patience levels decreased during a conflict with the nurses, their interpersonal patience levels did not change. These results suggest that executive nurses maintain communication with nurses by looking at events situationally to ensure the continuity of their work. Their interpersonal patience levels decrease during a conflict with other employees. This may suggest that they individualise the events more. The literature shows a positive relationship between patience and decision-making skills [50]. Therefore, the decrease in the interpersonal patience levels of executive nurses may affect their problem-solving skills and create new clash environments. In this case, it may lead to communication loss with other employees. The study found no relationship between patience level and conflict resolution. In this case, hypothesis 1 is rejected.

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.

70.7% of the participants in the study stated that they were peaceful, and their tranquillity levels were found to be moderate according to the scale. Also, there was a positive correlation between their tranquillity and short-term patience levels. This finding supports hypothesis 3. During a conflict with nurses whose short-term patience levels are low, there is expected to be a decrease in the tranquillity levels of executive nurses. The fact that their tranquillity level could have been higher in this study may be the fact that they always use the integration strategy. Considering this study, a positive correlation was found between the integration strategy and the level of tranquillity. This relationship supports hypothesis 2.

4.1. Limitations and Strengths. Including only public institutions in the study and the small number of managers may be a limitation. However, it is a strength that the issues of patience and peace of mind are addressed together. What makes this work powerful is that no studies have been found in the healthcare field in which conflict management strategies are being studied together with tranquillity and patience. In addition, the fact that studies on patience and tranquillity in nurses are limited in general makes this study vital.

5. Conclusion and Recommendations

Accordingly, the participants used all conflict management strategies, mostly "integration" and frequently "obliging" and "compromising." Also, their educational status was influential in their conflict management strategy preferences. In addition, the patience and tranquillity levels of the participants were moderate. While their long- and short-term patience levels decrease in case of a conflict with nurses, their interpersonal patience levels decrease in a conflict with other employees in the hospital. This study has also revealed that the level of tranquillity increases as the integration strategy is used in conflict resolution. On the other hand, no relationship was found between patience and conflict management strategies. This finding indicates that executive nurses maintain professionalism and exhibit the same attitude in the face of events.

Due to its nature, health services have a complex structure, and it is an area where different disciplines work together, so conflicts are inevitable. They need to be managed in a way that will result in a positive outcome as it will affect cooperation and quality of health service delivery. For tranquillity, activities such as in-service training are recommended to increase the use of "integration" by all managers. It is crucial to draw attention to this issue, especially in the postgraduate education process. A unit can be established within the organisation for staff only, where nurses can receive support when they feel that their level of patience and peace of mind has decreased. It is recommended that similar issues be studied with nurses and other health professionals in future studies. In addition, qualitative research methods can be used to examine the issues in depth.

Aim. The study's aim was to examine the relationship between transformational leadership, organizational justice, and nurses' quality of work life. *Background*. There is an increasing emphasis on the welfare of nurses and their influence on healthcare services. There is a dearth of comprehensive studies on the influence of transformational leadership and justice within organizations on work-related quality of life. Understanding these connections is critical for improving workplace dynamics and fostering nurse well-being. *Methods*. This cross-sectional research included a convenience sample of nurses working in a general hospital. The data were obtained through self-report questionnaires encompassing three reliable and validated scales: the global transformational leadership scale, organizational justice scale, and quality of nursing work-life scale. The data were then analyzed with SPSS 23 and statistical methods (descriptive statistics, Pearson correlation coefficient, and hierarchical linear regression). This study adhered to the STROBE guidelines. *Results*. A sum of 527 out of 566 nurses responded to the questionnaires (response rate = 93.1%). The nurses had a high perception of transformational leadership behaviors but had a more moderate view of organizational fairness and the quality of their nursing work life. Transformational leadership was significantly associated with organizational fairness. Also, a positive relationship was found between transformational leadership, justice within organizations, and nurses' quality of work life. *Conclusions*. Nurses who consider their leaders as transformative and have the sense of a fair organizational climate are more likely to have higher levels of quality of work life. *Implications for Nursing Management*. Nurse managers should strive to develop transformational leadership behaviors and promote organizational justice to enhance the well-being and satisfaction of nurses in their work environments.

1. Introduction

The World Health Organization (WHO) estimates that by 2030, the world will need nine million nurses and midwives to attain the goal of health and well-being [1]. Within the healthcare industry, nurses hold a significant position as they are the frontline caregivers who have a profound impact on patient outcomes and overall healthcare quality [2]. In this context, healthcare organizations require leaders who possess not only a position of authority but

also the ability to inspire and guide their teams effectively. The achievement of improved organizational practices in the field of nursing relies on the combined efforts of leadership and staff collaboration. Transformational leadership plays a crucial role in this process, acting as a mediator and yielding favorable outcomes for all parties involved [3].

Transformational leadership is characterized by its capacity to inspire followers to embrace the organization's vision, goals, and strategies actively. This leadership style, marked by its inspirational and motivating nature, has a significant impact on the nursing turnover rate [4]. The implementation of transformational leadership concepts has the potential to impact various aspects of both the workforce and the company. These effects encompass the reduction of burnout, the enhancement of job satisfaction, the retention of nursing staff, and the improvement of overall productivity [5]. As leaders, nurse managers are also essential in fostering a secure, empowering, and gratifying atmosphere for staff members and patients [4].

Transformational leaders tend to promote a fair and equitable work environment, fostering trust, respect, and the provision of adequate resources [6–9]. Nurses working under transformational leaders perceive organizational justice, including distributive justice, procedural justice, and interactional justice, which positively affect their job satisfaction, commitment, and overall well-being [7, 10, 11].

Nurse managers bear the responsibility of maintaining patient safety, promoting quality of care, enhancing quality of work life, and managing the dynamics of change in health care [7]. The leadership/management style is a significant factor influencing nursing job satisfaction and has a direct impact on nurses' quality of work life [12].

Quality of work life is a complex concept that encompasses a range of factors, including possibilities for professional growth, the effective application of talents and abilities, pay, the balance between work and personal life, and the overall state of well-being within the work setting [5].

Transformational leadership is essential to improve productivity at work and quality of life simultaneously. Worker happiness and a sense of justice inside the workplace are also connected to the quality of work life. Nurses' quality of work life and job happiness may improve if managers are fair in their dealings, use inspiring leadership techniques, and make fair decisions [13]. The consideration of leadership's effect on nurses' productivity and working-life quality is of significant importance. Developing a transformational nursing leadership style is a viable organizational approach to enhance nurse performance and foster improved patient care outcomes [12]. The transformational approach of leadership is widely acknowledged as a successful leadership style that may significantly influence several aspects of an employee's professional life, such as career satisfaction, engagement, and performance [2, 11, 14, 15].

Additionally, organizational justice, a critical aspect of workplace dynamics, has a documented association with nurses' health and well-being, as well as positive work-related outcomes [16]. Organizational justice pertains to the perceptions held by employees on the just and equitable treatment they receive within the organization. This concept incorporates various aspects such as equity, fairness, and social ties that are present in the workplace [17]. Nurses who possess a perception of fairness and justice within their respective healthcare organizations are inclined to exhibit behaviors that surpass their prescribed job responsibilities [16, 17].

Organizational justice has been found to have a significant impact on the quality of work life [18–21]. High organizational justice improves work-related outcomes, health, and well-being among registered nurses environment [16, 22–24]. On the other hand, low organizational justice is linked to undesired work-related outcomes and health problems [16, 23, 24]. Nurses who perceive low organizational justice may experience dissatisfaction with their profession and organization, leading to a lower quality of work life.

Furthermore, previous studies have demonstrated a significant association between organizational justice in healthcare environments and the level of job satisfaction among nurses [20, 25]. Berthelsen et al., [26] have also demonstrated a positive correlation between the perception of organizational justice at the unit level and the reported quality of care by staff members. In light of the intricate nature of the present-day healthcare landscape, it is imperative for nurse leaders to accord utmost importance to the concept of organizational justice [16].

Nevertheless, the current body of literature mostly examines transformational leadership, organizational justice, and quality of work life as distinct concepts, failing to acknowledge the potential combined impact they may have on improving the well-being of nurses and the quality of healthcare. The study aims to provide significant findings that can help healthcare leaders, administrators, and policymakers implement strategies to enhance nurse well-being, justice practices within organizations, and overall quality of nursing life at the workplace.

1.1. Aim of the Study. The aim of this study is to investigate the relationship between transformational leadership, organizational justice, and the quality of work life in the nursing profession.

1.2. The Theoretical Framework. The conceptual model employed in this study was founded upon a theoretical framework that has been constructed from the job demands-resources (JD-R) model (Figure 1). The JD-R model provides a framework for examining the impact of job characteristics on employees' well-being [27, 28]. Job demands referred to the physical cognitive or emotional requirement of a job that can be perceived as stressful or challenging for employees. These demands can include high workload time pressure emotional labor and other factors that require effort and may drain employee energy. On the other hand, your job resources are the aspect of the work environment that can help employees to achieve their work goals [27, 28]. According to the job demands-resources model (JD-R), transformational
FIGURE 1: The proposed conceptual model of the study.

leadership and organizational justice can be viewed as job resources that can enhance the quality of nursing work life by providing support, autonomy, and fairness.

1.3. Literature Review and Hypotheses Development

1.3.1. Transformational Leadership and Quality of Nursing Work Life. Transformational leadership is a leadership style characterized by the leader's ability to inspire and motivate their followers to achieve their higher level of performance and personal growth [29]. This leadership approach has been widely studied and recognized as a key determinant of employee satisfaction, commitment, and overall organizational success [10, 30]. In the context of nursing, the transformational leadership style has been founded to positively influence various aspects of nurses' work life and include job satisfaction, organizational commitment, and professional development [2, 3, 7, 12, 21, 31]. Therefore, the following hypothesis developed:

> H1. Higher levels of transformational leadership will be positively associated with improved quality of nursing work life.

1.3.2. Organizational Justice and Quality of Nursing Work Life. Numerous studies examined the relationship between organizational justice and quality of work life. These studies consistently suggested that higher levels of organizational justice are associated with improved work-related outcomes. For instance, Arab and Atan [22] argued that perceived distributive, procedural, and interactional justice all contribute to employee job satisfaction and job performance. Berthelsen et al. [26] demonstrated that the shared perception of organizational justice climate was significantly associated with perceived quality of care and affective commitment to the organization. In the nursing context, the study of Dong et al. [17] revealed that perceived job characteristics and organizational justice can improve nursing care quality through work engagement. We can conclude that nurses are more likely to feel valued and motivated, leading to increased job satisfaction, commitment, and overall positive work outcomes. Therefore, the following hypothesis developed:

H2: High perceptions of organizational justice will correlate with enhanced quality of nursing work life

1.3.3. Transformational Leadership and Organizational Justice. Transformational leaders are more likely to be perceived as fair and just by their employees. This is because they are seen as role models who exhibit ethical behaviors, treat employees with respect, and involve them in the decision-making process. The leaders that exhibit transformational leadership conduct in a manner that is regarded by their followers as respectful, fair, and aligned with moral and ethical principles might anticipate a higher level of organizational attachment from their followers as a suitable reaction to the provision of interactional justice [32]. The study of Deschamps et al. [33] demonstrated that transformational leaders have a positive impact on their employees' motivation through different aspects of organizational justice. Also, the mediation study of Gillet et al. [31] revealed that transformational leaders influenced positively on nurses' perception of organizational justice. Therefore, the following hypothesis developed:

> H3. Higher levels of transformational leadership will be positively associated with increased perceptions of organizational justice among nurses

The proposed conceptual model of the research was developed to visually clarify the relationship between the study variables. The circular shapes were employed to represent the key study variables, and arrows indicated the directional relationships, with plus (+) denoting positive associations.

2. Methods

2.1. Study Design and Setting. The present cross-sectional research was conducted at a general hospital that is associated with the Egyptian Ministry of Health institutions. This hospital serves a catchment area with an estimated population of over 300,000 individuals. The hospital offers a wide range of medical services including many disciplines such as internal medicine, obstetrics and gynecology, surgery, pediatrics, ophthalmology, orthopedics, dermatology, and psychiatry. In addition, the facility provides diagnostic services including laboratory testing, radiography, and ultrasound. The healthcare system in Egypt is pluralistic, with public and private providers offering diverse services. The government ensures universal health coverage, while private services are accessible to those with financial means. The study follows the STROBE reporting guidelines [34].

2.2. Participants. The study utilized a convenience sample strategy due to its practicality and ability to recruit the participants efficiently. The study included registered nurses who are experienced nurses with at least one year in their current nursing position, full-time employed, and directly involved in patient care. Nursing interns and nurses who held management positions or served as shift leaders were excluded from this study. The Egyptian nursing syndicate

categorizes registered nurses based on their level of education and qualifications. These categories encompass nurses with technical education, comprising nurses holding a diploma or institute nursing degree (referred to as technical nurses), as well as those possessing a bachelor's degree and postgraduate degree (referred to as specialist nurses).

2.3. Data Collection Procedure. The study employed self-administered hard-copy questionnaires to collect data. The initial page of the anonymized questionnaire included the aim of the study and clear instructions on how to complete the surveys, and the deadline for receiving questionnaires was set a week to encourage timely responses and emphasize confidentiality. Following distributing a questionnaire to a group of nurses, the researchers reminded the participants about the significance of their responses. They explicitly requested truthful answers and guaranteed the nurses that the gathered data would be exclusively utilized for scientific research endeavors. Additionally, the researchers checked each questionnaire immediately upon receipt from the nurses after a limited time to avoid missing data. The data collection period spanned from February 10, 2023, until April 25, 2023.

2.4. Measures. The questionnaires had three scales that assessed the research variables and the demographic features of the nurses.

This study's demographic factors included age, gender, marital status, nursing categories, and experience.

The researchers utilized the global transformational leadership scale created by Carless et al. [35] to assess the perception of transformational leadership exhibited by nurses' direct leaders/managers. The scale comprises seven items designed to assess four dimensions: two items measure idealistic impact, two measure inspirational motivation, two items measure individual consideration, and one item measures intellectual stimulation and critical thinking. The value of Cronbach's alpha found in this research was 0.87.

The organizational justice scale was developed by Niehoff and Moorman [36] to assess nurses' perceptions of fairness within healthcare organizations. The scale consists of twenty items categorized into three primary dimensions of justice: (1) distributive justice, which encompasses five items; (2) interactional justice, consisting of nine items; and (3) procedural justice, which includes six items. The Cronbach's alpha coefficients for the constructs in this study were as follows: organizational justice (Cronbach $\alpha = 0.94$), distributive justice (Cronbach $\alpha = 0.87$), interactional justice (Cronbach $\alpha = 0.90$), and procedural justice (Cronbach $\alpha = 0.75$).

The quality of nursing work-life scale was initially developed by Brooks [37] to evaluate nurses' subjective perception of the quality of life at their workplace. The scale comprised a total of forty-two items, which were classified into four distinct subscales: (1) work life/home life, consisting of seven items; (2) work design, consisting of ten items; (3) work context, consisting of twenty items; and (4) work world, consisting of five items. The study reported Cronbach's alpha coefficients for various constructs as

follows: quality of nursing work life (Cronbach $\alpha = 0.81$), work life/home life (Cronbach $\alpha = 0.80$), work design (Cronbach $\alpha = 0.75$), work context (Cronbach $\alpha = 0.87$), and work world (Cronbach $\alpha = 0.71$).

The nurses were asked to indicate their degree of agreement with sixty-nine questionnaire items. They were given a 5-point Likert scale, ranging from one represented "strongly disagree" to five represented "strongly agree."

The evaluation of the study variables was determined by calculating the average score of each variable, which was obtained by dividing the total score by the number of items within the corresponding scale and subscales. The approach utilized in this study involved the conversion of original ratings into a standardized Likert scale, which encompassed a range from 1 to 5. Hence, scores falling within the range of 1–2.59 signify a low level of perception, while scores ranging from 2.60 to 3.39 suggest a moderate level of perception. On the other hand, scores falling within the range of 3.40–5.0 signify a high level of perception [38].

The researchers adhered to a translation and back-translation methodology for the English version of the scales that aligned with established practices observed in previous studies [39–42]. The researchers translated the study scales from English to Arabic and compared the translated texts to generate an initial version. An English teacher translated the scales back into English, and a native English speaker reviewed it to ensure it matched the original version. A panel of five specialists evaluated the Arabic version of the scales to assess readability, clarity, meaningfulness, and face validity. The final version was validated after incorporating revisions suggested by the reviewers. Translating the scales into Arabic acknowledges participants' linguistic proficiency in their native tongue, reduces language barriers, enhances cultural relevance, respects linguistic diversity, and improves data accuracy. This method aligns with research best practices and emphasizes the need for a careful translation process for validity and reliability.

The scales included in our research, namely the global transformational leadership scale, organizational justice scale, and quality of nursing work-life scale, were subjected to a thorough evaluation of content validity following the principles outlined by Davis [43]. The content validity of all scales was found to be strong, with scores of 1.00, 0.97, and 0.98, respectively. The subscales present in these instruments likewise demonstrated values over the threshold of 0.90, while the individual items had an item-content validity index that topped 0.80. The obtained results provide confirmation of the meticulous construction and validation process of our instruments, confirming their pertinence and suitability for assessing the constructs of our study [43]. Before data collection, the researchers conducted a pilot study that included 25 nurses to assess the research framework and methodologies and address any potential challenges. The pilot study data were excluded from the total study population. Based on the recommendations provided by the pilot study sample and experts' input, the rating scale for assessing the quality of nursing work life was modified from a six-point Likert scale to a five-point Likert scale. This modification was implemented based on the belief that the five-point Likert scale would offer

enhanced clarity and facilitate more effective respondent comprehension and response.

2.5. Ethical Considerations. The participants were provided with information on the voluntary nature of their involvement, the assurance of anonymity in their replies, and the option to withdraw from the study at any point. Their choice to participate did not affect their professional occupation. Participants provided verbal consent before distributing a questionnaire, and they further solidified their consent by signing an informed consent form. The study received ethical approval from the College of Nursing Ethics Committee at Mansoura University, Egypt, with reference number [P.0397].

2.6. Statistical Analysis. The statistical analysis was performed using IBM SPSS Statistics, version 23. The normality assumption was accepted based on the central limit theory as a sample size greater than 30 participants [44]. The descriptive statistics included demographic characteristics and study variables. Categorical variables were provided as frequency and percentage, while continuous data were represented by mean and standard deviation. The study employed Pearson correlation coefficients analysis to investigate the associations among transformational leadership, organizational justice, and quality of nursing work life. The study utilized hierarchical linear regression analysis on two occasions. The initial hierarchical linear regression analysis, referred to as model 1, was used to identify factors associated with quality of nursing work life (dependent variable). The first step included the demographic variables. Transformational leadership was added in the second step (independent variable) and organizational justice in the third step (independent variable). The second hierarchical linear regression (model 2) was conducted to ascertain the factors that are linked to organizational justice (dependent variable). The initial stage involved including demographic data to mitigate their influence. The inclusion of transformational leadership occurred during the second phase (independent variable). The categorical variables were recoded as dummy variables (control variables).

Before conducting hierarchical linear regression, the research variables underwent mean-centering before multiplication. This was carried out to mitigate the issue of multicollinearity throughout the analysis and uphold the assumption of independence of errors among the variables. The possible presence of multicollinearity for the regression model was assessed through tolerance (model 1: 0.17–0.98; model 2: 0.17–0.96) and the variance inflation factor (model 1: 1.03–6.02; model 2: 1.04–6.03), confirming that the basic requirements of regression analysis were satisfied. Statistical significance was set at an alpha level of 0.05 for inferential data analysis.

3. Results

Out of a total of 566 nurses, 527 nurses completed the survey resulting in a response rate of 93.1%. The mean age of the nurses included in the study was 33.23 years, with a standard deviation of 7.18 years. Most of the nurses were female (96.2%), married (85.2%), and had a technical degree of education (67.9%). The mean experience year of the nurses was 11.79, with a standard deviation of 7.95 (Table 1).

The mean score of transformational leadership was found to be 3.42 (SD = 0.70). The mean organizational justice score was 2.93 (SD = 0.65). In terms of the subscales of organizational justice, the mean scores for distributive justice, interactional justice, and procedural justice were 2.97 (SD = 0.73), 2.90 (SD = 0.76), and 2.94 (SD = 0.66), respectively. The mean score of quality of nursing work life was 3.29 (SD = 0.44). The subscales work life/home life, work design, work context, and work world received mean scores of 2.97 (SD = 0.59), 3.39 (SD = 0.45), 3.49 (SD = 0.53), and 2.77 (SD = 0.76), respectively (Table 2).

Positive relationships were observed between transformational leadership and organizational justice and its subscales. There is a positive correlation between transformational leadership and the quality of nursing work life and the various subscales. There was a favorable relationship between organizational justice and the quality of nursing work life and its subscales (Table 3).

Hierarchical regression model 1 explains 24.9% of the variance in organizational justice. The strongest predictor of organizational justice was transformational leadership ($\beta = 0.468$, $p < 0.001$), followed by age (31–40 years) ($\beta = -0.133$, $p = 0.021$) and nursing categories ($\beta = 0.112$, $p = 0.006$). This indicates that technical nurses who perceived their leaders as transformational were likelier to report higher organizational justice levels. Also, nurses aged 31–40 years had a significant negative association with organizational justice, suggesting that they perceived lower levels of justice compared to those aged more than 40 years. Hierarchical regression model 2 explains 51.7% of the variance in the quality of nursing work life. The highest predictor of quality of nursing work life was organizational justice ($\beta = 0.451$, $p < 0.001$), followed by transformational leadership ($\beta = 0.350$, $p < 0.001$). This means nurses who had their leader as transformational and experienced elevated levels of organizational justice were more likely to report a higher quality of nursing work life (Table 4).

4. Discussion

This study aimed to explore the relationship between transformational leadership, organizational justice, and quality of nurses' work life. Additionally, the study aimed to evaluate the variables under investigation.

The study's findings provided empirical support for hypotheses 1 and 2, demonstrating that transformational leadership and organizational justice emerge as substantial predictors of the quality of nursing work life. This underscores the pivotal role these factors play in shaping nurses' experiences and job satisfaction. These findings may be due to different assumptions; first, transformational leadership fosters a positive and supportive work environment where nurses feel valued and motivated. This enhances the overall quality of nurses' work life by promoting job satisfaction and engagement [2, 12, 23]. Second,

TABLE 1: Demographic characteristics of the studied nurses (N = 527).

TABLE 2: Descriptive statistics of the study variables (N = 527).

The study variables	Min-max	Mean (SD)
Transformational leadership	1.43–5.00	3.42 (0.70)
Organizational justice	1.30–4.45	2.93 (0.65)
Distributive justice	1.00–5.00	2.97 (0.73)
Interactional justice	1.00–4.89	2.90 (0.76)
Procedural justice	1.00–4.33	2.94 (0.66)
Quality of nursing work life	2.12–4.43	3.29 (0.44)
Work life/home life	1.29–5.00	2.97 (0.59)
Work design	2.00–4.70	3.39 (0.45)
Work context	2.00–4.60	3.49 (0.53)
Work world	1.00–5.00	2.77 (0.76)

organizational justice enhances trust and respect among employees, as they believe that the organization treats them fairly [9]. Trust and respect are vital components of a high-quality work life, leading to stronger work relationships and job satisfaction [22]. Third, fostering a positive work environment and promoting perceptions of justice can contribute to the mitigation of burnout and turnover intentions among nurses. Consequently, this enhances the overall quality of the nursing work environment [24].

The study aligns with Akar and Ustuner's [6] research, which found a positive correlation between teachers' perceptions of transformational leadership by school administrators and their work-life quality. This relationship was mediated by their perceptions of organizational support and justice. The study conducted by Gillet et al. [31] revealed that transformational leadership directly affects the quality of work life for nurses and this effect is mediated by justice. In a study, Kasim and Aldarmaki [45] investigated the connection between justice, quality of work life, and turnover intention among police personnel in the United Arab Emirates. Their findings suggested that the quality of work life acts as a mediator in the relationship between justice and turnover intention.

The study by Totawar and Nambudiri [13] discovered that organizational justice has a positive relationship with quality of work life and that this relationship was mediated by job satisfaction. The study by Prameswari et al. [46] found that organizational justice and transformational leadership positively and significantly impact job satisfaction, which is a crucial aspect of the overall quality of nursing work life. Kamel et al. [47] observed a significant positive correlation between the quality of nursing work life, organizational justice, and citizenship behaviors. Moghimi et al. [19] examined the correlation between organizational justice and quality of work life in public organizations in Qom Province, Iran. The study revealed a positive association between distributive, procedural, and interactional justice, and quality of work life.

The study's findings support the cognitive evaluation theory, which suggests that transformational leadership promotes intrinsic motivation in nurses by meeting their needs for autonomy, competence, and relatedness [48]. Transformational leaders empower nurses by granting them autonomy in decision-making, fostering professional growth opportunities, and creating a supportive work environment. These studies have shown that nurses' intrinsic motivation and job satisfaction are improved, leading to a higher quality of work life [12, 19, 49].

The study's results supported the third hypothesis, revealing a favorable link between transformational leadership and organizational justice, which is consistent with previous research conducted in numerous settings and nations [10, 30, 31, 33, 50–52]. Transformational leaders tend to advocate for fairness and transparency and encourage participative decision-making, which are essential components of organizational justice [8]. When nurses perceive their leaders as transformational, they are more likely to feel that decisions are made fairly and that their voices are heard, leading to a higher level of organizational justice perception [31]. Transformational leadership behaviors of nurse managers, such as inspiring, stimulating, considering, and influencing their staff nurses, have been associated with positive outcomes for nurses, patients, and organizations. The results involve diverse aspects including favorable work settings, employee behaviors, fairness in the workplace, safety culture for patients, and contentment with the job [11, 15, 53, 54].

The study found that nurses demonstrated a high perception of transformational leadership, suggesting the presence of positive and inspiring leadership behaviors in their work environment. Furthermore, the participants' perception of justice was at a moderate level. This suggests that there exists an ascertain level of fairness and equity within the workplace, but there may be areas that need to be improved. Additionally, the study showed that nursing work life exhibited a moderate quality from nurses' perspectives. These findings indicate that nurses' work conditions, job satisfaction, and well-being were moderately satisfactory indicating potential for improvement in their work-related experiences. These findings indicate that nurses' work conditions, job satisfaction, and well-being are moderately satisfactory, indicating potential for improvement in their

work-related experiences. These findings align with prior studies conducted by Gillet et al. [31]; Sürücü [52]; Akdemir [50]; and Khan et al. [51], which reported high transformational leadership perceptions between nurses and other participants.

Regarding organizational justice, the study by Sürücü [52] aligns with our findings, indicating moderate levels of organizational justice. In contrast, Gillet et al. [31], Moghimi et al. [19], and Yasir et al. [30] reported divergent findings, indicating that nurses exhibited low levels of justice perception and experienced an unfavorable quality of work life. The literature presents diverse findings regarding the quality of nursing work life. Kamel et al. [47] observed a high level of work-life quality and organizational justice. Conversely, Akar and Ustuner [6] discovered a moderate work-life quality and organizational justice level.

4.1. Limitations of the Study. This study had some limitations. First, the utilization of a cross-sectional design in this study presents limitations in establishing causal relationships between variables. Second, the utilization of convenience sampling in this research may potentially add selection bias and restrict the ability to generalize results to a broader population of nurses. Finally, it is crucial to recognize that the study was carried out solely inside the confines of a singular general hospital, which may potentially restrict the generalizability of the findings to alternative healthcare settings.

4.2. Further Research. In the light of limitations mentioned previously, there are several avenues for further research that can enhance the depth and the breadth of our understanding in this area. Future research should consider employing longitudinal or experimental designs to better establish causal relationships between the variables of interest. Furthermore, conducting an inquiry into the fundamental mechanisms and potential moderators of these associations can offer a more profound comprehension of how to optimize the nursing work environment and boost the quality of patient care. Also, the forthcoming studies should utilize random sampling procedures, such as simple random sampling or stratified random sampling, and include multiple healthcare settings to overcome selection bias and restriction of generalizability of results to a broader population of nurses in the other healthcare settings.

5. Conclusions

The study discovered that nurses had a high perception of transformational leadership and moderate levels of organizational justice and quality of nursing work life. Moreover, a positive correlation existed between transformational leadership and organizational justice, indicating that these factors significantly improve the quality of work life for nurses. Those who view their leaders as transformational and work in a fair organizational climate are more likely to report higher levels of quality of work life.

6. Implications of the Study

Hospital administrators should invest in developing transformational leadership training programs for nurse leaders to promote a fair and supportive work environment. Additionally, efforts to improve organizational justice and fairness in resource allocation can lead to enhanced nurse well-being and overall job satisfaction. Therefore, nurse managers can enhance the work environment for nurses and yield benefits for both employees and the organization by prioritizing these factors.

Aim. To develop a valid, reliable assessment tool to measure risk factors associated to low back pain (LBP) in intensive care unit (ICU) nurses. *Background*. LBP is defined as the pain extending from the 12th rib to the iliac crest and often coexists with buttock pain. Nursing has been identified among the top professions at risk of LBP. A mean of 70% prevalence per year in ICU nurses was reported, exceeding those employed in heavy industry. Environmental factors in workplace were also most important risks related to LBP in this population except factors including individual, physical, psychosocial, and lifestyle. However, there is lack of tools to assess environmental risk related to LBP for nurse managers currently. *Methods*. Focus group interviews, field research, and panel discussion were used to develop item pool. Two-round expert reviews and preinvestigation were carried out to form initial scale named Environmental Risk Assessing Instrument-Occupational Low Back Pain in Nurses (ERAI-N). A cross-sectional survey with 188 ICU participants in Hunan Province in China was implemented to collect data. Cronbach's alpha, split-half reliability, and test-retest reliability were used to test ERAI-N's reliability. Expert review was performed to test ERAI-N's content validity, and confirmatory factor analysis (CFA) was performed to assess its construct validity, being carried out in IBM SPSS Amos 26 Graphics. *Results*. Final version of ERAI-N scale had five dimensions with 18 items that were space, equipment, belief, guideline, and safe culture. ERAI-N scale's score of Cronbach's alpha, Guttman split-half, and intraclass correlation coefficient (ICC) was 0.958, 0.927, and 0.994, respectively. Item-level content validity scores ranged from 0.89 to 1.0, and scale-level content validity was 0.983. Standardized factor loadings ranged from 0.567 to 0.974. Model adjusted fit statistics were as follows: the chi-square statistic and degrees of freedom (χ^2/df) = 3.943, root mean square error of approximation (RMSEA) = 0.071, incremental fit index (IFI) = 0.905, comparative fit index (CFI) = 0.904, parsimony normed fit index (PNFI) = 0.641, and parsimonious comparative fit index (PCFI) = 0.661. *Conclusions*. ERAI-N scale had moderate reliability, content validity, and construct validity. *Implications for Nursing Management*. Designers may use ERAI-N scale to plan the interior layout when design a new ICU. Nurse managers might utilize this instrument as a managing tool to assess whether there is environmental risk factors related to LBP in ICU.

1. Introduction

Low back pain (LBP) is defined as the pain extending from the 12th rib to the iliac crest and often coexists with buttock pain [1]. LBP is one of the most common public health problems, especially in middle-aged to older women, with the prevalence [2] ranging [3] from 40% to 90% [4]. LBP has some other prominent features such as high annual incidence leading to severe functional limitation [5] in addition to high prevalence. A study done in 195 countries found that LBP was the leading cause of worldwide productivity loss as measured in years and the top cause of years lived with disability [6].

Nursing has been identified among the top professions at risk of LBP [7], especially for those on duty in intensive care unit (ICU). A mean of 70% prevalence per year was reported,

exceeding those employed in [8] heavy industry [9]. It is also reported that being a nurse is independently related to spinal pain [10]. LBP can induce disrupted or reduced proprioceptive signaling which likely plays a pivotal role in driving long-term changes in the top-down control of the motor system via motor and sensory cortical reorganization [11]. There were lots of publications which revealed that LBP for ICU nurses may lead to work absenteeism, reduction of nursing workforce efficiency [12], and burnout [13] and may incur economic costs of personal or national finance.

In order to reduce the prevalence of LBP among ICU nurses, investigations have been focused on individual, physical, psychosocial, and lifestyle factors which might play an essential role on the [14] occurrence of LBP [15] in recent decades. Based on human factors theory [16], lots of publications revealed that environmental factors in workplace were the most important risk factors for LBP [17, 18] in ICU nurses [8]. Omura et al. [19] proved that the use of a sliding sheet can significantly lower levels of low back subjective fatigue for caregiver in clinic when performing patient repositioning [19]. Alamgir et al. [18] found that healthcare workers preferred to use ceiling lifts because of less physically demanding work [18]. It is also reported that high-level lift availability was half as likely to have work-related LBP [20]. However, less than half (46%) of respondents working in ICU reported that their employer provided lifts [20], and this means limited availability and adoption of lifting equipment have been a persistent problem [21].

On the other hand, spatial requirements for a bed space are also essential in a critical care setting [22]. It is reported that an average of $23.26 \, m^2$ was needed for a bed-to-bed transfer followed by $22.87 \, m^2$ for a resuscitation task [23]. Nevertheless, little investigations were made to make sure whether the bed space in ICU meets the requirements. In terms of culture of safe nursing activities for the prevention of LBP in ICU nurses, there is research indicating that it is urgent to make efforts to broadcast safety operations, to formulate nursing procedures for nurses such as manual handling task, and to carry out guidance for safe handling patients, so as to reduce the occurrence of occupational LBP [24] in ICU nurses [25].

In spite of this, there are currently less reports about these strategies and no established research instruments designed to measure them as well. The aim of the current study was to develop and validate the Environmental Risk Assessing Instrument-Occupational Low Back Pain in Nurses (ERAI-N), with the intent of providing a high-quality instrument with clinical practical value that may be utilized by nurse administrators or researchers.

2. Methods

2.1. Participating Units.
This was an instrument development and validation study. Sample and data collection was performed in the tertiary general hospitals in Hunan Province in China from March to May 2022, except those specialized hospitals like military hospital, child care hospital, maternal and child health care hospital, stomatological hospital, tumor hospital, reproductive hospital, and traditional Chinese medicine hospital. The final scale used in this investigation has 20 items. The sample size was calculated according to 5 to 10 times of the number of items, 100 to 200 ICUs would be selected for this assessment, and the final sample size was about 110 to 220 ICUs, considering a 10% sample failure rate. There were 2 ICUs being assessed in every tertiary general hospital with random sampling principle. A flowchart of the sampling method is shown in Figure 1.

2.2. Procedure

2.2.1. Item Generation.
A qualitative study was conducted from January to March 2022. The initial questionnaire was developed through focus group interviews and field research, which were instructed by human factors theory. A convenience sample of 5 head nurses and 3 registered nurses working in a single prestigious general health care center was selected for group interviews. The interview was carried out by 3 of our research team in one conference room in the hospital. Participants were asked to discuss about LBP and environmental risk and safe culture related to the pain. Interviews continued until data saturation was achieved. For further certainty in addition to the focus group interviews, a field research was performed, and descriptive observation and focal observation were used by 2 of our research team in two ICUs. Subsequently, based on the qualitative study and literature review, the preliminary questionnaire containing 27 items was developed.

2.2.2. Content Validity.
An expert reviews process based on Delphi [26] was used for this study. The number of experts to be consulted for the Delphi method ranged from 15 to 30, depending on the depth of the research content [27]. Because the instrument is intended to measure factors of working environment and safe culture related to LBP in the context of an inpatient department, 20 researchers in the field of nursing management, ergonomics, or occupational safety were identified as experts, who were from the provinces of Taiwan, Beijing, Hunan, Gansu, Shanghai, Jiangsu, Chongqing, Guangxi and Anhui in China, respectively. All experts were contacted by WeChat and consented to participate in the study.

Two rounds of expert reviews were conducted. Nineteen of these twenty reviewers (95.0%) completed the first round review and 18 of them (94.7%) completed the second round. All of nineteen experts have achieved the top class technique title in the research, and 11 of them had completed postgraduate degree education. For the two-round reviews, the authority coefficient of experts (Cr) was 0.76~1.00 (0.90 ± 0.08) and 0.75~1.00 (0.89 ± 0.08), respectively, greater than 0.7; Kendall's W values of the measurement items were 0.223 ($P < 0.001$) and 0.107 ($P < 0.001$); and coefficient of variation (CV) was 0.05~0.29 (0.11 ± 0.06) and 0.05~0.22 (0.09 ± 0.03), less than 0.25, indicating that the overall coordination degree of expert scores was at a relatively high level. Experts used Likert 5-score scale to rate each questionnaire item's relevance and its respective concept; a score of 5 means very important, and a score of 1

FIGURE 1: Flowchart of the cluster stratified sampling with random principle.

means not important. The screening criterion was the combination of an item importance score with a mean of ≥4 and CV ≤ 0.25. In the first round, 11 experts put forward suggestions for modification, accounting for more than 57.9%. In the second round, 5 experts put forward suggestions for revision, accounting for 26.3%. After synthesizing expert opinions and group discussions, 6 items were merged, 2 were deleted, 1 item was added, and 2 items were modified. The initial scale with 20 items was obtained.

2.2.3. Preliminary Investigation. To further screen the items of the initial scale that whether their descriptions were suitable for ICU nurse administrators, preinvestigation was performed in 31 ICUs of tertiary medical institutions in Changsha, which were half of nonprofit tertiary hospitals in Changsha. Critical ratio, correlation coefficient, and factor analysis method were used for the screening criteria for project analysis.

2.3. Instruments. The final ERAI-N instrument was used as the instrument to collect the data. Participants responded to each item of the scale using a Likert-type scale with five response options: very inconsistent = 1, not very consistent = 2, uncertain = 3, fairly consistent = 4, and very consistent = 5.

2.4. Statistical Analysis

2.4.1. Validity Test. After the initial scale was formed, 9 authoritative and highly motivated experts who participated in the first reviews were consulted to test its content validity, evaluating fit degree between the measured content of the scale items and the expected measured content. Experts used the content validity index (CVI) to rate each questionnaire item's relevance and its respective concept. The item CVI (I-CVI) is determined by calculating the proportion of experts rating each item as "quite relevant" or "very relevant." The I-CVIs were averaged to calculate a scale CVI (S-CVI). I-CVI and S-CVI were used to evaluate item-level and scale-level content validity, respectively.

Construct validity was assessed using confirmatory factor analysis, being carried out in IBM SPSS Amos 26 Graphics. According to the literature, the chi-square statistic and degrees of freedom (χ^2/df) and the root mean square error of approximation (RMSEA) were used as absolute fit indices, comparative fit index (CFI), incremental fit index (IFI), and normed fit index (NFI) were used as incremental fit indices, and parsimony normed fit index (PNFI) and parsimonious comparative fit index (PCFI) were used as parsimonious fit indices [28]. The overall model fit was confirmed to be acceptable when χ^2/df was between 3 and 5 and excellent if it was between 1 and 3. Other acceptable fit criteria were RMSEA < 0.08, CFI > 0.9, IFI > 0.9, NFI > 0.9, PNFI > 0.5, and PCFI > 0.5. Guided by modification indices, residual correlations were specified for several items. Standardized factor loading was used for item-level content validity assessment. Factor loading greater than 0.40 was considered to be adequate. After confirming the model fit, individual standardized parameter estimates of paths (i.e., coefficients values) were assessed for magnitude, statistical significance ($p \leq 0.05$), and direction.

2.4.2. Reliability Test. Internal consistency reliability was assessed using coefficient alpha and split-half reliability, calculated in SPSS (IBM 26). McDonald's omega reliability

Figure 2: Distribution of the hospital locations.

coefficient was calculated using SPSSAU (https://spssau. com/). Nunnally and Bernstein [29] suggest that internal consistency reliability values greater than 0.7 are generally sufficient [29]. In this study, test-retest reliability was also performed to assess the instrument's reliability. Forty ICUs were reevaluated 2 weeks after the initial survey. Intraclass correlation coefficients (ICCs) were used to determine test-retest reliability. A series of two-way mixed-effects models with measures of absolute agreement were used. ICCs were determined as <0.40 (poor), 0.40~0.75 (fair to good), and >0.75 (excellent) [30].

2.5. Ethical Considerations. The Medical Research Ethics Committee of Xiangya Hospital of Central South University approved the study protocol (#202109003). Prior to collecting the data, written informed consent was obtained from each participant. The study was conducted in accordance with the Declaration of the World Medical Association and the Helsinki Declaration on the testing of human subjects.

3. Results

3.1. Characteristics of the Participating Units. Of the 94 third-level hospitals surveyed, 19 were in Changsha, accounting for 20.2%, followed by Shaoyang, Changde, and Zhuzhou, with 10 (10.6%), 9 (9.6%), and 9 (9.6%), respectively. The distribution is shown in Figure 2. Fifteen (16.0%) hospitals had <1000 available beds, 50 (53.2%) had 1000–1999 beds, 12 (12.8%) had 2000–2999 beds, and 17 (18.1%) had ≥3000 beds. 56.4% of ICUs were available with 10–19 beds, and 28.7% of ICUs were available with 20 and more beds. In 57.4% of ICUs, half or more of the nurses complained of low back pain due to nursing operations. In 27.7% of ICUs, half or more of the nurses suffered acute low back muscle injuries caused by nursing operations (Table 1).

3.2. The Final ERAI-N Instrument. Our hypothetical model, the ERAI-N, theorized that five distinct mechanisms in hospital units contribute to LBP in nurses. These

mechanisms are spatial requirement, equipment, belief, guideline, and atmosphere of safe culture. An initial set of items was developed based on human factors theory and was refined through focus group interviews and field research. The final ERAI-N instrument comprises 18 items, with each construct measured by a minimum of 3 and a maximum of 5 items. The total scale score was 18-90. The maximum value in this survey was 90, and the minimum value was 21, with a mean value of 54.7 ± 16.3.

3.2.1. Reliability

(1) Cronbach's Alpha Score. Cronbach's alpha scores ranged from 0.793 to 0.982 for the instrument's five factors. Guttman split-half scores ranged from 0.708 to 0.928. McDonald's omega reliability coefficient ranged from 0.866 to 0.986., The overall scale was 0.963 (Table 2). These scores all exceed the 0.7 standard proposed by Nunnally [29].

(2) Test-Retest Reliability. In this study, ICC was further analyzed to comprehensively examine the reliability level of the scale, ICC scores ranged from 0.616 to 0.924, and the scale's ICC was 0.994 (Table 3).

3.2.2. Validity

(1) Content Validity. In this study, 9 authoritative and highly motivated experts were consulted for the evaluation opinions on the correlation of scale items. The results show that item-level CVI ranged from 0.89 to 1.0, greater than 0.78 [31]. A total of 17 items in the scale were unanimously rated as "relevant" by all experts (3 or 4 points), the scale-level unanimity CVI was equal to 0.85, greater than 0.8 [32], and scale-level average CVI was 0.983, greater than 0.9 [32], which mean the content validity of both item level and scale level was good.

Table 1: General information of participating units ($n = 188$).

Characteristics	Number (n)	Percentage
Type of ICU you work in		
Comprehensive ICU (central ICU)	90	47.9
Specialty ICUs	98	52.1
Respiratory ICU	40	21.3
Emergency ICU	22	11.7
Neurology ICU	8	4.3
Neurosurgical ICU	16	8.5
Cardiac surgical ICU	2	1.1
PICU	4	2.1
Cardiovascular ICU	6	3.2
Number of beds available in your ICU		
<10	28	14.9
10–19	106	56.4
≥20	54	28.7
Have any nurses from your ICU complained of low back pain as a result of nursing operations?		
75–100%	48	25.5
50–74%	60	31.9
26–49%	68	36.2
1–25%	8	4.3
0%	4	2.1
Have nurses from your ICU suffered acute low back muscle injuries as a result of nursing operations?		
75–100%	24	12.8
50–74%	28	14.9
26–49%	82	43.6
1–25%	36	19.1
0%	18	9.6

Table 2: Coefficient reliability estimates.

Scale	Coefficient alpha	Split-half reliability	McDonald's omega
Space	0.793	0.708	0.866
Equipment	0.808	0.759	0.875
Belief	0.982	0.938	0.986
Guideline	0.946	0.855	0.965
Atmosphere	0.823	0.806	0.884
The overall scale	0.958	0.927	0.963

Table 3: Test-retest reliability.

Dimensionality	The first	The second	ICC
Space	13.55 ± 3.43	13.3 ± 3.96	0.819**
Equipment	13.60 ± 3.49	13.03 ± 3.93	0.772**
Belief	14.33 ± 5.82	12.98 ± 5.98	0.924**
Guideline	8.83 ± 3.36	8.10 ± 3.52	0.834**
Atmosphere of safe culture	15.43 ± 2.92	14.80 ± 3.07	0.616**
The overall scale	65.73 ± 16.76	62.20 ± 18.50	0.994**

ICC, intraclass correlation coefficient. ** $p < 0.001$.

(2) Construct Validity. Construct validity was assessed by confirmatory factor analysis. The maximum likelihood method was used to estimate the factor loadings. In the initial model, χ^2/df was approximately 5, and neither IFI nor CFI was equal to or greater than 0.9. After several times adjusting of model and group discussion, 2 items were deleted. The final model fit indices showed acceptable model fit (Table 4). All parameters in the model were significant at $p < 0.001$ (Figure 3).

The five-factor hypothesized adjusted model resulted in the following goodness-of-fit indices. The standardized factor loadings ranged from 0.567 to 0.974 and exceeded the recommended 0.40 threshold (Table 5).

3.2.3. Minimum Detectable Change. Nurses' complaints of low back pain due to nursing operations were negatively correlated with scale scores, with a Spearman correlation

Table 4: Modified model fit test.

Index classification	Indices	Evaluation criterion	Fitted value	Meet the standard
Absolute fit indices	$\chi^2/\mathrm{d}f$	<3 good 3~5 (fail to good)	3.943	Yes
	RMSEA	<0.08	0.071	Yes
Incremental fit indices	IFI	>0.9	0.905	Yes
	CFI	>0.9	0.904	Yes
Parsimonious fit indices	PNFI	>0.5	0.641	Yes
	PCFI	>0.5	0.661	Yes

$\chi^2/\mathrm{d}f$, the chi-square statistic and degrees of freedom; RMSEA, root mean square error of approximation; IFI, incremental fit index; CFI, comparative fit index; PNFI, parsimony normed fit index; PCFI, parsimonious comparative fit index.

Figure 3: CFA model diagram of Environmental Risk Assessing Instrument-Occupational Low Back Pain in Nurses (ERAI-N).

coefficient of −0.434. Using receiver operating characteristic (ROC) curve analysis, ICUs in which ≥50% of nurses had complained of low back pain due to nursing operations were considered high risk. The AUC was 0.745, $p = 0.001$, the maximum Yordon index was 0.414, and the cutoff value was 62.5 (Figure 4).

4. Discussion

Environmental factors in the work place have been found to be an important risk related to LBP in ICU nurses [8, 33]. HealthWISE published by the World Health Organization and International Labour Organization indicated top ten

TABLE 5: Scale items and standardized factor loadings.

Scale items	Standardized factor loadings
Space	
Spatial requirements for a bed space meets the standard of 15 to 18 square meters	0.567
The height of the sickbed is adjustable	0.630
The height of the work surfaces (desks, trolleys, and shelves) is adjustable for nurses working with the natural posture	0.771
The height of the seat and the height of the lumbar support pillow are adjustable, and the structure of the lumbar support pillow is elastic and rigid enough, so it is comfortable and stable	0.798
Equipment	
Auxiliary equipment such as slip and bed easy is available at any time	0.610
Patient lifting system is available at any time	0.772
The height of the interface of common devices is suitable. Nurses do not need to bend or bend excessively when operating the interface (such as monitoring devices and ventilators).	0.709
Belief	
An organizational policy system of working safely has been established	0.917
Promote the concept of "safe patient handling, no manual lift" in the work place	0.952
Training nurses about the knowledge of ergonomics related to the prevention of lumbar and back musculoskeletal injury	0.974
Training nurses on the skill of biomechanics of lumbar spine related to the prevention of lumbar and back musculoskeletal injury	0.973
Evaluate nurses' knowledge and skills in the prevention of lumbar and back musculoskeletal injury	0.965
Guideline	
There were safe work procedures for nurses to prevent low back musculoskeletal injury	0.985
There was risk assessment checklist of safe patient handling	0.856
There were emergency plans to deal with lumbar and dorsal musculoskeletal injuries for nursing staff	0.929
Atmosphere of safe culture	
Nurses have the vision of "I want to work safely"	0.636
Nurses have the initiative to carry out the risk assessment of safe patient handling	0.877
There was a culture of safety named "team work, safe patient handling" in the work environment	0.646

ergonomic principles including working in neutral positions, keeping everything within easy reach, and maintaining a comfortable environment [34]. However, these were instructive principles, and a tool with the capacity of accurately identifying risks in clinic would be more popular than those theoretical principles for clinical administrators. Therefore, we sought to develop such a simple instrument to help clinical administrators complete the identification of environmental risk factors related to LBP in nurses.

4.1. Scale Content Analysis. ERAI-N scale had five dimensions with 18 items that were space, equipment, belief, guideline, and safe culture. Jafari et al. [35] developed a scale for predicting LBP occurrence among nurses, including three dimensions with 40 items, which were occupational, psychosocial, and individual [35]. Kazemi [36] developed an instrument to assess occupational low back pain prevention behaviours among nurses, including six aspects that are knowledge, attitude, behaviour, self-efficacy, reinforcing factors, and enabling factors. But the knowledge subscale was with low reliability [36]. However, previous scales related to the low back pain risk assessment in nurses have focused

less on the direct and controllable factors that produce these risk behaviours. In addition to safe working procedures [37] and improving nurses' work posture, a safe working environment is also essential. A study showed that providing ceiling lifts was associated with reduced LBP in nurses [21]. Therefore, the instrument is intended to measure factors of working environment and safe culture related to LBP in the context of an inpatient department.

4.2. The Results from the Expert Consultation Are Reliable. The experts participating in this review were involved in the fields of nursing management, ergonomics, or occupational safety. The authority coefficient of experts for two reviews was higher than the standard, and it indicated that the experts in this study were highly authoritative. More than half experts put forward suggestions for modification and participated in the consultation for the evaluation of model fit degree, and they fully expressed their concern and support for this study. Furthermore, CV scores were less than 0.25 in two-round reviews indicating that the overall coordination degree of expert scores was at a relatively high level.
Figure 4: ROC curve.

4.3. ERAI-N Had Moderate Reliability. In terms of the internal reliability, this scale only had a moderate internal consistency.

Reliability analysis is to test the reliability of measuring tools, which is an index reflecting the consistency degree of the result measured from the tool. In this study, coefficient alpha, split-half reliability, and test-retest reliability were used to test ERAI-N's reliability. Coefficient alpha reliability coefficient is the most commonly used reliability coefficient, and it is often used to test scale's intrinsic consistency. The method of split-half reliability means to divide the survey item into two halves and then calculate the correlation coefficient of the scores of the two halves, and it is also used to test scale's intrinsic consistency. For the data analyzed in this study, both coefficient alpha reliability and split-half reliability surpassed generally accepted standards, and this means ERAI-N had moderate reliability. In order to test the results' stability, 40 ICUs were reevaluated 2 weeks later. The scale's ICC was 0.994, greater than the standard of 0.75, indicating that the stability of ERAI-N was excellent [36].

4.4. ERAI-N Had Moderate Validity. In this study, in order to ensure the accuracy of phrasing and the importance of entry item, two-round expert consultation was carried out. In the consultation letter, open information collecting columns of "Indicators to be added" and "Opinions and suggestions" was set to obtain experts' advice as more as possible. The evaluation from authoritative experts showed that the CV of both item level and scale level exceeded the standard, this indicated that ERAI-N had excellent content validity, and its items had a good correlation with the corresponding dimension and content.

In order to ensure the scientific research, it is necessary to test the suitability of the questionnaire model. The indices of the initial model including absolute fit indices, incremental fit indices, and parsimonious fit indices basically meet the relevant parameter requirements. Based on it, the initial model was modified in this paper so as to pursue better fitting results. The fitness test results of the modified model showed that χ^2/df was not at the range of excellent, but at the range of fair to good. Meanwhile, CFI, IFI, PNFI, and PCFI reached up to the level of excellent. These findings indicated adequate internal consistency of the items within each factor and a close alignment with the ERAI-N's theoretical factor structure. Therefore, it can be illustrated that ERAI-N had a moderate goodness of fit.

4.5. Implications for Nursing Management. There are several clinical and research implications that follow this study. When a new ICU is built, ERAI-N may help the designer to decide the number of sickbed for an area so that a bed space meets ICU spatial requirement standard. It also can help them to determine the location of special equipment such as invasive ventilators that are frequently operated by the nurse so as to keep operators in a natural posture while operating the equipment's interface. Nurse managers can utilize ERAI-N as a managing tool to assess whether there are environmental risk factors related to LBP in their own unit and then form an improvement report and put forward it to supplementary departments. Researchers may tentatively utilize the tool to assess the status quo of environmental risks leading to LBP in ICU.

4.6. Limitations of ERAI-N and Future Directions. ERAI-N was developed and tested on a sample from one province; therefore, there is a need for future research focusing on further evaluating the ERAI-N's reliability and validity. For example, it would be national and cross-cultural study with variation in the ERAI-N structure and distribution. The individual factors related to LBP in ICU nurse population can be summarized and set up a connection with the ERAI-N scale. Otherwise, it is urgent to develop practical intervention strategies according to specific conditions for ICU. Of course, it is important for researchers in the future to focus on the study of putting into effect interventions to reduce or eliminate these risk factors, so as to realize its real value of research and development.

5. Conclusion

This study introduces a reliable and valid instrument (ERAI-N) for clinical administrators to measure risk factors of low back pain in ICU nurses. The ERAI-N scale had five dimensions with 18 items that were space, equipment, belief, guideline, and safe culture. It demonstrates good levels of reliability, content validity, and construct validity in the process of initial testing and appears promising. Clinical administrators or researchers may tentatively utilize the tool to assess the status quo of environmental risks leading to LBP in ICU. There is a need for future research focusing on further evaluating the ERAI-N's reliability and validity, developing and putting into effect interventions to reduce or eliminate these risk factors, so as to realize its real value of research and development.

The retention and recruitment of care providers are ongoing concerns in healthcare globally. Examining intention to leave (ITL) as a measure of retention, the existing literature has focused on nurses working in hospitals, with less attention paid to other care providers and other areas of practice. The purpose of this study was to gain a better understanding of the unique factors influencing ITL among three categories of care providers in home care: registered practical nurses, registered nurses, and personal support workers. This study assessed and compared predictors of ITL, including organizational commitment, job satisfaction, perceived supervisor support, burnout, role stress, work/family conflict, and community satisfaction. A convenience sample of home care staff working in one agency in a Canadian province was sent an electronic survey by e-mail in 2021. Responses ($n = 185$) underwent data analysis including descriptive statistics, analysis of variance, and multiple linear regression, as well as thematic analysis of two open-ended items. The results of the study indicated that 54% ($n = 99$) of respondents were considering leaving their job, and respondents were dissatisfied with their salary and benefits. Role stress, work-family conflict, and burnout differed significantly between groups. Several themes emerged for strategies to promote employees to stay with the agency, with the overwhelming strategy being higher wages/salary. Themes for why employees stayed with the agency included love for clients and commitment to their care, as well as fondness for the teams within which respondents worked. The findings of the study lead to several important implications and recommendations for the home care sector. Advocating for wage parity among healthcare sectors and other opportunities for compensation for home care workers is necessary. Additional strategies include supportive and innovative approaches for scheduling, teamwork, and working with staff to identify barriers and solutions in home care.

1. Introduction

Recruitment and retention of staff is an ongoing and global issue for healthcare agencies, presenting challenges for maintaining the adequate staffing needed to provide quality care. Intention to leave (ITL) is a common measure used to help assess retention in the workforce. In nursing, leaving positions, employers, and sometimes the profession has been a concern researched for decades. This "turnover" is especially problematic in times of nursing and staff shortages. Within home care in Canada, these concerns are heightened by lower rates of pay and the need to increase capacity to support greater provision of care in the community.

The significance of ITL is better documented in nursing than among unregulated care providers, such as personal support workers (PSWs). Within nursing, the concern of pending shortages over the last two decades has been linked to the aging population and the looming retirement of nurses. In 2009, the Canadian Nurses Association (CNA) reported concerns about significant shortages over the next 15 years in Canada [1] which we are currently acutely experiencing. The intention to leave and subsequent turnover are causes of concern for the quality of patient care and work environments. In addition, there are significant financial implications of ITL due to the reorientation of staff, overtime for covering shifts, and increased absenteeism.

Concerns over turnover and retention are also noted in rural communities, which present additional challenges. This is important to consider in the content of ITL in home care, which spans both urban and rural communities in Canada. Physical isolation, fewer resources, and providers requiring a broader knowledge base, as well as personal factors such as finding jobs for a spouse, a sense of belonging, and relationships with rural organizations have all been reported to influence recruitment and retention in rural settings [2].

The study aimed to better understand the unique factors influencing ITL among the different types of care providers in home care, including RNs, PSWs, and registered practical nurses (RPNs), also known as licenced practical nurses across Canada. Although there is significant literature related to ITL among hospital nurses, there are few studies examining ITL in home care. Understanding these predictors will help inform organizational initiatives targeting recruitment and retention strategies as part of health human resource planning. Prior to the COVID-19 global pandemic, home care was experiencing staffing shortages, which have only worsened with the pandemic and heightened the need to better understand the unique factors in home care that attract and retain staff to ensure quality delivery of care. While this study focuses on home care in Canada, the findings have broader implications for understanding and preventing turnover in home care in various healthcare structures. From the literature reviewed, many regions of the world are grappling with the recruitment and retention of healthcare workers, including in home and community care settings. The findings of this study point to both issues and practical measures in home care that could benefit studies of ITL across the globe.

1.1. Conceptual Framework. A conceptual framework of ITL [3] guided the study. The framework proposes that job satisfaction, workplace organization, community characteristics and satisfaction, and individual worker characteristics either directly or indirectly predict ITL [3], which subsequently relates to turnover.

1.2. Literature Review. The literature reviewed for ITL identified several predictors, the most important of which are discussed below and align with the components of the conceptual framework.

1.2.1. Intention to Leave. The decision to leave a job or organization is usually superseded by one's intention to leave a job. The construct of ITL is recognized as the greatest predictor of turnover behavior, with corresponding features that can be grouped as workplace factors and personal factors. Attributes of the workplace influencing ITL are readily found in the literature and include organization commitment as one of the most commonly reported predictors, along with job satisfaction, work environment, and empowerment.

In Irvine and Evans [4] seminal study on ITL, they reported that ITL is a key predictor of retention. Yet, measurement of ITL is often inconsistent, and different language is used (e.g., ITL, intention to stay, and intention to search). A literature review conducted by Hayes et al. [5] found that the inconsistent usage of terms in related research can lead to a lack of comparability over time. For example, varying applications of the term "turnover" in ITL studies can make it challenging to monitor trends and compare findings. Despite these concerns, variations in measures of behavioural intentions have continued to be used. For example, some studies have included "intention to stay" as opposed to ITL. This is the case in Berta et al. [6], where researchers examined the relationship among workplace factors and outcomes (i.e., intention to stay) of PSWs in Ontario long-term care and community care settings. Berta et al. reported that intent to stay was significantly associated with job satisfaction, work engagement, and organizational commitment. These findings align with similar studies using the measure of ITL in nurses, suggesting that despite such variations, the findings are comparable and applicable to research examining ITL [7].

1.2.2. Job Satisfaction. Similar to ITL, job satisfaction is variously defined in literature. Despite this potential for variation and subjectivity, studies reveal that there are specific aspects of one's job that are consistently reported to be important to job satisfaction, specifically in the healthcare context. Pay [8], work design, and management support [9] are all factors that influence healthcare workers' job satisfaction and, in turn, their ITL and their decision to stay or leave an employer.

Chamberlain et al. [10] studied individual and organizational predictors of PSWs' job satisfaction in long-term care in Western Canada. Job satisfaction was reported to be an important factor in the intention to leave the job, and lower reported job satisfaction was associated with increased reporting of burnout [10]. Similarly, in their literature review examining international research published between 2000 and 2016, Halcomb et al. [11] ascertained that job satisfaction is consistently found to be a predictor of nurses' intentions to leave or stay. However, the researchers concluded that while the relationship between job satisfaction and ITL is well established in scholarship, the contributing factors to job satisfaction (or dissatisfaction) are less well known. They point to the need for more research on such contributing factors to better understand ITL and thus improve retention rates of nurses.

1.2.3. Workplace Organization. Examinations of workplace organization as a factor in ITL predominantly consider workplace organization in acute care settings [5]. Recent studies that do examine ITL and the role of workplace organization in home care point to the specific elements that influence ITL in home care, including increasing pressures due to an aging population and decreasing support due to limited resources and high turnover [12]. Factors that have been found to encourage home care nurses to remain on the

job are similar to those noted for hospitals: greater autonomy, flexible scheduling, manageable workloads, sufficient support, and adequate pay [8]. Looking to fill the gaps in evidence regarding the home care work environment and patient outcomes (rates of hospitalization and discharge), Olga et al. [13] studied RNs in home care agencies across three states (California, New Jersey, and Pennsylvania). Characteristics of a "poor" work environment included longer shifts, whereas "better" work environments had more satisfied nurses and fewer reports of burnout. Olga et al. [13] found that home care agencies with good work environments had lower rates of nurse burnout and hospitalization and higher rates of discharge.

1.2.4. Community Characteristics and Satisfaction. One factor considered in relation to home care or community care nurses is community satisfaction. Stewart et al. [3] reported that community satisfaction was a significant factor associated with ITL for rural and remote nurses across Canada. The researchers assessed items such as community friendliness, social and recreational activities, quality of school, safety, ability to stay current in practice, level of anonymity, size of community, and distance from larger centers.

1.2.5. Individual Characteristics. Typically collected through surveys, analyses of demographic characteristics have identified several individual or personal characteristics that predict ITL. These include age, years of experience, level of education, and home-life obligations such as having children or other dependents [3, 5, 14].

Recently, Möckli and colleagues [15] reported that work-family conflict and work stressors were strongly correlated with emotional exhaustion (a component of burnout) in home care workers in Switzerland. Some specific concerns related to home care that Möckli et al. report include time pressure while commuting and the need for flexible scheduling to promote work-family balance. These unique concerns align with previously reported influences on intention to stay among Ontario home care nurses [8].

In summary, there is limited research examining retention or ITL in home care. The majority of ITL studies have focused on RNs working in hospital settings; hence, there is a gap in knowledge to guide decision-making. The originality of this study is that it seeks to examine factors influencing ITL among different types of workers (RNs, RPNs, and PSWs).

2. Research Questions

To identify the predictors of ITL in home care, across different categories of care providers, and to understand the relationship between these predictors, the following research questions were investigated:

(1) What is the relationship between personal characteristics, community characteristics and satisfaction, job satisfaction, workplace organization, and ITL?

(2) Do the predictors of ITL differ between categories of healthcare providers (RN, RPNs, and PSWs)?

(3) What do healthcare providers identify as strategies to promote their retention in home care, and do these differ between categories of healthcare providers (RN, RPNs, and PSWs)?

3. Materials and Methods

The research design for the study was quantitative and nonexperimental and incorporated a cross-sectional survey. Prior to commencing the study, ethical approval was obtained from the Trent University's Research Ethics Board (File #26700). The study was initiated in partnership with a home care agency. The home care agency provides services across the province of Ontario, Canada's second-largest province and home to approximately 13.5 million people across one million square kilometers [16] in rural, urban, and remote communities. Services provided by the agency include those funded by the provincial government, such as visiting nursing, personal support and homemaking, and end-of-life care, as well as programs within schools and other residential settings. Options for alternative employment vary greatly across the province, with more options available in highly populated areas. An advisory group from the agency, consisting of five leaders with responsibility for home care delivery across the province, contributed to the proposal development, survey development, and recommendations.

Measurement tools used to assess the key constructs of the framework are identified in Table 1. The measures assessed personal factors, workplace/organizational factors, community characteristics and satisfaction, and ITL. In addition to the tools, demographic questions were included, along with an open-ended question asking participants to identify strategies that would encourage them to stay working in home care and with their current employer. In total, the survey asked participants to rate 108 items and 2 open-ended items, for a total of 121 questions.

3.1. Sample. A convenience sample was used. A total of 1038 employees from one home care agency in Ontario, including RNs, RPNs, and PSWs were surveyed. The advisory group provided lists of employee emails for the researcher to distribute the electronic survey by e-mail, which occurred from November to December 2021. A total of 225 respondents opened the survey but only 185 respondents were useable for data analysis. The overall response rate was 18%.

3.2. Data Analysis. The raw data was only available to the researchers. Descriptive and inferential statistics were completed using SPSS© (version 28). To answer the first two research questions, data analysis included bivariate correlations, multiple linear regression, and one-way and multivariate analysis of variance. The data from the open-ended questions was analyzed in Microsoft excel by the principal investigator and research assistant, both with previous experience completing thematic analysis. Thematic analysis

Table 1: Measurement tools assessing key constructs of conceptual framework.

Component of theoretical model	Variable	Measurement tool (source)
Personal factors	Home-life obligations	Work-family conflict [17]
	Stress	Role stress [18]
	Burnout	Burnout assessment tool [19]
Job satisfaction	Job satisfaction	Global job satisfaction [20]
	Aspects of job	Component of Casey-Fink new nurse experience survey [21]
Workplace organization	Organizational commitment	Organizational commitment questionnaire [22]
	Supervisor support	Perceived supervisor support scale [23]
Community characteristics and satisfaction	Community satisfaction	Community satisfaction [24]
ITL	Intention to leave	Turnover intention [25]

was used to identify themes in the written responses of participants [26]. Initially, analysis was completed separately, then findings were shared by the principal investigator and research assistant, and congruency was found among themes.

4. Results

An equal number of RNs and RPNs completed the survey, 46 in each group, and a larger number of PSWs, 77 completed the survey. Most respondents were employed full-time, female, working one job, and associated with the visiting nursing program. Table 2 provides characteristics of the sample.

4.1. Study Variables. Table 3 provides ranges, means, and reliability coefficients of the measures used for the study variables. Cronbach's alpha ranged from 0.84 to 0.97, including subscales. Given the reliability, minimal missing data (less than 5%), and normal distribution of the data, data analysis proceeded.

4.1.1. Intention to Leave. A total of 99 respondents, 54% of sample, indicated they were thinking about leaving their job in a subsequent question (*If you are thinking about leaving your job, are you considering. . .*). Respondents who indicated they were thinking about leaving their job could select more than one option to specify their intentions. Respondent selections were as follows: leaving home care ($n = 62$), leaving healthcare ($n = 32$), staying in home care but leaving their current employer ($n = 27$), going back to school ($n = 27$), and moving to a new community ($n = 10$). Many respondents selected "other" ($n = 43$) A variety of comments were received but the most frequent was retirement ($n = 12$). In follow-up, respondents were asked the following subsequent question: If you are considering leaving your job, when do you plan to leave?" Most respondents indicated they were unsure or did not know ($n = 37$). Others responded that they planned to leave within 6 months ($n = 20$), planned to leave within the year ($n = 16$), or planned to leave in greater than 2 years ($n = 16$). Finally, some indicated they were leaving immediately or had taken another job ($n = 7$)

4.2. Question 1. The first research questions examined the relationship among personal characteristics, community characteristics and satisfaction, job satisfaction, workplace organization, and ITL. As expected, significant correlations were noted among the study (see Table 4). Multiple linear regression was used to test the conceptual framework of ITL for the entire sample. The overall analysis was significant ($F = 7.264$, $p < 0.001$), and the model accounted for 39% of the variance in ITL (measured by turnover intention). Organizational commitment was significantly associated with ITL (standardized $\beta = -0.42$, $p < 0.001$). None of the other variables entered in the model significantly relate to ITL.

4.3. Question 2. The second research question examined if the predictors of ITL differ between categories of healthcare providers (RNs, RPNs, and PSWs). The data met the assumptions for one-way analysis of variance (ANOVA) and multivariate analysis of variance (MANOVA). Initially, MANOVA determined that there were significant differences among the group means, followed by one-way analysis of variance. The results (see Table 5) identified significant differences in means between groups for the measures of role stress, work-family conflict, and burnout. Post hoc analysis was done using the Bonferroni method to understand the differences in these measures among the groups, with both tests identifying the same significant differences among groups. For RNs, role stress was significantly higher than for PSWs. Examining the subscales of role stress (role ambiguity and role overload), role overload was higher in RNs, contributing to the significant difference. For RNs and RPNs, work-family conflict was significantly higher than that reported by PSWs, although not significantly different between RNs and RPNs. For RNs, burnout was significantly higher than reported by PSWs. Finally, satisfaction with several aspects of the job was also rated. These job aspects included salary, vacation, benefits, scheduling, weekends off, amount of responsibility, orientation and onboarding, opportunities for professional development, traveling, and amount of responsibility. Of these aspects, satisfaction with salary was significantly different between role types ($F = 7.76$, $p < 0.001$), with RPNs reporting lower satisfaction than PSWs and RNs, despite all categories reporting low satisfaction with salary.

TABLE 2: Characteristics of study participants ($n = 185$).

Characteristic	Frequency (n)	Percentage	Mean (SD)
Role description			
RN	46	25	
RPN	46	25	
PSW	77	42	
Length of time working in healthcare (years)			15.65 (11.72)
Length of time employed with the agency (years)			8.14 (8.87)
Number of jobs (including with the agency)			
One	115	62	
Two	33	18

4.4. Question 3. The third research question explored what care providers identify as strategies to promote their retention in home care and whether there are differences between RNs, RPNs, and PSWs. A total of 156 responses were provided for the two open-ended items, and thematic analysis was completed. The themes that emerged, along with descriptions of the strategies and examples offered by respondents, are presented in Table 6. For strategies to keep

staff (i.e., promote retention), three themes emerged: compensation, scheduling, and management opportunities. Overall, the themes were the same between RNs, RPNs, and PSWs with the following exceptions: nursing respondents (RPNs and RNs) suggested more training and education, and RPNs suggested safety concerns be addressed by management.

Respondents were also asked why they stayed with the home care agency. Five themes emerged from these responses (see Table 7) and included patients/clients, nature of community care, the "Team," work practices, and financial need. Overall, the themes were the same between RNs, RPNs, and PSWs apart from work practices by nursing respondents. Both RPNs and RNs reported the unique skill set used in community nursing and opportunities for learning.

5. Discussion

The primary motivation for the study was to determine if there were differences in predictors of ITL among categories of home care workers (RNs, RPNs, and PWSs) to help inform retention and recruitment strategies. While there was no difference in reported ITL among RNs, RPNs, and PSWs, organization commitment was the key predictor of ITL. There were significant differences among some of the predictors, including role stress, work-family conflict, burnout, and one aspect of job-satisfaction with salary and wages. These predictors and differences among categories are discussed .

Overall, the relationships among the study variables were expected. Although weak, higher community satisfaction correlated with lower role stress, lower work-family conflict, and lower burnout. In previous research, community satisfaction was identified as a unique predictor of ITL in rural RNs [3, 24]. To better understand if there was a difference in community satisfaction between rural and urban respondents, additional analysis was completed, yet no difference was found. Therefore, community satisfaction seems to be important regardless of whether one lives or works in urban or rural communities, yet further investigation is warranted, including consideration of how an employer can contribute to community satisfaction or dissatisfaction.

5.1. Organizational Commitment. When examining all the predictors of ITL for the entire sample, the most significant predictor of ITL was organizational commitment. The items assessed in the measurement of organization commitment include alignment of one's values with the organizational values. Organizational commitment is a globally a well-recognized predictor of retention in nursing, yet little evidence is available for home care and the different categories of workers. Research that does exist indicates that strategies that promote employee empowerment [27, 28], supervisory support and leadership [27], professional development and training [28], and the implementation of evidence-based leadership approaches [29] can contribute to organizational commitment and thus reduce ITL.

5.2. Role Stress. RNs reported higher role stress than both RPNs and PSWs. Upon investigation, the component of role stress that differed was role overload. Role overload is the result of being expected to complete a variety of tasks in insufficient time [18]. The unique skill set of RNs in home care and the concerns noted about scheduling practices may contribute to issues of overload. Workload has been recognized by nurses as contributing to ITL, especially for new nurses, where workload contributes to stress [30]. Additional research could further examine the relationship between workload and category of employment in community care to determine, for example, if and how higher skill set requirements contribute to role stress in the specific environment of community care.

5.3. Work-Family Conflict. Both RNs and RPNs reported higher work-family conflict than PSWs. Upon further examination, there were no significant differences in the groups having dependents at home which may contribute to this; however, other contributing factors were not explored to help understand what is contributing to the conflict. From the themes that emerged, traveling and scheduling practice may influence work-family conflict. Studies have shown that work-family conflict is a significant predictor for healthcare workers' ITL and that this is particularly the case for home care workers [31]. However, more research is needed to understand the variables that contribute to this relationship,

TABLE 6: Themes on strategies to keep staff.

Theme	Details from respondents	Quotes
Compensation	Overwhelming theme across the three groups, with suggestions for salary and wage increases Discrepancies between sectors acknowledged, and not reflective of responsibilities Additional types of compensation acknowledged (improved vacation, benefits, bonuses for "staying," improved mileage or provision of gas cards)	"Pay parity with hospitals"
Scheduling	Desire for greater continuity of patient assignment Fewer weekends Less pressure to pick up shifts Job sharing opportunities Improve scheduling to reduce driving Options for settings that don't require driving (e.g., clinics) Avoid consecutive days or shifts More staff needed to improve workloads and scheduling Provide time for hand-off Refrain from mandatory overtime	"Almost every shift" (mandatory overtime)
Management opportunities	Treat staff fairly and provide recognition for their work Personal contact-listening, showing concern (including for mental health) Improved communication and approachability more training and education* Address concerns of safety and accommodations**	"Favouritism" "It's not fair" "Overall, not appreciated"

*RN and RPN respondents. **RPN respondents.

TABLE 7: Themes related to why employees stay.

Theme	Details from respondents	Quotes
Patient/clients	"Love" for clients Concern for clients if not there	"Wake up every morning excited to go to work," "the patients keep me..."
Nature of community care	Being close to home Having an impact on the community The duties work and skills (critical thinking)*	"Believe in the value, necessity and quality of community health care"
The "team"	The company, management, and coworkers Friendly and helpful coworkers	"Feels like a family," "amazing supervisor" "Love the team"
Work practices	Having vacation and sick days, flexibility and independence, availability of overtime Opportunities for continued learning	"Love the support"
Financial need	Years of services and pension stopped employees from leaving Need for job/wages contractual obligation	

*RN and RPN respondents.

specifically with respect to different employment categories within home care.

5.4. Burnout.

RNs reported higher burnout than both RPNs and PSWs. The burnout measure consisted of four subscales, including exhaustion, mental distress, cognitive impact, and emotional impact. Upon further examination, it was the exhaustion subscale that was significantly different. Schaufeli and colleagues [19] describe exhaustion as the "heart of the burnout syndrome" (p. 13) and one of the core symptoms of burnout. The items assessing exhaustion considered both mental and physical exhaustion. Burnout is a recognized predictor of ITL in nurses [9, 32].

These concerns about burnout align with the findings from Moloney and colleagues [9] in New Zealand who reported that workload and work-life interference contributed to burnout in RNs, which in turn was a significant predictor of ITL. Although Moloney's findings were not specific to home care, focused on RNs only, and were in a different jurisdiction, the findings align with this study. The concern of role overload and work-family conflict reported in nursing respondents, especially RNs, are likely contributing to the exhaustion. Therefore, strategies to address workload, work-family conflict, and exhaustion should be considered in a retention strategy.

5.5. Dissatisfaction with Salary and Wages.

Dissatisfaction with wages and salaries was a quantitative and qualitative finding from the study. Among the categories of work, all three groups reported low satisfaction with salary and wages but there was a significant difference with RPNs, who reported greater dissatisfaction than PSWs. Although details of the salary dissatisfaction were not obtainable, other studies have found that dissatisfaction with wages and compensation greatly contributes to overall job dissatisfaction and ITL [33]. This is especially so when healthcare workers feel there is a disparity between workload and compensation, which is often found to be the case in community care [34]. Dissatisfaction with wages has also been found to contribute to ITL early in employment (e.g., within the first year), particularly for those working in home care [35].

5.6. Recommendations.

Based on the results of the study, the following recommendations are made. The recommendations support retention.

5.6.1. Address Compensation Dissatisfaction.

Addressing the dissatisfaction with compensation includes increasing salary and wages of home care workers and providing additional compensation strategies including mileage, travel time, and benefits are needed. The respondents recognized the differences in wages between healthcare sectors as well as the complexity of seeking wage increases, noting the need to work with the government and advocacy for the change. Although all members of the team can advocate, senior leaders are well positioned and can use existing relationships with government at the provincial level. Advocating for wage parity among healthcare sectors will also signify an understanding and respect for home care. Without this parity, the low wages represent undervalue of home care and the workers in the sector.

Separate from wage parity, other payment strategies can be considered and seen as advantageous for staff. Non-wage-related compensation strategies suggestions include increasing mileage compensation and payment for travel time between clients' homes. For benefits, it was recognized by respondents that the cost of current benefits was disproportionate to their wages. Although the details of the cost of participating in benefit programs were beyond the scope of this study, it is recommended that a review of options and employee costs be undertaken. Many respondents recognized the increased costs associated with the vehicle requirement of working in home care. Specific recommendations to address these include increasing the mileage provided to support the cost of gas and vehicle maintenance. In addition, some respondents suggested offering work that does not require traveling, such as clinics.

5.6.2. Examine Scheduling Practices.

A variety of strategies were suggested by respondents for improving scheduling, including some conflicting suggestions (for example, less overtime and more overtime offered). Several strategies can be considered to enhance satisfaction with scheduling in the workplace. It is recommended that practice includes creating a staff scheduling committee and ensuring a common understanding and application of collective agreements. A staffing scheduling committee with staff can help address scheduling concerns raised by staff and serve as a forum for management and supervisors to be present with staff. In addition, revisiting and possibly revising scheduling practices could ensure fairness and efficiency in terms of assignments (less travel time), staff satisfaction, and continuity of clients [3, 36]. In a review of literature on nurse's ITL, Al Zamel et al. [37] highlight the consistent significance of job satisfaction and work environment. They suggest that ensuring job satisfaction includes monitoring and being aware of staff concerns and then implementing specific strategies that address those concerns. Creating a staffing scheduling committee would provide ongoing opportunities to understand and respond to such concerns.

Given the comments regarding fairness in scheduling, it is suggested that where appropriate (i.e., for unionized environments), education to managers, supervisors, and schedulers be provided to help ensure a common understanding of the collective agreements and application, specifically for scheduling. This is consistent with findings in the study conducted by Stewart et al. [3], which examined nurses' intentions to leave in rural care, Canada. Stewart et al. noted that factors contributing to the intention to leave within the next 12 months of the study included high stress and dissatisfaction with scheduling. In contrast, in the study carried out by Tourangeau et al. [8], home care nurses in community settings in Canada reported a higher intention to remain employed when scheduling practices were flexible, work environments were supportive, and workloads were

manageable and varied. Opportunities for collaboration, education, and support from leadership are conducive to positive work environments, increased workplace safety, and lower dissatisfaction overall [29, 38]. Managers can take a proactive and open approach to concerns around safety. Butler [38] determined in a study involving 252 home care aides that the ability to discuss concerns with leadership promoted feelings of safety for employees.

5.6.3. Enhanced Management Support and Practices. Managers and supervisors are positioned to promote the team dynamic and demonstrate appreciation and recognition of staff. Based on the findings of this study, the need for recognition for work done and providing support was separate from compensation. On a positive note, the "team" was an important reason for staying with the home care agency. Recommendations to help management (and supervisors) meet identified needs and promote the "team" include creating opportunities for teams to work together, utilizing reward and recognition programs, and implementing a values-based approach to recruitment to promote organizational commitment.

Existing studies support the significance of fostering team cohesion and supportive work environments. In their study involving survey results from 16,707 nurses in England, Carter and Tourangeau [39] conclude that adequate support and resources contribute to a more positive work environment. They further highlight that a positive work environment is a significant factor in employee retention. Nurses who reported feeling more engaged (psychologically involved) in their work had lower rates of ITL. Collegial work settings, improved work relationships, and an emphasis on team building have been shown to benefit home healthcare workers and have been suggested to improve retention [33].

Opportunities for teams to work together, learn about one another, and work directly with managers are needed. If these opportunities are already present, seek feedback from staff about what is missing from the meetings, what can be added to make them more engaging and meaningful, and hear what else might be done. These strategies will not only help open communication channels, create teams, and foster trust among team members, but will also provide an opportunity for management to engage in authentic and transactional leadership practices. There are many resources for supporting team development available, for free, from several organizations.

Additional efforts could be made to implement or strengthen recognition programs. Research shows that perceiving the workplace as fair and feeling appreciated are factors in reducing the intention to leave [29]. If a recognition system already exists, evaluate how it is being used by managers and supervisors, including what barriers might prevent its use and what might encourage its use of the system. Depending on the barriers and staff feedback on the existing system, consider what a new recognition system might look like. There are many examples of innovative recognition systems ranging from formal recognition (e.g., certificate of recognition) to informal types of recognition (e.g., peer-recognition). In addition to being connected with organizational commitment, recognition and rewards in the workplace have been linked to staff resilience and improved mental health [40].

Secondly, given the importance of the link between organizational commitment and retention in the workplace, leaders need strategies that promote organizational commitment as early as the recruitment phase. Organizational commitment has been demonstrated to be a significant factor in ITL in that the higher the organizational commitment, including in healthcare work environments, the lower the level of ITL [5, 29]. In terms of fostering organizational commitment as early as recruitment, one approach to interviewing is values-based [41]. Values-based interviews focus on how and why an individual is oriented towards making certain choices in the workplace. Questions in the values-based approach seek to gain information about what is important to the applicant and assess if their values are appropriate for the role and organization.

5.6.4. Maintain and Expand upon Existing Practices That Support Staff. The findings highlighted several practices that should be reinforced and continued. Respondents were satisfied with orientation, onboarding, and professional development opportunities. These practices are essential in a healthy work environment, which supports recruitment and retention in the workplace. In addition to the connection with clients/patients, the "love" and "joy" staff reported to have received from providing care were evident and an overwhelming finding from the comments received.

Ongoing monitoring of the onboarding and orientation activities, inclusive of feedback from participants should be practiced to continually improve in these areas. In their literature review of research on job satisfaction, [42] note that "what makes a job satisfying or dissatisfying does not only depend on the nature of the job but also on the expectations that individuals have of what their job should provide" (p. 1018). Many of the studies examining ITL in healthcare incorporate self-report surveys, and employees consistently report that support from managers as well as opportunities for engagement and professional development contribute to job satisfaction. Professional development opportunities for all staff could be enhanced with special consideration for nursing and the unique skill set required by nursing in home and community care. An approach that takes into consideration the specific circumstances of home and community care is more likely to encourage retention in this sector [34].

Leaders can explore opportunities to learn more about what can be done to help employees find joy in home care and/or remove barriers so that they have improved work enjoyment. The Institute of Health Improvement, Framework for Improving Joy in Work, is a free resource that organizations can use to help guide leaders identify barriers to joy in the workplace and work with colleagues to create meaningful strategies. This suggestion is consistent with literature demonstrating that healthcare providers who feel

more engaged in their workplace, who have a sense of being part of a team, and who are provided opportunities for being "psychologically involved" in their work report lower ITL [39]. Seeking opportunities for a more positive work environment that emphasizes teamwork can contribute to job satisfaction and subsequent retention [43].

5.7. Limitations. There are several limitations to this study, including the use of a convenience sample, the cross-sectional design method, self-reporting, and the sample size. Future studies would benefit from a random sample, with multiple employers and additional measures. The self-reporting approach to data collection used in this study has the potential for response bias such as carelessness, social desirability, or acquiescence [44]. Furthermore, the study and analysis required a high response rate. Although there was good representation across each category of worker, more responses were desired from RNs and RPNs to help distinguish differences among the groups of workers. Therefore, generalization of the results is limited, and future research is needed with consideration for other research methods and larger sample sizes.

In addition, the survey was circulated and completed during the COVID-19 pandemic. Although limited comments were received related to the pandemic in the open-ended items, the impact of the pandemic on healthcare providers must be acknowledged as a potential limitation to the study. Results may be influenced by the ongoing stress of being an essential service, including but not limited to working short-staffed due to restrictions on multiple employers imposed by the government and the risk of transmissibility in the community.

6. Conclusion

This study has contributed to the existing literature by examining the unique factors that influence ITL among home care providers in three categories: registered practical nurses, registered nurses, and personal support workers. In assessing and comparing predictors of ITL (organizational commitment, job satisfaction, perceived supervisor support, burnout, role stress, work/family conflict, and community satisfaction) for 185 respondents, this study has led to several significant implications for possibilities to improve both recruitment and retention in home care.

The chief concern among all three categories of care providers was dissatisfaction with wages and salaries. Strategies aimed at wage parity across the healthcare sector and increased opportunities for compensation for home care workers should be encouraged to improve recruitment and retention. Another commonality among the categories was an expressed dedication to the clients, to the team, and to the job. However, inadequate pay and insufficient recognition of the unique circumstances of home care contributed to feelings of being underappreciated and dissatisfied. As such, scheduling practices should be revisited and improved to ensure fairness and respond to the specific concerns and needs of home care providers. Incorporating or enhancing opportunities for team cohesion, management and supervisor support, and staff recognition are also suggested for both recruitment and retention efforts. The implications of high rates of turnover in healthcare represent an ongoing concern and a growing issue, particularly in the face of an aging population and the lingering impacts of a global pandemic. This paper contributes to an understanding of ITL in home care and offers suggestions to improve recruitment and retention specific to the unique work environment of home care.

Data Availability

The data used to support the findings of this study are restricted. Participants of this study did not give written consent for their data to be shared publicly.

Additional Points

What Is Known about This Topic? (i) ITL is known to be a key predictor of turnover, influenced by organizational, personal, and community factors. (ii) The models of ITL have been studied on Registered Nurses but limited evidence is available assessing models with different workers. (iii) Home care faces unique challenges which may influence ITL and retention. *What This Paper Adds?* (i) Similarities and differences of predictors of ITL among Registered Nurses, Registered Practical Nurses, and Personal Support Workers working in home care are reported. (ii) Dissatisfaction with wages and salary was reported by the three categories, along with recognition of disparity across sectors. For some respondents, wage disparity contributes to the feeling that home care is undervalued and underappreciated. (iii) Unique considerations for home care workers related to retention include scheduling, continuity of clients assigned, travel time, concerns of mileage and related expenses, and safety with traveling and being in the community.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Aim. To identify and examine the structures and processes that support the director of nursing role in long-term care homes. *Background*. The director of nursing in long-term care homes is central to overseeing and supporting the workforce and delivery of safe, quality resident care. With ongoing health human resource challenges and an aging population requiring care from long-term care homes, it is important to understand what individual and organizational factors support the director of nursing leadership in these settings. *Evaluation*. This review was guided by Cooper's five stages of the integrative review process. Donabedian's structure-process-outcome framework was applied to synthesize the literature. *Key Issue(s)*. Five individual-level structures (years of experience, level of education, demonstrated leadership capabilities, completed certification and/or established linkages with a professional association, and completed continuing education); three organizational-level structures (physical presence of leadership across the organization, a clear job description, and salary); and four processes (nursing home administrators and the director of nursing relationship, availability of onsite continuing education opportunities targeting directors of nursing and support for continuing education, cultivating relationships and enhancing networks beyond the long-term care home, and orientation to the role) were identified across 11 articles to support the director of nursing role in long-term care homes. *Conclusion(s)*. The findings indicate that there are individual characteristics that support the director of nursing in their role. Notably, there are organizational structures and processes that can be modified at the practice and policy level to better recruit, retain, and support the performance of directors of nursing. *Implications for Nursing Management*. There are actionable steps that leaders and decision-makers can take to support nursing leadership across long-term care homes and directly address health human resource challenges.

1. Introduction

1.1. Background

1.1.1. The Long-Term Care Setting. Long-term care homes provide 24-hour health and personal care services to individuals with complex needs who do not require hospital level care but cannot be safely cared for in their own home [1]. Despite strict regulations within long-term care homes in North America, quality of care across homes remains an ongoing concern [2, 3]. The COVID-19 pandemic was an example of the shortcomings in long-term care homes globally creating an environment that is increasingly unpredictable, underresourced, and complex to lead [2, 4–8]. A public inquiry into the operations of the long-term care sector in Ontario, Canada, instigated by poor resident and family outcomes in the first wave of COVID-19, revealed a neglected system and called for immediate government attention and investment [2, 9, 10]; similar findings were also noted across long-term care homes in the United States [11] and Australia [12]. In European countries, factors contributing to the virus' spread in long-term care homes were

inadequate staff training, lack of personal protective equipment, poor surveillance testing for both staff and residents who are at increased risk by virtue of their underlying health conditions, and the congregate type setting [13]. Critical to the success of implementing many of the recommendations outlined in these reports is the director of nursing, who alongside the nursing home administrator and medical director, is a member of the senior interprofessional leadership team with direct responsibility for the nursing department [14].

1.1.2. The Director of Nursing Role. The director of nursing in long-term care homes is defined as a senior nurse leader who is responsible for planning, organizing, and directing nursing care in the nursing department. They are also a clinician expert, educator, collaborator, and advocate in the home and participate in quality improvement, emergency planning, risk management, regulation compliance, and advancing the health and safety of staff [3, 15].

Research demonstrates a link between the director of nursing role performance and staff satisfaction, retention, quality improvement, and overall performance in the home [16, 17]. Despite the reach and demonstrated importance of the role in the literature, there is a sustained history of long-term care homes experiencing vacancies or high turnover rates for this critical leadership position published in the literature that ranges from 24% to 147% a year [17, 18]. Factors influencing the director of nursing turnover include a disconnect between preferred and expected responsibilities [19], low satisfaction and low perception of autonomy/ participation in decision-making, and working in a for-profit home [20]. Lower levels of tenure were also noted amongst directors of nursing with higher levels of education and those working in for-profit chain homes, as compared to directors of nursing working in not-for-profit homes or in for-profit nonchain homes [21]. The consequences of high turnover rates of the director of nursing role result in a disruption to the team and negative impact on the quality of care to residents [17, 22–24].

The director of nursing role may not be mandated in long-term care homes internationally; rather, the specific regulations and requirements for this role can vary depending on the governing bodies in different countries and regions [8, 25]. However, in Ontario, Canada, and across the US, the director of nursing role is mandated within the long-term care homes with minimum qualifications (i.e., being a Registered Nurse (RN) with at least one year of experience working in the sector, three years of experience working in a managerial/ supervisory capacity in a healthcare setting, and demonstrated leadership and communication skills) with no expectation for continued education or formal leadership training [11, 14]. Two recent scoping reviews examined the characteristics of the nursing home administrator/director of nursing senior leadership role in long-term care homes and impact on quality outcomes [26, 27]. Both reviews found that the influence of the nursing home administrator/director of nursing role on quality is inadequately described in the literature, role preparedness in aged care is poorly defined and focused

primarily on the nursing home administrator role, and quality outcomes mostly relate to care and to a lesser extent as an outcome to the leader and organization. Despite the critical nature of the director of nursing role in long-term care homes, none of the included studies in these reviews focused on specifically examining the structures and processes of the director of nursing role as a unique role that differs from the nursing home administrator and influences work ethos and quality care. The current review will contribute to the growing body of the literature by examining international research in which the director of nursing is exclusively sampled and identifying modifiable structures at the organizational level and processes that may support their leadership role in long-term care homes.

2. Aim

The aim of this integrative review is to synthesize the literature related to the director of nursing role through the application of Donabedian's structure-process-outcome quality framework by addressing the research question: What are the structures and processes that support the role of the director of nursing in long-term care homes?

3. Methods

3.1. Design. An integrative review approach was employed, as it provides the opportunity to examine phenomenon broadly through the inclusion of both empirical and theoretical publications, which are common to nursing research [28, 29]. Cooper's five stages of the integrative review process were applied as follows: problem formulation, literature search, data evaluation, data analysis, and presentation [30].

3.1.1. Theoretical Framework. The theoretical framework underpinning the analysis for this review is Donabedian's structure-process-outcome quality framework [31, 32]. This framework is commonly utilized in research to examine factors influencing quality in healthcare such as program delivery, characteristics of leaders, and burnout amongst care providers [16, 33, 34]. The framework consists of three distinct components—structures, processes, and outcomes. Structures have been described as the physical and organizational setting where care is delivered; processes as the mechanisms and actions allow for healthcare delivery; and outcomes describe the result on individuals and/or communities [31, 32].

For the purposes of this review, we examined structures and processes, defined as characteristics of the individual and organization, and actions of individuals and organizational approaches that impact the director of nursing role, respectively. Outcomes stemming from their performance are outside the scope of this literature review.

3.2. Search Strategy. The review assessed electronically available papers that were published between January 2000 and February 2022. The search was limited to this timeframe because long-term care homes changed considerably in 2000, with an increase in resident frailty, integration of

technology, and workforce challenges that all impact the director of nursing role [2]. A university health science librarian assisted with the search strategy in five electronic databases: Medline, Embase, CINAHL, AgeLine, and Cochrane Database of Systematic Reviews. Table S1 in the online appendix describes the full-search strategy.

The inclusion criteria for studies were as follows: (a) focused on the role of the registered nurse in a director of nursing position within the long-term care home with oversight of the nursing department; (b) for qualitative studies or mixed methods studies, described a relationship or theme relating to a structure or process describing or influencing the role; (c) for quantitative studies, reported a relationship between the structure and process and an outcome measure directly related to the role; and (d) published in the English language. The exclusion criteria for studies were as follows: (a) settings that were not long-term care; (b) focused on other executive roles (e.g., administrator); and (c) other reviews, dissertations, conference proceedings, editorials, personal reflections, and commentaries. A snowball search of the reference lists from eligible studies was also completed; from this, 21 studies were identified. However, they were not included in the final review as they did not meet the eligibility criteria.

3.3. Data Screening, Extraction, Study Evaluation, and Analysis

3.3.1. Data Screening. Screening of papers took part in two stages using Covidence: at the title/abstract level and at the full-text level. During screening, JF and AW reviewed abstracts and full texts independently. KM and CC resolved any conflicts. After abstract screening, the primary researcher electronically contacted four authors directly to obtain five articles following the Dillman total design survey method [35]. The authors also utilized the university's interlibrary loan services which can access additional closed-access journals beyond the institution's library collection in an attempt to acquire the digital copies of the same five articles and one additional article. From these efforts, three articles were obtained: one from authors and one through interlibrary loan. The remaining four articles were not included as they were not available.

3.3.2. Data Extraction. Data were extracted from each article into a Microsoft Excel table. Study, setting, and sample characteristics are available in Table S3 in the online appendix. To ensure rigor in the data extraction process, JF and AW extracted data independently, and comparison and conflict resolution was performed by JF.

3.3.3. Data Evaluation/Quality Assessment. The quality of each individual study was appraised using the Mixed Methods Assessment Tool (MMAT) [36]. The MMAT tool was selected to be inclusive of all possible research designs. Each study was appraised independently by JF and AW against the corresponding criteria, and KM and CC resolved

any conflicts. All articles were retained to support a comprehensive review of the literature [36].

3.3.4. Data Analysis and Presentation. Data were analyzed by JF by reviewing each article and identifying subthemes that met the descriptions under each structure and process component of the framework. Structures were identified at the individual level to provide insight into characteristics of the director of nursing and at the organizational level to determine factors that were modifiable. The subthemes were then counted to determine the frequency in which they appeared in the literature and were categorized into larger themes as appropriate. The data were then analyzed by comparing commonalities, relationships, and differences to draw conclusions in the review [28, 29]. The results are presented in a PRISMA flow diagram in Figure 1 with tables and thematic narration detailed in Supplementary Materials.

4. Results

The initial search yielded 4,716 findings. Following the removal of duplicates, 2,905 papers proceeded to title/abstract screening. After full-text screening, 11 papers were included in this review. Figure 1 includes the PRISMA flow diagram which illustrates the search findings, and Table S2 in the online appendix demonstrates the impact of limiters.

4.1. Study Characteristics and Quality Assessment. Five of the 11 studies in this review were quantitative [24, 37–40], and six were qualitative [3, 15, 23, 41–43]. Study and setting characteristics are described in Table S3 in the online appendix.

4.1.1. Sample Characteristics. Sample sizes of the participants ranged from 4 to 247 across the 11 studies. The age of the director of Nursing was reported as a mean in five of the studies, with a mean range of 46–50 years of participant age [3, 15, 23, 37, 38]. The sex of the director of nursing was reported in three of the studies, with females representing 83% to 98.7% of the samples [3, 15, 38]. Educational preparation was reported in six of the studies, with participants holding predominantly a nursing diploma or an associated degree. Current tenure was reported as a mean of 4- 5 years across three studies [23, 24, 37].

Of the 11 studies, directors of nursing were sampled exclusively in three studies [23, 37, 38], and the remaining eight studies included directors of nursing and other personnel including unit managers, nursing home administrators, and staff nurses in their samples.

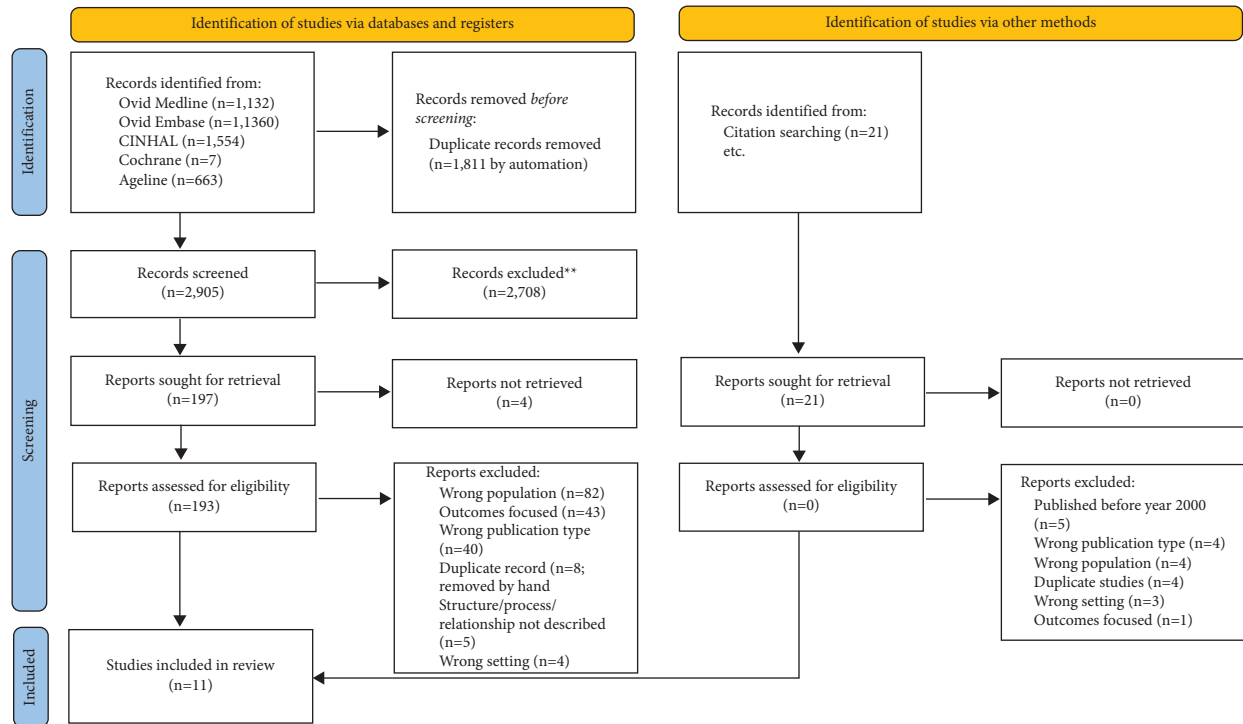
4.1.2. Quality Assessment. Results of the quality assessment are presented in Tables S4-S5 in the online appendix. The most common limitations were the use of convenience sampling ($n = 4$), small samples ($n = 2$), and low response rates ($n = 1$), which impacted generalizability of findings, and secondary analysis of data ($n = 3$) which limited researchers' ability to confirm interpretation.


FIGURE 1: PRISMA illustration.

4.2. Structures Related to the Director of Nursing Role. Five structures were identified in the studies at the individual director of nursing level: years of experience ($n = 7$), level of education ($n = 5$), demonstrated leadership capabilities ($n = 4$), completed certification and/or established linkages with a professional association ($n = 2$), and completed continuing education ($n = 2$). Three structures were identified at the organizational level: physical presence of leadership across the organization ($n = 4$), job description that outlines the director of nursing's key responsibilities and expectations ($n = 3$), and salary ($n = 1$). Tables S6 and S7 in the appendix describe the structures.

4.2.1. Director of Nursing-Level Structures. Previous years of experience was shown to have the greatest effect on the director of nursing role and was the most reported structure across the studies ($n = 7$). This was reported in the form of years of experience as a registered nurse, as a director of nursing, and as a nurse leader/manager. The most commonly reported level of experience was experience as a director of nursing which was reported across six studies [15, 24, 37, 38, 40, 42]. The literature suggests that previous years of experience enhanced the director of nursing's knowledge and ability to lead in complex, unpredictable environments.

Level of education was the second most reported director of nursing structure across five studies [23, 24, 37, 41, 43]. The literature suggests that advanced education beyond a diploma or an associate degree strengthens the director of nursing's ability to strategically

plan finite resources and support the interprofessional care team based on advanced knowledge of scopes of practice [23, 43].

Demonstrated leadership capabilities were reported across four studies [3, 15, 39, 41]. Cruttenden [41] observed directors of nursing demonstrate compassion and care through their engagement and support of staff, their belief in ongoing learning, and their desire to be a role model. Siegel et al. [15] noted directors of nursing demonstrating commitment by working long hours to "make a good building" (pg. 220) and advancing their vision through negotiation and influence.

Completed additional licensing certification and/or established linkages with professional associations were reported in two studies [37, 41]. Aroian et al. [37] found directors of nursing that were licensed long-term care administrators scored higher on professional nursing and long-term care leadership than directors of nursing without licensing. In the study by Cruttenden [41], directors of nursing highlighted the importance of gerontological nursing knowledge and being visible in the community and establishing a collaborative insight to help with policy and managerial learning.

Similarly, completed continuing education that furthered professional development was also reported in two studies as helping to further develop competencies and connections [37, 42]. In the study by Aroian et al. [37], continuing education was found to be the most significant structure other than education preparation or experience to support the director of nursing performance.

4.2.2. Organizational-Level Structures. Physical presence of leadership across the organization was an organizational-level structure reported in four studies [15, 23, 38, 42]. This was expressed as the physical presence of leaders in critical roles such as the administrator, department heads, and consulting experts that collaborated with the director of nursing and provided expertise [15, 23, 38, 42].

A job description that outlines the director of nursing key responsibilities and expectations was noted in three studies to support the director of nursing [15, 23, 43]. The literature showed that despite the varied nature of the director of nursing role which, depending on the organization, focused more on either clinical or administrative duties [15, 23, 43], a clear job description made a difference to support the abilities of the director of nursing.

Finally, one study found that a higher salary was an organizational-level structure that impacted the director of nursing. Directors of nursing earning more than $60,000.00 USD were found to be more involved in organization development, professional nursing, and long-term care leadership than directors of nursing who earned less than $60,000.00 USD, who spent more time on resident care and care plans [37].

4.3. Processes Related to the Director of Nursing Role. Four processes were identified: nursing home administrator and director of nursing relationship ($n = 4$), availability of onsite continuing education opportunities targeting directors of nursing and support for continuing education ($n = 4$), cultivating relationships and enhancing networks beyond the long-term care home ($n = 3$), and orientation to the role ($n = 3$). Table S8 available in the online appendix describes process-related themes.

The nursing home administrator and director of nursing relationship was cited across four studies [3, 15, 23, 42]. A relationship built on trust, mutual respect, and collaboration was reported as integral to the director of nursing's ability to perform their role and their sense of autonomy [23]. This was described as the nursing home administrator supporting the director of nursing's continued training and professional development and engaging the director of nursing in decision-making that influences the long-term care home and organizational goals [23].

The availability of onsite continuing education opportunities targeting directors of nursing and support for continued education was a process factor found across four studies [37, 38, 41, 42]. These opportunities were described as onsite workshops, in-services, and meetings on a variety of clinical and nonclinical topics targeted for the director of nursing. Support for continued education was demonstrated through lessening barriers for participation, such as facilitating time away from responsibilities and providing financial reimbursement [37, 38, 41, 42].

Cultivating relationships and enhancing networks beyond the long-term care home setting was a process found across three studies [37, 41, 42]. This was described as a physical presence in the community, participation in meetings, and membership with associations to facilitate peer networks [37, 41]. Peers helped directors of nursing find resources in the community, addressed learning needs related to policies and human resources, and helped manage stress associated with the work environment, role responsibilities, and the regulatory process [37, 41].

Orientation to the director of nursing role was a process identified in three studies [23, 42, 43]. Furthermore, the experiences of directors of nursing that received support from parting directors of nursing, nursing home administrators, or associate directors of nursing were more successful in their transition and orientation to their role and in their overall performance than those without this support [23].

5. Discussion

To our knowledge, this is the first review to focus exclusively on the director of nursing, rather than as part of a subset of the sampled population with results describing the collective experiences of medical directors, nursing home administrators, and nonnursing leaders in long-term care. The literature examining the role of the director of nursing in long-term care describes a disconnect between the minimal qualifications required to perform the role and actual duties, responsibilities, and reach impacting their duration in the role. This review describes several modifiable structures at the organizational level and processes that may support the director of nursing in their role which can impact the high turnover of directors of nursing who are often in their roles for less than a year and those with higher levels of education leaving the role sooner [20, 21, 24, 37, 43]. For those who remain in the position longer, the literature shows that the first five years of the director of nursing role is critical. The identified structures and processes can be targeted within this timeframe to enable directors of nursing ability to effectively lead, positively influence job satisfaction, and remain in the role over time. For example, effective staff orientation during the director of nursing transitions has shown positive effects on their experiences in the role [23]. Skills and knowledge-based competencies including expertise in gerontology that increase directors of nursing confidence and enhance the effectiveness of the director of nursing leadership across long-term care homes can only develop over time.

The organizational-level structures that influence the director of nursing role were the physical presence of leaders across the organization in roles such as nursing home administrators and department directors, a clear job description that outlines roles and responsibilities, and salary. Research shows that the continual pull on the director of nursing role to take on roles and responsibilities outside of nursing may result in job dissatisfaction and further perpetuate laissez-faire or a transactional approach to leadership, with a focus on tasks and not on relationships [23, 24, 39, 43]. Hence, the presence and support of these nursing home administrators and other leaders serve as valuable support to help the director of nursing advance transformative change across the long-term care home. Additional research on the role of the director of nursing

within quality assurance and the interprofessional context, including but not limited to the role of the medical director and nurse practitioner, needs to be conducted.

Furthermore, a clear job description assists in determining education, training, certification, and competencies required for the role. It is clear from the literature that expectations of the director of nursing role vary between long-term care homes with some directors of nursing performing their roles focusing on clinical care and others focusing on staffing and responding to regulatory requirements which require leadership and managerial competencies [15, 43]. Future research is needed to determine which type of role leads to better staff and resident outcomes.

The nursing home administrator plays an integral role in the mentorship, coaching, and support of the director of nursing and the directors of nursing effectiveness in leading within the long-term care home. A strong relationship rooted in trust and respect is foundational to the director of nursing authority and decision-making ability. Fleming and Kayser-Jones [23] also recognize the power dynamics of the relationship, as the director of nursing is hired by and reports directly to the nursing home administrator, suggesting that not all directors of nursing may be comfortable with asking the nursing home administrator for support. Understanding the nuances of the nursing home administrator/director of nursing relationship and the impact this has on the director of nursing retention is another area for future research.

5.1. Strengths and Limitations. The review has several strengths. First, the search strategy included several databases and snowball searching of relevant articles. Second, the review was guided by expert researchers with advanced knowledge in the theoretical model, the integrative review process, and the long-term care home sector. A team approach was used throughout the integrative review process to enhance the quality of the review [44]. One limitation of the review is that our definition of the director of nursing required an RN to fulfill the position which is common practice in North America; however, this may have excluded articles focused on the director of nursing role held by another profession. The quality of the results is limited by the quality of the studies included, which includes a relatively small number of studies that were found to be relevant. Furthermore, not all authors reported findings equally for each of the sampled populations (e.g., nursing home administrator education was reported, but director of nursing education was not reported) [40]. Our search was also limited to electronically available peer-reviewed articles and did not include grey literature such as government reports or dissertations; as such, we may have missed examples of other supports that enhance the director of nursing performance in their role. Many of the included studies in this review had methodology weaknesses in their design, thus limiting generalizability of findings. Lastly, our review findings and implications are limited to the North American context.

6. Conclusions

The 11 articles synthesized in this integrative review present the structures and processes that support the director of nursing role in long-term care homes. The findings of this review have implications for leaders, decision-makers, practice experts, and researchers and identify specific structures and processes to focus interventions and innovations to support the director of nursing. Inadequate preparation, poor hiring practices, lack of orientation, unclear expectations, and increases in regulatory practices and stress as described across the studies can impact recruitment and retention of competent directors of nursing to the role, further perpetuating the human health resource crisis.

6.1. Implications for Nursing Management. There have been long-standing issues with the nursing leadership workforce in long-term care that have only worsened during the pandemic; this coupled with an increasing need for long-term care, concerns around quality, and a health human resource crisis made for a sector that is expected to deliver care to vulnerable populations while experiencing tremendous pressure. The director of nursing role within long-term care homes is critical to the overall operations impacting workforce stability and the delivery of quality care. Given the impact of this nursing leadership role, investment in the director of nursing role in the form of orientation, mentoring, and support for continued professional development is also an investment in the staff and the residents that call long-term care their home.

There is a global nurse shortage, and researchers have made great efforts in trying to unveil the reasons for turnover and how to increase retention. However, such research has had a tendency to study variables related to intention to leave (ITL) or turnover as isolated phenomena. *Objective*. To simultaneously explore what factors motivate experienced nurses in the workplace and the underlying reasons for strong ITL and high staff turnover within the profession. *Design*. An inductive qualitative content analysis was used based on data from open-ended survey questions. The data originated from the longitudinal analyses of nursing education/employment/entry (LANE) in work-life study. The qualitative data analyzed in this study were distributed in October 2017–January 2018, to all nurses in three cohorts corresponding to 11-, 13- and 15-year postgraduation. Of the 2,474 nurses answering the survey, 1,146 (46%) responded to one or more of the open-ended questions. *Results*. The result showed that what motivates experienced nurses, their intention to leave (ITL), and reasons for turnover could be described in the form of five broad categories, namely, organizational characteristics, work characteristics, relationships at work, work recognition, and health issues. There was rarely a one single reason described, rather several reasons needed to be experienced over time for nurses to stay motivated or leave the profession. *Conclusions*. There is no single reason that makes nurses leave the profession, nor is there one single reason that makes them motivated to stay. Retention and turnover are complex processes and need to be addressed as this, not as a single isolated phenomenon.

1. Introduction

Nursing is defined by autonomous as well as collaborative care with the aim of preventing illness and nursing sick, injured, disabled, or dying people of all ages. Moreover, nursing encompasses caring and advocating for families and loved ones, shaping healthcare policy, management, education, and research [1, 2]. Since the start of the COVID-19 pandemic in 2020, the vital role nurses play in society and healthcare systems worldwide has become more evident than ever before [3]. Today, nurses make up over half of all healthcare professionals and are often the first, and sometimes the only healthcare professional a patient will meet,

which further highlights the significance of nurses in the healthcare sector [4–6].

Nurses perform a plethora of tasks and care for people in a multitude of healthcare settings, often shouldering a high workload and working long hours [7]. During the last decade, increased staff turnover among nurses has led to a global needs-based shortage of nurses [6, 8]. Global efforts have been made to increase the number of nurses, including various local retention strategies [9, 10] and increasing the number of places in nursing programmes. Despite these efforts, the World Health Organization (WHO) forecasts a shortfall of almost 6 million nurses by the year of 2030 and emphasises the importance of retaining experienced nurses

in the workforce [6]. For some time now, researchers have made great efforts to try to understand the reasons why nurses leave the profession.

Studies looking at why nurses leave the profession often focus on intention to leave (ITL) or the underlying reasons for staff turnover [8, 11]. ITL is clearly a complex issue triggered by organisational factors, such as the work environment, leadership, staffing levels, and the state of working relationships [12, 13], as well as individual factors such as stress, burnout, and a sense that the work nurses perform is not valued [13, 14]. Earlier studies have revealed that turnover is driven by management style, highlighting a lack of good visible leaders, high workload, stress, disempowerment, and/or lack of autonomy [8, 15]. Previous research has shown that the final decision of nurses to leave the profession (turnover) is often proceeded by a lengthy period of consideration, or ITL [16]. It therefore seems unviable to study these variables independently.

One way to understand retention and/or turnover is Herzberg's two-factor theory, which relates job satisfaction/dissatisfaction to motivation [17]. According to the theory, there are two dimensions to job satisfaction: hygiene and motivation. Hygiene factors are essential to maintain a pleasant workplace, and their absence will lead to dissatisfaction; meanwhile, motivation factors can create satisfaction by fulfilling the employee's needs for personal growth and a sense of meaning [18]. In the context of nursing, hygiene factors include a manageable workload, sufficient staffing levels, and reasonable salary and benefits, while motivators include a diversity of tasks, stimulating responsibilities, and seeing patients recover [19, 20]. Although the two-factor theory has proved useful in exploring job satisfaction and retention in nursing, it has also been found that, when describing their motivators, nurses contradict the basic tenets of the theory [19]. This suggests that further research on motivation may be beneficial in terms of understanding retention.

Given the global shortage of nurses and the general high level of work-life stress in the nursing profession, there is every reason to increase our understanding of all aspects that influence nurses to remain in or leave the profession. Rather than seeking to understand motivation, ITL, or turnover as isolated phenomena, this study aims to simultaneously explore what factors motivate experienced nurses in the workplace and the underlying reasons for strong ITL and high staff turnover within the profession. This approach may help further understand both the turnover and retention of nurses.

2. Materials and Methods

The data used here originate from the longitudinal analysis of nursing education (LANE) study [21]. The LANE study is a prospective national study in which three Swedish national cohorts (2002, 2004, and 2006) of nurses were repeatedly surveyed early in their career, with a follow-up 11–15 years after graduation. The qualitative data analyzed in this study were collected through open-ended questions in a survey distributed between October 2017 and January 2018 to all nurses in the three cohorts, i.e., 11, 13, and 15 years after graduation.

2.1. Sample. Of the 2,474 nurses answering the survey, 1,146 (46%) responded to one or more open-ended questions and thus constituted the sample for this study.

2.2. Data Collection. Initially, all nursing students enrolled at the 26 Swedish universities offering nursing programmes graduating in the autumn of 2002, 2004, and 2006 were invited to participate in the LANE study. A total of 4,316 graduates consented to participate when invited, and 4,002 were still eligible for participation when the long-term follow-up (11–15 years after graduation) was conducted in 2017. The response rate at the long-term follow-up was 62% (2,474). Data used in this study were collected from three open-ended questions included in the long-term follow-up questionnaire. The three questions addressed (a) engagement and motivation, (b) ITL, and (c) reasons for leaving the profession. The open-ended questions and the number of answers in the form of written comments to each question are presented in Table 1. In total, 1,146 participants gave 1,542 answers to the questions (29 participants answered all three questions, 338 answered two questions, and 779 answered one question).

2.3. Data Analysis. The analysis process followed the inductive qualitative content analysis framework presented by Graneheim and Lundman [22]. The written comments to the three questions (Table 1) constituted the unit of analysis and were initially treated as three subject areas: professional work motivation, why nurses intend to leave, and why nurses have left the profession/turnover. All the written comments were scanned and digitally transferred to the data analysis program NVivo [23]. The primary responsibility for analysing different subject areas was shared among the researchers. CG and MSN analysed the text about motivation, while AH and AR analysed the text related to ITL and turnover, all following the analytical steps outlined below. In the first step, the written comments were read and meaning units—the relevant text for the purpose of the study—were identified. In the second step, the meaning units were coded. Coding involved labelling the meaning units with a descriptive word close to the original text [24]. In the third step, the codes were abstracted and sorted into subcategories. These three steps were followed by a comparison of the two research groups' preliminary results. The purpose of this comparison was to identify similarities and differences related to the three subject areas. During this process, the labelling and definition of five categories could be completed (Table 2). Finally, each category could be described based on what emerged in all three subject areas.

2.4. Ethical Considerations. Approval for the study was received from the Regional Research Ethics Committee at Karolinska Institutet, Stockholm, Sweden (ref. no. 01–045), and the Regional Ethics Review Board in Stockholm, Sweden

TABLE 1: The open-ended questions from the LANE survey and the number of answers in the form of written comments to each question (total number of comments 1,542).

Areas	Question in survey	Number of comments
Professional work motivation	"If you have something else you would like to say about yourself or the study, you are welcome to write it here. Of particular interest are your views and experiences regarding what factors do you consider to be crucial for being engaged and motivated in the work in the long-term?"	807
Intention to leave the profession	"If you are thinking about leaving the profession—please state why below." The open-ended question was preceded by three closed-ended questions on intention to leave the nursing profession including thoughts about leaving and leaving behaviour (i.e., 1. I think a lot about leaving the profession, 2. I am actively looking for another job outside the nursing profession, and 3. I will leave the nursing profession as soon as possible)	542
Exit: having left the profession	"If you have chosen to leave the profession as a nurse/specialist nurse/midwife/other specialization, - if possible, please state why below."	193

TABLE 2: Example of the analysis process and verbatim quotes to each subcategory.

	Meaning unit	Code	Subcategory	Category
Motivation	Having some say over daily working hours, duties and long-term shift arrangements is an important motivator	Ability to control working hours	Influence over working hours	Organization characteristics
ITL	The desire for a job that does not require that almost all off-duty time be used for recovery. A job without weekend or night shifts that allows me to spend weekends and holidays with my family and friends	Call for work that enables private and family life	Working hours affect private and family life	Organization characteristics
Turnover	I was no longer able to cope with constantly changing working hours and shifts, the sense that I never had time to get everything done, to do the job I was supposed to be doing	Unsustainable scheduling	Difficulty to combine work with private life	Organization characteristics
Motivation	That, as a nurse, you have the time and opportunity to develop knowledge and skills. A career ladder: which paths and opportunities are open to me? A good salary. Responsive managers that take matters seriously	Opportunities for professional development in nursing	Development and challenges	Work characteristics
ITL	Nursing is a demanding and responsible career that can be burdensome at times. Even at home, it can be difficult to stop thinking about work	Demanding and distressing work	Emotional and physically distressing work	Work characteristics
Turnover	There is no time to be the nurse I want to be. Sometimes I am completely drained after having responsibility for almost 50 patients	No chances to perform the care I believe in	No opportunity for nursing care	Work characteristics
Motivation	The most important factor for engendering commitment and motivation is a pleasant work climate: understanding and helpful colleagues, and a manager who is responsive, fair, sympathetic, humble and capable of leading the team	Pleasant work climate	Well-functioning team collaboration	Relationships at work
ITL	Does not enjoy the job because of the high workload and poor climate between colleagues, and between colleagues and management	Bad collegial climate	Lack of teamwork	Relationships at work
Turnover	I had no possibilities to influence my work situation and the work environment was too hierarchical	Hierarchies in healthcare	Hierarchical collegial structure	Relationships at work
Motivation	I consider appreciation of the work one does to be vital to wellbeing. The most important factor is an adequate salary. This is why I have worked as a travel nurse for the last two and a half years. This provides me with a good salary. I can influence my own working hours and I am appreciated at work every day	Good and fair salary	Fair salary	Recognition
ITL	In my current workplace, there is little possibility to affect my salary even if I continuously develop my competence and take on greater responsibility	Little opportunity to affect salary	No influence on the salary	Recognition
Turnover	The working hours and high workload cause ill health. I no longer wish to work for the regional health authority because of the poor pay and dreadful salary development	Poor pay and salary development	Not the right salary for the job performed	Recognition
Motivation	—	—	—	—
ITL	The stress of my job affects me physically. I don't want to become ill with stress. I would like to have a job without responsibility for other people's health. The responsibility is too great	Worries about the own health	Fear of developing health issues	Health issues
Turnover	Stress and the dreadful working conditions, with such weak leadership, made me ill [. . .]. I didn't see how I could ever be well as long as I remained in the profession	Didn't think I could stay and get well	Health negatively affected	Health issues

(ref. no. 04–587 and ref. no. 2016/793–32). All respondents in the study gave informed consent to participation. A cover letter emphasising the voluntary nature of participation and the option to terminate participation in the study at any time was attached to the survey, as was information on how to contact the research team. All participants gave informed consent.

3. Results and Discussion

Among the respondents, 1,035 (90%) were female, and the age distribution was as follows: 504 (44%) were younger than 39 years, 391 (34%) were aged 40–49 years, and 251 (22%) were older than 50 years. It had been between 11 and 15 years since they graduated from nursing education. In addition, 57% of the respondents had received specialist nurse education, and they worked across various sectors of the healthcare system, including inpatient care, outpatient care, home care, prehospital ambulance care, research, and management.

The result showed that what motivates experienced nurses, what sparks their ITL, and reasons for high turnover could be divided into five broad categories: organisational characteristics, work characteristics, relationships at work, work recognition, and health issues (Figure 1). The three subject areas motivation, ITL, and turnover are illustrated horizontally, and descriptions of the categories and subcategories within each of the three subject areas are illustrated vertically.

It was rare for a single motivator or underlying cause for ITL or turnover to be stated. Motivation often seemed to be linked to several accumulating factors. Similarly, a combination of reasons was often stated by nurses who either intended to leave or had already left the profession. Although the content of the categories interacts in the interests of clarity, the categories will be described separately. Verbatim quotes related to each subcategory can be found in Table 2.

3.1. Organisational characteristics

3.1.1. Motivation. Nurses were motivated when the organisation clearly defined roles, goals, and tasks. Another motivator was when management offered employees opportunities to influence routines and work schedules. This was particularly true of scheduling working hours, which enabled nurses to better plan their personal lives and achieve work-life balance, both between shifts and when not scheduled to work. A manager's ability to translate overarching organisational objectives into tangible and specific daily goals was also an important motivator. Those who could do this and reorganise work when workloads became excessive and ensure adequate staffing were described as responsible managers.

3.1.2. ITL. Organisational characteristics could also be found in data regarding why nurses often thought about leaving the profession. These included working hours, the difficulty of combining work with family or personal life, lack of time for recovery, and frustration with management and the organisation of work. The nurses also described a lack of organisational resources, including inadequate staffing levels. The results of the analysis also revealed that nurses who felt unable to influence their work often considered leaving the profession.

3.1.3. Turnover. Among the organisational characteristics referred to by the nurses who had left the profession were poor leadership, lack of influence, and inadequate staffing levels. These nurses described a lack of leadership and a lack of trust in their immediate manager, as well as discontent with constant reorganisation. Excessive administrative demands and a high nurse-to-patient ratio were described as draining. The decision to leave was also made due to demanding working hours that precluded a healthy work-life balance. More specifically, a schedule with too many short turnarounds with inadequate rest, too many shifts in a month, or excessive overtime were stated as the reasons for high staff turnover, as was a lack of foresight regarding holidays and scheduling that made it impossible to combine work with family life.

3.2. Work Characteristics

3.2.1. Motivation. Work characteristics described as motivational included being able to nurse based on a humanistic approach and in line with the nurse's own personal values. This was described as a matter of considering and protecting the patient's dignity and integrity throughout the care situation. Another motivational factor was being afforded a large measure of professional autonomy. Autonomy was described as the opposite of when tasks were controlled in detail by others. Nursing was also considered motivational when the nurse was able to take responsibility, both individually and as a member of a team, for achieving operational goals, developing nursing, and providing high-quality, evidence-based care. Continuing professional and personal development was also a motivator.

3.2.2. ITL. Nurses with intention to leave the profession also highlighted specific work characteristics. Several nurses described their duties as not being in line with nursing ethics and values. The issue of patient safety was raised, such as when managers and nurses had different thresholds for when patient care could be considered safe. They highlighted moral distress experienced when unable to meet the personal needs of patients and their loved ones by providing high-quality care. Work factors were described as emotionally and physically demanding; caring for the sick had begun to drain them. They also noted that the nature of their work left no opportunity for desired personal and professional development. Nurses described changing job or profession as one way of acquiring this sought-after development.

Subject area	Motivation	Intention to leave	Turnover
Category **Subcategories**	**Organisational characteristics** Clearly formulated goals and tasks Influence over working hours Flexibility in life (e.g., family) Responsive managers Adequate staffing	**Organisational characteristics** Working hours affect private and family life Frustration about organizational changes and the management Lack of sufficient organizational resources Little opportunity to influence work and working hours	**Organisational characteristics** Lack of leadership Too much administration Too high patient/nurse ratio Inconvenient working hours Lack of influence on working conditions Impossible to combine work with private life
Category **Subcategories**	**Work characteristics** Humanistic work approach Shared values Work content aligned to nursing ethics and values Personal responsibility Evidence based work Development and challenges	**Work characteristics** Not shared values about patient safety and care Emotional and physically distressing work Tired of the sick Sees no professional development Looking for new personal challenges	**Work characteristics** Emotionally and socially distressing work No opportunity for nursing care Unused competence Lack of professional development Looking for personal development
Category **Subcategories**	**Relationships at work** Well-functioning team collaboration Qualified, competent and supportive colleagues Humor at the workplace Safe collegial climate Being part of a work community	**Relationships at work** Frustration with colleagues Lack of teamwork	**Relationships at work** Hierarchical collegial structure
Category **Subcategories**	**Recognition** Fair salary Salary development in relation to competence and responsibility Societal recognition Respectful feedback from manager, colleagues and patients	**Recognition** Unfair salary in relation to working hours, work performed and education No influence on the salary Unsatisfactory salary development The profession is not recognized	**Recognition** Not the right salary for the job performed No salary development Lack of recognition from managers
Category **Subcategories**		**Health issues** Deteriorating health Emotionally exhausted Insomnia Fear of developing health issues	**Health issues** Developed a work-related illness Health negatively affected

Figure 1: Illustration of the result including subject areas (horizontal), categories, and subcategories (vertical).

3.2.3. Turnover. Nurses who had left the profession described the job as unsustainable by nature due to the weight of emotional and ethical distress. They also stated that there was too little focus on patient safety and providing high-quality nursing care. One major reason for turnover was the perception that caring had "disappeared" from nursing, their competence as nurses was not being utilised, and they were therefore unable to provide patients with high-quality care. Nurses who had left the profession also stated that there was little opportunity for professional development and that they wanted to develop both personally and professionally.

3.3. Relationships at Work

3.3.1. Motivation. Good relationships and well-functioning teamwork among competent, qualified, and supportive colleagues were stated as important motivational factors. A supportive, collegial climate was also described as facilitating continuous learning and development and thus as particularly motivational. The important qualities in a relationship included being able to express one's thoughts, feelings, and opinions freely and to share laughter with colleagues even when work was stressful or emotionally taxing. A safe, tolerant, and inclusive collegial climate that provided a sense of belonging was also a motivation. It was also considered

important that equality should be an accepted part of the work community.

3.3.2. ITL. Frustration with collegial relationships was mentioned as one reason why nurses often thought about leaving the nursing profession. That said, these comments consisted of short statements that lacked further detailed information. Although brief, many comments concerned a lack of teamwork and a lack of trust and collaboration with the colleagues closest to the respondents.

3.3.3. Turnover. Nurses who had left the profession mentioned the professional hierarchy as a reason. One cause of hierarchical tension was when the nurse believed that they were considered to be doing no more than following orders given by doctors.

3.4. Recognition

3.4.1. Motivation. Recognition is clearly important for sustaining motivation at work, including in terms of being paid a reasonable living wage. The factors that nurses included in the definition of a reasonable wage included individual salary setting, as well as the profession's salary level. It was considered motivating when the salary was set fairly

taking into account individual performance and hard work, unsociable working hours, competence, and training. Remuneration for additional responsibilities or developing work on the ward was perceived as having a motivational effect. Moreover, a salary commensurate with the important societal function of the nursing profession was seen as important to sustaining motivation. It was also considered motivational when, in addition to any personal recognition nurses might receive, the significance of nursing as a profession was acknowledged at governmental and societal levels. For example, nurses described themselves as motivated when political decisions concerning the organisation of healthcare including the nursing perspective, or when the mass media covered the work of nurses in an insightful way. Recognition at a personal level was described in terms of nurses being treated with respect, receiving positive feedback, and feeling appreciated by patients, colleagues, or management.

3.4.2. ITL. One frequently stated reason why nurses often thought about leaving the profession was a lack of recognition, particularly in terms of salary. Salary was described as unfair in relation to the workload, commitment, unsociable working hours, and short shift turnaround. Furthermore, when the salary was not perceived as compensating for the price nurses pay in terms of their family and personal life, they began to consider leaving the profession. There were descriptions of salaries not rising despite efforts such as further education, taking on extra assignments, or showing commitment. Aside from salary, lack of recognition from colleagues, patients, managers, and society was also mentioned as the reason to consider leaving the profession.

3.4.3. Turnover. In terms of recognition, the nurses who had left the profession did name the lack of a fair salary, salary development, or recognition from managers as a reason for leaving the profession.

3.5. Health Issues. The fifth category, health issues, was represented in two of the subject areas (ITL and turnover).

3.5.1. ITL. Common reasons behind ITL were deteriorating health, emotional exhaustion, and/or insomnia. Some nurses who often thought about leaving stated that, although their health had not yet been affected, they were afraid that their health would suffer if they continued working in nursing.

3.5.2. Turnover. Stress, insomnia, and fatigue were described as contributing factors to deteriorating health and a reason for leaving. From some of the comments, it was clear that, while the nurses themselves did not want to leave the profession, they felt that this was the only way to take control of their health and sustain a personal life.

4. Discussion

To the best of our knowledge, this is the first study to simultaneously explore motivation, ITL, and turnover in the context of nursing. The current view of staff turnover in nursing is that it is the result of a negative spiral that ultimately ends with nurses abandoning the profession [25], hence Selberg and Mulinari's [25] concept of turnover contagion; one nurse's decision to leave a failing clinic prompts other nurses to follow suit. In other words, "quitting leads to quitting" (p.96). By addressing all four areas in which, according to the result of this study, there seems to be an interrelation between motivation, ITL, and turnover, we may be able to not only halt a negative spiral but also increase motivation and, in the long term, wellbeing in the workplace.

Taken together, the five categories—organisational characteristics, work characteristics, relationships at work, recognition, and health issues—are crucial for sustaining motivation and avoiding staff turnover. This study reveals that while organisational characteristics can be highly motivating, they can also be the underlying causes of ITL and staff turnover. Judging by the result of this study, organisational characteristics can motivate nurses even when involving a high level of responsibility and challenge; however, this is highly dependent on management and leadership. This is in line with the previous research showing that nursing leadership plays a vital role in creating healthy work environments and manageable workloads [12, 26, 27]. Nurses in leadership positions also play an important role in ensuring that their fellow nurses have control over their work and shifts and have sufficient time for recovery [28, 29], as well as authorising work schedules that take account of the individual nurse's life situation [26, 30]. The organisational characteristics category clearly showed the underlying problems in terms of affording nurses the possibility to influence their own work and working hours and to recover between shifts. Furthermore, the result of this study clearly shows that nurses that are unable to achieve a healthy work-life balance find it difficult to sustain motivation and remain in the profession.

In the category work characteristics, nurses stated that meeting and caring for patients were highly motivational, thus revealing a true passion for the profession of nursing. Even among those who intended to leave or had left, there was clearly a strong wish to continue nursing; however, according to their accounts, the situation made it impossible to provide care in a manner consistent with their professional values. Also, in the category of work characteristics, nurses who had left the profession gave emotional distress as one of the reasons for doing so. Nursing is clearly demanding work, and the negative impact of emotional stress on the wellbeing of nurses has been thrown into stark relief by the COVID-19 pandemic [3, 5]. It could be argued that the stress that nurses experience is inherent to the profession, given the highly unpredictable nature of the job and the unsociable working hours nurses must work in order to provide healthcare around the clock. To make such demanding work characteristics motivational, and so that nurses can thrive in their jobs, the emphasis should be on providing adequate resources and individual control over their work [31]. Toode et al. [30] underline that even a more intense workload may be motivating when it leads to an

increased sense of professional accomplishment, career opportunities, or professional development. This reasoning is in line with the findings of another Swedish study conducted by Gadolin et al. [32], which showed that when nurses perceived that their contribution was valued and their wellbeing was being safeguarded, they could focus on their main task of providing care.

Furthermore, Gadolin's results [32] reveal the importance of validating nurses' sense of competency and utilising their competence in the role of nurse. The results of our study also show that when nurses perceived their nursing competence to be valued and appropriately utilised by the organisation, it positively influenced their working experience. One core characteristic of nursing has been said to be that of "caring about" patients and their loved ones by providing psychosocial support, compassion, and sympathy [33]. At the same time, paradoxically and partly contrary to these earlier studies, our study shows that nurses did not feel that their competence was being fully utilised; in other words, there is a discrepancy between what nurses have the ability to do and what they were permitted to do. It has been argued that the lingering and obsolete traditionalist view of nurses as being merely the physician's assistant continues to play down and negatively affect the expertise of nursing practice [34]. In the relationships at work category of this study, these views were described in terms of hierarchical collegial relationships and as one reason for turnover. More and more noncaring tasks, such as cleaning and administration, have also been described as stealing valuable time away from caring [33]. Incongruity between the nurse's professional values and competence and tasks they are expected to perform may leave them caught in-between and faced with ethical dilemmas [35].

The category relationships at work also highlight how important relationships in the workplace and being able to rely on the competence of colleagues are to motivation and remaining in the profession. Management in workplaces perceived as healthy organisations is described as creating a culture of openness, respect, fairness, and justice [36]. Coomber and Louise Barriball [37] describe poor relationships with colleagues as one of the most significant factors behind work-related stress, leading to ITL and turnover. The social aspects of the workplace, such as being able to share and discuss opinions and concerns about patient care with colleagues, have been found to be associated with empowerment, thus reducing the likelihood of nurses leaving the profession [12]. Furthermore, good collaboration, social support, and positive team spirit on a ward where nurses are treated as equally valued healthcare professionals has been highlighted as important motivators [30]. Although interpersonal relationships are presented as hygiene factors in Hertzberg's two-factor theory [18], the result of our study, in line with prior research [19, 30], concludes that nurses describe good collegial relationships as motivational factors that contribute to job satisfaction and motivation for retention. Gadolin et al. [32] recently demonstrated that sound relationships with colleagues are vital if nurses are to feel supported by the organisation,

which in turn is associated with a variety of favourable outcomes such as greater commitment and improved wellbeing [38]. It is also a prerequisite if quality improvement work in healthcare is to succeed [39]. So, the results of this study support previous studies in underlining the importance of collegiality in healthcare.

The results of the present study further highlight the importance of recognition to the work of nurses, and this was emphasised in all subject areas. One of the key aspects of recognition is a fair and adequate salary, and the study shows that nurses' salaries are frequently perceived as both unfair and inadequate. According to the findings in the review by Coomber and Louise Barriball [37], one often-stated concern regarding nurses' salaries was the perceived inequity of pay given the high level of knowledge, responsibility, and workload compared to "less qualified professions." Experienced nurses also felt that their level of experience was not recognised as important [37]. Recognition of such factors, or lack thereof, in a nurse's pay packet can either be a motivator or lead to ITL and staff turnover. Again, the result of this study contrasts Hertzberg's two-factor theory [18] as salary and monetary compensation are hygiene factors. The result of the present study indicates that recognition in terms of a fair salary can be motivation factors as it signals that nurses are recognized as important. That said, it is important to emphasise that, in line with prior research, this study demonstrates that while salary was often stated as one reason for ITL or leaving the profession, it was rarely the sole source of discontent; nurses also demanded other forms of recognition [12].

Although health issues were only raised in two subject areas, they were described as a major obstacle to remain in the profession, prompting ITL and departures. This confirms the results of an earlier quantitative study showing that early-career burnout left nurses feeling disengaged and exhausted at work, leading to higher [14] and escalating levels of intention to leave the profession [40]. Moreover, there were increasing symptoms of burnout, while undergraduates predicted nurses' ITL and turnover after graduation [41]. Interestingly, this qualitative study based on nurses' own words raises similar issues regarding fear of or actual deteriorating health. It is clear that, while health was not considered a motivational factor at work, the deleterious effects of the job on health were considered too high a price to pay for remaining in the profession. Hence, employers taking preventive measures that detect the early signs of burnout in order to reduce staff turnover is important.

4.1. Limitations. Among respondents who stated that they had left the nursing profession, some had moved on to other roles in healthcare such as university teachers, ward managers, or working with healthcare development. As these are vocations in which Sweden clearly needs nursing competence, one must question why these nursing graduates felt that they had left the profession. Further research is needed to investigate whether nurses themselves see a distinction between leaving the profession and carving out a career elsewhere in healthcare, such as in academia or

management: is remaining "in the profession" solely associated with clinical practice?

In this study, data quality did not allow for coding of the "underlying" meaning (i.e., it was not considered possible to derive any themes). Therefore, the analysis resulted in a descriptive manifest level of the data [24]. The quality of data varied from concise answers to more expansive descriptions. At times, it was problematic to separate mutually exclusive categories, and the right level of abstraction was sometimes hard to determine. This was partly due to the interconnectedness of content, i.e., descriptions of a series of events that all affected one another. For example, working in a context in which it feels possible to provide high-quality care to patients is a prerequisite for feeling both that one is working effectively and that one is supported by the organisation, and various organisational aspects might explain why nurses felt that they had no time for recovery.

Being aware of potential errors in the coding process, the authors checked and discussed coding precision during the analysis. As the units of analysis provided insight into experiences of work motivation, ITL, and departures from the nursing profession without direct interaction between the researchers and informants, interviewer bias could be avoided [42]. One obvious limitation was the lack of opportunity to ask follow-up questions to deepen contextual understanding. Another disadvantage was the absence of information from nurses who did not answer the open-ended questions. That said, postal surveys can be assumed to exert minimum pressure on respondents to give 'socially acceptable' responses. So, it may have been easier for some groups to respond—for example, those with critical opinions, those who are more reticent or nurses on sick leave—and harder for others, such as nurses with reading and writing difficulties. The strength of the study was the large national sample with a wide range of experience gained in many parts of the healthcare sector, which improved the prospects of shedding light on a range of experiences relating to work motivation and turnover. The transferability of results is restricted by the fact that this is a "self-selected" subsample within the LANE study. However, by representing a subsample of the larger national LANE study, the context of the sample was well defined [21] and represents 46% of the nurses in the LANE study cohorts.

5. Conclusions

Although motivation, intention to leave the profession, and turnover are complex phenomena influenced by multiple factors, by exploring them together, it was possible to identify important clues as to how the profession might retain more experienced nurses. Based on the results of this study, we conclude that ensuring that nurses have a manageable workload, that they have autonomy, that their competence is utilised, and that they enjoy adequate support from management will go some way to addressing the forecast shortage of nurses, by promoting the wellbeing of and motivating experienced nurses and decreasing staff turnover. Furthermore, according to nurses with over ten years of professional practice, a sustainable working life is

dependent on collegiality, being able to work in competent teams, and being afforded multiple career opportunities. When deciding whether to remain in or leave the profession, recognition of the demands of the profession and individual knowledge and skills in the form of a fair and reasonable salary are considered key factors. The result of this study also indicates that what may be considered hygiene factors in some contexts may function as motivation factors in nursing. Finally, the study makes clear that an organisation must be alert to and able to address the early signs of work-related ill health in its employees if it is to mitigate ITL and staff turnover.

Data Availability

Data obtained for the study will not be accessible to others due to survey respondents being assured raw data would remain confidential.

Conflicts of Interest

The authors declare that they have no conflicts of interest regarding the publication of this paper.

Research Article

Exploring the Associations between Chronotype, Night Shift Work Schedule, Quality of Work Life, and Sleep Quality among Maternal and Child Health Nurses: A Multicentre Cross-Sectional Study

Aim. To examine the state of sleep quality among maternal and child health (MCH) nurses and explore the associations between chronotype, night shift work schedule, quality of work life, and sleep quality among MCH nurses. *Background*. MCH nurses, who play an important role in protecting the health of women and children, often experience poor sleep quality. However, research on the sleep quality of MCH nurses has been scarce following implementation of the three-child policy in China. *Methods*. A multicentre cross-sectional study was conducted with 1426 MCH nurses. Data were collected using a demographic questionnaire, participants' self-reported chronotype, the Pittsburgh Sleep Quality Index, and the Work-Related Quality of Life-2 scale. A chi-squared test, independent samples *t*-test, Pearson correlation test, and binary logistic regression analysis were used to analyse the data. *Results*. Of the 1426 respondents, 57.9% reported poor sleep quality. Binary logistic regression analysis indicated that chronotype, including intermediate-morning, intermediate-evening, and evening (reference: morning), and quality of work life, including stress at work, control at work, and general well-being, had effects on sleep quality among MCH nurses. Older age, frequent caffeine intake, and irregular meals were also associated with poor sleep quality. However, night shift work schedule did not affect sleep quality in the adjusted model. *Conclusions*. Poor sleep quality was common among MCH nurses. The findings of this study also illustrate that chronotype and quality of work life are closely related to sleep quality. *Implications for Nursing Management*. Nursing managers should be aware of MCH nurses' chronotype and quality of work life and tailor interventions to address both modifiable and nonmodifiable factors associated with sleep to improve MCH nurses' sleep quality.

1. Background

The health of women and children is an important global concern and an indicator of people's health on a national level [1]. According to the People's Republic of China's National Health Commission, in 2022, China's maternal mortality ratio had dropped to 15.7 deaths per 100,000 people, while infant mortality had dropped to 4.9 deaths per 1000 people [2], owing to the efforts of maternal and child health (MCH) workers [3]. As the largest professional group

of MCH workers, MCH nurses play a vital role in safeguarding the health of women and children. Women and children are generally considered a vulnerable population. Physically, women require specialised care because of pregnancy and the possibility of gynaecological disorders [1]. Children require extra care and attention because they are immature and less able than adults to adapt to their surroundings [4]. Psychologically, women and children are susceptible to social and family pressures and have complex psychological needs that require care and comfort [5, 6].

Therefore, MCH nurses need compassion, concentration, and expertise in their work to meet the needs of these special groups and provide the best possible nursing care. Furthermore, children are prone to emergencies at night due to their young age and frailty [7], and nighttime births are highly likely [8]; therefore, MCH nurses need to be alert and provide constant observation and care during night shifts. The nighttime environment and work intensity can negatively affect MCH nurses' sleep quality. Furthermore, China's "three-child" policy has led to increasing rates of pregnancies in women of advanced reproductive age or repeated caesarean deliveries [9], exacerbating the shortage of MCH nurses. Based on these conditions, MCH nurses in China may bear the burden of increased workloads, resulting in poor sleep quality. Therefore, nursing managers should pay close attention to this issue.

Sleep quality is a crucial health indicator, reflecting self-perceived levels of satisfaction with sleep [10]. However, people are increasingly reporting complaints of poor sleep quality and its negative impact on daytime functioning [11]. Poor sleep poses numerous risks to individual health, including cognitive impairment, chronic fatigue, metabolic syndrome, cardiovascular disease, and hormonal disease [12–14]. Poor sleep has become a widespread issue among medical staff. Over half of nurses and midwives have reported severe or very severe daytime dysfunction [15]. Moreover, research has shown that between 32.18 and 64.5% of MCH nurses experience poor sleep [16–18], which is associated with increased rates of burnout (59.71%) and health-risk stress (54.3%) [19, 20]. Furthermore, poor sleep can affect the of MCH nurses' professional performance and increase their risk of errors and accidents, which can cause patients to feel frustrated and uncomfortable [21, 22]. Higher staff turnover caused by sleep problems negatively affects the functioning of MCH hospitals, which can directly and indirectly affect the health of women and children. In addition, research shows that sleep quality is closely associated with physical, psychological, environmental, occupational, social, and behavioural factors [23, 24]. Dissonance between an individual's chronotype and shift work schedules may be the mechanism responsible for poor sleep. Quality of work life may also affect the occurrence of sleep issues because it is a multidimensional definition that reflects well-being and quality of life in the workplace. Work-related factors, such as shift work schedules, are arranged by nursing administrative staff and deserve further exploration. Previous research has also noted the impact of work schedules involving 16-hour night shifts, 12.5-hour night shifts, and three-shift rotations on sleep quality in Japan [25]. However, the prevalence of poor sleep among MCH nurses remains unclear. No extensive research has been conducted on whether chronotype, night shift work schedule, and quality of work life affect sleep quality. In response to these gaps in the literature, this study aimed to investigate the associations between chronotype, night shift work schedule, and quality of work life with sleep quality among MCH nurses.

2. Materials and Methods

2.1. Setting and Sampling. This study used a cross-sectional survey and followed the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) guidelines. The sample size was estimated using the single population proportion formula: $N = (Z\alpha/2)^2 \times p(1-p)/d^2$. According to a meta-analysis, the prevalence of poor sleep among Chinese nurses is 49.9% [26]. Given this criterion ($\alpha = 0.05$; $d = 0.03$), 1068 participants were required. We ultimately decided on a minimum sample size of 1187 after considering a 10% nonresponse rate. The following inclusion criteria were used: MCH nurses who have (a) obtained professional qualification certificates and (b) agreed to participate in the study. The exclusion criteria were as follows: (a) retired nurses, refresher nurses, and student nurses; (b) less than 6 months of work experience; and (c) missing more than one month of work due to illness, marriage, maternity, or other personal matters. Cluster sampling was used to recruit the study participants. Based on the annual reported number of nurses in the province, four MCH hospitals were required to meet the sample size requirements. First, convenience sampling was used to select four MCH hospitals in Fujian province. Second, all MCH nurses working at those hospitals who met the inclusion and exclusion criteria were recruited for the study between December 2022 and January 2023.

2.2. Measures

2.2.1. Demographic Questionnaire. A demographic questionnaire was designed by the researchers based on a literature review. Personal variables included age, height, weight, sex, educational level, marital status, number of children, duration of mobile phone use before bedtime, frequency of irregular meals, frequency of caffeine intake, frequency of sugar intake, and physical activity. Physical activity was assessed using the short version of the International Physical Activity Questionnaire (IPAQ-SF). The Chinese version of the IPAQ-SF has been validated among Chinese university students [27] and measures the intensity, frequency, and duration of physical activity over the last seven days. According to the guidelines for data processing and analysis of the IPAQ [28], participants' physical activity levels were categorized into three groups: low, moderate, and high.

Work-related variables included personal monthly income, department, professional rank, employment type, and night shift work schedule. Participants' night shift work schedules were classified as non-night shift, forward-rotating night shift (i.e., evening shift between 16:00 and 24:00 h and night shift between 00:00 and 08:00 h the next day), backward-rotating night shift (i.e., night shift between 00:00 and 08:00 h and evening shift between 16:00 and 24:00 h the next day), and 12-hour rotating night shift (i.e., night shift between 20:00 and 08:00 h).

2.2.2. Self-Reported Chronotype. Chronotype reflects an individual's preferred time of day for an activity/rest cycle. Chronotypes were assessed using a subjective question

asking participants to self-classify themselves by chronotype. Individuals were classified according to the following chronotypes: morning ("definitely morning person"), intermediate-morning ("more a morning than an evening person"), intermediate-evening ("more an evening than a morning person"), and evening ("definitely evening"). Self-reported chronotypes have been validated using self-reported sleep-wake times [29].

2.2.3. The Pittsburgh Sleep Quality Index (PSQI). The PSQI is a 19-item self-report instrument that measures sleep quality during the last month [30]. The PSQI consists of seven components: subjective sleep quality, sleep latency, sleep duration, sleep efficiency, sleep disturbance, sleep medication, and daytime dysfunction. Each component included one or more items scored on a scale ranging between 0 and 3 points, where 0 indicated "normal", 1 indicated "mild dysfunction", 2 indicated "moderate dysfunction", and 3 indicated "severe dysfunction". The scores of the seven components were summed to obtain a global score ranging between 0 and 21, with higher scores indicating poorer sleep quality. The Chinese version of the PSQI demonstrates good overall reliability ($r = 0.82$–0.83) and test-retest reliability ($r = 0.77$–0.85) [31]. In addition, a cutoff point of seven could effectively differentiate between good and poor sleep quality in the Chinese population [32]. Therefore, the poor sleep group was defined as participants with a PSQI total score >7, while the good sleep group was defined as participants with a PSQI total score ≤7. In this study, Cronbach's α coefficient for this scale was 0.752.

2.2.4. The Work-Related Quality of Life-2 Scale (WRQOL-2). The WRQOL-2 is a 34-item instrument used to assess quality of working life and was developed by Van Laar et al. and translated into Chinese and modified by Shao et al. [33, 34]. The WRQOL-2 measures seven dimensions: working conditions (WCS), stress at work (SAW), control at work (CAW), home-work interface (HWI), employment evaluation of nurses (EEN), general well-being (GWB), and job and career satisfaction (JCS). Respondents indicated their level of agreement for each dimension on a five-point scale. Furthermore, a reverse scoring method is employed for the SAW dimension. Higher scores signified a higher quality of nursing work life. The Chinese version has demonstrated good psychometric properties, with previous research reporting Cronbach's α coefficients of 0.939 for the total scale and between 0.652 and 0.859 for each dimension [33]. In this study, Cronbach's α coefficient was 0.960 for the total scale and ranged between 0.744 and 0.931 for each dimension.

2.3. Data Collection. Permission was obtained from the nursing department directors at each of the four hospitals prior to the study. The researchers conducted a uniform training session for the four investigators from the sample hospitals and presented the study protocol. Data were collected via WenJuanXing (a professional questionnaire survey platform). After obtaining informed consent from the participants, the investigators explained the method for completing the questionnaires to the participants using questionnaire guidance language. The participants were guaranteed anonymity and confidentiality and could withdraw freely from the study at any time and for any reason.

2.4. Statistical Analyses. IBM SPSS version 27.0 was used for all data analyses, and GraphPad Prism version 9.0 was used to prepare the graphs. All the data were found to be approximately normally distributed. Continuous variables were presented as mean ± standard deviation (M±SD), and categorical variables were presented as frequencies and percentages. A chi-square test and independent samples t-test were used to identify statistically significant differences in demographic characteristics, night shift work schedule, chronotype, and quality of work life scores between the good sleep and poor sleep groups. Pearson's correlation test was used to examine the correlation between quality of work life and sleep quality. A binary logistic regression analysis model was used to calculate odds ratios (ORs) and 95% confidence intervals (95% CIs) for poor sleep quality (PSQI > 7), which was adjusted for potential confounding variables (univariate correlates: age, educational level, duration of mobile phone use before bedtime, frequency of irregular meals, frequency of caffeine intake, personal monthly income, department, professional rank, and employment type). The model was verified using the Hosmer–Lemeshow goodness-of-fit test. All tests were two-sided, and a P value <0.05 was considered statistically significant.

2.5. Ethical Considerations. This study was approved by the Ethics Committee of the main researcher's hospital (No. 2022YJ071). All participants took part in the study voluntarily and could withdraw at any time. All methods in this study were performed according to the relevant guidelines and regulations.

3. Results

3.1. Participant Characteristics. Among the 1510 questionnaires, 1426 valid questionnaires were obtained after removing those with apparent logical errors, representing an effective response rate of 94.4%. The mean participant age was 30.20 (SD = 7.60), ranging between 20 and 60 years. Participants' average BMI was 20.95 (SD = 2.70) kg/m^2. Most participants were female ($n = 1401$, 98.2%), married ($n = 766$, 53.7%), graduated from junior college ($n = 754$, 52.9%), had no children ($n = 725$, 50.8%), used their mobile phones for 1–3 hours before bedtime ($n = 753$, 52.8%), had irregular meals 1-2 times/week ($n = 821$, 57.6%), had a caffeine intake frequency of 3–5 times/week ($n = 787$, 55.2%), had a sugar intake frequency of 3–5 times/week ($n = 972$, 68.2%), engaged in a moderate level of physical activity ($n = 634$, 44.5%), were senior nurses ($n = 604$, 42.4%), and worked as contract employees ($n = 952$, 66.8%; Table 1).

TABLE 1: Demographic characteristics of participants ($n = 1426$).

Variables	N (%)/$M \pm$ SD			t/x^2	p

Bold values indicate that the p value is less than 0.05, indicating statistical significance.

3.2. Sleep Quality among MCH Nurses.

In the current study, good and poor sleep quality were noted in 600 (42.1%) and 826 (57.9%) MCH nurses, respectively. PSQI global scores ranged from 0 to 21, with a mean of 7.90 (SD = 3.67). Regarding the components of PSQI, 710 (49.8%) of the respondents reported that their subjective experience of sleep quality was fairly good. Regarding sleep latency, 487 (34.2%) participants had mild difficulties falling asleep. In terms of sleep duration, 604 (42.4%) of the respondents reported sleeping for 6–7 hours per night. For sleep efficiency, 733 (51.4%) participants scored higher than 85%. There were 860 (60.3%) respondents with mild sleep disturbance, and 1222 (85.7%) had not used sleep medication in the past month. Regarding daytime dysfunction, 475 (33.3%) of the respondents had mild dysfunction (Table 2). Across all seven components, the highest scores were observed for sleep latency, followed by subjective sleep quality and daytime dysfunction. Sleep medication had the lowest scores (Table 1).

3.3. Personal and Work-Related Factors Associated with Sleep Quality.

Regarding personal factors, sleep quality was significantly related to age, educational level, duration of mobile phone use before bedtime, frequency of irregular meals, and frequency of caffeine intake ($P < 0.05$). For work-related factors, sleep quality was significantly correlated with personal monthly income, department, professional rank, and employment type ($P < 0.05$; Table 1).

3.4. Chronotype and Night Shift Work Schedule Associated with Sleep Quality.

Anintermediate-evening chronotype ($n = 743$, 52.1%) was the most prevalent among participants, followed by an intermediate-morning chronotype ($n = 341$, 23.9%), evening chronotype ($n = 227$, 15.9%), and morning chronotype ($n = 115$, 8.1%). Participants with an evening chronotype ($n = 171$, 75.33%) were the most likely to experience poor sleep problems, followed by those with an intermediate-evening chronotype ($n = 462$, 62.2%), intermediate-morning chronotype ($n = 157$, 46.0%), and morning chronotype ($n = 36$, 31.3%). Significant differences were observed between poor sleep and chronotype ($P < 0.001$). When each component of sleep quality was divided into two categories, a chi-square test suggested that chronotype was associated with subjective sleep quality, sleep latency, sleep duration, sleep efficiency, and daytime dysfunction ($P < 0.05$; Figure 1(a)).

Among the participants, 376 (26.4%) worked non-night shifts, 110 (7.7%) worked forward-rotating night shifts, 704 (49.4%) worked backward-rotating night shifts (the largest proportion of MCH nurses), and 236 (16.5%) worked 12-hour rotating night shifts. Over 50% of participants reported poor sleep for each of the night shift work schedules. MCH nurses working 12-hour rotating night shifts had the highest rate of poor sleep ($n = 148$, 62.7%), followed by those working backward-rotating night shifts ($n = 420$, 59.7%), forward-rotating night shifts ($n = 62$, 56.4%), and non-night shifts ($n = 196$, 52.1%). Significant differences in poor sleep quality were observed between night shift work schedules ($P < 0.05$). According to the chi-square test, night shift work schedule was associated with subjective sleep quality, sleep latency, and sleep efficiency when a score of 2 was the cutoff point for each sleep quality component ($P < 0.05$; Figure 1(b)).

3.5. Associations between Quality of Work Life and Sleep Quality.

The mean (SD) WRQOL-2 scores for the good and poor sleep groups were 3.98 (SD = 0.56) and 3.70 (SD = 0.55), respectively. In terms of the seven parts of WRQOL-2, the highest scores were for homework interface, while the lowest were for stress at work. The independent samples t-test revealed that all dimensions, including working conditions, stress at work, control at work, home-work interface, evaluation at work, general well-being, and job career, were significantly different between the good and poor sleep groups ($P < 0.001$; Figure 2).

The Pearson correlation test revealed that quality of work life was negatively correlated with sleep quality ($r = -0.27$, $P < 0.01$). Specifically, the strongest negative association with quality of work life was found for daytime dysfunction ($r = -0.31$, $P < 0.01$), followed by subjective sleep quality ($r = -0.27$, $P < 0.01$) and sleep disturbance ($r = -0.24$, $P < 0.01$). Quality of work life was weakly correlated with sleep latency ($r = -0.15$, $P < 0.01$), sleep duration ($r = -0.15$, $P < 0.01$), and sleep medication ($r = -0.08$, $P < 0.01$). No significant correlation difference was observed between sleep efficiency and quality of work life ($r = -0.04$, $P = 0.181$). The correlation heat map is shown in Figure 3.

TABLE 2: PSQI and its component score among MCH nurses ($n = 1426$).

Components	Group	Scores	N (%)
Subjective sleep quality	Very good	0	91 (6.4)
	Fairly good	1	710 (49.8)
	Fairly bad	2	529 (37.1)
	Very bad	3	96 (6.7)
Sleep latency[†]	0	0	187 (13.1)
	1-2	1	487 (34.2)
	3-4	2	451 (31.6)
	5-6	3	301 (21.1)
Sleep duration	Greater than 7 h	0	256 (18.0)
	6-7 h	1	604 (42.4)
	5-6 h	2	476 (33.4)
	Less than 5 h	3	90 (6.3)
Sleep efficiency	Greater than 85%	0	733 (51.4)
	75%–85%	1	407 (28.5)
	65–74%	2	185 (13.0)
	Less than 65%	3	101 (7.1)
Sleep disturbance[‡]	0	0	175 (12.3)
	1–9	1	860 (60.3)
	10–18	2	356 (25.0)
	19–27	3	35 (2.5)
Sleep medication	Not during the past month	0	1222 (85.7)
	Less than once a week	1	133 (9.3)
	Once or twice a week	2	50 (3.5)
	Three or more times each week	3	21 (1.5)
Daytime dysfunction[§]	0	0	296 (20.8)
	1-2	1	475 (33.3)
	3-4	2	396 (27.8)
	5-6	3	259 (18.2)
PSQI global score	Good sleep	≤7	600 (42.1)
	Poor sleep	>7	826 (57.9)

[†]Sleep latency: scored on two items, including how long it takes to fall asleep each night and how often it is difficult falling asleep within 30 minutes. [‡]Sleep disturbance: scored on nine items, including waking up in the middle of the night or early morning, getting up to use the bathroom, breathing uncomfortably, coughing or snoring loudly, feeling cold, feeling hot, having bad dreams, having pain, and other reason of troubling sleep. [§]Daytime dysfunction: scored on two items including the frequency of having trouble staying awake and the frequency of keeping up enough enthusiasm.

3.6. Binary Logistic Regression Analysis for Poor Sleep Quality. The binary logistic regression analysis for sleep quality is presented in Table 3 (good sleep = 0; poor sleep = 1). The ORs (95% CI) for the intermediate-morning, intermediate-evening, and evening chronotypes (reference: morning chronotype) were 1.87 (1.20–2.93), 3.61 (2.37–5.50), and 6.70 (4.08–11.01), respectively, in the crude model. In the adjusted model (adjusted for age, educational level, duration of mobile phone use before bedtime, frequency of irregular meals, frequency of caffeine intake, personal monthly income, department, professional rank, and employment type), chronotype remained statistically associated with sleep quality. Regarding night shift work schedules, the ORs (95% CI) for the backward-rotating and 12-hour rotating shifts (reference: day shift) were 1.36 (1.06–1.75) and 1.54 (1.11–2.15), respectively, in the crude model. However, no statistically significant differences were observed based on night shift work schedule for sleep quality in the adjusted model. Significant differences were observed across all dimensions of quality of work life in the crude model; however, the adjusted factors modified the association between quality of work life and sleep quality. The adjusted ORs (95% CI) for stress at work, control at work, and general well-being were 0.53 (0.45–0.63), 2.00 (1.39–2.89), and 0.31 (0.21–0.48), respectively. Working conditions, home-work interface, employment evaluation of nurses, and job and career satisfaction were not significant factors in the adjusted model.

Among the adjusted factors, age, frequency of irregular meals, and frequency of caffeine intake were associated with poor sleep quality. The adjusted ORs (95% CI) for ages 36–45 and ≥46 (reference: age ≤25) were 2.31 (1.23–4.34) and 4.14 (1.56–10.97), respectively. The ORs (95% CI) for irregular meals sometimes, often, and always (reference: never) were 2.73 (1.87–3.98), 4.74 (3.03–7.42), and 7.02 (3.08–16.01), respectively. For caffeine intake frequency, the OR (95% CI) for always (reference: sometimes) was 1.65 (1.12–2.41). For more details, see Supplemental Table S1 (logistic regression analysis for poor sleep quality).

4. Discussion

This study revealed a concerningly high rate of poor sleep quality among MCH nurses (57.9%), which was higher than that of nurses in the community (46%) [35], psychiatric hospitals (38.1%) [36], and general hospitals (55%) [16]. This may be due to differences in workplaces and workflows between healthcare organisations, as MCH nurses have to deal with challenging situations such as inappropriate children, overbearing families, noisy workplaces, excessive workloads, a high risk of workplace violence, and emotionally traumatic events [19, 37–39]. Additionally, most of the MCH nurses in this study were female (98.2%). Due to their physiological characteristics, social struggles, and household responsibilities, female nurses experience more

psychological distress and sleep problems [40]. These factors may disrupt their circadian rhythms and produce stress that acts on the hypothalamus-pituitary-adrenal axis, increasing the likelihood of sleep problems [41]. In summary, evidence-based strategies for sleep optimisation should be adopted [42].

The current study demonstrated that chronotype may be related to MCH nurses' sleep quality. MCH nurses with evening chronotypes were approximately four times more likely to experience poor sleep than those with morning chronotypes, which is similar to the findings of previous studies [25, 43, 44]. Individuals with evening chronotypes reported chronic disruption of their circadian rhythms and were more susceptible to light-at-night disturbance of melatonin secretion [45]. MCH nurses with evening chronotypes tend to stay up and sleep late and find it difficult to naturally fall asleep early the night before a workday, resulting in sleep deprivation and exhaustion during the workday. Conversely, if they deliberately advance their bedtime to acclimate themselves to their work schedule, it will result in difficult sleep initiation and lower sleep efficiency. Moreover, people with evening chronotypes prefer having snacks at night, which may further delay bedtime and impair subjective sleep quality [46]. Therefore, managers should attempt to create shift schedules in accordance with the natural chronotypes of MCH nurses to increase their sleep quality and quantity.

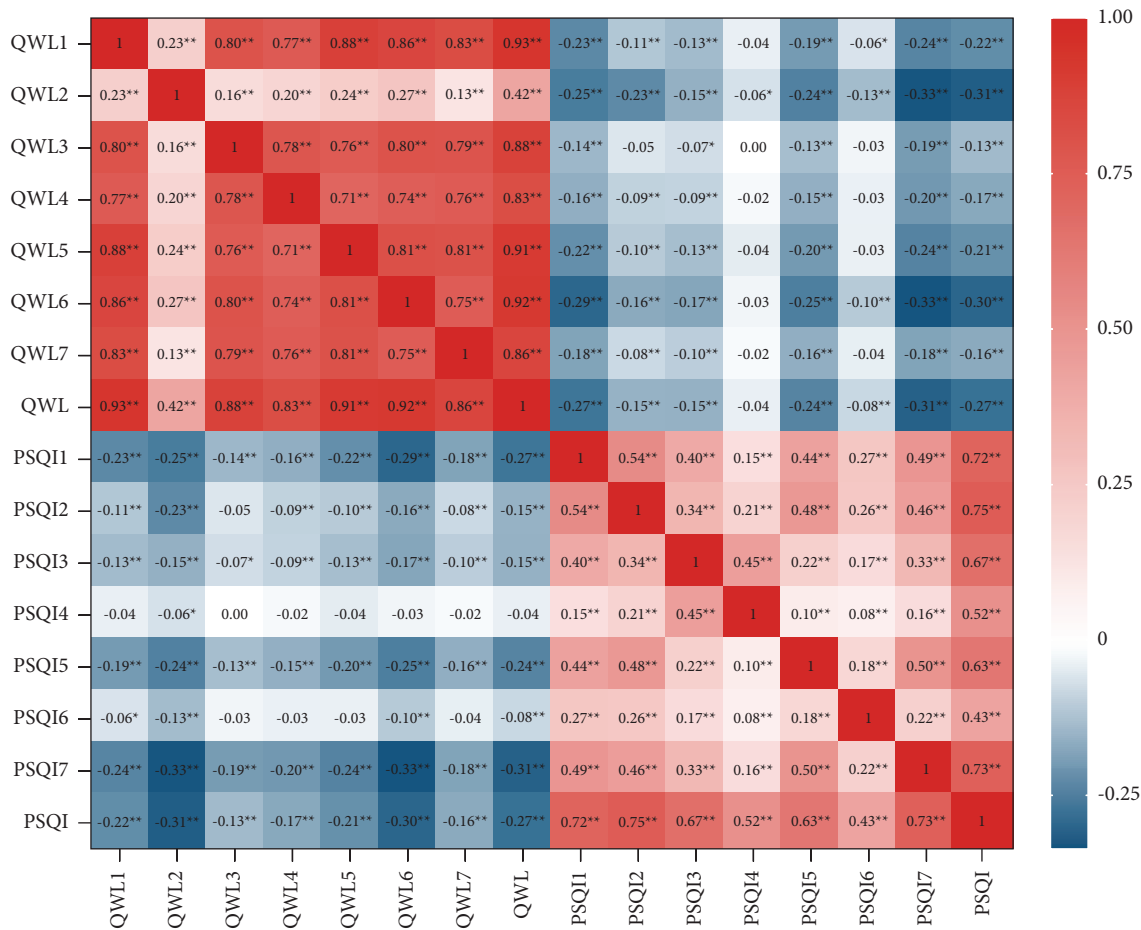
Univariate analysis revealed an association between night shift work schedule and poor sleep quality. However, this effect was not significant after adjusting for related factors, which may be related to the uneven distribution of various shift types, with nearly half of the participants


FIGURE 3: Heat map of Pearson correlation between quality of work life and sleep quality among MCH nurses ($n = 1426$). $^{*}P < 0.05$. $^{**}P < 0.01$. PSQI: the Pittsburgh Sleep Quality Index, PSQI1: subjective sleep quality, PSQI2: sleep latency, PSQI3: sleep duration, PSQI4: sleep efficiency, PSQI5: sleep disturbance, PSQI6: sleep medication, and PSQI7: daytime dysfunction; QWL: the Work-Related Quality of Life-2 scale, QWL1: working conditions (WCS), QWL2: stress at work (SAW), QWL3: control at work (CAW), QWL4: home-work interface (HWI), QWL5: employment evaluation of nurse (EEN), QWL6: general well-being (GWB), and QWL7: job and career satisfaction (JCS).

working backward-rotating night shifts. Nevertheless, shift work is a crucial component of nurses' work lives. Several studies have demonstrated that shift work causes a misalignment of circadian rhythms, and the body's sensitivity to the sleep-wake cycle is diminished, disrupting the rhythm of cortisol and melatonin and leading to sleep problems [47]. Similar to previous studies [48, 49], our study found that participants on a 12-hour rotating night shift showed the highest rates of poor sleep quality, and those on forward-rotating night shifts had better sleep quality than those on either 12-hour rotating or backward-rotating night shifts. As an ergonomic and health-promoting option, a forward-rotating night shift is better adapted to sleep because the human circadian sleep-wake cycle physiology tends to move forward [50, 51]. Consequently, a forward-rotating night shift is recommended to optimise the rotation.

The MCH nurses in this study reported a moderately high level of quality of work life. The stress at work dimension had the lowest score, indicating that MCH nurses typically work under severe stress. Excessive work stress is one contributor to sleep problems, which is consistent with our finding of a high rate of poor sleep. Furthermore, high

control at work is a risk factor for poor sleep. Control at work reflects the ability to be competent in nursing and decision-making latitude in the workplace [52]. MCH nurses with higher control at work have difficulty disengaging from the high level of work alertness and repeatedly think about today's work or worry about that of tomorrow even when off duty [53, 54]. This prevents them from fully relaxing and impairs their sleep. In contrast, MCH nurses' general well-being was a protective factor that supported healthy sleep. General well-being is an important component of quality of work life, reflecting satisfaction with overall work life. Good well-being promotes physical and mental health and helps individuals take action to cope with stress and enjoy good sleep [55]. Thus, these findings offer a new perspective on promoting good sleep quality through interventions (e.g., mindfulness and cognitive-behavioural therapy) to improve quality of life at work.

Older age, frequent caffeine consumption, and irregular meals were also associated with poor sleep quality in this study. MCH nurses over 35 years of age were more likely to experience poor sleep quality. With respect to biology, aging causes sleep to become fragmented, and older persons may

TABLE 3: Binary logistic regression analysis for poor sleep based on chronotype, night shift work schedule, and quality of work life.

Job and career satisfaction	0.63 (0.53–0.75)	**<0.001**	0.75 (0.50–1.11)	0.152

[†]Adjusted for age, educational level, duration of mobile phone use before bedtime, frequency of irregular meals, frequency of caffeine intake, personal monthly income, department, professional rank, and employment type. ORs: odds ratios; CI: confidence interval. Bold values indicate that the p value is less than 0.05, indicating statistical significance.

awaken several times during the night [56]. In terms of work, older nurses with rich work experience take on greater responsibilities, take on heavier nursing workloads, face critical patients and emergencies, and supervise junior nurses, all of which expend more energy and lead to poor sleep. Notably, to induce wakefulness on duty and optimise alertness off duty, MCH nurses as shift worker may become dependent on caffeine because it increases alertness in a dose-dependent manner [57, 58]. Consequently, many of these nurses regularly consume caffeine and experience sleep disturbance. Consistent with previous research [23], irregular meal habits were found to be a risk factor for poor sleep quality. Dietary factors influence or modulate neurotransmitter mechanisms in the brain, which may have downstream effects on sleep [59]. Furthermore, poor diet quality and quantity may affect tryptophan availability and serotonin and melatonin synthesis, leading to poor sleep quality [60]. Thus, these factors are worth considering when in relation to altering sleep quality.

4.1. Limitations. The present study has a few limitations. First, the study was conducted among nurses working in four MCH hospitals in one province of China, which may not be representative of all Chinese MCH nurses. Second, owing to the cross-sectional design of this study, the analysis may explain the sleep quality level at a certain point in time. Third, the data were self-reported rather than objectively measured (e.g., actigraphy), which may have introduced subjectivity and bias.

5. Conclusions

This study showed that poor sleep quality was common among MCH nurses. The findings of this study also illustrated that sleep quality was associated with older age, frequent caffeine intake, irregular meals, chronotype, and quality of work life. These findings have substantial implications for future studies and policy interventions to enhance MCH nurses' sleep quality and well-being.

6. Implications for Nursing Management

This study provides new insights into improving sleep quality to enhance quality of work life and professional satisfaction in the nursing management sector of MCH hospitals. To target current modifiable factors, it is critical to establish a scientific shift work schedule that meets the physical and psychological needs of MCH nurses, ensures adequate rest, and maintains a balance between family and work. In addition, nursing managers can form psychological support teams to provide professional counselling and intervention services for MCH nurses. Accurate sleep information, such as maintaining a balanced diet, avoiding large meals before bedtime, and limiting caffeine to 6 h before sleep, can be conveyed to MCH nurses through brochures or lectures. However, to target nonmodifiable factors, nursing managers should allocate human resources appropriately according to chronotype and age. For example, nurses with morning chronotypes should be assigned to early shifts, whereas those with evening chronotypes

should have a delayed start time for their work. As older nurses' energy and fitness levels decline, their night shifts should be reduced and their supervisory and teaching responsibilities should be increased. Night shifts could be added for young nurses to help them develop their clinical skills while increasing their salaries.

Aim(s). This study conducted a multilevel analysis of mealtime difficulties in older adults with dementia based on the social-ecological model. *Background*. Mealtime difficulty in this population should be examined from an extensive perspective, rather than approaching it as an individual problem. *Method(s)*. This was a cross-sectional study involving 342 participant dyads from 57 long-term care facilities; 114 direct care workers; and 342 older adults with dementia. A multilevel regression analysis was conducted using the MPlus 8.0 program. *Results*. Among intrapersonal factors, age, cognitive function, activities of daily living, and number of beds in the facility were identified as affecting mealtime difficulty. Environmental factors included meal assistant education experience and whether an environment suitable for eating had been established. *Conclusion(s)*. The results show that intrapersonal factors exert a large influence on the mealtime difficulties of older adults with dementia in long-term care facilities and support the need to improve environmental factors, which are modifiable. *Implications for Nursing Management*. This study provided useful information about the influence of leaders on mealtime difficulties in older adults with dementia. Leaders should establish an environment in the facility for reduced mealtime difficulties.

1. Introduction

Mealtime difficulties in older adults with dementia are defined as frustrations or problems that arise during mealtimes [1, 2] and generally occur in individuals in the middle or late stages of dementia [3]. They gradually experience difficulty picking up food with utensils, putting it in their mouth, chewing, and swallowing. Eventually, in the late stages of dementia, swallowing quality appears to fail [4]. Older adults with dementia and mealtime difficulties experience symptoms such as reduced nutritional intake, weight loss, dehydration, and aspiration [5]; secondary weight loss increases the incidence of myasthenia, bedsores, and immobility [4].

The social-ecological model helps to determine the complex interplay of factors affecting mealtime difficulties experienced by older adults with dementia [6, 7] in which it can be used to identify influences on eating performance from a multilevel perspective, encompassing their intrapersonal-, interpersonal-, environmental-, and policy-related aspects [8–10]. Intrapersonal factors affecting mealtime difficulty include age, cognitive function, physical ability, complications, behavioral and psychological symptoms of dementia, and the individual perspectives of older adults with dementia [11–14]. Interpersonal factors consist of the knowledge, attitudes, and behaviors contributing to direct care workers' interactions [7, 12, 15]. Environmental factors include aspects of the physical environment (e.g.,

type of meal, how food is served, and appropriate staffing levels) that might affect mealtime difficulties [11, 13, 16, 17] as well as care facility factors such as work-oriented policies and provision of appropriate accommodations [12, 18].

As such, the factors that influence mealtime difficulties in older adults with dementia can be multifaceted. Therefore, based on the social-ecological model, it is necessary to address older adults with dementia, caregivers, and environment levels to identify factors that may be associated with mealtime difficulties. Multilevel models allow for the examination of how individual characteristics, such as cognitive impairment and functional ability, interact with group level factors, such as staffing levels, and the care environment to predict the outcome of mealtime difficulties [19]. This type of analysis provides a more comprehensive understanding of the complex and dynamic factors that contribute to mealtime difficulties in older adults with dementia in long-term care facilities.

Multilevel model analysis is used to study mealtime difficulties in older adults with dementia living in long-term care facilities because it takes into account both individual and group level factors that may influence the outcome of interest [13, 20]. In previous studies [13, 20], the effects of individual and environmental characteristics on mealtime performance were confirmed by multilevel analysis, and the direct care worker factor was analyzed at the environmental level. However, care workers play an essential role in providing eating assistance for older adults with dementia, who depend highly on help from others to accomplish their activities of daily living [21]. The direct caregiver factor is important because it is a factor that can be more easily modified and adjusted than other factors to alleviate mealtime difficulties [12, 21]; therefore, it is necessary to analyze interpersonal factors independently when assessing the mealtime difficulties of older adults with dementia. In addition, the reflection of cultural factors in mealtime difficulties, including the influence of sociocultural contexts and care facility policies, is crucial; however, there is a lack of research that addresses this issue specifically in the Korean context.

2. Methods

2.1. Design.
This study used a multilevel cross-sectional design to determine the relationship between intrapersonal-, interpersonal-, and environmental-level factors and the mealtime difficulties of older adults with dementia in long-term care facilities and to identify which aspects of the factors are influential.

2.2. Participants.
Following Maas and Hox [22] criteria, as the group level sample size is statistically more important than the individual-level sample size, Schoeneberger [23] proposed recruiting over 30 groups of 10 or more individual subjects.

The long-term care facilities participating in this study were categorized based on the total number of beds (less than 30, more than 30 but less than 50, 50 to 100, and more than 100) and the results of regular evaluation scores (A, B, C, D, or E) by the Korean National Insurance Corporation. Sixty institutions that agreed to participate in the study were selected based on a dropout rate of 20%.

According to the literature review, the number of analysis levels was three. The number of participating long-term care facilities was 60 (Level 3); the number of participating direct care workers (care workers who provide hands-on assistance, support, and care to older adults with dementia in long-term care facilities) was 120 (Level 2), twice the number of long-term care facilities; and the number of older adults with dementia who participated was 360 (Level 1), three times the number of direct care workers. Direct care workers were matched with two older adults under their care so we could observe and record any mealtime difficulties encountered.

A preliminary survey was conducted to measure response time and check whether any questions were not understood after the survey. The participants in this preliminary survey comprised two long-term care facilities (Level 3), four direct care workers (Level 2), and 12 older adults with dementia (Level 3). The current study participants comprised 342 dyads from 57 long-term care facilities, 114 direct care workers, and 342 older adults with dementia. Data excluding attrition of 5% (insufficient response) were used for the final analysis.

2.3. Variables and Measures

2.3.1. Level 1: Intrapersonal Factor.
A 37-item tool related to cognitive impairment currently used in nursing homes was used to measure elements such as reduced orientation, judgment, attention, and concentration, with a higher score indicating lower cognitive function. The functional independence measure was used to measure seven items related to eating-related activities of daily living, with a higher score indicating more independence. The mealtime difficulty scale for older adults with dementia was used to measure mealtime difficulty [24], with higher scores indicating greater mealtime difficulty. In this study, we modified any negative words used that might have confused survey participants. At the time of development, Cronbach's α was 0.91; in this study, Cronbach's α was 0.92.

2.3.2. Level 2: Interpersonal Factor.
The survey of direct care workers included general characteristics of age, gender, level of education, work experience, duty, attitude, and knowledge about feeding. Attitudes toward feeding were measured using the Formal Direct Care Workers' Attitude toward Feeding Dementia Patients Questionnaire, developed by Chang and Roberts [11] and translated by Hong and Gu [25]; the higher the score, the more negative the attitude towards feeding. In Hong and Gu [25], Cronbach's α was 0.73; in this study, Cronbach's α was 0.83. In addition, knowledge about feeding was assessed using the Formal Direct Care Workers' Knowledge of Feeding Dementia Patients Questionnaire, developed by Chang and Roberts [11] and translated by Hong and Gu [25], which has a total of 21 questions. The

higher the value, the higher the level of knowledge. In a study by Hong and Gu [25], Kuder-Richardson (KR) was 20 = 0.63; in this study, KR-20 = 0.63.

2.3.3. Level 3: Environmental Factor.

Organizational-level variables were investigated for the head of the nursing facility, and characteristics related to mealtime difficulty at the facility (year of establishment, facility operator, certificate possessed by the facility manager, number of nurses in the facility, number of nursing assistants in the facility, number of direct care workers in the facility, facility residents, whether regular education was performed, facility size, need for food support education, and environmental factors related to difficulty in eating) were investigated.

2.4. Statistical Analysis.

The collected data were verified for statistical significance based on $p < 0.05$ using SPSS 25.0, Microsoft Office Excel, and MPlus 8.0 [26]. Descriptive statistical analysis was used to describe each variable, and Cronbach's α was used to assess the reliability of the research measurements. A three-level random intercept model was used to analyze the factors influencing mealtime difficulties experienced by older adults with dementia in long-term care facilities. The multilayer model estimation method of Mplus was used for estimation, and the full-information maximum likelihood (FIML) method, which is known to be robust even in violation of the statistical assumptions of the data, was used as well. The z-test, which is the Mplus estimation method, was performed for the parameter test.

2.5. Ethical Considerations.

This study was conducted after OOOO University's Institutional Review Board approved the research ethics (OOOO-202203-0007-01). All participants were provided with sufficient information about the study and instructed that they could withdraw from the study at any time. All data were kept confidential.

3. Results

3.1. Participants' Characteristics.

Table 1 shows the general characteristics of the participants in long-term care facilities. There was 342 Level 1 participants (older adults with dementia), with an average cognitive function of 15.25 ± 7.12 and activities of daily living of 4.64 (all within the middle range). The average mealtime difficulty in older adults with dementia was 34.49 ± 11.34. There were 114 Level 2 participants (direct care workers). The average attitude toward feeding was 7.46 ± 10.85, and the average knowledge of feeding was 11.14 ± 3.26. There were 57 Level 3 participants (the heads of the long-term care facilities). Twenty-two facilities had 25–50 beds (28.6%), accounting for the largest proportion. Forty-seven (82.5%) of the facilities had meal assistant education experience, and most facilities ($n = 56$, 98.3%) required meal assistant education experience.

3.2. Multilevel Analysis.

Level 1 (intrapersonal factors) and Level 3 (environmental factors) were statistically significant for mealtime difficulties in older adults with dementia, with the explanatory powers being 53.7% for Level 1 and 23.0% for Level 3. The explanatory power of the model incorporating Levels 1, 2, and 3 was 39.7%. Level 1 most significantly explained mealtime difficulties. As a result of the multilevel analysis, age, cognitive function, activities of daily living, the total number of beds in the facility, meal assistant education experience, and the number of suitable environments for meals were identified as factors affecting mealtime difficulties in older adults with dementia. The analysis results for each model are as follows.

3.2.1. Model 1.

Table 2 presents the results of the three-level multilevel regression model. There was a difference between intrapersonal and environmental factors in the mealtime difficulty score, which is the dependent variable. As the result of estimating the intraclass correlation coefficient (ICC), the Level 2 ICC estimate was found to be 0.008, which can be explained by the fact that only 0.8% had mealtime difficulties due to the interpersonal factor difference. The Level 3 ICC estimate was found to be 0.489, which means that 48.6% of mealtime difficulties occurred because of the difference in environmental factors. The degree of mealtime difficulty experienced differs depending on the environmental factors, a characteristic of the group; therefore, the necessity of multilayer analysis was confirmed.

3.2.2. Model 2.

Model 2 predicted that older adults with dementia, lower cognitive function, and activities of daily living would experience more mealtime difficulty. Moreover, it was predicted that males would experience more mealtime difficulty. The residual variance at Level 1 was 53.65, which was lower than that at 65.12, which means that the selected Level 1 predictors sufficiently explain the variability in the dependent variable (mealtime difficulty).

3.2.3. Model 3.

Among the Level 2 independent variables, gender, cognitive function, and activities of daily living were statistically predicted to significantly impact mealtime difficulties. While controlling for Level 1 predictors, no statistically significant predictors of mealtime difficulties were added among the Level 2 predictors. This may be because the Level 2 variance (r^2) was very small (0.987) and not statistically significant ($p = 0.871$), so there was little difference in mealtime difficulties due to variance in direct care workers.

3.2.4. Model 4.

Level 1 R^2 was 0.309, and the predictors explained 30.9% of the variability in the Level 1 dependent variable (mealtime difficulty). Among the Level 2 predictors, no statistically significant predictors of mealtime difficulties existed. At Level 2, R^2 was 0.368, and the predictors explained 36.8% of the variability in the Level 2 dependent variable (mealtime difficulty). In addition, this model confirmed the statistical significance of Level 3, Level 1, and Level 2 predictors in the final model of the study. It was predicted that a group with meal assistant education, a large facility size, and a few suitable environments for meals

TABLE 1: Participant characteristics.

Characteristics	Categories	Total n (%) or M ± SD	Range
Level 1 (older adults with dementia = 342)			
Intrapersonal factor			
Age		84.08 ± 7.12	60–104
Gender	Male	79 (23.1)	
	Female	263 (76.9)	
Cognitive function		15.25 ± 7.12	0–32
Activities of daily living		4.64 ± 1.82	1–7
Period of institutionalization		3.22 ± 2.58	0–21
Mealtime difficulty		34.49 ± 11.34	19–78
Level 2 (direct care workers = 114)			
Interpersonal factor			
Level of education	<Middle school	13 (11.41)	
	High school	78 (68.42)	
	≥University	23 (20.18)	
Duty	Fixed	20 (17.54)	
	8-hour shift	26 (22.81)	
	12-hour shift	65 (57.02)	
	24-hour	3 (2.63)	
Current work experience (years)		4.52 ± 4.27	
Attitude toward feeding		73.46 ± 10.85	43–100
Knowledge toward feeding		11.14 ± 3.26	4–19
Level 3 (long-term care facility = 57)			
Environmental factor			
Length of the facility establishment		12.09 ± 4.63	4–26
Facility type	Private	24 (42.1)	
	Corporate	33 (57.9)	
		55.88 ± 44.23	13–258
Facility size	≤25 beds	4 (7.0)	
	25–50 beds	22 (38.6)	
	50–75 beds	11 (19.3)	
	75–100 beds	14 (24.6)	
	≥100–200 beds	6 (10.5)	
Number of suitable environment for meals		4.68 ± 2.69	1–10
Meal assistant education experience	Yes	47 (82.5)	
	No	10 (17.5)	
Meal assistant education requirements	Very required	23 (40.4)	
	Required	33 (57.9)	
	Not required	1 (1.8)	
Number of nurses		0.56 ± 1.35	0–8
Number of nurse assistants		2.46 ± 1.81	0–10
Number of direct care workers (≥6 month)		15.96 ± 12.03	2–57

would have a higher likelihood of experiencing mealtime difficulty at Level 3 while controlling Level 1 and Level 2 predictors. By controlling for Level 1 and Level 2 predictors, at Level 3, the group with meal assistant education experienced more mealtime difficulties, and the larger the facility size, the smaller the number of suitable environments for meals and the more mealtime difficulty encountered. The predictors accounted for 30.9% of the variability in the Level 3 dependent variable (mealtime difficulty), with $R^2 = 0.309$ at Level 3. In addition, the multicorrelation square of the entire model integrating all levels was calculated [19], and the multicorrelation square R^2 of Model 4 was 0.397. This is larger than Model 1 (0%), Model 2 (29.1%), Model 3 (33.4%), and Model 4 (39.7%), which explains its largest variability in mealtime difficulties.

4. Discussion

This study aimed to conduct a multilevel analysis of mealtime difficulties in older adults with dementia based on the social-ecological model. According to this model, mealtime difficulty variables were classified into and analyzed as three levels: Level 1 (intrapersonal), Level 2 (interpersonal), and Level 3 (environment). Among these, the level that most affected the degree of mealtime difficulties experienced was Level 1. At Level 1, sex, cognitive function, and activities of daily living influenced mealtime difficulties. At Level 3, the degree of meal assistant education, the size of the facility, and the number of suitable environments for meals at the environmental level influenced mealtime difficulties. However, no variable predicted mealtime difficulties at Level 2.

TABLE 2: Multilevel analysis of the four fitted models on mealtime difficulties in older adults with dementia.

Parameters	Classifications	Model 1 Estimate	ρ	Model 2 Estimate	ρ	Model 3 Estimate	ρ	Model 4 Estimate	ρ
Fixed effect									
Intercept		34.49	<0.001	34.49	<0.001	34.49	<0.001	34.48	<0.001

$R\,^2$		0		0.291		0.334		0.397	

The findings of this study suggest that cognitive function and activities of daily living play a significant role in mealtime difficulties. Individuals with lower cognitive function may find it more challenging to eat them, whereas those with higher abilities in performing activities of daily living may experience less challenges. The results are similar to those of previous studies [7, 27]. This may be because eating dependence increases as cognitive function and physical function decreases [28]. In addition, the study indicates that women may experience more mealtime difficulties than men and it is similar with some previous studies [29, 30]. This is because these results may occur due to changes in dental conditions according to gender [27]. However, since there was no difference in gender in most of the studies [7, 31], further studies are needed on the effect of additional intrapersonal factors, including dental characteristics, depression, and polymedications on mealtime difficulties [32, 33].

The lower the cognitive function is, the more difficult it is to eat independently, as shown in previous research [7, 28]. Because the older adults with dementia have difficulty describing their intentions, care workers should be trained to recognize and manage various expressions of mealtime difficulties. In a previous study on mealtime difficulties in older people, the lower the daily living activity is, the more difficult it was to eat. The same results were also found in this study [7, 28, 31]. This may be due to the deterioration of physical function as dementia progresses, thus limiting the range of movement needed to use eating utensils [11, 34]. A pre-emptive approach is needed to prevent the deterioration of physical function, including the eating function of older people with dementia. Direct care workers need to encourage and help residents to eat meals independently rather than providing unconditional mealtime assistance.

The mealtime difficulties of older adults with dementia were greater in the group in which direct care workers received mealtime difficulty education. This result differs from the general expectation that mealtime difficulty education would result in fewer difficulties experienced during mealtimes. In this study, however, it is notable that although the participating facility provided training, 47.4% of the direct care workers in the facility scored less than 50% in tests to demonstrate their feeding-related knowledge. Even though feeding training was conducted, the knowledge of direct care workers did not improve, and mealtime difficulties were subsequently not reduced. This result may be that direct care workers tend to rely on habit or experience rather than education [35]. Nevertheless, previous studies have proven that direct care workers' knowledge and attitudes affect mealtime difficulties experienced by those they assist [2, 11]. Thus, continuous education that improves the quality of care provision is necessary to reduce mealtime difficulties.

The current results showed that the larger the size of the facility is, the more mealtime difficulties were experienced. This is related to previous studies that the proportion of residents with high nursing demands is high in large-scale facilities [36]. The high nursing demand means that the ability to perform daily life is low [37], and the lower the ability to perform daily life, the more difficult it is to eat [12]. Therefore, mealtime difficulties might increase in large-size facilities with many people with low daily performance. In the previous study, the higher the nursing demand is, the more direct care workers are needed [38]. Therefore, proper staffing is necessary to adequately assist older adults with high nursing demands and difficulties in mealtime due to low ADL. Likewise, in a recent qualitative study of direct care workers, inadequate staffing was found to be a barrier to mealtime assistance [20].

Preparing an appropriate mealtime environment is essential to prevent or address eating difficulties. The appropriate environment presented in this study included providing adequate food and utensils regarding individual preference or eating abilities, proper space for dining (noise, light, odor, and furniture), and enough time to eat, and mealtime was taken together with other residents. Slaughter et al. [14] proposed that residents can eat without difficulty by using "finger food," no-spill cups, appropriate utensils, and plate guards as assistive eating devices and customizing mealtimes based on food preferences and swallowing function. A brighter and quieter dining environment might prevent residents with dementia from being distracted by environmental factors and alleviate their sundowning syndrome [11, 31]. In Korea, long-term care facilities are evaluated every 3 years. The evaluation only considers items related to "pleasant environments" and "falls prevention." Guidelines for the care environment that consider the needs of older adults with dementia, including those related to dining and meals, have not been presented. Therefore, developing guidelines to maintain an appropriate environment to reduce mealtime difficulties for residents with dementia is necessary.

Lastly, at Level 2, no variable was found that predicted mealtime difficulties. Direct care workers' knowledge and attitudes were reported as influential factors in mealtime difficulties [7, 12, 15]. In this study, however, only 0.8% of the total change was explained at the interpersonal level, perhaps because the knowledge and attributes of the direct care workers who participated were distributed with low variance in the low score range, and there were no significant results in the multilevel analysis; therefore, to confirm the effect of Level 2 factors on meal difficulties, direct care workers must be analyzed again after improving their knowledge and attitudes to some extent through continuing qualitative meal difficulty education.

5. Limitations

This study has several limitations. First, the cross-sectional nature of the data limits the interpretation of causality. Second, variables related to interpersonal and environmental factors are sensitive to sociocultural influences, so caution is required when generalizing to other countries. Third, the institutional-grade was not used as an environmental variable because a participating institution had not yet been officially graded at the time of the study due to severe acute respiratory syndrome coronavirus 2 restrictions. Hence, a study that considers the institutions'

quality grading is necessary. Finally, studies on other possible influencing factors are needed because we considered only a limited number of factors related to eating difficulties. In particular, interpersonal factors require consideration based on actual observations. A strength of this study is that quota sampling was performed that considered region, institution grade, and the number of beds. Theoretically, we identified factors related to eating difficulties in older people with dementia using robust sample size and at various levels.

6. Conclusions

Our study demonstrates the effects of intrapersonal, interpersonal, and environmental factors on eating difficulties in older people with dementia. Our findings confirm that intrapersonal factors significantly influence the eating difficulties experienced by older adults with dementia in long-term care facilities and support the need for an approach that considers the environmental factor, which is modifiable [39–42].

The [research] data used to support the findings of this study are restricted by the [Ewha Research Ethics and Compliance Online System] in order to protect [PATIENT PRIVACY]. Data are available from [Eunju Choi, celestial_@naver.com] for researchers who meet the criteria for access to confidential data.

Additional Points

Nurse managers should consider improving the quality of education and providing staff education to reduce mealtime difficulty in older adults with dementia. Furthermore, it is essential that different levels of adequate nursing staff be set according to facility size. Nurse managers must identify individual needs and preferences to create and implement an environment that can reduce mealtime difficulties. In addition, nursing managers should position more direct care workers so that residents can assist with meals adequately.

Conflicts of Interest

The authors declare that they have no known conflicts of interest or personal relationships that could have appeared to influence the work reported in this paper.

Authors' Contributions

Dukyoo Jung conceptualized the study, performed methodology, wrote and prepared the original draft, performed project administration, and provided funding acquisition. Jennie C. De Gagne conceptualized the study, wrote, reviewed, and edited the manuscript, and supervised the study. Eunju Choi conceptualized the study, wrote and prepared the original draft, and wrote, reviewed, and edited the manuscript. Hyesoon Lee conceptualized the study and wrote and prepared the original draft. Leeho Yoo conceptualized the study and wrote and prepared the original draft. Jisung Park conceptualized the study and wrote and prepared the original draft.

Although individual factors play a vital role in determining professional autonomy, their specific impact during the coronavirus disease 2019 (COVID-19) pandemic has not been studied. This study aimed to compare nurses' professional autonomy when caring for patients with COVID-19 and for other patients and explore factors related to autonomy when caring for these patients. A paper-based questionnaire survey was conducted from June to August 2022 among nurses working at a university hospital in Japan. The survey included demographic factors (10 items, including, age, section, years of nursing experience, position, educational background, ladder level, and having certified nurse specialists or certified nurse qualifications) and individual experience factors (4 items: number of COVID-19 patients experienced, frequency and contents of searching for the latest information about COVID-19, frequency of using scientific sources, and frequency of training/study sessions on COVID-19 attended at the hospital). Additionally, basic knowledge of COVID-19 was evaluated. The scale for nurses' professional autonomy was developed based on a previous study. A paired t-test and stepwise multiple linear regression were used for the analyses. Overall, 241 nurses participated in the survey. The average length of nursing experience was 10.3 ± 9.2 years. The total scores for nurses' professional autonomy in all 5 factors 27 items were significantly lower ($t = -12.1$, $p < 0.001$) when caring for COVID-19 patients than when caring for other patients. Specifically, Factor 1 (Cognition) exhibited the most decreased scores when caring for COVID-19 patients than when caring for other patients. Factor 4 (Abstract judgment) differed the least between caring for COVID-19 and for other patients, but the average score was the lowest. More years of nursing experience ($\beta = 0.208$, $p = 0.001$) and a higher number of patients with COVID-19 cared for ($\beta = 0.140$, $p = 0.026$) were associated with higher autonomy scores. In conclusion, to enhance professional autonomy during an unprecedented pandemic, nurses must enhance cognition and abstract judgment. In the event of a future pandemic, nurses need to create an environment in which they routinely access and utilize the latest information and scientific evidence to provide high-quality nursing care based on their professional judgment and competence.

1. Introduction

The coronavirus disease 2019 (COVID-19) was caused by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and became a global pandemic [1]. The first cases of novel coronavirus were detected in China in December 2019,

and the virus has then spread rapidly to other countries worldwide. This led the World Health Organization to declare a Public Health Emergency of International Concern on January 30, 2020, and to characterize the outbreak as a pandemic on March 11, 2020 [1]. As of March 16, 2023, over 760 million confirmed cases and over 6.8 million deaths

have been reported globally since the COVID-19 pandemic started, with a large number of patients requiring medical treatment and intensive care in hospitals [1, 2]. However, this phenomenon occurs not only in hospitals but also in clinics, home nursing service stations, midwifery centers, and other facilities [3]. The COVID-19 pandemic has required nurses to provide quality nursing care for patients with COVID-19 even though they are not trained for this unprecedented situation.

Nurses' professional autonomy is defined as "having the authority to make decisions and freedom to act in accordance with one's professional knowledge" [4]. There are two main components of nurses' professional autonomy: independence in decision-making and the ability to utilize one's own competence. Nursing competence is defined as the ability of a nurse to effectively demonstrate a set of attributes, such as personal characteristics, values, attitudes, knowledge, and skills that are required for nurses to fulfill their professional responsibilities [5]. The utilization of personal competence has been recognized as necessary for nurses' autonomy, including deciding their approach to nursing care [6]. Nurses' professional autonomy is strongly related to job satisfaction, job stress, and psychological distress, which can affect their work engagement [7–10].

Factors that affect nurses' professional autonomy reported before COVID-19 can be classified into individual and environmental factors. Individual factors including sex, educational level, nursing experience, job position, critical thinking, professional skills, and clinical ladder level contribute to the utilization of nurses' professional autonomy [11, 12]. Male nurses have higher independence in decision-making than female nurses. Educational level, nursing experience, job position, critical thinking, and clinical ladder are strongly and positively associated with nurses' professional autonomy [10–12]. Furthermore, the number of patients experienced is also related to nurses' professional autonomy [13]. Meanwhile, environmental factors that can affect nurses' professional autonomy include supportive leadership [14], shared leadership, interprofessional and intraprofessional collaboration, and healthy work environments [6]. Supportive leadership can enhance nurses' professional autonomy, as it has a significant impact on decision-making in nursing care and fosters a positive workplace environment. In contrast, autocratic/non-supportive management may adversely affect nurses' autonomy [14]. Autocratic management is typically marked by a leader's inclination to centralize decision-making and consolidate power, often resulting in complete control over all aspects of their subordinates' activities, with little regard for input from the subordinates [15]. Nurse-physician collaboration and cooperation among nurses without authoritarian impositions could increase nurses' professional autonomy [16]. Meanwhile, poor nurse-physician relationships could reduce nurses' professional autonomy [14]. A healthy working environment promotes nurses' autonomy through good team spirit without conflict or teasing and a well-balanced workload [14].

The COVID-19 pandemic had a significant impact on nurses, with an increase in psychological distress and a decrease in job satisfaction [7, 17]. Nurses experienced significant stress and moral distress due to unfavorable job demands [17]. Common reasons for moral distress include a lack of decision-making autonomy, insufficient workplace respect, and inadequate psychosocial support mechanisms to help nurses cope with ethical dilemmas in both intensive care units [18] and general units [17, 19–21]. One study indicated that nurses' psychological stress during the COVID-19 pandemic could be related to their lower autonomy and competence [7]. However, it is unclear how the current pandemic has affected nurses' professional autonomy. Previous studies have investigated the relationship between environmental factors and professional autonomy during the pandemic. One study reported that the nurse-physician relationship improved because of the COVID-19 pandemic, and shared education and collaboration had a significantly positive influence on the nurses' professional autonomy [16]. Other studies reported that a high level of autonomy was associated with greater organizational citizenship behavior [22, 23] and low work-family conflict [24]. Organizational citizenship behavior is a type of cooperative behavior that increases a person's tendency toward helping and sharing information [22, 23]. However, no study has reported individual factors that can predict professional autonomy during the COVID-19 pandemic. One study reported that more younger nurses felt their professional autonomy increased than older nurses during the pandemic [25], but this study did not measure and compare professional autonomy using scores. Therefore, it was unknown whether age is related to increased autonomy.

Although individual factors play a vital role in determining professional autonomy, their specific impact in this particular scenario has not been studied. It is necessary to identify the individual factors that can affect professional autonomy during a pandemic, which can be used to develop individual training and educational programs. Therefore, this study specifically focused on investigating individual factors. This study aimed to (1) compare nurses' professional autonomy of the same nurses when caring for patients with COVID-19 and other patients and (2) explore individual factors related to nurses' autonomy when caring for patients with COVID-19.

2. Materials and Methods

2.1. Study Design. This cross-sectional study used the convenience sampling method as researchers' accessibility to participants. This study was approved by the Ethics Review Committee of the Institute of Education of Tokyo Medical and Dental University (Approval No.: C2022-01) and was conducted according to the tenets of the Declaration of Helsinki. Informed consent was obtained from all participants.

2.2. Participants and Setting. Participants were nurses who were employed at the 750-bed university hospital in an urban area of Japan during the study period. The study hospital had been actively contributing to measures against

COVID-19 since 2020. The inclusion criteria were working at the hospital for more than 1 year and having experience caring for COVID-19 patients. Nurses in the director's office were excluded. A paper-and-pencil questionnaire was provided to nurses. Data were collected between July and August 2022.

2.3. Data Collection. The first author explained the purpose, significance, and methods of the survey to the nurse managers of each section at their meeting after approval from the director of nursing. The informed consent included the explanation about voluntary participation with no rewards or demerits regardless of participation, anonymity, and not to be used for work evaluation. The first author provided a total of 997 survey forms in the director of the nursing office, which were divided into 30 sections according to the number of nurses in each section. The nurse manager in each section took the survey forms to his/her section and asked nurses to voluntarily collaborate on the survey at their convenience and return it after putting it into the sealed envelope to the designated collection bags provided in their respective sections. Nurse managers returned the bags containing the questionnaires in sealed envelopes, as well as any remaining survey forms, in 2-3 weeks to the director of the nursing office, and the survey materials were collected by the first author.

2.4. Variables and Instruments. The survey consisted of four main parts: (1) demographic factors (10 items), (2) individual experience factors (4 items), (3) basic knowledge of COVID-19 (20 items), and (4) professional autonomy questions (27 items). Items included demographic factors, individual experience factors, and basic knowledge of COVID-19 which were individual factors potentially related to professional autonomy based on previous research.

Demographic factors included sex [12], age [12], section, years of nursing experience [7, 12, 13], position [11], educational background [12], ladder level [24], and having certified nurse specialists (master level) or certified nurse (six-months training) qualifications. Individual experience factors included the number of COVID-19 patients experienced [13], frequency and contents of searching for the latest information about COVID-19, frequency they used scientific sources [26], and frequency of training/study sessions on COVID-19 attended at the hospital [19]. Basic knowledge of COVID-19 [4, 7] included coronavirus disease, infection period, polymerase chain reaction (PCR) test, nasopharyngeal antigen test, risk of complications, and infection control measures. These individual experience factors and basic knowledge are considered to be related to professional autonomy [4, 6, 27].

The questions for knowledge about COVID-19 were developed by researchers, including a middle-level nurse caring for patients with COVID-19 and a nurse manager of the COVID-19 ward who was not included in the research team based on her ward's COVID-19 guidelines. The ward's COVID-19 guidelines were previously created by external experts, and the head nurse confirmed the contents.

Participants responded right or wrong for each statement, and the number of correct answers was counted. The possible scores ranged from 0 (lowest) to 20 (highest). As the pilot test, five midlevel nurses with experience in caring for COVID-19 patients were asked to answer the 20 items for basic knowledge of COVID-19 twice with a 3-day interval [27]. We used the test-retest reliability to assess the total score stability with the intraclass correlation coefficient (ICC). The consistency was considered favorable if the ICC value was ≥0.70 [27], and the ICC in the current study was 0.833.

Contents of searching for the latest information about COVID-19 included general information about COVID-19 (the disease itself), the contagion of COVID-19, infection control measures, clinical studies results, treatment methods of COVID-19, nursing care for patients with COVID-19, nursing case study of the patients with COVID-19, others, and not searched. These items were also decided by researchers and the nurse manager of the COVID-19 ward based on the necessary knowledge to take care of patients with COVID-19 [4, 7, 26]. Participants were asked if they ever searched or not for each item.

Regarding nurses' professional autonomy, we modified the scale developed by Kikuchi and Harada published in 1997 after obtaining Kikuchi's permission [28]. Although there are several scales to measure nurses' professional autonomy, we selected the scale for the following reasons. One review [29] showed that 15 measures of nurses' autonomy were developed worldwide between 1974 and 2015, and 3 of them were developed by Japanese researchers. The scale developed by Kikuchi [28] was used in more nursing studies (eight) in Japan and had higher internal consistency than the scale developed by Tao in 1979 and the professional autonomy scale in nursing developed by Shijiki in 1999 [30]. Overall, 7 of the 12 professional autonomy scales outside of Japan are commonly used [29]. Among these 7 scales, 3 are validated in Japanese [31–33]. However, these scales may not necessarily be appropriate for the Japanese situation, including items such as "I consider I will gain the proper education and experience and begin working independently like a nurse practitioner" because there is no nurse practitioner who can work independently in Japan.

Kikuchi viewed nursing activities as cognition, judgment, and performance and developed their scale for Japanese nurses. Kikuchi original scale included 5 subscales with 47 items, namely, cognition (14 items), performance (14 items), concrete judgment (7 items), abstract judgment (7 items), and independent judgment (5 items) [28]. This scale covers the two main components of nurses' professional autonomy [6]: independence in decision-making including three types of judgments and the ability to utilize own competence of cognition and performance. During the COVID-19 pandemic, nurses were required to make decisions by themselves and work in unprecedented situations. Therefore, these scales were important in our study, which was conducted during the COVID-19 pandemic. However, Kikuchi's original scale was developed more than two decades ago and has some items that were not necessary in our study. Thus, researchers including the supervising professor

discussed with the head nurse of the COVID-19 ward and modified it to fit the current clinical situation. The number of items was reduced to 27 items to decrease the participant burden. The revised scale included cognition (9 items), performance (6 items), concrete judgment (4 items), abstract judgment (6 items), and basic nursing judgment (2 items). Each item was rated on the same 5-point Likert scale, with the scores ranging from 1 (strongly disagree) to 5 (strongly agree). The total score ranged from 27 to 135. Pilot testing using the revised scale was conducted among the same five middle-level nurses with nursing experience caring for COVID-19 patients, and face validity was confirmed. The internal consistency of the pilot study for the total score of nurses' professional autonomy when caring for COVID-19 patients was evaluated using Cronbach's α, with a value of ≥ 0.7 considered acceptable [34]. Cronbach's α in this was 0.952. We also used test-retest reliability to assess the score stability, with an ICC of 0.963 for the total score. The ICC values of the 5 factors were 0.960, 0.905, 0.860, 0.900, and 0.885, respectively.

2.5. Statistical Analyses. The target sample size for this study was calculated using G*Power (version 3.1.9.7). To detect a small effect size (d) of 0.2 with an α error of 0.05 (two-tailed) and a power of 0.8 by the paired t-test, 199 participants were required. Participant characteristics are described as descriptive statistics. The normality of data distribution was assessed using the skewness-kurtosis test, with a skewness of < -2 or >2 defined to indicate non-normally distributed data [35]. The total scores of the autonomy scale when caring for COVID-19 patients had a skewness value of -0.22 and a kurtosis value of 1.61; when caring for other patients, the values were -0.83 and 1.34, respectively. Therefore, the data were regarded to be normally distributed; hence, parametric tests were used. A paired t-test was used to compare the total score, average score of each factor, and each autonomy score between caring for COVID-19 patients and for other patients. The statistical significance level was set at $p < 0.01$ to decrease alpha error in the paired t-test for 27 individual items. Cohen's d was used to compare the effect size of the difference between caring for COVID-19 patients and for other patients among the factors and items of professional autonomy.

The total scores of professional autonomies when caring for COVID-19 patients were compared among three or more groups (sections) using an analysis of variance. Further, comparisons between two independent groups such as sex, age (20–40 years vs. 41–60 years), having a qualification of certified nurse specialist/certified nurse or not, and searching for the latest information about COVID-19 or not were performed using an independent t-test. Spearman's correlation coefficients (ρ) were used to analyze the association between nurses' professional autonomy when caring for patients with COVID-19 and non-normally distributed continuous variables such as age (four groups), years of nursing experience, and ordinal variables of educational level, position, ladder level, frequency of searching for the

latest information about COVID-19, frequency of using scientific sources, number of COVID-19 patients cared for, and frequency of attending training/study sessions at the hospital. Significant factors related to nurses' autonomy when caring for COVID-19 patients in the bivariate analyses ($p < 0.1$) were included in the stepwise multiple linear regression analysis to explore the independent factors related to nurses' professional autonomy. The normality of the residuals was confirmed using the Durbin–Watson ratio (between 1.5 and 2.5) [36]. Multicollinearity was checked using the variance inflation factor (VIF) (<10.0). An alpha level of 0.05 was set to indicate significance in the stepwise multiple linear regression. All statistical analyses were performed using SPSS version 22 (SPSS Inc., Chicago, IL, USA) software.

3. Results

3.1. Participant Demographics and Experiences. A total of 318 questionnaires were collected, yielding a response rate of 31.8%. Duplicate responses were checked using identified duplicate cases function in SPSS, and no duplicates were identified. Overall, 63 participants were excluded because they had not cared for COVID-19 patients. After excluding 14 questionnaires with missing values, data from 241 participants were used in the analysis (effective response rate, 94.5%). Table 1 presents the participants' characteristics. The average length of nursing experience was 10.3 ± 9.2 years. In total, 51.9% of the respondents were aged ≤ 30 years, and 93.4% were female. Most participants were staff nurses (87.6%) and had a Bachelor's degree (70.1%), with only 1.2% having a Master's degree. The most frequent educational backgrounds by age group were as follows: 92.0% of nurses aged 20–30 years and 76.8% of those aged 31–40 years completed a 4-year university nursing program, and 51.4% of those aged 41–50 years and 80% of those aged 51–60 years completed a 3 year vocational nursing school program. For the distribution according to station, 20.7% of nurses were from internal medicine; 30.7%, surgery; 11.6%, outpatient; and 36.9%, other stations. Over half (59.3%) of the participants did not attend any training sessions on COVID-19 at the hospital during the pandemic (Table 1). Approximately, 60% of the participants searched the information about COVID-19 (the disease itself), while less than 5% of them searched for the results of clinical studies and nursing case studies about patients with COVID-19 (Table 2).

3.2. Basic Knowledge of COVID-19. The average number of correct answers was 17.4 ± 1.4. Table 3 shows the questions ranked in order by the highest correct rates. Five items, such as the fatality rate of COVID-19 and utilization of N95 masks when caring for infectious patients, were responded to 100% correctly (nos. 1–5). Eight items, including risk factors of severe disease, personal protective equipment (PPE) usage when working with a deceased body, choosing rapid PCR testing for patients suspected of COVID-19,

Table 1: Participant characteristics and association with the total score of professional autonomy when caring for patients with COVID-19 ($n = 241$).

Characteristics	Categories	n (%)/M ± SD	Average professional autonomy score ± SD when caring for patients with COVID-19	ρ^a	p

TABLE 3: Basic knowledge of COVID-19 ($n = 241$).

	Items	Correct response (%)
1	The fatality rate remains constant regardless of age or underlying diseases	100.0
2	Wear an N95 mask when suctioning airway secretions from suspected or positive patients	100.0
3	Wear an N95 mask while performing endotracheal intubation on suspected or positive patients	100.0
4	Wear an N95 mask when applying noninvasive positive pressure ventilation (NPPV) to suspected or positive patients	100.0
5	Wear an N95 mask when performing bronchoscopy on suspected or positive patients	100.0
6	Chronic kidney disease, type 2 diabetes, and hypertension are not risk factors for severe disease	99.6
7	Personal protective equipment is not required when providing direct care to the dead body of an infected patient	99.2
8	If there is a suspicion of COVID-19, even if the antigen test was negative, one rapid PCR testing should be performed in the hospital	98.8
9	A surgical mask is sufficient when talking to suspected or positive patients at a distance	98.3
10	Wear an N95 mask when performing cardiopulmonary resuscitation (CPR) on suspected or positive patients	97.5
11	If the patient (positive) is not present, the staff member performing the environmental disinfection is not required to wear gloves and gowns	97.1
12	If you are only serving meals to suspected or positive patients in their hospital rooms, only surgical masks and gloves are required	96.3
13	The infectious period starts 2 days prior and lasts 7–10 days after the onset of symptoms	95.4
14	If a new COVID-19 infection is suspected after admission, even if the screening test result is negative, a nasopharyngeal antigen test should be performed promptly	87.1
15	Respiratory therapy options for critically ill patients are high-flow oxygen therapy and noninvasive positive pressure ventilation	71.8
16	The peak of viral shedding for COVID-19 is 2-3 days after onset	70.5
17	The incubation period of COVID-19 (omicron strain) is approximately 2-3 days	69.7
18	Alcohol is effective as a disinfectant against COVID-19, but hypochlorous acid water is not	66.0
19	Always wash and sanitize dishes used by patients (positive) separately from other patients	58.5
20	Order of removing personal protective equipment (PPE), in case of double gloving: hand disinfection ⟶ outer gloves ⟶ hand disinfection ⟶ remove gown and inner gloves while turning them inside out ⟶ hand disinfection ⟶ face shield and goggles ⟶ hand disinfection ⟶ cap ⟶ hand disinfection ⟶ mask ⟶ hand disinfection	33.6

surgical mask and N95 using situations, PPE usage when performing environmental disinfection, and infectious period of COVID-19 (nos. 6–13), had a correct response rate of over 90%. However, 4 items (nos. 17–20), including the peak viral shedding and the incubation period of COVID-19 and practices (alcohol disinfection and sanitizing patients'

dishes) for infection prevention and control, had a low correct response rate (<70%). The item with the lowest correct response rate (33.6%) pertained to the order of removing PPE (no. 20).

3.3. Differences in Autonomy Scores between Caring for COVID-19 and Other Patients. The total score for nurses' professional autonomy was significantly lower ($t = -12.1$, $p < 0.001$, Cohen's $d = 0.780$) when caring for COVID-19 patients than for other patients (Table 4). The scores for the five factors and all their items were significantly lower when caring for patients with COVID-19 than for other patients ($p < 0.001$). The highest mean score when caring for COVID-19 patients was for Factor 2 (performance), while the lowest mean score was for Factor 4 (abstract judgment). The highest Cohen's d was for Factor 1 (cognition), while the lowest Cohen's d was for Factor 5 (basic nursing judgment). Cohen's d of two items in Factor 1 was ≥0.7: "I can predict the physical effects of the treatment on the patient" and "I can predict future problems that may occur to the patient based on the course of events to date." Further, 7 items had Cohen's d of 0.6 to 0.5, and 18 items had Cohen's d of 0.4 to 0.3. The item with the lowest Cohen's d (0.314) was "I can use the latest scientific evidence including the nursing articles to decide appropriate nursing," which belonged to Factor 4 (Abstract judgment). Table 4 includes the overall Cronbach's alphas and the subscales for both caring situations.

3.4. Factors Influencing Nurses' Professional Autonomy When Caring for Patients with COVID-19. Table 1 shows the association between the total score for professional autonomy when caring for patients with COVID-19 and each variable. Participants aged ≥41 years had higher professional autonomy than those aged ≤40 years ($p = 0.015$). Years of nursing experience ($\rho = 0.163$, $p = 0.011$), number of COVID-19 patients experienced ($\rho = 0.176$, $p = 0.006$), and frequency of attending training/study sessions about COVID-19 at the hospital ($\rho = 0.150$, $p = 0.020$) were positively associated with professional autonomy. Although clinical ladder was positively associated with professional autonomy ($\rho = 0.152$, $p = 0.018$), the highest professional autonomy (96.0 ± 21.0) was observed among nurses with a clinical ladder level "0."

The total score of professional autonomy did not significantly differ according to four age groups, sex, stations, position, nursing certification, educational background, frequency, and contents searched for the latest information about COVID-19, and frequency of using scientific sources.

Based on the bivariate analyses, 2 age groups (20–40 and 41–60 years), years of nursing experience, clinical ladder level, frequency of attending training/study sessions at the hospital, and the number of COVID-19 patients cared for were entered into the stepwise multiple linear regression analysis. The results indicated that longer years of nursing experience ($\beta = 0.208$, $p = 0.001$, adjusted $R^2 = 0.040$) and a higher number of patients with COVID-19 experienced ($\beta = 0.140$, $p = 0.026$, adjusted $R^2 = 0.015$) were significantly related to higher autonomy scores. The explanatory variance of these two factors was 5.5% (Table 5).

4. Discussion

This study found that nurses' professional autonomy with all investigated five factors and 27 items was significantly lower when caring for COVID-19 patients than when caring for other patients. Specifically, Factor 1 (cognition) exhibited the most decreased scores when caring for COVID-19 patients than when caring for other patients. Factor 4 (abstract judgment) showed the smallest difference between caring for COVID-19 and for other patients, but the score was the lowest. On the other hand, Factor 5 (basic nursing Judgment) demonstrated relatively higher scores, even when caring for COVID-19 patients. Factors related to higher professional autonomy when caring for COVID-19 patients were longer years of nursing experience and experiencing more patients with COVID-19. To the best of our knowledge, this is the first study to compare the professional autonomy of the same nurses when caring for COVID-19 and for other patients and to report individual factors related to professional autonomy when caring for COVID-19 patients using a scale.

Among the five factors of professional autonomy, Factor 1 (cognition) exhibited the highest Cohen's d score, with 5 items greater than 0.5. The predictive items for patient outcomes were significantly lower when caring for COVID-19 patients than when caring for other patients. The items with the highest Cohen's d scores were to predict the effects of the treatment and future problems, to identify changes in a patient's condition, and to understand the relationship between test results and symptoms. These results may be attributed to a lack of sufficient information on COVID-19, limited experience in acquiring the necessary knowledge and skills to predict treatment responses, and provision of appropriate care for COVID-19 patients [37], resulting in an inability to effectively apply knowledge, skills, and judgment [5].

Factor 5 (basic nursing judgment) had the lowest Cohen's d, and the average score was relatively high with the items focused on choosing appropriate nursing methods considering a patient's needs. It is assumed that nurses gained the basic nursing skills required to work with COVID-19 patients, which can also be common with other patients. Additionally, the item about using the latest scientific evidence in nursing practice in Factor 4 (abstract judgment) showed the smallest difference between caring for COVID-19 and for other patients, but the average score was the lowest. Although it was important for the participants to obtain appropriate information about the unprecedented COVID-19 pandemic, very few participants searched for clinical studies and nursing practice cases, consistent with previous reports [38–40]. Collectively, these results support that most nurses may not use scientific evidence in their nursing practice, regardless of the current pandemic situation [38–40]. In Japan, approximately 12% of nurses working in hospitals had a university degree, and 1.3% had completed graduate education [41]. In our study, although the majority of the participants were university graduates (68.9%), only a similar proportion held Master's degree (1.2%). This indicates that undergraduate education alone is

TABLE 4: Differences in nurses' professional autonomy scores between caring for COVID-19 and other patients ($n = 241$).

Items	When caring for COVID-19 patients		When caring for other patients		Cohen's d	p
	Mean ± SD	α	Mean ± SD	α		
Factor 1: cognition	3.4 ± 0.5	0.85	3.8 ± 0.4	0.87	0.86	<0.001
I can predict the physical effects of the treatment on the patient	3.3 ± 0.8		3.9 ± 0.5		0.72	<0.001
I can predict future problems that may occur to the patient based on the course of events to date	3.2 ± 0.8		3.8 ± 0.6		0.70	<0.001
I can accurately identify changes in a patient's general condition	3.2 ± 0.8		3.6 ± 0.6		0.64	<0.001
I can understand the relationship between a patient's test results and symptoms	3.4 ± 0.7		3.8 ± 0.5		0.60	<0.001
I can fully understand the values of my patients	3.2 ± 0.8		3.5 ± 0.7		0.57	<0.001
I can understand the discrepancy between a patient's verbal and emotional behavior	3.3 ± 0.8		3.6 ± 0.6		0.48	<0.001
I can predict the psychological impact of hospitalization and treatment on the patient	3.5 ± 0.8		3.9 ± 0.6		0.47	<0.001
I am able to gather the information needed for nursing care (patient's personality, lifestyle, psychological problems he/she may have)	3.5 ± 0.8		3.9 ± 0.5		0.46	<0.001
I can show empathic understanding of the patient's words and actions	3.7 ± 0.8		4.0 ± 0.6		0.43	<0.001
Factor 2: performance	3.5 ± 0.6	0.85	3.8 ± 0.5	0.84	0.62	<0.001
I am able to provide nursing care based on the patient's distinctive characteristic of individual or social life	3.4 ± 0.7		3.8 ± 0.5		0.53	<0.001
I am able to prioritize and systematically carry out my nursing duties	3.7 ± 0.6		3.9 ± 0.5		0.52	<0.001
I can cooperate with other professionals	3.7 ± 0.7		4.2 ± 0.6		0.48	<0.001
I can allay a patient's distrust and anxiety about medical care by providing sufficient explanation	3.3 ± 0.7		3.6 ± 0.6		0.46	<0.001
I am able to provide nursing care calmly in an emergency	3.1 ± 0.9		3.4 ± 0.8		0.45	<0.001
I can handle a patient's emotions (anger, sadness)	3.4 ± 0.7		3.7 ± 0.6		0.38	<0.001
Factor 3: concrete judgment	3.4 ± 0.7	0.83	3.8 ± 0.6	0.85	0.61	<0.001
I can assess a patient's condition from various information and choose nursing care that is appropriate for the patient's needs	3.3 ± 0.7		3.7 ± 0.6		0.57	<0.001
I can perform nursing assessments and provide recommendations to achieve the highest quality of care	3.4 ± 0.7		3.8 ± 0.6		0.50	<0.001
I can respond to sudden physiological changes in the patient (hematemesis, loss of consciousness, hypotension, chills)	3.3 ± 0.9		3.6 ± 0.7		0.46	<0.001
I can prioritize a patient's problem and clarify the most important problem among the many problems	3.5 ± 0.7		3.7 ± 0.6		0.42	<0.001
Factor 4: abstract judgment	3.2 ± 0.7	0.89	3.4 ± 0.6	0.86	0.50	<0.001
I can proactively present patient's problems and lead to solve it at the medical meetings	3.2 ± 0.8		3.5 ± 0.7		0.46	<0.001
I can evaluate a patient's symptoms and test results and select appropriate nursing methods	3.4 ± 0.7		3.7 ± 0.6		0.45	<0.001
I can make nursing decisions based on the medical situation without sufficient information	2.9 ± 0.8		3.1 ± 0.9		0.39	<0.001
I can plan nursing care using the nursing model and introduce it to my coworkers	3.2 ± 0.8		3.4 ± 0.7		0.34	<0.001
The nursing plan that I developed can be approved by my coworkers	3.4 ± 0.7		3.6 ± 0.7		0.32	<0.001
I can use the latest scientific evidence including nursing articles to decide on appropriate nursing	2.7 ± 0.9		2.9 ± 1.0		0.31	<0.001
Factor 5: basic nursing judgment	3.5 ± 0.7	0.83	3.7 ± 0.6	0.75	0.43	<0.001
I can choose nursing methods considering the patient's needs	3.5 ± 0.7		3.8 ± 0.6		0.42	<0.001
I can choose appropriate nursing methods, regardless of the patient's words and actions	3.4 ± 0.7		3.6 ± 0.6		0.33	<0.001
Total scores	91.1 ± 14.5	0.95	99.9 ± 11.8	0.94	0.78	<0.001

Paired t-test, α: Cronbach's α coefficients. The items within each factor are arranged in descending order of Cohen's d.

inadequate to apply scientific evidence and achieve higher professional autonomy in pandemic situations.

Further, in our study, age, educational background, clinical ladder level, and using scientific sources were not related to nurses' professional autonomy when caring for COVID-19 patients. A previous study reported that years of experience, but not age, was significantly correlated to the nurses' professional autonomy [8], consistent with the current results. Regarding educational background, three nurses had Master's degrees and had the highest professional

Table 5: Factors related to nurses' professional autonomy when caring for patients with COVID-19 ($n = 241$).

Factors	β	T	p	VIF	Adjusted R^2
Years of nursing experience	0.208	3.311	0.001	1.000	0.040
Number of patients with COVID-19 experienced	0.140	2.233	0.026	1.000	0.015

Stepwise multiple linear regression. Dependent variable: total scores of nurses' professional autonomy when caring for COVID-19 patients. Final model: Durbin–Watson = 2.115, overall adjusted $R^2 = 0.055$. VIF: variance inflation factor of all variables.

autonomy score in this study. Despite having higher educational backgrounds, young nurses (i.e., those aged ≤40 years) had fewer years of nursing experience and tended to exhibit lower levels of professional autonomy compared with older nurses (i.e., those aged ≥41 years). Additionally, it should be noted that some older nurses who did not take the clinical ladder were on level 0 despite their longer nursing experience and higher professional autonomy. In our study, less than 5% of the participants searched for results of clinical studies and nursing case studies about patients with COVID-19. There was no obvious association between using scientific sources and professional nursing autonomy, although previous studies reported that using scientific sources increased critical thinking [26] and that critical thinking is strongly associated with professional nursing autonomy [26]. Previous studies reported that educational backgrounds were significantly related to the use of research results [42–46], in which over 15% of nurses had a Master's degree. In our study, only 1.2% of nurses had a Master's degree, which can be the reason that the educational levels were not significantly related to professional autonomy scores.

Basic knowledge of COVID-19 and attending training/study sessions on COVID-19 at the hospital were not related to nurses' professional autonomy, either. The correct response rates regarding the peak viral shedding and the incubation period of COVID-19 items (nos. 16–17) were lower than those of the standard precaution items of infection prevention and control (nos. 2–5), which were common infection control protocols and not specific for COVID-19. The item with the lowest correct response rate (33.6%) was the order of PPE removal. PPE removal is a complicated multistep task that requires not only knowledge but also multiple practice. A previous study reported no significant correlation between knowledge and nurse compliance with the use of level 2 PPE [47], and consistent findings were observed in the current study. This indicates that experience-based learning systems such as simulation and role play may be necessary for improving nurses' professional autonomy, in addition to acquiring knowledge.

4.1. Limitations. This current study has several limitations. First, the findings cannot be generalized to all hospital settings because the study was conducted at a university hospital in an urban area in Japan, where the educational level is relatively high. Nationwide surveys, not only in Japan but also in other countries, need to be conducted. Second, subjectivity and response bias are inherent challenges in self-reported questionnaires. The response rate (31.8%) was not high enough, which could have caused a participation bias,

in which nurses with higher professional autonomy could have been included. Third, because there were no rewards for participation and no duplicated answers were found, it was unlikely that the same person responded more than once; however, there is no guarantee that this was the case in this anonymous study. Fourth, the timings of working with COVID-19 patients or other patients were not specified, and some nurses might not have been working with other patients at the time of the investigation. Participants had to consider their previous experiences, which could have caused a memory bias. Fifth, the current study reported a low model fit ($R^2 = 0.055$); only approximately 6% of the variance related to professional autonomy was explained. More factors related to professional autonomy other than those measured in this study should be explored. As this study focused on individual, rather than environmental factors, it is also necessary to further investigate the environmental factors that may affect professional autonomy during the pandemic. Finally, it is not possible to establish causality among variables owing to the cross-sectional study design.

Regardless of these limitations, our study contributes by expanding the existing body of research and offering novel insights into nurses' autonomy. Although factors related to professional autonomy during the COVID-19 pandemic were similar to those before the pandemic, our findings indicate that "cognition" is vulnerable to decrease and "abstract judgment" is as low as during usual conditions among professional autonomy domains.

4.2. Practical Implications. To enhance professional autonomy during unprecedented pandemics, nurses must enhance cognition and abstract judgment. To enhance cognition and abstract judgment, it is necessary to promote the integration of up-to-date information and clinical evidence into their practice, and the following recommendations at the three levels are suggested.

At the individual level, for nurses to be able to predict patients' condition and mitigate the uncertainty experienced during the COVID-19 pandemic, it is crucial to actively obtain information about patients' progress. Nurses should attend the information-sharing meetings and training.

At the organizational level, it is necessary to guide nurses on how to access up-to-date clinical information and research evidence and effectively utilize it. Creating study groups sharing clinical cases and experiences among multiple professionals is crucial in fostering collaboration and knowledge exchange, which may promote nurses' professional growth and autonomy, empowering them to deliver high-quality care. Healthcare organizations should also

incorporate experience-based simulations and role-play practice into their training programs to allow nurses to practice and apply their skills in realistic scenarios. Hospital administrators also need to hire more nurses with graduate education, who play a role in connecting research and practice.

At the policy-making level, it is necessary to make accurate up-to-date information about the infectious disease available to healthcare professionals as soon as possible. In the long run, it is necessary to mandate more education in undergraduate nursing programs on how to use research evidence and to encourage and support more nurses to study in graduate programs. In addition, support may be needed for universities to strengthen research and measures to develop experience-based simulations, such as using virtual reality technology. Further studies are required to clarify the effects of experience-based learning systems in enhancing professional autonomy.

5. Conclusions

Nurses' professional autonomy in all 5 factors and 27 items was significantly lower when caring for COVID-19 patients than when caring for other patients. Specifically, Factor 1 (cognition) exhibited the most decreased scores when caring for COVID-19 patients than when caring for other patients. Factor 4 (abstract judgment) showed the smallest difference between them, but the average score was the lowest. Factors related to higher professional autonomy when caring for COVID-19 patients were longer years of nursing experience and experiencing more patients with COVID-19. To enhance professional autonomy during an unprecedented pandemic, it is necessary for nurses to enhance cognition and abstract judgment. In the event of a future pandemic, nurses need to create an environment in which they routinely access and utilize the latest information and scientific evidence so that they can provide high-quality nursing care based on their own professional judgment and competence. Experience-based learning systems may also be necessary to enhance professional autonomy.

Although individual factors play a vital role in determining professional autonomy, their specific impact during the coronavirus disease 2019 (COVID-19) pandemic has not been studied. This study aimed to compare nurses' professional autonomy when caring for patients with COVID-19 and for other patients and explore factors related to autonomy when caring for these patients. A paper-based questionnaire survey was conducted from June to August 2022 among nurses working at a university hospital in Japan. The survey included demographic factors (10 items, including, age, section, years of nursing experience, position, educational background, ladder level, and having certified nurse specialists or certified nurse qualifications) and individual experience factors (4 items: number of COVID-19 patients experienced, frequency and contents of searching for the latest information about COVID-19, frequency of using scientific sources, and frequency of training/study sessions on COVID-19 attended at the hospital). Additionally, basic knowledge of COVID-19 was evaluated. The scale for nurses' professional autonomy was developed based on a previous study. A paired t-test and stepwise multiple linear regression were used for the analyses. Overall, 241 nurses participated in the survey. The average length of nursing experience was 10.3 ± 9.2 years. The total scores for nurses' professional autonomy in all 5 factors 27 items were significantly lower ($t = -12.1$, $p < 0.001$) when caring for COVID-19 patients than when caring for other patients. Specifically, Factor 1 (Cognition) exhibited the most decreased scores when caring for COVID-19 patients than when caring for other patients. Factor 4 (Abstract judgment) differed the least between caring for COVID-19 and for other patients, but the average score was the lowest. More years of nursing experience ($\beta = 0.208$, $p = 0.001$) and a higher number of patients with COVID-19 cared for ($\beta = 0.140$, $p = 0.026$) were associated with higher autonomy scores. In conclusion, to enhance professional autonomy during an unprecedented pandemic, nurses must enhance cognition and abstract judgment. In the event of a future pandemic, nurses need to create an environment in which they routinely access and utilize the latest information and scientific evidence to provide high-quality nursing care based on their professional judgment and competence.

1. Introduction

The coronavirus disease 2019 (COVID-19) was caused by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and became a global pandemic [1]. The first cases of novel coronavirus were detected in China in December 2019, and the virus has then spread rapidly to other countries worldwide. This led the World Health Organization to declare a Public Health Emergency of International Concern on January 30, 2020, and to characterize the outbreak as a pandemic on March 11, 2020 [1]. As of March 16, 2023, over 760 million confirmed cases and over 6.8 million deaths

have been reported globally since the COVID-19 pandemic started, with a large number of patients requiring medical treatment and intensive care in hospitals [1, 2]. However, this phenomenon occurs not only in hospitals but also in clinics, home nursing service stations, midwifery centers, and other facilities [3]. The COVID-19 pandemic has required nurses to provide quality nursing care for patients with COVID-19 even though they are not trained for this unprecedented situation.

Nurses' professional autonomy is defined as "having the authority to make decisions and freedom to act in accordance with one's professional knowledge" [4]. There are two main components of nurses' professional autonomy: independence in decision-making and the ability to utilize one's own competence. Nursing competence is defined as the ability of a nurse to effectively demonstrate a set of attributes, such as personal characteristics, values, attitudes, knowledge, and skills that are required for nurses to fulfill their professional responsibilities [5]. The utilization of personal competence has been recognized as necessary for nurses' autonomy, including deciding their approach to nursing care [6]. Nurses' professional autonomy is strongly related to job satisfaction, job stress, and psychological distress, which can affect their work engagement [7–10].

Factors that affect nurses' professional autonomy reported before COVID-19 can be classified into individual and environmental factors. Individual factors including sex, educational level, nursing experience, job position, critical thinking, professional skills, and clinical ladder level contribute to the utilization of nurses' professional autonomy [11, 12]. Male nurses have higher independence in decision-making than female nurses. Educational level, nursing experience, job position, critical thinking, and clinical ladder are strongly and positively associated with nurses' professional autonomy [10–12]. Furthermore, the number of patients experienced is also related to nurses' professional autonomy [13]. Meanwhile, environmental factors that can affect nurses' professional autonomy include supportive leadership [14], shared leadership, interprofessional and intraprofessional collaboration, and healthy work environments [6]. Supportive leadership can enhance nurses' professional autonomy, as it has a significant impact on decision-making in nursing care and fosters a positive workplace environment. In contrast, autocratic/non-supportive management may adversely affect nurses' autonomy [14]. Autocratic management is typically marked by a leader's inclination to centralize decision-making and consolidate power, often resulting in complete control over all aspects of their subordinates' activities, with little regard for input from the subordinates [15]. Nurse-physician collaboration and cooperation among nurses without authoritarian impositions could increase nurses' professional autonomy [16]. Meanwhile, poor nurse-physician relationships could reduce nurses' professional autonomy [14]. A healthy working environment promotes nurses' autonomy through good team spirit without conflict or teasing and a well-balanced workload [14].

The COVID-19 pandemic had a significant impact on nurses, with an increase in psychological distress and a decrease in job satisfaction [7, 17]. Nurses experienced significant stress and moral distress due to unfavorable job demands [17]. Common reasons for moral distress include a lack of decision-making autonomy, insufficient workplace respect, and inadequate psychosocial support mechanisms to help nurses cope with ethical dilemmas in both intensive care units [18] and general units [17, 19–21]. One study indicated that nurses' psychological stress during the COVID-19 pandemic could be related to their lower autonomy and competence [7]. However, it is unclear how the current pandemic has affected nurses' professional autonomy. Previous studies have investigated the relationship between environmental factors and professional autonomy during the pandemic. One study reported that the nurse-physician relationship improved because of the COVID-19 pandemic, and shared education and collaboration had a significantly positive influence on the nurses' professional autonomy [16]. Other studies reported that a high level of autonomy was associated with greater organizational citizenship behavior [22, 23] and low work-family conflict [24]. Organizational citizenship behavior is a type of cooperative behavior that increases a person's tendency toward helping and sharing information [22, 23]. However, no study has reported individual factors that can predict professional autonomy during the COVID-19 pandemic. One study reported that more younger nurses felt their professional autonomy increased than older nurses during the pandemic [25], but this study did not measure and compare professional autonomy using scores. Therefore, it was unknown whether age is related to increased autonomy.

Although individual factors play a vital role in determining professional autonomy, their specific impact in this particular scenario has not been studied. It is necessary to identify the individual factors that can affect professional autonomy during a pandemic, which can be used to develop individual training and educational programs. Therefore, this study specifically focused on investigating individual factors. This study aimed to (1) compare nurses' professional autonomy of the same nurses when caring for patients with COVID-19 and other patients and (2) explore individual factors related to nurses' autonomy when caring for patients with COVID-19.

2. Materials and Methods

2.1. Study Design. This cross-sectional study used the convenience sampling method as researchers' accessibility to participants. This study was approved by the Ethics Review Committee of the Institute of Education of Tokyo Medical and Dental University (Approval No.: C2022-01) and was conducted according to the tenets of the Declaration of Helsinki. Informed consent was obtained from all participants.

2.2. Participants and Setting. Participants were nurses who were employed at the 750-bed university hospital in an urban area of Japan during the study period. The study hospital had been actively contributing to measures against

COVID-19 since 2020. The inclusion criteria were working at the hospital for more than 1 year and having experience caring for COVID-19 patients. Nurses in the director's office were excluded. A paper-and-pencil questionnaire was provided to nurses. Data were collected between July and August 2022.

2.3. Data Collection. The first author explained the purpose, significance, and methods of the survey to the nurse managers of each section at their meeting after approval from the director of nursing. The informed consent included the explanation about voluntary participation with no rewards or demerits regardless of participation, anonymity, and not to be used for work evaluation. The first author provided a total of 997 survey forms in the director of the nursing office, which were divided into 30 sections according to the number of nurses in each section. The nurse manager in each section took the survey forms to his/her section and asked nurses to voluntarily collaborate on the survey at their convenience and return it after putting it into the sealed envelope to the designated collection bags provided in their respective sections. Nurse managers returned the bags containing the questionnaires in sealed envelopes, as well as any remaining survey forms, in 2-3 weeks to the director of the nursing office, and the survey materials were collected by the first author.

2.4. Variables and Instruments. The survey consisted of four main parts: (1) demographic factors (10 items), (2) individual experience factors (4 items), (3) basic knowledge of COVID-19 (20 items), and (4) professional autonomy questions (27 items). Items included demographic factors, individual experience factors, and basic knowledge of COVID-19 which were individual factors potentially related to professional autonomy based on previous research.

Demographic factors included sex [12], age [12], section, years of nursing experience [7, 12, 13], position [11], educational background [12], ladder level [24], and having certified nurse specialists (master level) or certified nurse (six-months training) qualifications. Individual experience factors included the number of COVID-19 patients experienced [13], frequency and contents of searching for the latest information about COVID-19, frequency they used scientific sources [26], and frequency of training/study sessions on COVID-19 attended at the hospital [19]. Basic knowledge of COVID-19 [4, 7] included coronavirus disease, infection period, polymerase chain reaction (PCR) test, nasopharyngeal antigen test, risk of complications, and infection control measures. These individual experience factors and basic knowledge are considered to be related to professional autonomy [4, 6, 27].

The questions for knowledge about COVID-19 were developed by researchers, including a middle-level nurse caring for patients with COVID-19 and a nurse manager of the COVID-19 ward who was not included in the research team based on her ward's COVID-19 guidelines. The ward's COVID-19 guidelines were previously created by external experts, and the head nurse confirmed the contents.

Participants responded right or wrong for each statement, and the number of correct answers was counted. The possible scores ranged from 0 (lowest) to 20 (highest). As the pilot test, five midlevel nurses with experience in caring for COVID-19 patients were asked to answer the 20 items for basic knowledge of COVID-19 twice with a 3-day interval [27]. We used the test-retest reliability to assess the total score stability with the intraclass correlation coefficient (ICC). The consistency was considered favorable if the ICC value was ≥0.70 [27], and the ICC in the current study was 0.833.

Contents of searching for the latest information about COVID-19 included general information about COVID-19 (the disease itself), the contagion of COVID-19, infection control measures, clinical studies results, treatment methods of COVID-19, nursing care for patients with COVID-19, nursing case study of the patients with COVID-19, others, and not searched. These items were also decided by researchers and the nurse manager of the COVID-19 ward based on the necessary knowledge to take care of patients with COVID-19 [4, 7, 26]. Participants were asked if they ever searched or not for each item.

Regarding nurses' professional autonomy, we modified the scale developed by Kikuchi and Harada published in 1997 after obtaining Kikuchi's permission [28]. Although there are several scales to measure nurses' professional autonomy, we selected the scale for the following reasons. One review [29] showed that 15 measures of nurses' autonomy were developed worldwide between 1974 and 2015, and 3 of them were developed by Japanese researchers. The scale developed by Kikuchi [28] was used in more nursing studies (eight) in Japan and had higher internal consistency than the scale developed by Tao in 1979 and the professional autonomy scale in nursing developed by Shijiki in 1999 [30]. Overall, 7 of the 12 professional autonomy scales outside of Japan are commonly used [29]. Among these 7 scales, 3 are validated in Japanese [31–33]. However, these scales may not necessarily be appropriate for the Japanese situation, including items such as "I consider I will gain the proper education and experience and begin working independently like a nurse practitioner" because there is no nurse practitioner who can work independently in Japan.

Kikuchi viewed nursing activities as cognition, judgment, and performance and developed their scale for Japanese nurses. Kikuchi original scale included 5 subscales with 47 items, namely, cognition (14 items), performance (14 items), concrete judgment (7 items), abstract judgment (7 items), and independent judgment (5 items) [28]. This scale covers the two main components of nurses' professional autonomy [6]: independence in decision-making including three types of judgments and the ability to utilize own competence of cognition and performance. During the COVID-19 pandemic, nurses were required to make decisions by themselves and work in unprecedented situations. Therefore, these scales were important in our study, which was conducted during the COVID-19 pandemic. However, Kikuchi's original scale was developed more than two decades ago and has some items that were not necessary in our study. Thus, researchers including the supervising professor

discussed with the head nurse of the COVID-19 ward and modified it to fit the current clinical situation. The number of items was reduced to 27 items to decrease the participant burden. The revised scale included cognition (9 items), performance (6 items), concrete judgment (4 items), abstract judgment (6 items), and basic nursing judgment (2 items). Each item was rated on the same 5-point Likert scale, with the scores ranging from 1 (strongly disagree) to 5 (strongly agree). The total score ranged from 27 to 135. Pilot testing using the revised scale was conducted among the same five middle-level nurses with nursing experience caring for COVID-19 patients, and face validity was confirmed. The internal consistency of the pilot study for the total score of nurses' professional autonomy when caring for COVID-19 patients was evaluated using Cronbach's α, with a value of ≥ 0.7 considered acceptable [34]. Cronbach's α in this was 0.952. We also used test-retest reliability to assess the score stability, with an ICC of 0.963 for the total score. The ICC values of the 5 factors were 0.960, 0.905, 0.860, 0.900, and 0.885, respectively.

2.5. Statistical Analyses. The target sample size for this study was calculated using G*Power (version 3.1.9.7). To detect a small effect size (d) of 0.2 with an α error of 0.05 (two-tailed) and a power of 0.8 by the paired t-test, 199 participants were required. Participant characteristics are described as descriptive statistics. The normality of data distribution was assessed using the skewness-kurtosis test, with a skewness of < -2 or > 2 defined to indicate non-normally distributed data [35]. The total scores of the autonomy scale when caring for COVID-19 patients had a skewness value of −0.22 and a kurtosis value of 1.61; when caring for other patients, the values were −0.83 and 1.34, respectively. Therefore, the data were regarded to be normally distributed; hence, parametric tests were used. A paired t-test was used to compare the total score, average score of each factor, and each autonomy score between caring for COVID-19 patients and for other patients. The statistical significance level was set at $p < 0.01$ to decrease alpha error in the paired t-test for 27 individual items. Cohen's d was used to compare the effect size of the difference between caring for COVID-19 patients and for other patients among the factors and items of professional autonomy.

The total scores of professional autonomies when caring for COVID-19 patients were compared among three or more groups (sections) using an analysis of variance. Further, comparisons between two independent groups such as sex, age (20–40 years vs. 41–60 years), having a qualification of certified nurse specialist/certified nurse or not, and searching for the latest information about COVID-19 or not were performed using an independent t-test. Spearman's correlation coefficients (ρ) were used to analyze the association between nurses' professional autonomy when caring for patients with COVID-19 and non-normally distributed continuous variables such as age (four groups), years of nursing experience, and ordinal variables of educational level, position, ladder level, frequency of searching for the

latest information about COVID-19, frequency of using scientific sources, number of COVID-19 patients cared for, and frequency of attending training/study sessions at the hospital. Significant factors related to nurses' autonomy when caring for COVID-19 patients in the bivariate analyses ($p < 0.1$) were included in the stepwise multiple linear regression analysis to explore the independent factors related to nurses' professional autonomy. The normality of the residuals was confirmed using the Durbin–Watson ratio (between 1.5 and 2.5) [36]. Multicollinearity was checked using the variance inflation factor (VIF) (<10.0). An alpha level of 0.05 was set to indicate significance in the stepwise multiple linear regression. All statistical analyses were performed using SPSS version 22 (SPSS Inc., Chicago, IL, USA) software.

3. Results

3.1. Participant Demographics and Experiences. A total of 318 questionnaires were collected, yielding a response rate of 31.8%. Duplicate responses were checked using identified duplicate cases function in SPSS, and no duplicates were identified. Overall, 63 participants were excluded because they had not cared for COVID-19 patients. After excluding 14 questionnaires with missing values, data from 241 participants were used in the analysis (effective response rate, 94.5%). Table 1 presents the participants' characteristics. The average length of nursing experience was 10.3 ± 9.2 years. In total, 51.9% of the respondents were aged ≤30 years, and 93.4% were female. Most participants were staff nurses (87.6%) and had a Bachelor's degree (70.1%), with only 1.2% having a Master's degree. The most frequent educational backgrounds by age group were as follows: 92.0% of nurses aged 20–30 years and 76.8% of those aged 31–40 years completed a 4-year university nursing program, and 51.4% of those aged 41–50 years and 80% of those aged 51–60 years completed a 3 year vocational nursing school program. For the distribution according to station, 20.7% of nurses were from internal medicine; 30.7%, surgery; 11.6%, outpatient; and 36.9%, other stations. Over half (59.3%) of the participants did not attend any training sessions on COVID-19 at the hospital during the pandemic (Table 1). Approximately, 60% of the participants searched the information about COVID-19 (the disease itself), while less than 5% of them searched for the results of clinical studies and nursing case studies about patients with COVID-19 (Table 2).

3.2. Basic Knowledge of COVID-19. The average number of correct answers was 17.4 ± 1.4. Table 3 shows the questions ranked in order by the highest correct rates. Five items, such as the fatality rate of COVID-19 and utilization of N95 masks when caring for infectious patients, were responded to 100% correctly (nos. 1–5). Eight items, including risk factors of severe disease, personal protective equipment (PPE) usage when working with a deceased body, choosing rapid PCR testing for patients suspected of COVID-19,

TABLE 1: Participant characteristics and association with the total score of professional autonomy when caring for patients with COVID-19 ($n = 241$).

Characteristics	Categories	n (%)/M ± SD	Average professional autonomy score ± SD when caring for patients with COVID-19	ρ^a	p
Age, years (four groups)	20–30	125 (51.9)	90.1 ± 13.6	0.100	0.122[a]
	31–40	56 (23.2)	89.2 ± 15.8

Table 3: Basic knowledge of COVID-19 ($n = 241$).

	Items	Correct response (%)
1	The fatality rate remains constant regardless of age or underlying diseases	100.0
2	Wear an N95 mask when suctioning airway secretions from suspected or positive patients	100.0
3	Wear an N95 mask while performing endotracheal intubation on suspected or positive patients	100.0
4	Wear an N95 mask when applying noninvasive positive pressure ventilation (NPPV) to suspected or positive patients	100.0
5	Wear an N95 mask when performing bronchoscopy on suspected or positive patients	100.0
6	Chronic kidney disease, type 2 diabetes, and hypertension are not risk factors for severe disease	99.6
7	Personal protective equipment is not required when providing direct care to the dead body of an infected patient	99.2
8	If there is a suspicion of COVID-19, even if the antigen test was negative, one rapid PCR testing should be performed in the hospital	98.8
9	A surgical mask is sufficient when talking to suspected or positive patients at a distance	98.3
10	Wear an N95 mask when performing cardiopulmonary resuscitation (CPR) on suspected or positive patients	97.5
11	If the patient (positive) is not present, the staff member performing the environmental disinfection is not required to wear gloves and gowns	97.1
12	If you are only serving meals to suspected or positive patients in their hospital rooms, only surgical masks and gloves are required	96.3
13	The infectious period starts 2 days prior and lasts 7–10 days after the onset of symptoms	95.4
14	If a new COVID-19 infection is suspected after admission, even if the screening test result is negative, a nasopharyngeal antigen test should be performed promptly	87.1
15	Respiratory therapy options for critically ill patients are high-flow oxygen therapy and noninvasive positive pressure ventilation	71.8
16	The peak of viral shedding for COVID-19 is 2-3 days after onset	70.5
17	The incubation period of COVID-19 (omicron strain) is approximately 2-3 days	69.7
18	Alcohol is effective as a disinfectant against COVID-19, but hypochlorous acid water is not	66.0
19	Always wash and sanitize dishes used by patients (positive) separately from other patients	58.5
20	Order of removing personal protective equipment (PPE), in case of double gloving: hand disinfection $\longrightarrow$ outer gloves $\longrightarrow$ hand disinfection $\longrightarrow$ remove gown and inner gloves while turning them inside out $\longrightarrow$ hand disinfection $\longrightarrow$ face shield and goggles $\longrightarrow$ hand disinfection $\longrightarrow$ cap $\longrightarrow$ hand disinfection $\longrightarrow$ mask $\longrightarrow$ hand disinfection	33.6

surgical mask and N95 using situations, PPE usage when performing environmental disinfection, and infectious period of COVID-19 (nos. 6–13), had a correct response rate of over 90%. However, 4 items (nos. 17–20), including the peak viral shedding and the incubation period of COVID-19 and practices (alcohol disinfection and sanitizing patients'

dishes) for infection prevention and control, had a low correct response rate (<70%). The item with the lowest correct response rate (33.6%) pertained to the order of removing PPE (no. 20).

3.3. Differences in Autonomy Scores between Caring for COVID-19 and Other Patients. The total score for nurses' professional autonomy was significantly lower ($t = -12.1$, $p < 0.001$, Cohen's $d = 0.780$) when caring for COVID-19 patients than for other patients (Table 4). The scores for the five factors and all their items were significantly lower when caring for patients with COVID-19 than for other patients ($p < 0.001$). The highest mean score when caring for COVID-19 patients was for Factor 2 (performance), while the lowest mean score was for Factor 4 (abstract judgment). The highest Cohen's d was for Factor 1 (cognition), while the lowest Cohen's d was for Factor 5 (basic nursing judgment). Cohen's d of two items in Factor 1 was ≥0.7: "I can predict the physical effects of the treatment on the patient" and "I can predict future problems that may occur to the patient based on the course of events to date." Further, 7 items had Cohen's d of 0.6 to 0.5, and 18 items had Cohen's d of 0.4 to 0.3. The item with the lowest Cohen's d (0.314) was "I can use the latest scientific evidence including the nursing articles to decide appropriate nursing," which belonged to Factor 4 (Abstract judgment). Table 4 includes the overall Cronbach's alphas and the subscales for both caring situations.

3.4. Factors Influencing Nurses' Professional Autonomy When Caring for Patients with COVID-19. Table 1 shows the association between the total score for professional autonomy when caring for patients with COVID-19 and each variable. Participants aged ≥41 years had higher professional autonomy than those aged ≤40 years ($p = 0.015$). Years of nursing experience ($\rho = 0.163$, $p = 0.011$), number of COVID-19 patients experienced ($\rho = 0.176$, $p = 0.006$), and frequency of attending training/study sessions about COVID-19 at the hospital ($\rho = 0.150$, $p = 0.020$) were positively associated with professional autonomy. Although clinical ladder was positively associated with professional autonomy ($\rho = 0.152$, $p = 0.018$), the highest professional autonomy (96.0 ± 21.0) was observed among nurses with a clinical ladder level "0."

The total score of professional autonomy did not significantly differ according to four age groups, sex, stations, position, nursing certification, educational background, frequency, and contents searched for the latest information about COVID-19, and frequency of using scientific sources.

Based on the bivariate analyses, 2 age groups (20–40 and 41–60 years), years of nursing experience, clinical ladder level, frequency of attending training/study sessions at the hospital, and the number of COVID-19 patients cared for were entered into the stepwise multiple linear regression analysis. The results indicated that longer years of nursing experience ($\beta = 0.208$, $p = 0.001$, adjusted $R^2 = 0.040$) and a higher number of patients with COVID-19 experienced ($\beta = 0.140$, $p = 0.026$, adjusted $R^2 = 0.015$) were significantly related to higher autonomy scores. The explanatory variance of these two factors was 5.5% (Table 5).

4. Discussion

This study found that nurses' professional autonomy with all investigated five factors and 27 items was significantly lower when caring for COVID-19 patients than when caring for other patients. Specifically, Factor 1 (cognition) exhibited the most decreased scores when caring for COVID-19 patients than when caring for other patients. Factor 4 (abstract judgment) showed the smallest difference between caring for COVID-19 and for other patients, but the score was the lowest. On the other hand, Factor 5 (basic nursing Judgment) demonstrated relatively higher scores, even when caring for COVID-19 patients. Factors related to higher professional autonomy when caring for COVID-19 patients were longer years of nursing experience and experiencing more patients with COVID-19. To the best of our knowledge, this is the first study to compare the professional autonomy of the same nurses when caring for COVID-19 and for other patients and to report individual factors related to professional autonomy when caring for COVID-19 patients using a scale.

Among the five factors of professional autonomy, Factor 1 (cognition) exhibited the highest Cohen's d score, with 5 items greater than 0.5. The predictive items for patient outcomes were significantly lower when caring for COVID-19 patients than when caring for other patients. The items with the highest Cohen's d scores were to predict the effects of the treatment and future problems, to identify changes in a patient's condition, and to understand the relationship between test results and symptoms. These results may be attributed to a lack of sufficient information on COVID-19, limited experience in acquiring the necessary knowledge and skills to predict treatment responses, and provision of appropriate care for COVID-19 patients [37], resulting in an inability to effectively apply knowledge, skills, and judgment [5].

Factor 5 (basic nursing judgment) had the lowest Cohen's d, and the average score was relatively high with the items focused on choosing appropriate nursing methods considering a patient's needs. It is assumed that nurses gained the basic nursing skills required to work with COVID-19 patients, which can also be common with other patients. Additionally, the item about using the latest scientific evidence in nursing practice in Factor 4 (abstract judgment) showed the smallest difference between caring for COVID-19 and for other patients, but the average score was the lowest. Although it was important for the participants to obtain appropriate information about the unprecedented COVID-19 pandemic, very few participants searched for clinical studies and nursing practice cases, consistent with previous reports [38–40]. Collectively, these results support that most nurses may not use scientific evidence in their nursing practice, regardless of the current pandemic situation [38–40]. In Japan, approximately 12% of nurses working in hospitals had a university degree, and 1.3% had completed graduate education [41]. In our study, although the majority of the participants were university graduates (68.9%), only a similar proportion held Master's degree (1.2%). This indicates that undergraduate education alone is

TABLE 4: Differences in nurses' professional autonomy scores between caring for COVID-19 and other patients ($n = 241$).

Items	When caring for COVID-19 patients		When caring for other patients		Cohen's d	p
	Mean ± SD	α	Mean ± SD	α		
Factor 1: cognition	3.4 ± 0.5	0.85	3.8 ± 0.4	0.87	0.86	<0.001
I can predict the physical effects of the treatment on the patient	3.3 ± 0.8		3.9 ± 0.5		0.72	<0.001
I can predict future problems that may occur to the patient based on the course of events to date	3.2 ± 0.8		3.8 ± 0.6		0.70	<0.001
I can accurately identify changes in a patient's general condition	3.2 ± 0.8		3.6 ± 0.6		0.64	<0.001
I can understand the relationship between a patient's test results and symptoms	3.4 ± 0.7		3.8 ± 0.5		0.60	<0.001
I can fully understand the values of my patients	3.2 ± 0.8		3.5 ± 0.7		0.57	<0.001
I can understand the discrepancy between a patient's verbal and emotional behavior	3.3 ± 0.8		3.6 ± 0.6		0.48	<0.001
I can predict the psychological impact of hospitalization and treatment on the patient	3.5 ± 0.8		3.9 ± 0.6		0.47	<0.001
I am able to gather the information needed for nursing care (patient's personality, lifestyle, psychological problems he/she may have)	3.5 ± 0.8		3.9 ± 0.5		0.46	<0.001
I can show empathic understanding of the patient's words and actions	3.7 ± 0.8		4.0 ± 0.6		0.43	<0.001
Factor 2: performance	3.5 ± 0.6	0.85	3.8 ± 0.5	0.84	0.62	<0.001
I am able to provide nursing care based on the patient's distinctive characteristic of individual or social life	3.4 ± 0.7		3.8 ± 0.5		0.53	<0.001
I am able to prioritize and systematically carry out my nursing duties	3.7 ± 0.6		3.9 ± 0.5		0.52	<0.001
I can cooperate with other professionals	3.7 ± 0.7		4.2 ± 0.6		0.48	<0.001
I can allay a patient's distrust and anxiety about medical care by providing sufficient explanation	3.3 ± 0.7		3.6 ± 0.6		0.46	<0.001
I am able to provide nursing care calmly in an emergency	3.1 ± 0.9		3.4 ± 0.8		0.45	<0.001
I can handle a patient's emotions (anger, sadness)	3.4 ± 0.7		3.7 ± 0.6		0.38	<0.001
Factor 3: concrete judgment	3.4 ± 0.7	0.83	3.8 ± 0.6	0.85	0.61	<0.001
I can assess a patient's condition from various information and choose nursing care that is appropriate for the patient's needs	3.3 ± 0.7		3.7 ± 0.6		0.57	<0.001
I can perform nursing assessments and provide recommendations to achieve the highest quality of care	3.4 ± 0.7		3.8 ± 0.6		0.50	<0.001
I can respond to sudden physiological changes in the patient (hematemesis, loss of consciousness, hypotension, chills)	3.3 ± 0.9		3.6 ± 0.7		0.46	<0.001
I can prioritize a patient's problem and clarify the most important problem among the many problems	3.5 ± 0.7		3.7 ± 0.6		0.42	<0.001
Factor 4: abstract judgment	3.2 ± 0.7	0.89	3.4 ± 0.6	0.86	0.50	<0.001
I can proactively present patient's problems and lead to solve it at the medical meetings	3.2 ± 0.8		3.5 ± 0.7		0.46	<0.001
I can evaluate a patient's symptoms and test results and select appropriate nursing methods	3.4 ± 0.7		3.7 ± 0.6		0.45	<0.001
I can make nursing decisions based on the medical situation without sufficient information	2.9 ± 0.8		3.1 ± 0.9		0.39	<0.001
I can plan nursing care using the nursing model and introduce it to my coworkers	3.2 ± 0.8		3.4 ± 0.7		0.34	<0.001
The nursing plan that I developed can be approved by my coworkers	3.4 ± 0.7		3.6 ± 0.7		0.32	<0.001
I can use the latest scientific evidence including nursing articles to decide on appropriate nursing	2.7 ± 0.9		2.9 ± 1.0		0.31	<0.001
Factor 5: basic nursing judgment	3.5 ± 0.7	0.83	3.7 ± 0.6	0.75	0.43	<0.001
I can choose nursing methods considering the patient's needs	3.5 ± 0.7		3.8 ± 0.6		0.42	<0.001
I can choose appropriate nursing methods, regardless of the patient's words and actions	3.4 ± 0.7		3.6 ± 0.6		0.33	<0.001
Total scores	91.1 ± 14.5	0.95	99.9 ± 11.8	0.94	0.78	<0.001

Paired t-test, α: Cronbach's α coefficients. The items within each factor are arranged in descending order of Cohen's d.

inadequate to apply scientific evidence and achieve higher professional autonomy in pandemic situations.

Further, in our study, age, educational background, clinical ladder level, and using scientific sources were not related to nurses' professional autonomy when caring for COVID-19 patients. A previous study reported that years of experience, but not age, was significantly correlated to the nurses' professional autonomy [8], consistent with the current results. Regarding educational background, three nurses had Master's degrees and had the highest professional

Table 5: Factors related to nurses' professional autonomy when caring for patients with COVID-19 ($n = 241$).

Factors	β	T	p	VIF	Adjusted R^2
Years of nursing experience	0.208	3.311	0.001	1.000	0.040
Number of patients with COVID-19 experienced	0.140	2.233	0.026	1.000	0.015

Stepwise multiple linear regression. Dependent variable: total scores of nurses' professional autonomy when caring for COVID-19 patients. Final model: Durbin–Watson = 2.115, overall adjusted $R^2 = 0.055$. VIF: variance inflation factor of all variables.

autonomy score in this study. Despite having higher educational backgrounds, young nurses (i.e., those aged ≤40 years) had fewer years of nursing experience and tended to exhibit lower levels of professional autonomy compared with older nurses (i.e., those aged ≥41 years). Additionally, it should be noted that some older nurses who did not take the clinical ladder were on level 0 despite their longer nursing experience and higher professional autonomy. In our study, less than 5% of the participants searched for results of clinical studies and nursing case studies about patients with COVID-19. There was no obvious association between using scientific sources and professional nursing autonomy, although previous studies reported that using scientific sources increased critical thinking [26] and that critical thinking is strongly associated with professional nursing autonomy [26]. Previous studies reported that educational backgrounds were significantly related to the use of research results [42–46], in which over 15% of nurses had a Master's degree. In our study, only 1.2% of nurses had a Master's degree, which can be the reason that the educational levels were not significantly related to professional autonomy scores.

Basic knowledge of COVID-19 and attending training/ study sessions on COVID-19 at the hospital were not related to nurses' professional autonomy, either. The correct response rates regarding the peak viral shedding and the incubation period of COVID-19 items (nos. 16–17) were lower than those of the standard precaution items of infection prevention and control (nos. 2–5), which were common infection control protocols and not specific for COVID-19. The item with the lowest correct response rate (33.6%) was the order of PPE removal. PPE removal is a complicated multistep task that requires not only knowledge but also multiple practice. A previous study reported no significant correlation between knowledge and nurse compliance with the use of level 2 PPE [47], and consistent findings were observed in the current study. This indicates that experience-based learning systems such as simulation and role play may be necessary for improving nurses' professional autonomy, in addition to acquiring knowledge.

4.1. Limitations. This current study has several limitations. First, the findings cannot be generalized to all hospital settings because the study was conducted at a university hospital in an urban area in Japan, where the educational level is relatively high. Nationwide surveys, not only in Japan but also in other countries, need to be conducted. Second, subjectivity and response bias are inherent challenges in self-reported questionnaires. The response rate (31.8%) was not high enough, which could have caused a participation bias,

in which nurses with higher professional autonomy could have been included. Third, because there were no rewards for participation and no duplicated answers were found, it was unlikely that the same person responded more than once; however, there is no guarantee that this was the case in this anonymous study. Fourth, the timings of working with COVID-19 patients or other patients were not specified, and some nurses might not have been working with other patients at the time of the investigation. Participants had to consider their previous experiences, which could have caused a memory bias. Fifth, the current study reported a low model fit ($R^2 = 0.055$); only approximately 6% of the variance related to professional autonomy was explained. More factors related to professional autonomy other than those measured in this study should be explored. As this study focused on individual, rather than environmental factors, it is also necessary to further investigate the environmental factors that may affect professional autonomy during the pandemic. Finally, it is not possible to establish causality among variables owing to the cross-sectional study design.

Regardless of these limitations, our study contributes by expanding the existing body of research and offering novel insights into nurses' autonomy. Although factors related to professional autonomy during the COVID-19 pandemic were similar to those before the pandemic, our findings indicate that "cognition" is vulnerable to decrease and "abstract judgment" is as low as during usual conditions among professional autonomy domains.

4.2. Practical Implications. To enhance professional autonomy during unprecedented pandemics, nurses must enhance cognition and abstract judgment. To enhance cognition and abstract judgment, it is necessary to promote the integration of up-to-date information and clinical evidence into their practice, and the following recommendations at the three levels are suggested.

At the individual level, for nurses to be able to predict patients' condition and mitigate the uncertainty experienced during the COVID-19 pandemic, it is crucial to actively obtain information about patients' progress. Nurses should attend the information-sharing meetings and training.

At the organizational level, it is necessary to guide nurses on how to access up-to-date clinical information and research evidence and effectively utilize it. Creating study groups sharing clinical cases and experiences among multiple professionals is crucial in fostering collaboration and knowledge exchange, which may promote nurses' professional growth and autonomy, empowering them to deliver high-quality care. Healthcare organizations should also

incorporate experience-based simulations and role-play practice into their training programs to allow nurses to practice and apply their skills in realistic scenarios. Hospital administrators also need to hire more nurses with graduate education, who play a role in connecting research and practice.

At the policy-making level, it is necessary to make accurate up-to-date information about the infectious disease available to healthcare professionals as soon as possible. In the long run, it is necessary to mandate more education in undergraduate nursing programs on how to use research evidence and to encourage and support more nurses to study in graduate programs. In addition, support may be needed for universities to strengthen research and measures to develop experience-based simulations, such as using virtual reality technology. Further studies are required to clarify the effects of experience-based learning systems in enhancing professional autonomy.

5. Conclusions

Nurses' professional autonomy in all 5 factors and 27 items was significantly lower when caring for COVID-19 patients than when caring for other patients. Specifically, Factor 1 (cognition) exhibited the most decreased scores when caring for COVID-19 patients than when caring for other patients. Factor 4 (abstract judgment) showed the smallest difference between them, but the average score was the lowest. Factors related to higher professional autonomy when caring for COVID-19 patients were longer years of nursing experience and experiencing more patients with COVID-19. To enhance professional autonomy during an unprecedented pandemic, it is necessary for nurses to enhance cognition and abstract judgment. In the event of a future pandemic, nurses need to create an environment in which they routinely access and utilize the latest information and scientific evidence so that they can provide high-quality nursing care based on their own professional judgment and competence. Experience-based learning systems may also be necessary to enhance professional autonomy.
