The participants of the focus groups positively evaluated the use of the face mask, due to its efficacy against other respiratory illnesses (common cold, flu) and affirmed their possible continued use during the transitional period after the pandemic:

“...the mask worked correctly, I think that everyone will use it during winter. The flu and common cold cases have decreased. . .” BM_4

Other measures listed due to their efficacy against the disease were physical distance and ventilation of the spaces:

“Yes, distancing and ventilation, yes. . .they were very beneficial. . .especially ventilation. . .easy to use.” CM_92

More specifically, with respect to hand-washing, a series of statements were made, which the participants had to identify if they were correct or incorrect. Only 5.1% of the sample correctly defined all the responses (* in Table 3). Below, the responses to each of the statements are detailed (Table 3). It should be underlined that most knew about the importance of hand-washing, despite the virus not being transmitted through contact (95.7%) and that only water was not enough (97.9%). On the contrary, only 25.5% knew that it was necessary to dry their hands so that washing was effective and two thirds of the sample did not know that washing had to be done with water and soap if they were dirty.

TABLE 1: Areas explored in the focus groups.

Areas	Question asked
Knowledge	What are the preventive measures to deal with COVID-19? And of these, which do you think are the most effective?
	What is your opinion about information and communication media? Which of them do you trust more?
Attitudes	What is your opinion about the COVID-19 vaccine? What are the reasons of the population for vaccination or not vaccination?
	How do you assess the impact of the pandemic at the emotional and/or with respect to mental health?
	What feelings or emotions has COVID-19 generated? Do you think the feelings or emotions at the start of the pandemic are the same as today?
	Have you overcome these feelings? Or are they still there? To what degree? Do you think the pandemic has provided some positive elements?
Practices	Due to the pandemic, how has your lifestyle changed?

TABLE 2: What measures do you consider important for avoiding or reducing COVID-19 infection?

Measures		Number (<i>n</i>)	Frequency (%)
(1) Washing of hands with soap and water*	Yes	1240	79.5
	No	319	20.5
(2) Washing of hands with hydroalcoholic solution*	Yes	750	48.1
	No	809	51.9
(3) Use of face mask*	Yes	1354	86.9
	No	205	13.1
(4) If the mask is not needed, put it under one's chin, hanging from an ear, or the neck, wrist, on top of the head, and so on	No	1527	97.9
	Yes	32	2.1
(5) Removing one's mask to sneeze, to not get it dirty	No	1511	96.9
	Yes	48	3.1
(6) Avoid touching the eyes, nose, and mouth with hands*	Yes	916	58.8
	No	643	41.2
(7) Avoid greeting other people with two kisses on the cheeks, hugs, or touching hands*	Yes	1007	64.6
	No	552	35.4
(8) Maintain a certain distance (minimum of 1 to 1.5 m) with other people if the mask is not being used*	Yes	1219	78.2
	No	340	21.8
(9) Open windows in reduced or closed spaces*	Yes	1253	80.4
	No	306	19.6
(10) Reduce social relations when COVID-19 symptoms are detected*	Yes	1198	76.8
	No	361	23.2
(11) Vaccinate*	Yes	1232	79.0
	No	327	21.0

*Correct measure for avoiding or reducing COVID-19 infection.

On the other hand, according to the other questions related to hand-washing, 82.4% of the participants believed they had enough knowledge for correct hand hygiene, 71.6% affirmed that washing of hands was an act of responsibility, and 66.6% that their hand hygiene habits had improved due to COVID-19, as they became more aware about its importance. As for the frequency, the daily mean of hand-washing was 12.1 (± 10.0), oscillating between none to 150 times per day. As for the practices of hand-washing (Table 4), only 21% did so on the necessary occasions, with the most prevalent being after going to the bathroom, before eating, and before preparing any kind of food (higher than

90% of the sample), and the least being before going to the bathroom (39.6%).

According to the QUAL data, the general perception of the participants about hand-washing knowledge was good. However, when exploring this aspect more deeply, some did not know about the efficacy of the products they utilized. Confusion was observed between different hand hygiene terms (washing and disinfection of hands) and the efficacy between the hydroalcoholic solution and soap and water:

“...washing of hands is better with soap and water than with the hydroalcoholic solution...” CM_97

TABLE 3: Which of the following statements do you think are true with respect to hand-washing?

Statements		Number (<i>n</i>)	Frequency (%)
The hydroalcoholic solutions can always substitute hand-washing	Incorrect*	1255	80.5
	Correct	304	19.5
How much time is spent when washing one's hands is not important	Incorrect*	1317	84.5
	Correct	242	15.5
Hot water increases the effectiveness of hand-washing	Incorrect*	1286	82.5
	Correct	273	17.5
It is necessary to dry one's hands after washing for it to be effective	Correct*	398	25.5
	Incorrect	1161	74.5
Now, washing one's hands is less important, as it is known that COVID-19 is not transmitted through contact	Incorrect*	1492	95.7
	Correct	67	4.3
Washing one's hands with only water is also correct	Incorrect*	1527	97.9
	Correct	32	2.1
Hands must be washed with soap and water when they are dirty	Correct*	558	35.8
	Incorrect	1001	64.2

*Correct answer.

TABLE 4: When do you wash your hands?

Hand-washing occasions*		Number (<i>n</i>)	Frequency (%)
Before going to the bathroom	Yes	617	39.6
	No	942	60.4
After going to the bathroom	Yes	1488	95.4
	No	71	4.6
Before eating	Yes	1485	95.3
	No	74	4.7
After eating	Yes	941	60.4
	No	618	39.6
When getting home or when going into buildings	Yes	1261	80.9
	No	298	19.1
Before preparing any food	Yes	1437	92.2
	No	122	7.8
After blowing one's nose, cough or sneeze	Yes	1063	68.2
	No	496	31.8
After touching rubbish or money	Yes	1302	83.5
	No	257	16.5
After touching outdoor surfaces	Yes	944	60.6
	No	615	39.4
Before visiting someone who is ill	Yes	1070	68.6
	No	489	31.4
After visiting someone who is ill	Yes	1140	73.1
	No	419	26.9
After touching animals	Yes	1024	65.7
	No	535	34.3

*All hand-washing occasions are necessary.

“Anything is useful.” CM_98

It should also be mentioned that only a small number of participants was aware that their hand-washing behavior was not correct:

“We don't wash our hands well!” BM_77

3.3. Lifestyle Habits. With respect to the eating habits, the daily mean portions of fruit and vegetables were 3.4 (SD = 1.6), with the weekly mean for legumes being 2.2 (SD = 1.3). As for the consumption of red meat and ultra-processed foods, about 2 weekly portions (2.1 ± 1.6 and 2.0 ± 2.0 , respectively) and sugary drinks were consumed 1.2 ± 2.2 times on average. As for the practice of physical

exercise, 56.8% of the sample did so in a planned manner, with a mean of 4 hours per week. And lastly, with respect to toxic habits, 34.1% of the participants had them, with the most prevalent being the consumption of alcoholic drinks (19.6%) and tobacco (18.7%), followed by self-medication (4.7%) and taking narcotics (1.0%).

The QUAL analysis highlighted the presence of changes in the eating habits with these modifications being divergent. On the one hand, the participants expressed a greater consumption of fresh, closer, and healthier foods. This was justified, in part, by the greater availability of time for cooking:

“Fresh fish was consumed... this is good.” CH_10299

“I think that healthier, but we must take into account that we had more time for cooking.” CH_229

And on the other hand, the participants increased food consumption between meals:

“I ate more between meals because I did not leave the house as much.” CH_231

Lastly, on the subject of activity and physical exercise, this habit was promoted as a coping strategy against the negative emotions and feelings that surged during the COVID-19 pandemic:

“Young people started doing physical exercise because we were bored.” CP_213

“In general, people started to go out to walk for leisure, and this habit was maintained.” CP_214

3.4. Sources of Information. As for sources of information, as shown in Table 5, the source that was most utilized for obtaining information about the pandemic was the television, more specifically the news or specific documentaries about the subject (43.2%). However, the source of information they considered to be more trustworthy was health professionals, according to more than 70% of the sample studied. Nevertheless, only 35% of the participants utilized the source of information they considered to be more reliable.

In addition, the QUAL findings detected the emergence of the perception that the population was informed, although excessively, causing saturation:

“I’m sorry, but personally, I’m saturated with respect to COVID-19.” CI_120120

“Every day, when I woke up, the media was talking about COVID-19. The information about it was important, but it was excessive...” BI_14

Also, the way the information was transmitted led to difficulties in its interpretation, as it was considered as always changing, incoherent, and lacking in personalization according to age groups and overly sensationalist. On many occasions, this resulted in emotions such as fear:

“They changed the information they provided very often!” CI_114

“...I couldn’t leave the house from midnight to six in the morning. So, does the virus come out at night?” BI_12

“The information given was the same, both for young people and for older people. ...And the information aimed at youth had to have a motivating purpose.” BI_8

“On television, they showed images that were too sensationalists...” CI_186

“The images shown created fear.” CI_189

3.5. Vaccination. As for their state of vaccination (Table 6), 93.8% of the participants was vaccinated, and of these, 66.4% with the third dose. The reasons for becoming vaccinated, from highest to lowest percentage, were as follows: because they believed in science and the vaccines as a prevention method (75.3%), to attain herd immunity (47.2%), because they wanted the pandemic to end (46.2%), to be able to travel and for leisure activities (12.1%), due to social pressure (7.2%), and others such as because they were health professionals or being in contact with at-risk individuals (3.6%). Also, 12.1% believed that the vaccine had some negative effect on their health, with alterations in the menstrual cycle being identified as the most prevalent (50.3%). Of those who were not vaccinated (6.2%), the most common reasons were as follows: they did not trust vaccines (42.7%), because of the risk of adverse reactions due to which the vaccines were greater than the risk of becoming infected (42.7%), and because they had created them too fast (36.5%).

The QUAL data corroborated the ambivalent feelings about vaccination. On the one hand, herd immunity and protection were recognized, and the benefits that the vaccination provided in social life:

“We who are vaccinated increasingly weaken the virus.” BV_21

On the other hand, the vaccines have also created a lack of trust in two levels: one at the economic level and two in relation to the possible adverse effects:

“Of course, it’s all about business!” BV_19

“Little has been said about the secondary effects of the vaccine.” CV_128

3.6. Emotions Generated and Coping Strategies. With respect to the feelings and emotions generated during the pandemic (Table 7), uncertainty was identified by 47.8% of the participants, followed by fear of the situation (41.8%), sadness (38%), and distress (30.1%), among others. Some of these feelings and/or emotions were identified by 69.5% of the sample, and most identified aspects helped them to manage them (99.1%), such as to talk to their family (38.9%) or their circle of friends (33.1%). However, 52.9% of them still had some of the feelings or emotions described above. As for how they adapted to the new situation provoked by the

TABLE 5: During the pandemic, where did you get the most information about COVID-19 from, and which do you think is the most reliable source?

Source of information	Where did you obtain most of the information?		Most reliable source	
	Number (<i>n</i>)	Frequency (%)	Number (<i>n</i>)	Frequency (%)
Social networks (i.e. Instagram, Facebook, and Twitter)	158	10.1	16	1.0
TV: news programs or specific documentaries	674	43.2	223	14.3
TV: dissemination programs	109	7.0	34	2.2
Newspapers or magazines	42	2.7	24	1.5
Health professionals	313	20.1	1119	71.8
Internet	153	9.8	45	2.9
WhatsApp group	16	1.0	5	0.3
Family and friends	47	3.0	17	1.1
Others	47	3.0	76	4.9

TABLE 6: State of vaccination.

		Number (<i>n</i>)	Frequency (%)
Participants vaccinated		1463	93.8
Vaccine dose	1 dose	65	4.5
	2 doses	426	29.1
	3 doses	972	66.4
Reason for vaccination*	To believe in science and the vaccines as a prevention method	1101	75.3
	To want the pandemic to end	676	46.2
	To attain herd immunity	691	47.2
	Due to social pressure	106	7.2
	To be able to travel and for leisure activities	177	12.1
	Others	53	3.6
Negative health effect	Yes	177	12.1
	No	1017	69.5
	Does not know/does not answer	269	18.4
Why did you have a negative effect?*	Because I am more tired	55	31.1
	Because I have a headache or migraines	37	20.9
	Because I have had dermatological alterations	23	13.0
	Because my menstrual cycle has been altered	89	50.3
	Others	53	29.9
Nonvaccinated participants		96	6.2
Reason for nonvaccination*	Due to fear	7	7.3
	Lack of trust on the vaccine	41	42.7
	Due to its fast creation	35	36.5
	For fear of needles or shots	2	2.1
	Because of the risk of adverse reactions due to the vaccines was greater than the risk of becoming infected	41	42.7
	Because I think that if I follow a healthy lifestyle, it is enough	22	22.9
	Others	32	33.3

*Question with a multiresponse option.

COVID-19 pandemic, they maintained an optimist or positive attitude (62.3%), social contact (respecting the safety measures) (58.9%), and healthy habits (food, physical activity, and rest) (49.8%), and they also dosed the information on COVID-19 received (49.6%), among others. Lastly, as for the question of if they believed the pandemic, apart from the catastrophe, had contributed something positive, almost 60% said that it had help to put a spotlight on the work of health professionals.

According to the qualitative data, the experiences and the management of the disease could be classified into three categories: the emotions experienced by the participants, their consequences on them, and the techniques utilized to deal with the different situations. With respect to the emotions experienced, the focus group participants classified these emotions as negative as they caused fear, distress, feeling of being unprotected, or uncertainty, although at the same time, they were protective elements:

TABLE 7: Emotions generated and coping strategies.

		Number (n)	Frequency (%)
Have you felt any of these feelings or emotions during the pandemic: fear, distress, insomnia, stress, anxiety, uncertainty...?	Yes	1083	69.5
	No	476	30.5
What feelings or emotions were generated by COVID-19?* (n = 1083)	Fear of the situation	652	41.8
	Fear of going outside	226	14.5
	Distress	470	30.1
	Sadness	592	38.0
	Anxiety	439	28.2
	Insomnia	264	16.9
	Stress	423	27.1
	Uncertainty	745	47.8
	Others	358	23.0
Did you use personal tools to cope with them? (n = 1083)	Yes	1073	99.1
	No	486	0.9
More specifically, what helped you manage these feelings or emotions?* (n = 1083)	Talking to their circle of friends	516	33.1
	Talking to their family	607	38.9
	Talking to health professionals	256	16.4
	Writing	61	3.9
	Practicing some sports	306	19.6
Presently, do you still have some of these feelings or emotions? (n = 1083)	Others	153	9.8
	Yes	573	52.9
	No	444	41.0
	Does not know/does not answer	66	6.1
How did you adapt to the new pandemic situation provoked by COVID-19?*	Dosing the information on COVID-19 received	774	49.6
	Maintaining the social contact (respecting the safety measures)	919	58.9
	Maintaining healthy habits (food, physical activity, and rest)	776	49.8
	Keeping the mind occupied to not think about the pandemic	445	28.5
	Maintaining an optimist or positive attitude	972	62.3
	Seeking help if needed	180	11.5
	Others	44	2.8
	In general, do you believe that the pandemic, apart from the catastrophe, has contributed with some positive lessons?*	A greater group feeling	417
Better help in the neighborhood		367	23.5
To help to put a spotlight on the work of health professionals		921	59.1
To learn the management of health resources		318	20.4
To be less dependent on primary health care centers		272	17.4
None of the above (assess it negatively)		237	15.2
	Others	169	10.8

*Question with a multiresponse option.

“At the beginning, everyone was afraid, and the measures were extreme.” CP_185

“There was a lot distress, especially for going outside.” BP_51

“The feeling we had was as if we had been left unprotected!” BP_53

“We didn’t know when it would end. Now we are returning to the normal situation, but it is not known if it will last...” CP_191

In a parallel manner, they were able to determine the creation of cooperation as an element of social construction or value:

“The young people, such as us, took the shopping to the elderly, with the help from City Council.” CP_160

“We helped each other.” BP_65

Also, the participants observed experiences during the pandemic in the rural areas that were of higher quality as compared to the cities, due to the type of housing, low-density settlements, life closer to nature (vegetable gardens, fields), and a type of life that was more personal and human:

“I believe that we were privileged during the pandemic, since we lived in a rural area.” BP_36

“The confinement during the month of March was not experienced in the same way as in Lleida or Barcelona. It was very different. Here we were confined, but we were not distressed.” CP_155

The consequences of COVID-19 at the psychological level were characterized by changes in mood during the pandemic, the loss of social relations and loved ones, and a different view of the pandemic according to the different age groups, as well as the before and after marked by COVID-19 in the life of the participants:

“Now we are more relaxed than in the beginning.” CP_200

“Many relationships have been lost. . .” CP_192

“I missed my grandchildren and not being able to see my daughters.” CP_190

“The children, youth, and elders were the age groups that noted the negative consequences of COVID-19 more strongly than the rest, as they were confined at home” CP_208

“COVID-19 has changed everyone’s lives.” BP_52

“It will be hard for us to return to being as before.” CP_203

And lastly, the participants utilized tools such as in-house activities (cook, home improvement, and so on) and social activities from home (drinking vermouth, video-calls), to deal with the emotional situation in which they found themselves in:

“To disconnect from work at the hospital, I began to improve my house.” BP_70

“...each Sunday, we would drink vermouth from the balcony at home, and City Council would play music from the speakers.” CP_161

4. Discussion

The present study has allowed the identification of the knowledge and behaviors related with preventive measures, lifestyle habits, sources of information, vaccination, and the emotions generated and their coping strategies, as well as the

exploration of the personal experiences with respect to the knowledge, the attitudes, and the practices against COVID-19. Its mixed design has re-enforced the findings obtained, resulting in more profound and detailed knowledge [20]. This is a fundamental aspect for the design of HE interventions, as it must create learning experiences to help develop general skills that are transferable to health [21]. Good knowledge about health allows us to acquire health-promotion behaviors and to act against the challenges posed by COVID-19 [22] or in other possible health situations.

The profile of the QUAN study participants was women older than 50 years with a university degree, in agreement with other recent studies with online questionnaires during the COVID-19 pandemic [23, 24]. However, in the QUAL part, both sexes were equally represented, with a minimal predominance of men and with participants with a low level of education. This could be due to the rural nature of the places where the two focus groups took place. Given the dates and the time in the day of the focus groups (February and in the afternoon), a greater availability could be implied for the male group, as most were farmers, without any other employment obligations.

As for the knowledge of preventive measures against COVID-19, it was shown that they had a good general knowledge, especially related to the 3Ws (wear a mask, wash your hands, and watch your distance). Nevertheless, when specific questions were asked, it was found that they lacked in-depth and specific knowledge about them. One of the most recognized measures was related with the use of the face mask. Also, in our area, the general population had not used it until the arrival of the COVID-19 pandemic. In this sense, the awareness about the use of face masks was more present than other preventive measures [25], perhaps because they produce a false sense of protection, although the mandatory character of their use could have had an influence.

As for hand-washing, only one out of four participants knew that it was necessary to dry one’s hands for it to be effective. However, the need for information about the relative efficacy of different drying methods and if drying one’s hands completely could have spread SARS-CoV-2 had already been identified [26]. For this reason, the messages from public health authorities should have given the same importance to drying as washing, given the potential for cross-infection, as shown by a recent review on the subject [27]. As for the frequency and the times of hand-washing, the daily mean of hand hygiene events was 12.1 (± 10.0), and only 21.1% did so when needed, with these results very similar to other authors [28]. Another aspect that should be highlighted was the lack of knowledge about the efficacy of the hydroalcoholic solution in the prevention of infection and propagation of COVID-19, as compared to water and soap. However, since the outbreak of the disease, its use has increased considerably, and also, the population is more aware about the importance of hand-washing [29].

In general, the lifestyles of the participants were healthy, given that they met the physical activity and diet recommendations [30]. On the other hand, the multiple benefits for mental and physical health of physical activity during the

pandemic must be indicated, considering elements such as age, clinical conditions, and level of physical shape [31]. It has been demonstrated that the pandemic contributed towards the maintenance of healthy and active lives, as well as the consumption of fresh foods from nearby areas. Nevertheless, the intake of food during the pandemic was highly influenced by economic factors. Vulnerable individuals experienced food insecurity, which led to the buying of cheap and less healthy foods, such as packaged and ultra-processed foods [32]. In agreement with other authors [33], this study has shown that some individuals negatively modified their consumption habits in stressful situations, for example, snacking between meals.

The source from which they obtained more information was the television, specifically news programs or specific documentaries about the subject. However, the source of information they considered to be more reliable was health professionals. This is a very positive aspect given that it has been shown that those who trust health professionals with COVID-19 information tend to better adhere to preventive measures [34]. Another aspect that should be highlighted is their perception about an excess of information, which resulted in saturation and the possibility of receiving erroneous or hard-to-interpret information. In this sense, the Director-General of the WHO qualified the situation of disinformation about COVID-19 as an "infodemia" (that is, epidemic of disinformation or pandemic of disinformation), full of conspiracy theories, propaganda, and nonverified scientific statements with respect to the diagnosis, treatment, and prevention of the disease [35]. Therefore, the levels of digital health literacy of the population are also key for the preparation against future infodemias [36], as a low health literacy rate has been shown to result in practices and attitudes that compromise the health of individuals and also the rest of the population due to the proliferation of false information (misinfodemic) [37]. Therefore, it is necessary to consider that eHealth literacy could play an important role in promoting better prevention and control of infections [36]. Nevertheless, despite the messenger (author/source of information) being a fast and reliable indicator of information, the general population must be prepared to evaluate the message (content of information), to improve their levels of health literacy, in light of future infodemias [38].

The vaccination rate of our study sample was high. Nevertheless, there are global variations on the acceptance of the vaccine between populations, although the reasons for vaccination and acceptance of the vaccine are similar. According to a recent systematic review [39], the low acceptance of the vaccine has been associated with low levels of education and awareness and inefficient governmental efforts and initiatives. For this reason, investing in health literacy improves the acceptance of the vaccine and the making of health-related decisions, to reduce the impact of the COVID-19 pandemic [40]. On the other hand, the most prevalent secondary effect was alterations to the menstrual cycle. Recent studies have shown these effects in the shape of premenstrual symptoms (greater fatigue, abdominal distension, irritability, sadness or depression, headaches, and greater difficulty for falling sleep), as well as menstrual

changes (higher flows and stronger menstrual pain and shortening of the menstrual cycle) [41, 42].

Some authors [43, 44] corroborate the psychological impact from COVID-19 and the possible negative results for mental health, such as distress, anxiety, and fear, among others. However, the present study did not find more severe states such as depression, suicidal thoughts, or posttraumatic stress disorder (PTSD) [44]. On the one hand, the reasons could be explained with the findings in our focal groups, where it was confirmed that the rural environment seemed to be a protecting factor contrary to the urban areas, which are more complex due to their higher density, and the decreased possibility of maintaining isolation and physical distancing [45]. And, on the other hand, due to the equilibrium between the people who had feelings and/or emotions that could lead to mental health problems (69.5%), and those who used personal tools to cope with them (99.1%). It must be noted that worry or situational anxiety has positive effects, as they lead to preventive behaviors; although if these are persistent, they can result in mental health problems [46]. Also, our results are in agreement with other researchers [47]; when they indicated that people adapted to the guidelines according to the period in the pandemic, they sought ways to compensate for social distancing with other activities (in or outside the home) and other ways to communicate, such as online, or doubling measures of safety (ensuring protection by being outdoors and maintaining distance). In addition, this study shows the cooperation and solidarity during the COVID pandemic at interpersonal levels, by helping the most vulnerable (help nursing homes, older adults, and so on) or vaccinating to attain herd immunity. Lastly, it must be mentioned that the situation of the unprecedented pandemic, the uncertainty, and the risk to become infected are peritraumatic factors that are associated with psychopathology [43]. It is for this reason that 52.9% of the participants still had harbored some of the feelings or emotions mentioned above, without being able to manage them or without being able to find a useful tool to deal with them. Therefore, it is necessary to activate measures organized and centered on the person and based on strategies of active coping, acceptance, and positive thinking, to avoid avoidance strategies to obtain engaged coping that can lead to greater well-being [48].

Lastly, the comprehensive study (QUAN and QUAL) of the participants in a particular context allowed us to identify key elements of detection of needs. In this stage examined (two years after the start of the COVID-19 pandemic), key aspects can be inferred about the promotion, education, and health literacy [49]: more resources must be provided to improve community health, it is necessary to provide continuous training in health aspects to the population, and specific strategies must be established so that the population understand the information and act in a manner that is healthy. Also, HE implies the ability to evaluate the information and making decisions to promote protective behaviors [50], but this must be adapted to the context. For this, starting with the results found, it can be specified that (1) the pandemic has sensitized the population, and it is now aware of the importance of individual actions for the common good, for this is a key moment to act; (2) re-enforce the training on basic preventive measures against infectious diseases to achieve

behavioral changes that are more integrated and permanent in the population, into day-to-day actions such as hand-washing or the use of protective elements; (3) the information must be integrated as a communicative process and adapted to current channels and the use of technologies; (4) the postpandemic stage has left after-effects in the population at the physical and psychological levels, which must be continuously monitored and addressed, and (5) the lessons learned during the pandemic must help to create a “normality” that is impregnated of the social values that have emerged, such as equity, solidarity, and collectivity. In this sense, the results underline some determining factors of health literacy, but more studies are necessary to understand the impact and the evaluation of health literacy [51]. Nevertheless, the results can serve as the basis for the design of HE interventions, which can act as a modifying factor in health, and have a direct and fast impact on the population [22].

4.1. Limitations. Social bias limitations could exist in the data, as the participants could have provided socially desirable responses in relation to the preventive measures. Also, it must be considered that the study was conducted during the postpandemic period (2022), when the experience of the pandemic was still strong, but mediated by the current health situation (vaccinated population and so on). In addition, there could be a bias in the collection of QUAN data online due to Internet access availability. Lastly, the participation in the focus groups was voluntary, and there could therefore be a selection bias, although a broad invitation was performed through the city councils. Nevertheless, the multimethod combination utilized in the present study considerably minimizes these effects.

5. Conclusions

This study has allowed the identification of the knowledge and behaviors, as well as the exploration of the personal experiences related with the knowledge, the attitudes, and the practices two years after the start of the pandemic. The results showed that prevention measures must be reinforced, especially hand-washing, although its importance has already been recognized. However, the use of the face masks is well integrated, and their continued use is expected against respiratory pathologies. Lifestyles remained healthy, through the use of physical exercise as a source of well-being. The population trusted the information from health professionals, but it is excess due to the media, resulted in saturation and negative thoughts. Herd immunity and protection was recognized in vaccination, and although a psychological impact was found in the participants, it was cushioned with the activation of positive coping measures. Nevertheless, more than half of them still maintained it after two years. They must therefore be addressed for the maintenance of mental health.

5.1. Implications for Nursing Management. The role of nursing in the management of the COVID-19 pandemic was fundamental. However, studies were not found that

performed an in-depth analysis of the knowledge, attitudes, and practices of the population during this time. In this sense, this study allowed the detection of the current needs of the population, with an in-depth analysis of the object of study through the use of a mixed methodology approach. It provides the information needed by nursing personnel to be able to design an intervention adapted to the real needs of the population and to promote HE programs to address COVID-19 or other health situations. Therefore, the present study provides meaningful practical information that could be the starting point for other researchers, nurses and nurse managers and could be used to promote behaviors that favor the health of the general population.

Data Availability

The participants of this study did not give written consent for their data to be shared publicly, so due to the sensitive nature of the research, supporting data are not available.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

The authors thank the Consell Comarcal del Segrià and all its municipalities for their collaboration (Catalonia, Spain). Objective. To identify the latent classes of personality traits among nurses in acute and critical care departments, as well as the relationship between latent classes of different personality traits and workplace bullying. **Methods.** A total of 245 nurses working in the acute and critical care department at a 3 A-grade hospital in Shandong Province, China, were recruited by convenient sampling. The Chinese Big Five Personality Inventory brief version was used to assess personality traits, and the Negative Acts Questionnaire was used to measure workplace bullying. Latent profile analysis was used to identify the latent classes of personality traits. Multiple linear regression analysis was used to examine the relationship between latent classes of personality traits and workplace bullying. **Results.** Four latent classes of personality traits among acute and critical care nurses were identified, namely, the negative group (49.0%), flexible group (16.0%), neurotic group (18.1%), and stable group (16.9%), respectively. Compared with the neurotic group, the negative group ($B = -6.227, P < 0.05$), stable group ($B = -16.562, P < 0.001$), and flexible group ($B = -19.208, P < 0.001$) experienced less workplace bullying. **Conclusion.** Our findings explore latent classes of personality traits among acute and critical care nurses, identify subgroups susceptible to workplace bullying, and suggest the development of appropriate interventions to reduce workplace bullying. **Implications for Nursing Management.** Hospital managers can identify nurses who are prone to workplace bullying based on their personality traits and provide them with psychological counseling services and psychological healing groups to help them establish good interpersonal relationships and maintain their mental and physical health.

1. Introduction

Workplace bullying, as a workplace stressor, refers to the negative behaviors of work-related harassment, offense, and exclusion that an individual frequently and repeatedly experiences in the workplace for more than six months (at least once a week) [1]. Research has shown that workplace bullying is more common and severe for nurses than other professions [2], especially for acute and critical care nurses who work in the emergency room and intensive care unit [3]. Workplace bullying not only has adverse effects on the physical and mental health of nurses [4], but also causes job burnout [5], increases the turnover tendency of nurses [6],

and even affects the quality of nursing care and threatens the life safety of patients [6]. Therefore, more attention should be paid to identifying risk factors for workplace bullying among acute and critical care nurses.

Personality traits refer to the stable and unique psychological and behavioral patterns that distinguish oneself from others and are shaped under the combined action of congenital heredity and acquired environmental conditions. Previous studies have shown that personality traits, as a typical variable reflecting individual differences, play a significant role in predicting individuals' exposure to workplace bullying [7–9]. For example, Balducci et al. [10] found that neuroticism was positively correlated with

workplace bullying among 609 public sector employees in Italy. However, most studies focus on the relationship between a certain personality trait (e.g., neuroticism and agreeableness) and workplace bullying from a variable-centered perspective and neglect that different types of personality traits can exist simultaneously.

Latent profile analysis (LPA) [11] is a person-centered statistical analysis identifying different subgroups within populations that share certain outward characteristics. LPA can be used to analyze the relationship between personality traits and workplace bullying when taking different types of personality traits into consideration simultaneously. Studies have shown that individuals with the same level of personality traits show different characteristics in different dimensions [12, 13]. However, the relationship between the latent classes of personality traits and workplace bullying remains underinvestigated.

Therefore, this study aimed to apply LPA to explore different potential classes of personality traits of acute and critical care nurses and to analyze their relationship with workplace bullying.

2. Materials and Methods

2.1. Study Participants. From April to September 2022, a total of 245 acute and critical care nurses in a 3 A-grade hospital in Shandong Province were selected as participants by the convenience sampling method. The inclusion criteria for acute and critical care nurses were as follows: (1) registered nurse with valid license; (2) working in the acute and critical care departments for more than 3 months (three months is a probation period); and (3) informed consent and voluntary participation. The exclusion criteria were: not having been employed as a nurse in this hospital.

2.2. Procedures. In this study, the online questionnaire collection was carried out through the “Wenjuanxing” platform with the support of the consent of the nursing department and head nurses of all departments in the hospital. The study followed the principles of voluntary participation and informed consent with the ethics approval number 2020-R-061. Before completing the questionnaire, the objective and procedure of the questionnaire were detailed. Finally, 245 valid questionnaires were collected.

2.3. Study Tools

2.3.1. Sociodemographic Characteristics. Personal characteristics include sex, age, level of education, and marital status; job-related characteristics include average monthly income, employment relationship, professional title, working years, night shift involvement, number of monthly night shifts, and weekly working hours.

2.3.2. Chinese Big Five Personality Inventory Brief Version (CBF-PI-B). The CBF-PI-B [14] was used to assess personality traits by acute and critical care nurses. It comprises 40 items and can be classified into 5 dimensions (i.e.,

neuroticism, extroversion, openness, agreeableness, and conscientiousness). Each item was rated on a 5-point scale, with a point from 1 to 5 indicating “strongly disagree” to “strongly agree.” The higher the total score of each dimension is, the more obvious the corresponding personality characteristics are. Cronbach’s alpha of the total scale in this study was 0.878.

2.3.3. Negative Acts Questionnaire (NAQ). The NAQ was developed by Einarsen and Notelaers [15] and was translated into Chinese by Hongjing Xun [16] in 2012. It has been widely used in the measurement of workplace bullying suffered by Chinese nurses. The NAQ has 22 items and includes 3 dimensions (i.e., individual-related negative acts, work-related negative acts, and organizational injustice). A 5-point scale was used to rate each item, with a point from 1 to 5 indicating “never,” “occasionally,” “monthly,” “weekly,” and “daily,” respectively. The higher the total score is, the higher the level of workplace bullying nurses experience. Cronbach’s alpha of the total scale in this study was 0.980.

2.4. Statistical Methods. Firstly, for continuous variables conforming to a normal distribution, mean and standard deviation (SD) were used for description; for non-normal distribution data, median and interquartile range (IQR) were used for description; for categorical variables, frequency and percentage were used for description.

Secondly, LPA was conducted to identify latent profiles of personality traits. We started with a one-profile model and gradually increased the number of profiles until the optimal model was identified. The model was comprehensively evaluated according to Entropy, Bootstrap likelihood ratio test (BLRT), Lo–Mendell–Rubin adjusted likelihood ratio test (LMR), Akaike information criteria (AIC), Bayesian information criteria (BIC), sample-size-adjusted Bayesian information criterion (aBIC). The smaller the AIC, BIC, and aBIC values are, the better the fitting degree is. Entropy ranges from 0 to 1, with higher values (value ≥ 0.8) indicating a clearer classification [17]. When the results of LMR and BLRT are < 0.05 , it indicates that the K class model is superior to K-1 class model [18].

Thirdly, the chi-square test was used to analyze socio-demographic differences of potential personality traits among nurses in acute and critical care units.

Fourthly, the Kruskal–Wallis test was used to explore the relationship between the latent classes of personality traits of nurses and workplace bullying.

Fifthly, the Wilcoxon–Mann–Whitney test and Kruskal–Wallis test were used to analyze the differences in workplace bullying among acute and critical care nurses with different sociodemographic characteristics.

Finally, multiple linear regression was conducted to analyze the relationship between latent profiles of personality traits and workplace bullying, and statistically significant demographic variables in the univariate analysis were controlled as covariates. The significance level was set at $\alpha = 0.05$ (two sides). SPSS 25.0 and Mplus 8.0 were used for statistical analyses.

3. Results

3.1. Latent Profiles of Personality Traits among Acute and Critical Care Nurses. As shown in Table 1, six models were obtained by fitting from one to six latent classes, respectively. The entropy values of the 2-class to 6-class models were >0.8 , indicating good accuracy of these models. As the number of latent classes increased, AIC, BIC, and aBIC gradually decreased. In the model of Class 4, the P values of both LMR and BLRT were significant; indicating that the model of Class 4 was superior to the model of Class 3, but the P value of LMR of the model of Class 5 was nonsignificant. Therefore, the model of Class 4 was determined as the optimal model.

To verify the reliability of the analysis results of the above latent classes, the average posterior probability of different models is shown in Table 2. The results showed that the average posterior probability (column) of the four latent classes (row) of nurses' personality traits ranged from 0.786 to 0.954, indicating that the model fitting results of the four latent classes were reliable.

The first class (49.0%) called the "C1 negative group" scored higher on the neurotic dimension than the C2 flexible group and the C4 stable group but lower than the C3 neurotic group and the lowest on the dimensions of conscientiousness, agreeableness, openness, and extroversion. The second class (16.0%) had the lowest score on the dimension of neuroticism and the highest score on other dimensions and was named as "C2 flexible group." The third class (18.1%) had the highest score on the dimension of neuroticism, moderate scores on the dimensions of conscientiousness, agreeableness, openness, and extroversion, and was named as "C3 neurotic group." The final class (16.9%) had low scores in neuroticism, openness, and extroversion and high scores in conscientiousness and agreeableness, indicating conservative personality and stable mood, and was labeled as "C4 stable group" (Figure 1).

3.2. The Differences in Sociodemographic Characteristics of Nurses in Different Latent Classes of Personality Traits. Univariate analysis results showed that there were statistically significant differences ($P < 0.05$) in age, professional title, and monthly night shift number of nurses in different latent classes of personality traits (Table 3). Flexible group were older than neurotic group nurses. Compared with acute and critical care nurses of high professional titles, those with low professional titles accounted for a higher proportion in negative group and neurotic group. Compared with those without night shifts, acute and critical care nurses with night shifts accounted for a higher proportion in negative group and neurotic group.

3.3. Relationship between Latent Classes of Personality Traits and Workplace Bullying among Acute and Critical Care Nurses

3.3.1. Disparity between Latent Classes of Personality Traits and Workplace Bullying among Acute and Critical Care

Nurses. As shown in Table 4, the dimensions and total scores of workplace bullying showed significant differences in the latent classes of personality traits among acute and critical care nurses ($P < 0.001$). Post hoc analysis showed that the C1 negative group and the C3 neurotic group scored higher than the flexible group and stable group in the two dimensions of individual-related negative acts and work-related negative acts and the total score of negative acts. In the dimension of organizational injustice, the neurotic group scored higher than the flexible group and the stable group, and the negative group scored higher than the flexible group.

3.3.2. Wilcoxon–Mann–Whitney Test and Kruskal–Wallis Test Were Used to Analyze the Differences in Workplace Bullying among Acute and Critical Care Nurses with Different Sociodemographic Characteristics. The normality test of workplace bullying suffered by nurses showed a skewed distribution. Therefore, the Wilcoxon–Mann–Whitney test and Kruskal–Wallis test were used to analyze the relationship between sociodemographic characteristics and workplace bullying. The results showed that age, marital status, weekly working hours, and average monthly income of participating nurses correlated with workplace bullying significantly ($P < 0.05$).

3.3.3. Multiple Linear Regression Was Conducted to Analyze the Relationship between Latent Profiles of Personality Traits and Workplace Bullying. Multiple linear regression analysis showed that after controlling for age, marital status, weekly working hours, and average monthly income, compared with the neurotic group, the negative group ($B = -6.227$, $P < 0.05$), stable group ($B = -16.562$, $P < 0.001$), and flexible type ($B = -19.208$, $P < 0.001$) reported lower levels of workplace bullying (Table 5).

4. Discussion

This study found four heterogeneous groups of personality traits among acute and critical care nurses, including negative, neurotic, flexible, and stable groups. The stable group (16.9%) was introverted but rigorous, got along well with others, and had stable emotions. The flexible group (16.0%) was rigorous, extroverted, highly tolerant and empathetic to others, and able to handle interpersonal relations flexibly. Although the stable and flexible groups had been identified in previous studies [12, 13], this study still proposed two new groups of personality traits, namely, negative group and neurotic group. The negative group (49.0%) was introverted, indifferent to others with low social participation, and may show a negative attitude at work. The neurotic group (18.1%) was overly sensitive, lowly tolerant to others, prone to anxiety, and had an unstable personality. The reason may be related to the job content of emergency and critical care departments. Acute and critical care nurses face and rescue more critically ill patients with more workload, working time, work pressure, and night shifts, which may induce negative attitudes and negative emotions [19, 20], so there are the negative group and neurotic group.

TABLE 1: Latent profile analysis of personality traits among acute and critical care nurses.

Note. AIC: Akaike information criteria, BIC: Bayesian information criteria, aBIC: sample-size-adjusted Bayesian information criterion, LMR: Lo-Mendell-Rubin adjusted likelihood ratio test, BLRT: bootstrap likelihood ratio test.

In this study, there were significant differences in age, professional title, and number of monthly night shifts among latent classes of personality traits. Flexible group nurses were older than neurotic group nurses. Compared with acute and critical care nurses of high professional titles, those with low professional titles accounted for a higher proportion in the negative group and neurotic group. Compared with those without night shifts, acute and critical care nurses with night shifts accounted for a higher proportion in the negative group and neurotic group, which was consistent with the results of previous studies [12]. It is worth noting that the negative group and neurotic group were prone to anxiety, depression, and other negative emotions [21] and more likely to have career burnout [12]. Consistently, this study revealed that the negative group and the neurotic group exhibited higher overall scores of workplace bullying when compared to both the flexible group and the stable group, indicating a greater susceptibility to workplace bullying. Therefore, nursing managers should pay more attention to negative and neurotic nurses.

Multiple linear regression results showed that compared with the neurotic group, the negative, stable, and flexible groups all suffered from less workplace bullying considering nurses' sociodemographic characteristics and working hours as the potential confounders. This was consistent with the results of previous studies that personality traits are closely related to workplace bullying [9, 22]. This study found that nurses prone to workplace bullying did not have a single personality trait but a personality type composed of several personality traits. Individuals with low neuroticism, high conscientiousness, high agreeableness, high extroversion, and high openness and individuals with low neuroticism, high conscientiousness, high agreeableness, low extroversion, and low openness were not prone to workplace bullying [23]. According to the Victim Precipitation Theory [24], certain characteristics or behaviors exhibited by people may become their weaknesses, attract others' encroachment, and make them the targets to be hurt. Acute and critical care nurses in the neurotic group are emotionally unstable, difficult to get along with others and easy to be isolated by colleagues, and become the target of bullying. Nurses in both the flexible group and stable group are introverted or extroverted and can maintain a responsible and rigorous attitude with less negative emotions and better deal with interpersonal relationships; hence, they are less likely to be bullied by colleagues [25].

TABLE 2: Average posterior probability of latent classes of personality traits in acute and critical care nurses.

FIGURE 1: Latent classes of personality traits in acute and critical care nurses.

5. Limitations

There are several limitations of the present study. Firstly, using a cross-sectional design, this study could not predict the longitudinal trajectory of nurses' exposure to workplace bullying, nor could it draw a causal relationship between potential categories of personality and workplace bullying, which needs to be confirmed by more empirical studies in the future. Secondly, the representativeness of the existing study participants is limited. This study only surveyed nurses in the emergency critical care department of a 3 A-grade hospital, and the sample size was small. Third, confounding factors such as

working environment, organizational problems and other factors may not be fully taken into account in this study; it is suggested that more comprehensive confounding factors should be included in future studies for analysis.

6. Conclusion

There are four subtypes of personality traits among acute and critical care nurses: the negative group, flexible group, neurotic group, and stable group. Nurses in the neurotic group are more likely to suffer from workplace bullying. It is necessary to identify the personality traits of nurses and develop interventions to reduce workplace bullying.

7. Implications for Nursing Management

There are several implications for nursing management. First, hospital managers should pay attention to neurotic and negative nurses who are prone to workplace bullying. Although their personality characteristics are stable and not easy to change, managers should take active and effective measures to help them, such as setting up psychological counseling departments and psychological healing teams in the department to help nurses who have been bullied get rid of the adverse effects. Guide them to build good interpersonal relationships and maintain their mental and physical health. Second, hospital managers can help nurses to understand and cope with workplace bullying by organizing training related to workplace bullying, and carry out targeted training for nurses with different personality characteristics and different ages, so as to improve the awareness and handling ability of nurses. Third, department leaders can form a positive nursing work atmosphere by organizing team building activities or constructing department culture. At the same time, they can set a team work mode, comprehensively consider the characteristics of nurses, work ability, and other factors to assign team members, form a mutual help and harmonious group work atmosphere, and increase the ability to resist workplace

bullying. In addition, hospital managers can take the potential characteristics of nurses' personality traits as a reference index for the selection of nursing talents and the allocation of departments, assign nurses with different personalities to suitable departments, and select nursing talents more suitable for emergency and critical department posts [26].

Data Availability

The data used to support the findings of this study are available from the corresponding author upon reasonable request.

Ethical Approval

Prior to the study, the research protocol was approved by the Ethics Review Board of Shandong University School of Nursing and Rehabilitation (2020-R-061).

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

Meng Sun conceptualized and design the study, performed analysis, wrote the manuscript, and revised the manuscript. Jing Han contributed to interpretation of data and revised the manuscript. Ying Qiao performed data collection. Juan Wang proposed the methodology. Mei Jiang performed data collection. Min Zhang provided project administration, provided resources, performed supervision, contributed to validation, and wrote, reviewed, and edited the article. All the authors have approved the final draft.

Acknowledgments

We acknowledge all participants who took part in our studies.

Aim. The current study investigated the levels and predictors of leaders' humble leadership, participants' psychological safety, knowledge sharing in the team, and followers' creativity in nursing. **Background.** Humble leadership, psychological safety, knowledge sharing, and followers' creativity are non-nursing research fields, and humble leadership has recently been examined in nursing. **Methods.** A cross-sectional research design was employed via an online survey. A nonprobability convenience snowball sample of 245 nursing academics ($n = 85$, 34.70%), nurses ($n = 140$, 57.10%), and nursing leaders ($n = 20$, 8.20%) was recruited from three universities and three hospitals. **Results.** The participants rated "high" the leaders' humble leadership, knowledge sharing in the team, and followers' creativity in nursing. However, participants' psychological safety was precarious. The four variables' predictors were assessed based on the sample's characteristics. Leaders' humble leadership did not predict participants' psychological safety; the sole predictor of the variable was the organization's quality initiatives. The predictors of knowledge sharing in the team were leaders' humble leadership, age, level of education, and accreditation initiatives in the organizations. The predictors of followers' creativity were leaders' humble leadership, level of education, and quality initiatives in the organizations. The lowest means of the four variables should be immediately managed. **Conclusion.** Quality initiatives in organizations and the number of tenures were the most influential predictors of the four variables evaluated. Leaders' humble leadership predicted knowledge sharing in the team and followers' creativity, but not participants' psychological safety. As followers' psychological safety contributes to trustful relationships within the team, workplace boundaries and conducive work environments should be promoted. Training programs are required to develop humble nurses and leaders' leadership.

1. Background

Despite the developments in nursing leadership research, humble leadership continues to have certain evident disadvantages [1, 2]. Social information processing theory provides the theoretical basis for understanding how humble leadership influences followers' creativity [3]. This theory suggests that followers rely on information cues to understand their work environments and regulate their behaviors [3, 4]. Leaders are the key information sources, given

their higher status and direct involvement and interactions with followers [5, 6].

Today's healthcare environment faces many challenges that include but are not limited to development and innovations, meeting international requirements and competition, and developing new leadership approaches, such as humble leadership [7].

This leadership style is a new concept that has gained more attention in nursing leadership research as the term originates originally in psychology research [6, 7]. Humble

leadership, also called humility, is a top-down leadership style that focuses on leaders' openness about their developmental processes, including willingness to view themselves accurately, being open to feedback and creative ideas, and learning by doing [6–8]. This style is needed in nursing because nursing leadership has vital roles in healthcare services at all levels [7]. Nursing humble leaders have to create conducive work environments that promote nurses' engagement, creativity, and innovation [7] and, in turn, achieve different healthcare outcomes, particularly patient satisfaction and the quality of nursing care. An example of these outcomes is missed care or rationed care, which is a highly prevalent clinical healthcare problem resulting in many consequences that negatively influence patients, nurses, and healthcare organizations [9]. Organizations that have quality initiatives have more humble leaders [10], who are expected to solve efficiently the complicated issue of missed care by employing different interventions such as appropriate staffing levels, supplying enough resources, mutual communication and feedback, and teamwork [11].

Psychology-related variables include humble leadership, psychological safety, knowledge sharing, and followers' creativity. Traditional leadership is no longer appropriate because it is difficult for today's leaders to figure everything out at the top due to the increasingly chaotic healthcare work environment [6, 8]. In the quickly changing work environment, nurses' creativity and vigilant leaders have become a mandate [12, 13]. Nevertheless, the growth of creativity is not an instantaneous process; it necessitates an environment of psychological security and the exchange of knowledge to thrive [13, 14].

Being open to new ideas and criticism, valuing the abilities and contributions of others, and seeing oneself honestly are all interpersonal traits of *humble leadership* [15, 16]. Leadership researchers have only recently begun to empirically investigate the impact of leaders' humble leadership on followers' attitudes, such as job satisfaction and job engagement [16], psychological empowerment [6, 13, 15], and nurses' innovative behaviors [15, 17]. A humble leader's behavioral modeling A leader's humble approach can foster a mentally secure setting, potentially shaping a psychologically safe environment [15, 17], which, in turn, may inspire followers to engage in creative behaviors [6, 15].

Psychological safety is the perception of the consequences when taking interpersonal risks in work environments [6, 15]. For followers to be creative, a sense of safety is required [6, 10]. Humble leadership significantly impacts psychological safety [6, 14, 15]. Humble leaders accept their shortcomings and errors in public and see mistakes as a valuable part of the learning process [15, 18]. Such behaviors provide critical information to followers, allowing them to feel psychologically comfortable expressing themselves and taking interpersonal risks to realize their full potential, which also applies to nursing professionals. This is especially true when followers of humble leaders form remarkable leader-follower relationships [15, 16] as it lowers perceived risks and strengthens the safety climate [6, 15].

In addition, humble leaders constantly seek feedback and are open to new ideas [15]. This communicates to followers that speaking up and expressing novel ideas are acceptable and even expected [6, 15]. Humble nursing leaders appreciate their team members' talents and efforts [10] and foster a psychologically safe environment [19] by valuing and encouraging their ideas and opinions [6, 14]. As a result, the followers (nurses) feel free to express themselves and work without fear of negative consequences [6, 19].

Organizations must be creative to perform well, survive, and succeed [20, 21]. The value of creativity has boosted research interest in uncovering traits that lead to creativity during the last few decades [6]. Most of these studies emphasized the positive benefits of leadership styles, such as authentic, transformational, servant, empowering, and sharing, which can positively influence followers' (nurses') creativity [6, 21].

Creativity is inherently riddled with obstacles, uncertainties, and risks because new ideas cannot be guaranteed to produce the desired results [22]. In addition, leaders may not always support or accept new ideas from followers [6, 23]. As a result, a work environment that supports interpersonal risk-taking and expressing novel ideas is critical for motivating followers' creativity; it can even increase one's propensity to do so [6, 24]. Individuals are more likely to express new ideas and take risks in a safe environment, which helps them overcome their anxiety and fear of failure [6, 25].

The psychological safety of the followers has influenced their creativity [6, 14]. However, research on the connection between psychological safety and creativity has yielded contradictory results [6]. Surprisingly, psychological safety does not always result in creativity [6, 26]. As a result, the relationship between psychological safety and creativity is more complicated than anticipated [6, 27]. According to inconsistent empirical findings, boundary variables permit or inhibit the favorable impacts of psychological safety on creativity [6, 28]. However, regardless of the contradictory findings, a psychologically safe environment fosters intergroup trust [13], allowing followers to engage in risky creative activities [6, 14, 25]. Knowledge sharing is crucial for participants' psychological safety [14, 25] and creativity and motivation [12, 28]. The absence of cognitive capacity among followers hinders the generation and presentation of creative ideas [6, 29].

Knowledge sharing is essential for followers' creativity [6, 14]. Knowledge sharing allows followers to gain cognitive resources such as ideas, knowledge, and information, improve cognitive capabilities, and inspire creativity [6, 12, 14].

Research problem: due to the constantly changing work environment, today's leaders find it difficult to grasp humble leadership at the top [15, 18]. Top-down leadership has gone out of step with the times [30]. Despite calls for humble leadership, many unknowns exist regarding how it works in organizations, including healthcare and nursing [6, 18, 19].

As a result of their leaders' higher status and frequent interactions with their teams, followers often learn important information from their leaders' comments and behaviors, allowing them to alter their perspectives of work

settings and respond in the desired way [6, 31]. When humble leaders recognize and manage their flaws and errors, value their followers' strengths and contributions, and display teachability, followers may feel psychologically safe to speak and share new ideas [18, 32]. In response, the perception of a safe work environment may enhance followers' creativity [6, 33].

Theoretical background: despite the importance of humble leadership, there is a significant gap in knowing how humble leadership works in organizations [6, 18]. Consistent with Wang et al. [6] and Elhadidy and Gao [3], "social information processing" theory was adopted in this study. That is, leaders should give up the concept of the "great man," be transparent about their knowledge and experience limitations, and pay closer attention to the influence of followers on leader's performance. As a result, this study investigated how humble leadership influences followers' creativity.

The social information processing theory focuses on how individuals use environmental information to build and interpret events in the workplace [3, 4]. Followers seek information from their leaders to shape their perceptions of the work environments [6, 34]. They act as per the situational attractiveness of specific activities [6]. We assume that humble leaders admit their faults and shortcomings, demonstrate teachability, and value the abilities and contributions of their followers [18, 19]. Followers will feel psychologically comfortable to express fresh thoughts in this circumstance [6, 33]. As a result, followers' creativity would be encouraged if they perceived a safe work environment [6, 33]. According to social information processing theory, psychological safety contributes favorably to modest leadership and followers' creativity [3].

Purpose and significance: nursing research on humble leadership, psychological safety, knowledge sharing in the team, and followers' creativity is lacking. Like many other countries, Jordan is experiencing volatile work situations; hence, such a study is timely.

This is a large-scale project in which the current study answered the following research questions: (1) what are the levels of leaders' humble leadership, participants' psychological safety, knowledge sharing in the team, and followers' creativity in nursing? (2) What are the predictors of leaders' humble leadership, participants' psychological safety, knowledge sharing in the team, and followers' creativity in nursing based on the subjects' characteristics? (3) Do the leaders' humble leadership and the subjects' characteristics predict participants' psychological safety, knowledge sharing in the team, and followers' creativity in nursing?

Only one psychology-based study studied humble leadership, psychological safety, knowledge sharing, and followers' creativity together [6]. Our study is the first international and national study about the four concepts in nursing. Some studies exist about some concepts but were not conducted in nursing [35] or had limited concepts in nursing studies, such as leaders' humble leadership and nurses' psychological safety [19].

The outcomes of the current study will be used to develop leadership training for nurses and other professionals.

Nursing leaders should create supportive work environments to encourage followers' psychological safety and cultivate trusting relationships with their leaders and other experts. Leaders should share knowledge to help their team members achieve psychological safety because it has been demonstrated to reduce the impact of participants' psychological safety on their creativity. Organizations that foster psychological safety and knowledge-sharing circumstances should see high levels of followers' creativity.

2. Methods

2.1. Research Design and Sampling Technique. An online survey was used with a cross-sectional design. A non-probability convenience snowball sample of 245 nursing academics ($n = 85$, 34.70%), nurses ($n = 140$, 57.10%), and nursing leaders ($n = 20$, 8.20%) who worked in three universities and three hospitals were collected, with a response rate of 70.00%. Facebook and WhatsApp were used to collect responses from participants for the online survey. The principal investigator started collecting data by recruiting convenience samples through which the study was announced, and participants were selected if they wished to participate. Other participants were referred to the researcher through snowball recruitment.

The sample size in this study was determined by the formula of $N \geq 10(k) + 50$, where N is the sample size and k is the number of independent variables (four major variables and 12 subjects' characteristics); the minimum sample size should be 210 participants [36], however, 245 participants were obtained. The ability to use electronic platforms and being employed in universities or hospital settings were the sample inclusion criteria.

2.2. Ethical Considerations. The university's Institutional Review Board (IRB), where the current authors work, approved the study; the reference number is 11/8/2021/2022, dated July 25, 2022. Participants were informed in the invitation letter that they might decline to complete the online survey if desired and that their participation constituted their consent. The researchers stored a password on participants' coded responses in Google Drive; all participant data were anonymous. Confidentiality was assured by sharing the aggregate results with nursing leaders in the designated universities and hospitals.

2.3. Data Collection Procedures. Data were gathered in 2022 using a self-report survey administered online in English using Google Forms. The online survey was set to allow for one submission only and by using cookies. It was validated through a small pilot study to check that it was functional and appropriate for the Jordanian setting; no changes were required. The first researcher shared the survey link on the Facebook pages of the Faculty of Nursing and the first researcher's colleagues. To ensure that the target population of nursing academics, nurses, and nursing leaders was targeted, filtering questions were used at the beginning of the survey. The participants were encouraged to invite their contacts.

Data were collected across ten days, and participants were reminded to complete the survey only once after five days with a reminder e-mail. As a result, the online survey was built in this manner.

2.4. Research Instruments: Variables and their Operational Definitions. The subjects' characteristics measured in the current study were gender, marital status, age, time commitment, level of education, and work area if the organization of work is being accredited or if they have official quality initiatives (yes vs. no), tenure (a tenured is someone who has worked for an organization for several years), team size, type of sector, and title.

Following the methodology of Wang et al. [6], the English-version tools were used to collect data and piloted before the actual data collection; no adjustments were required. These research instruments are commonly used in psychology because they have high psychometric measures. Humble leadership, psychological safety, knowledge sharing, and creativity were continuous variables. All tool is a five-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). Thus, a score above 3 to 5 was considered high; around three was considered edgy or borderline, and below three was low.

2.4.1. Humble Leadership. The nine-item scale developed by Owens et al. [16] was used to measure leaders' humble leadership. "This leader often compliments others strength" is an example of an item. The original instrument has content and incremental validity that differentiate it from other positive leadership styles, such as servant, transformational, and ethical leadership [2]. The Cronbach's alpha for this instrument was 0.88 [6] and 0.93 in the current study.

2.4.2. Psychological Safety. The seven-item scale Edmondson [37] developed was used to measure participants' psychological safety. "It is difficult to ask other team members of the organization for help" is an example. The original instrument has discriminant validity [37]. The Cronbach's alpha for this tool was 0.76 [6] and 0.71 in the current study.

2.4.3. Knowledge Sharing. The seven-item scale developed by Lee [38] was used to measure knowledge sharing in the team. "Organizational members share each other's success and failure stories" is an example of an item. The original instrument was reported to have predictive validity [39]. The Cronbach's alpha for this instrument was 0.78 [6] and 0.93 in the current study.

2.4.4. Creativity. The 12-item self-rated creativity scale (SRCS) was modified [40] and used to measure followers' (nursing academics, nurses, and nursing leaders) creativity. "I come up with new and practical ideas to improve performance" is an example. The SRCS was created to evaluate

employees' creativity [40]. The original instrument was reported to have convergent, discriminant, and concurrent validities [40]. The SRCS had internal consistency, as indicated by the Cronbach's alpha of 0.84 [41] and 0.94 in the current study.

2.5. Data Analyses. The Statistical Package for the Social Sciences (SPSS) version 25 [42] calculated descriptive statistics as means, standard deviations, or frequencies and percentages at an alpha of 0.05. Data were visually checked for normality and outliers by drawing a histogram and checking for extreme standard deviations. There were no missing data as the online survey was set to answer all questions.

For the current study, humble leadership and subjects' characteristics were treated as independent variables, while psychological safety, knowledge sharing, and followers' creativity were the dependent variables.

The general linear model (GLM) was used to assess predictors of leaders' humble leadership, participants' psychological safety, knowledge sharing in the team, and followers' creativity based on subjects' characteristics [36]. Another GLM was run while assigning leaders' humble leadership and subjects' characteristics as independent variables, and participants' psychological safety, knowledge sharing in the team, and followers' creativity as dependent variables [36].

Following previous research [6], this study includes several control variables. The first researcher controlled gender, age, the number of tenures (the duration a person holds a job or title), and team size at the organization. Followers' gender, age, and team size were considered because they relate to followers' creativity [6].

3. Results

The majority of the sample was married females, nursing academics, or nurses or nursing leaders, young to middle-aged with baccalaureate degrees, and full-time nurses or academics; these governmental work settings were mostly accredited and had quality initiatives. The participants reported that they were tenured for ten years or more (above average tenure; the average is commonly four years) and worked in a large team with more than fifteen members (the ideal collaborative team size is 4–8) (Table 1).

3.1. Levels of Leaders' Humble Leadership. For the whole sample and a five-point Likert scale, the participants rated highly (agreed) the leaders' humble leadership (mean = 3.57; SD = 0.87). The highest mean of leaders' humble leadership was that the leader was open to the ideas of others (mean = 3.72; SD = 1.06) and showed appreciation for the unique contributions of others (mean = 3.71; SD = 1.06). The lowest mean of leaders' humble leadership was that they admitted when they did not know how to do something (mean = 3.28; SD = 1.14) (Table 2).

3.2. Levels of Participants' Psychological Safety. For the whole sample and a five-point Likert scale, the participants' psychological safety was on the border (mean = 3.09; SD = 0.64). The highest mean of participants' psychological safety was that they felt their unique skills and talents were valued and utilized when working with team members (mean = 3.49; SD = 0.98). The lowest mean of participants' psychological safety was having difficulty asking others for help (mean = 2.71; SD = 1.15) (Table 3).

3.3. Levels of Knowledge Sharing in the Team. For the whole sample and a five-point Likert scale, the participants rated high (agreed) knowledge sharing in the team (mean = 3.48; SD = 0.80). The highest mean was related to the implicit knowledge sharing related to service providers sharing "know-how" from work experience with each other (mean = 3.60; SD = 0.88). The lowest means were related to the explicit knowledge sharing related to service providers sharing each other's success and failure stories (mean = 3.42; SD = 1.01) and business knowledge obtained from different sources (mean = 3.42; SD = 1.01) (Table 4).

3.4. Levels of Followers' Creativity. For the whole sample and a five-point Likert scale, the participants rated high (agreed) followers' creativity within the team (mean = 3.75; SD = 0.63). The highest mean of followers' creativity was that they suggested new ways to increase the quality of work (mean = 3.90; SD = 0.92). The lowest mean of followers' creativity was that they were not afraid to take risks (mean = 3.59; SD = 0.95) (Table 5).

3.5. Significant Predictors of Leaders' Humble Leadership, Participants' Psychological Safety, Knowledge Sharing in the Team, and Followers' Creativity Based on the Subject's Characteristics. The GLM was used to assess predictors of the studied variables based on the subject's characteristics [36].

The predictors of leaders' humble leadership were marital status (t -test = -2.75; p value = 0.006) and the number of tenures (t -test = 1.26; p value = 0.010). The model was significant (F -test = 16.88; DF = 12; p value = 0.001; adjusted R^2 = 0.037) and explained 3.7% of the variance in the mean score of leaders' humble leadership.

The predictor of participants' psychological safety was only the quality initiatives in the organizations (t -test = -2.37; p value = 0.018). The model was significant (F -test = 18.78; DF = 12; p value = 0.001; adjusted R^2 = 0.012) and explained 1.2% of the variance in the mean score of participants' psychological safety.

The predictors of knowledge sharing in the team were marital status (t -test = -2.87; p value = 0.004), the accreditation initiatives in the organizations (t -test = -2.79; p value = 0.006), the quality initiatives in the organizations (t -test = -2.22; p value = 0.027), and the number of tenures (t -test = 2.39; p value = 0.018). The model was significant (F -test = 16.74; DF = 12; p value = 0.001; adjusted R^2 = 0.103) and explained 10.3% of the variance in the team's mean score of knowledge sharing in the team.

TABLE 1: Subject's characteristics (N = 245).

Characteristics	*N (%)
<i>Gender</i>	
Male	76 (31.00)
Female	169 (69.00)
<i>Marital status</i>	
Single	88 (35.90)
Married	145 (59.20)
Separated or widowed	12 (4.90)
<i>Age</i>	
Less than 25 years	56 (22.90)
25–34 years	56 (22.90)
35–44 years	85 (34.70)
45–54 years	36 (14.70)
55 years or more	12 (4.90)
<i>Time commitment</i>	
Full-time work	208 (84.90)
Part-time work	37 (15.10)
<i>Level of education</i>	
Diploma (2 years college degree)	19 (7.80)
Baccalaureate	127 (51.80)
Master	58 (23.70)
Doctorate	41 (16.70)
<i>Role</i>	
Nursing academics	85 (34.70)
Nurses	140 (57.10)
Nursing leaders	20 (8.20)
<i>Work area</i>	
Faculty	57 (23.30)
Units	124 (50.60)
Wards	64 (26.10)
<i>Accreditation initiatives in organizations</i>	
Yes	219 (89.40)
No	26 (10.60)
<i>Quality initiatives in organizations</i>	
Yes	214 (87.30)
No	31 (12.70)
<i>Number of tenures in work</i>	
Less than one year	61 (24.90)
1–2 years	20 (8.20)
3–4 years	35 (14.30)
5–9 years	25 (10.20)
10 years or more	104 (42.40)
<i>Team size in work</i>	
1–5 members	63 (25.70)
6–10 members	37 (15.10)
7–15 members	42 (17.10)
More than 15 members	103 (42.00)
<i>The sector of work</i>	
Governmental	188 (76.70)
Private	57 (23.30)

*N, sample size.

The predictors of followers' creativity were the level of education (t -test = 2.70; p value = 0.007), the quality initiatives in the organizations (t -test = -3.93; p value = 0.001), and the number of tenures (t -test = 2.20; p value = 0.029). The model was significant (F -test = 11.69; DF = 12; p value = 0.001, adjusted R^2 = 0.133) and explained 13.3% of the variance in the mean score of followers' creativity (Table 6).

TABLE 2: Levels of leaders' humble leadership (N = 245).

Items	Mean (SD*)	Strongly disagree 1	Disagree 2	Neutral 3	Agree 4	Strongly agree 5
This leader actively seeks feedback, even if it is critical	3.62 (1.13)	20 (8.20)	19 (7.80)	44 (18.00)	114 (46.50)	48 (19.60)
This leader admits it when they do not know how to do something	3.28 (1.14)	19 (7.80)	44 (18.00)	66 (26.90)	81 (33.10)	35 (14.30)
This leader acknowledges when others have more knowledge and skills than themselves	3.45 (1.13)	16 (6.50)	35 (14.30)	59 (24.10)	92 (37.60)	43 (17.60)
This leader takes notice of others' strengths	3.69 (1.04)	13 (5.30)	18 (7.30)	52 (21.20)	112 (45.70)	50 (20.40)
This leader often compliments others on their strengths	3.56 (1.06)	13 (5.30)	22 (9.00)	70 (28.60)	94 (38.40)	46 (18.80)
This leader shows appreciation for the unique contributions of others	3.71 (1.06)	15 (6.10)	16 (6.50)	47 (19.20)	114 (46.50)	53 (21.60)
This leader shows a willingness to learn from others	3.51 (1.13)	16 (6.50)	30 (12.20)	60 (24.50)	90 (36.70)	49 (20.00)
This leader shows that they are open to the advice of others	3.67 (1.07)	13 (5.30)	20 (8.20)	57 (23.30)	101 (41.20)	54 (22.00)
This leader shows that they are open to the ideas of others	3.72 (1.06)	14 (5.70)	14 (5.70)	56 (22.90)	103 (42.00)	58 (23.70)
Total mean score	3.57 (0.87)					

This 9-item scale is rated from 1 (strongly disagree) to 5 (strongly agree). *SD = standard deviation.

TABLE 3: Levels of psychological safety (N = 245).

Items	Mean (SD*)	Strongly disagree 1	Disagree 2	Neutral 3	Agree 4	Strongly agree 5
If you make a mistake on this team, it is often held against you	3.10 (1.05)	14 (5.70)	63 (25.70)	74 (30.20)	73 (29.80)	21 (8.60)
Members of this team can bring up problems and tough issues	3.24 (1.09)	17 (6.90)	49 (20.00)	62 (25.30)	93 (38.00)	24 (9.80)
People on this team sometimes reject others for being different	3.03 (1.13)	25 (10.20)	60 (24.50)	62 (25.30)	79 (32.20)	19 (7.80)
It is safe to take a risk on this team	3.02 (1.02)	21 (8.60)	50 (20.40)	91 (37.10)	70 (28.60)	13 (5.30)
It is difficult to ask other team members for help	2.71 (1.15)	37 (15.10)	83 (33.90)	53 (21.60)	57 (23.30)	15 (6.10)
No one on this team would deliberately act in a way that undermined my efforts	3.07 (1.01)	11 (4.50)	64 (26.10)	85 (34.70)	66 (26.90)	19 (7.80)
By working with members of this team, my unique skills and talents are valued and utilized	3.49 (0.98)	11 (4.50)	26 (10.6)	70 (28.60)	109 (44.50)	29 (11.80)
Total mean score	3.09 (0.64)					

This 7-item scale is rated from 1 (strongly disagree) to 5 (strongly agree). *SD = standard deviation.

TABLE 4: Levels of knowledge sharing (N = 245).

Items	Mean (SD*)	Strongly disagree 1	Disagree 2	Neutral 3	Agree 4	Strongly agree 5
Explicit knowledge sharing: we and our service provider share business proposals and reports with each other	3.50 (0.97)	11 (4.50)	25 (10.20)	66 (26.90)	116 (47.30)	27 (11.00)
We and our service provider share business manuals, models, and methodologies	3.44 (0.99)	12 (4.90)	29 (11.80)	67 (27.30)	112 (45.70)	25 (10.20)
We and our service provider share each other's success and failure stories	3.42 (1.01)	11 (4.50)	36 (14.70)	64 (26.10)	107 (43.70)	27 (11.00)
We and our service provider share business knowledge from newspapers, magazines, journals, and television	3.42 (0.99)	12 (4.90)	26 (10.60)	81 (33.10)	98 (40.00)	28 (11.40)
Implicit knowledge sharing: we and our service provider share know-how from work experience with each other	3.60 (0.88)	9 (3.70)	13 (5.30)	70 (28.60)	128 (52.20)	25 (10.20)
We and our service provider share each other's know-where and know-whom	3.48 (0.92)	8 (3.30)	27 (11.00)	72 (29.40)	116 (46.90)	23 (9.40)
We and our service provider share expertise obtained from education and training	3.55 (0.97)	11 (4.50)	24 (9.80)	58 (23.70)	123 (50.20)	29 (11.80)
Total mean score	3.48 (0.80)					

This 7-item scale rated from 1 (strongly disagree) to 5 (strongly agree). *SD = standard deviation.

TABLE 5: Levels of followers' creativity.

Items	Mean (SD*)	Strongly disagree 1	Disagree 2	Neutral 3	Agree 4	Strongly agree 5
I suggest new ways to achieve goals or objectives	3.81 (0.90)	8 (3.30)	10 (4.10)	49 (20.00)	131 (53.50)	47 (19.20)
I come up with new and practical ideas to improve performance	3.78 (0.84)	6 (2.40)	11 (4.50)	51 (20.80)	139 (56.70)	38 (15.50)
I search for new technologies, processes, techniques, and/or product ideas	3.73 (0.95)	8 (3.30)	13 (5.30)	65 (26.50)	110 (44.90)	49 (20.00)
I suggest new ways to increase the quality of work	3.90 (0.92)	8 (3.30)	7 (2.90)	49 (20.00)	118 (48.20)	63 (25.70)
I am a good source of creative ideas	3.80 (0.87)	5 (2.00)	9 (3.70)	64 (26.10)	118 (48.20)	49 (20.00)
I am not afraid to take risks	3.59 (0.95)	8 (3.30)	22 (9.00)	67 (27.30)	113 (46.10)	35 (14.30)
I promote and champion ideas to others	3.77 (0.85)	6 (2.40)	9 (3.70)	61 (24.90)	128 (52.20)	41 (16.70)
I exhibit creativity in my work when allowed	3.76 (0.92)	9 (3.70)	9 (3.70)	59 (24.10)	122 (49.80)	46 (18.80)
I often have new and innovative ideas	3.72 (0.81)	7 (2.90)	7 (2.90)	63 (25.70)	139 (56.70)	29 (11.80)
I come up with creative solutions to problems	3.74 (0.85)	7 (2.90)	9 (3.70)	59 (24.10)	135 (55.10)	35 (14.30)
I often have a fresh approach to problems	3.70 (0.79)	6 (2.40)	6 (2.40)	70 (28.60)	136 (55.50)	27 (11.00)
I suggest new ways of performing work tasks	3.74 (0.89)	9 (3.70)	11 (4.50)	52 (21.20)	136 (55.50)	37 (15.10)
Total mean score	3.75 (0.63)					

This 12-item scale is rated from 1 (strongly disagree) to 5 (strongly agree). *SD = standard deviation.

TABLE 6: Significant predictors of leaders' humble leadership, participants' psychological safety, knowledge sharing in the team, and followers' creativity based on the subject's characteristics using GLM ($N = 245$).

Dependent and significant predictors	B^*	T -test	p value	R^2	Adjusted R^2	F -test (df) ** (p value)
The total score of humble leadership				0.085	0.037	16.88 (12) (0.001)
Marital status	-3.32	-2.75	0.006			
Number of tenures	3.27	1.26	0.010			
The total score of psychological safety				0.061	0.012	18.78 (12) (0.001)
Quality initiatives in organizations	-2.17	-2.37	0.018			
The total score of knowledge sharing				0.147	0.103	16.74 (12) (0.001)
Marital status	-2.41	-2.87	0.004			
Accreditation initiatives in organizations	-3.27	-2.79	0.006			
Quality initiatives in organizations	-2.44	-2.22	0.027			
Number of tenures	2.10	2.39	0.018			
The total score of followers' creativity				0.175	0.133	11.69 (12) (0.001)
Level of education	3.30	2.70	0.007			
Quality initiatives in organizations	-6.18	-3.93	0.001			
Number of tenures	2.77	2.20	0.029			

* B , unstandardized coefficients; ** $p < 0.001$ (2-tailed).

3.6. *Leaders' Humble Leadership and Subject's Characteristics as Predictors of Participants' Psychological Safety, Knowledge Sharing in the Team, and Followers' Creativity.* The GLM was performed while handling leaders' humble leadership and subjects' characteristics as independent variables, and participants' psychological safety, knowledge sharing in the team, and followers' creativity as dependent variables [36].

The results of the GLM indicated that the only predictor of participants' psychological safety was the quality initiatives in the organizations ($B = -2.16$; p value = 0.020). The model was significant ($F(df = 13) = 17.11$; p value = 0.001; $R^2 = 0.008$; Table 7), and it explained 0.80% of the variance in the mean score of participants' psychological safety.

The predictors of knowledge sharing in the team were leaders' humble leadership ($B = 8.16$; p value = 0.001), age ($B = 2.79$; p value = 0.006), level of education ($B = -1.99$; p value = 0.047), and the accreditation initiatives in the organizations ($B = -2.55$; p value = 0.011). The model was significant ($F(df = 13) = 5.51$; p value = 0.020; adjusted $R^2 = 0.301$; Table 7) and explained 30.10% of the variance in the team's mean score of knowledge sharing.

The predictors of followers' creativity were leaders' humble leadership ($B = 7.16$; p value = 0.001), level of education ($B = 2.78$; p value = 0.006), and the quality initiatives in the organizations ($B = -3.57$; p value = 0.001). The model was insignificant ($F(df = 13) = 3.15$; p value = 0.077; Table 7), but it explained 28.70% of the variance in the mean score of followers' creativity.

In conclusion, the most influential predictors of leaders' humble leadership, participants' psychological safety, knowledge sharing in the team, and followers' creativity were quality initiatives in the organizations and the number of tenures. Leaders' humble leadership predicted knowledge sharing in the team and followers' creativity, but not participants' psychological safety.

4. Discussion

The current study's subjects fit the demographics of nursing academics, nurses, nursing leaders, and organizational characteristics in Jordan.

According to the social information processing theory [3, 4], humble leadership influences followers' creativity when they are well-informed, and knowledge is shared among the team; this reflects positively in their understanding of their work environments and regulating their behaviors accordingly [3, 4]. However, the staff's need for self-monitoring and constant scanning of their work environments may explain why they have borderline psychological safety.

The high rating for humble leadership stems from the benefits of humble leadership, which pave the path for better listening and improved collaboration (supported by Anser et al. [43] and Kelemen et al. [15]). As former nurses, nursing leaders, and current academic professionals, we like to be led by a sympathetic leader.

The high rating for knowledge sharing emanated from knowledge being one of any organization's most valuable intangible assets. While corroborating the assertions mentioned above as former healthcare professionals and current academics, Al Hawamdeh [44] asserted that staff members have grown more receptive to knowledge help. Staff employees are more prepared to deal with unexpected events since they are more knowledgeable. Thus, the study participants were aware that knowledge would flow from top leadership to staff members through knowledge exchange in the team, thus setting the way for creating relevant or new knowledge in the organization.

Followers' creativity within the team received a higher rating because of the improved teamwork it delivers to an organization, which is consistent with the studies of

TABLE 7: Significant leaders' humble leadership and subject's characteristics as predictors of participants' psychological safety, knowledge sharing in the team, and followers' creativity using GLM ($N=245$).

Dependent and significant predictors	B^*	T -test	p value	R^2	Adjusted R^2	F -test (df) ** (p value)
The total score of psychological safety				0.061	0.008	17.11 (13) (0.001)
Quality initiatives in organizations	-2.16	-2.34	0.020			
The total score of knowledge sharing				0.338	0.301	5.51 (13) (0.020)
Leaders' humble leadership	0.329	8.16	0.001			
Age	2.33	2.79	0.006			
Level of education	-2.41	-1.99	0.047			
Accreditation initiatives in organizations	-2.66	-2.55	0.011			
The total score of followers' creativity				0.325	0.287	3.15 (13) (0.077)
Leaders' humble leadership	0.425	7.16	0.001			
Level of education	3.08	2.78	0.006			
Quality initiatives in organizations	-5.12	-3.57	0.001			

* B , unstandardized coefficients; ** $p < 0.001$ (2-tailed).

Mrayyan [10], Sengupta et al. [45], as well as Wang et al. [6]. Collaboration is widely encouraged in a creative environment. As a result, the participants realized they needed to foster a continuous learning attitude while encouraging employees to seek new information, knowledge, and better ways to complete their responsibilities.

However, despite all preceding positive indicators, participants' psychological safety was borderline; this may imply issues with inclusion in teams and organizations, as Singh [14] suggests. In Jordan, we suffer limited inclusion in teams and organizations. Psychological safety is about enabling openness, inclusion is necessary for mutual learning, and the latter is necessary to progress in a complex and ambiguous world [46]. This pioneer researcher in psychological safety attested to the strong link between psychological safety, learning, and performance in teams and organizations.

4.1. Leaders' Humble Leadership. The participants rated highly (agreed) the leaders' humble leadership. This point again humbles leadership to leaders' ability to recognize their strengths and weaknesses alongside limitations, similar to Cho et al. [47] and Kelemen et al. [15].

Our participants agreed that a humble leader can be more persuasive [48]; this is human nature. Humans frequently support the underdog while opposing their competitors or opponents. Humble leadership puts leaders in a better position to inspire their team or followers. Furthermore, nurse leaders may readily persuade their followers to collaborate to realize a healthcare vision. Humble leadership engenders trust, loyalty, and enthusiasm more effectively than fear and manipulation, which is in line with studies of Kelemen et al. [15].

Humble leaders are open to other people's ideas and show respect for their unique contributions. This was the polar reverse of popular stereotypes, calling for nurse leadership to command a room with high success and authority. Participants recognized the importance of adopting a more inclusive and inviting communication style. The participants were part of a nursing leadership that encouraged workers to discuss their ideas. Taking this option

provides high operational flexibility and considerable levels of employee involvement. In comparison to their competitors that embrace authoritarian techniques, such nursing organizations demonstrate strategic alignment and retention, as well as a high level of performance [13], which is supported by Kelemen et al. [15].

On the other hand, humble leaders did not admit when they did not know how to do something. This illustrates that one of the major characteristics of humble leadership is the willingness to be taught and directed in areas where they are either inexperienced or lack knowledge. This kind of admittance shows the nurses their leaders and also fix opinion as opinions, and it helps the team come up with the right solutions, as demonstrated by Zhou and Li [49].

Some nurses may have encountered something similar in past work contexts, possibly in other roles. As a result, they will provide vital insight into the next best action. As seen across leading healthcare organizations, the most significant successes will likely emerge from not knowing [49].

4.2. Participants' Psychological Safety. The participants rated their psychological safety on the border, contrary to Wang et al. [6] and similar to Mrayyan and Al-Rjoub [19]; this warrants vigilant leadership to intervene immediately. Psychologically safe staff members, on the other hand, were open to ideas that would eventually lead the way for new solutions, as demonstrated by O'donovan and McAuliffe [50]. Nursing organizations acknowledge the power of variety through psychological safety. As a result, the participants advocate for psychologically safer workplaces throughout their businesses, with nurses encouraged to suggest new and innovative solutions.

Participants' psychological safety was high when they felt their unique skills and talents were valued and utilized when working with team members. This could imply that nursing leadership can provide psychological safety to team members by exploiting their particular abilities and talents. This will demonstrate to them that their organizations value their abilities and capabilities. The findings align with Mansour and Tremblay [51], who claimed that when firms better utilize their employees' skills, they have a higher job

satisfaction. Nursing staff workers are more prepared to adjust to recommended future changes when they have psychological safety.

On the other hand, participants' psychological safety was low when they had trouble asking others for support. Taylor et al. [52] validated the findings, arguing that some professionals, even leaders, think that asking for help will expose them as inexperienced or incapable. The researchers reported that some nursing staff members think that such a request may be a process of losing control. In many organizations, such as ours, asking for help might put the staff member in a vulnerable position, where the majority may avoid seeming weak, which is similar to the study of Taylor et al. [52].

4.3. Knowledge Sharing in the Team. The participants rated high (agreed) knowledge sharing in the team. Knowledge sharing emerged as a crucial attribute of nursing leadership, as did humble leadership [6, 10, 14]. Confirming our findings with Holmgren et al. [53], the participants recognized the importance of knowledge sharing in increasing the collective skills of medical staff members. Understanding a patient's condition and making healthcare-related decisions demonstrate the capacity.

The highest level of implicit knowledge sharing was associated with service providers exchanging "know-how" from their job experiences with one another. This step is crucial in ensuring that the team connects and performs better [6, 54]. Similarly to our view, Holmgren et al. [53] suggested that sharing implicit knowledge of the experience commanded by other nurses helps them become more vital professionals. This allows the organization to save more training resources while still capturing and maintaining knowledge during turnover [53].

The least explicit information sharing occurred when service providers shared each other's success and failure tales and business expertise collected from various sources. Participants agreed that, similar to our professional experience, such a move was critical in cooperating and producing collective knowledge. Explicit knowledge sharing promotes improved ways of carrying out nursing duties while fostering a learning culture [53].

4.4. Followers' Creativity. The participants rated high (agreed) followers' creativity within the team. The participants were aware that creativity is a factor that inspires staff members to operate as a team, as attested by Kohnen et al. [34]. As a result of such a creative process, an organization fosters a collaborative culture. Thus, with a continuous learning mindset, staff members would continuously seek new information and expertise as well as better ways of doing things [43].

When followers offered new approaches to improve the quality of work, their creativity was high. Creativity encompasses increased quality and quantity production [43]. As mentioned, staff members realize this when seeking new information and knowledge, which is possible when they identify new ways to do their jobs, as previously said.

Participants were unafraid to take risks, indicating that creative individuals are risk-takers. Creative people are always ready to take "good" risks, which leads them down an inventive road [43]. Furthermore, they will take social risks to keep the team safe.

4.5. Significant Predictors of the Studied Concepts Based on the Subject's Characteristics. The predictors of leaders' humble leadership were marital status and the number of tenures, which is one of the novel results of the current study. The current findings are supported by Wang et al. [55], who reported that the antecedents of creativity in teams were leaders' gender, marital status, age, education, and tenure, which may also apply to our leaders' humble leadership. Being female and having more tenure years may signify having better job control and self-discipline, as mentioned by Al Hawamdeh [44]. Similar to our situation, the researcher reported that gender and tenure made a leader more caring while exhibiting high levels of self-control. As a result, the staff members were more focused on achieving personal goals and meeting organizational objectives.

The predictor of participants' psychological safety was only the quality initiatives in the organizations, which is also one of the novel results in the current study. As Jordan is experiencing quality initiatives in most clinical and academic settings, organizational quality initiatives promote our belief that the nursing team enjoys the safety necessary for interpersonal risk-taking. Quality initiatives are critical in creating a psychologically safe environment where people can speak up and express their views.

Marital status, accreditation initiatives in organizations, quality initiatives in organizations, and the number of tenures were predictors of knowledge sharing in the team, which is a novel finding. The four variables may contribute to our participants' trust in knowledge sharing. Being female and having tenure were antecedents of team creativity, supported by Wang et al. [55]. This may also apply to knowledge sharing in our teams in the current study. Chen et al. [1] complemented our findings about the effect of accreditation and quality initiatives in organizations on team knowledge sharing. The researchers asserted that staff members working in accredited organizations confidently share their knowledge. The same applies to the quality initiatives in organizations that always keep the staff members' input and output in check.

Of the novel results, the predictors of followers' creativity were the level of education, the quality initiatives in the organizations, and the number of tenures. This demonstrates that creative people are more educated and experienced. Besides, with quality initiatives in place, staff members would always seek new ways of doing things, similar to what is reported by Chen et al. [1].

4.6. Leaders' Humble Leadership and Subject's Characteristics as Predictors of the Studied Concepts. The only predictor of participants' psychological safety was the quality initiatives in the organizations. This result is in line with our participants' rating high (agreed) the leaders' humble leadership (similar to Mrayyan and Al-Rjoub [19] and Wang et al. [6]),

but not their psychological safety (similar to Li et al. [26] and Mrayyan and Al-Rjoub [19]).

Previous studies reported a mediational model of psychological safety in the relationship between leadership and followers' creativity to account for the inconsistent findings in the literature [6, 26]. Although Wang et al. [6] reported that psychological safety has a mediating role between leadership and followers' creativity, Li et al. [26] reported no evidence of psychological safety mediation.

Previous research supported the relationship between leaders' humble leadership and participants' psychological safety [6, 56]; however, our study revealed that leaders' humble leadership does not predict participants' psychological safety. As former nurses and current academics, we strongly believe the problem is a lack of workplace boundaries. As a result, humble leaders must establish boundaries necessary for participants' psychological safety. Boundaries in the workplace are guidelines that employees make for themselves to determine what is psychologically safe and permissible for others to do around them [57]. Since they did not care for their well-being, our participants did not believe their workplace boundaries were healthy. Their team relationships did not blossom or grow well. They lacked the trust and belonging required to participate in the team. Everyone wants to set boundaries and have those boundaries respected. Healthy workplace boundaries are promoted by healthy work environments and cultures [57]. On the other hand, unhealthy boundaries lead to disengagement, depression, stress, and anxiety, and, this in turn, results in stress-induced physical illness [57].

Leaders' humble leadership, age, education, and organization accreditation initiatives were predictors of knowledge sharing in the team, which were comparable to Wang et al. [6], who reported that humble leadership influences knowledge sharing. Knowledge sharing is a humble leadership-boundary factor to enhance followers' creativity [6, 58]. Our participants rated high their humble leaders and knowledge sharing in the team. When there is a high level of knowledge sharing in the team, followers will offer and share new ideas, which does not suddenly happen. According to Mrayyan [10] and Wang et al. [6], humility leadership is the defining factor in such a setting and humble leaders should encourage team members to offer new ideas.

Leaders' humble leadership, education, and organizational quality initiatives were predictors of followers' creativity. According to Elhadidy and Gao [3] and Wang et al. [6], humble leaders influence their followers' creativity. These humble leaders were receptive to other people's views and appreciated the distinctive contributions of others [18, 19]. Thus, these positive characteristics of humble leaders will influence followers' creativity.

Chaman et al. [12] explained the psychological mechanisms between leaders' humble leadership and followers' creativity through intrinsic motivation and social learning. Those studies, however, concentrated on the old top-down leadership [30], whereas humble leadership is a new bottom-up leadership style [8]. Humble leaders are essential for any organization; however, humble leadership has only recently begun [59]. Moreover, Wang et al. [6] critiqued these studies

for focusing just only on one level of analysis, either the individual level or the team level. This single level of analysis resulted in an incomplete picture of what humble leadership is, implying that humble leadership has cross-level effects, or what Li et al. [26] referred to as the "spillover" from "team-level humble leadership" to "individual-level humble leadership."

4.7. Limitations. When nurses reflect on their leaders' humble leadership, they focus solely on their strengths, creating a bias in rating humble leaders. Self-reporting of leaders' humble leadership, participants' psychological safety, knowledge sharing in the team, and followers' creativity in nursing suggest possible bias. The major concern is related to the use of self-reported creativity. Many variables are already reported in the literature to predict creativity, such as personality traits, openness to experience, and age [6, 60]. Thus, in future studies, substantive control factors must be employed to isolate the effect of potential variables that may affect creativity. After controlling for potential interfering variables, potential predictors of creativity should be found.

Collecting data in Jordan involves a single data-gathering approach, thus limiting generalizability to other countries. The nonprobability convenience snowball sampling was used to collect data from universities and hospitals, restricting the generalizability of the results to other contexts. Due to the cross-sectional research design used in the current study which does not imply causation, the results should be evaluated carefully. Humble leaders involve other external or humble informal leaders, such as team mentors and coordinators, who were not studied in this research.

5. Summary and Conclusion

These lowest means of the studied concepts necessitate immediate organizational interventions. Quality initiatives in organizations and the number of tenures were the most effective predictors of leaders' humble leadership, participants' psychological safety, knowledge sharing in the team, and followers' creativity. Leaders' humble leadership predicted knowledge sharing in the team and followers' creativity, but not participants' psychological safety.

Leadership training and development programs are required to build nurses' and leaders' humble leadership as it contributes to followers' creativity. Workplace boundaries and supportive work environments should be established to improve participants' psychological safety pending knowledge sharing in the team, and in turn, followers' creativity occurs. Organizational attention towards creating conditions for participants' psychological safety and knowledge sharing would result in high levels of followers' creativity. Additional studies with a bigger random sample and other research designs are required in other settings and cultures, particularly those involving novel findings.

6. Implications

6.1. In Practice and Education. Leaders' humble leadership helps facilitate knowledge sharing in the team as it relates to followers' creativity of the current study's edgy participants'

psychological safety, indicating that psychological safety should not warrant creative outcomes only [6], but knowledge sharing should always be present. Furthermore, workplace limits should be established so that firms can get high levels of creativity from their followers; nevertheless, psychological safety, humble leadership, and knowledge sharing should be offered concurrently [6, 12].

Also, humble leadership helps facilitate followers' creativity. Humble leadership must be acquired, developed, and sustained [6], requiring training programs to assist leaders in understanding and developing humble leadership. Humble leaders should be chosen and employed while hiring.

Since it was tense, several organizational and leadership actions effectively developed participants' psychological safety [6]. This study included encouraging followers by respecting and exploiting their unique abilities and talents and avoiding the blame culture when someone makes a mistake. These acts would help to foster supportive relationships and establish trust between humble leaders and team members [13].

Humble leadership, psychological safety, knowledge sharing, and followers' creativity are non-nursing concepts that should be integrated into the nursing curricula at the undergraduate and graduate levels, as today's students are tomorrow's nurses.

6.2. In Research. According to Lusso et al. [61], the researcher could only study the complete population. As a result, the conclusions derived from the created sample were intended to extend to Jordan's full population of nursing academics, nurses, nursing leaders, and organizational characteristics. Thus, the researchers should choose a sample representative of the population mentioned above.

The current results indicate that participants' psychological safety was precarious; thus, further investigation of the causes is required, including integrating qualitative research designs or mediating mechanisms to determine how concepts studied relate to one another and how they produce followers' creativity.

Like Wang et al. [6], many professionals in Jordan work in a strongly collectivist and high-power distance culture. Since humble leadership is a culturally driven notion, more research in various cultures and countries is required. Thus, more research is needed to assess leaders' humble leadership and followers' creativity.

The current study reported many novel findings, including the predictors of the concepts such as that marital status predicted leaders' humble leadership and knowledge sharing. The quality initiatives predicted participants' psychological safety and followers' creativity. These unusual findings should be examined further with bigger, randomized samples in various situations.

Background. Nurses' creativity is an imperative necessity for healthcare organizations to grow. The creative abilities of nurses are affected by many factors; some of these factors are stimulants and some of these are inhibitors. Supervisors' knowledge sharing behavior and the capacity to absorb new knowledge and technologies are important factors in the recent era that delineate the creativity of nurses. **Aim of the Study.** Assess the effect of supervisor knowledge sharing behavior and organizational absorptive capacity on nurses' creativity. **Method.** Cross-sectional multicenter descriptive correlational exploratory research design was used to conduct the study. Data were collected conveniently from 700 nurses recruited from five large hospitals at Alexandria, Egypt, using three self-administered printed questionnaires. Findings were investigated via descriptive and inferential statistics as well as structured equation modeling. **Results.** Nurses' creativity was positively associated with supervisor knowledge sharing behavior and organizational absorptive behavior ($r=0.619$, p value <0.001 , and $r=0.545$, p value <0.001 , respectively). Supervisor knowledge sharing behavior accounted for 87% of variance in nurses' creativity, while organizational absorptive capacity accounted for 55% of variance in nurses' creativity. **Conclusion.** Supervisors' knowledge sharing behavior and absorptive capacity of organization are powerful significant stimulants for nurses' creativity. **Implications to Nursing Management.** Hospital directors, managers, and nursing leaders should cultivate knowledge sharing behavior in healthcare settings by establishing a reward and incentive system for healthcare workers who share their knowledge with their colleagues for mutual benefit and organizational development.

1. Introduction

The economic decline and inflation around the world have been affecting healthcare in all its aspects, which prompted organizations to attract cadres from creative health care providers [1]. Moreover, the sustainability and competitiveness of healthcare organizations in the contemporary highly turbulent economic environment articulated around three critical attributes, namely, organizational culture that motivate leaders to share their experiences and knowledge in

a successful manner, absorptive capacity of organization, and the ability of organization to recruit creative and innovative nurses who are able to use different sources of knowledge to provide efficient integrated nursing care [2].

Today, financial and technological resources are not the only advantages of healthcare organizations. It is important to have creative nurses who can compensate for the lack of other resources [3]. Understanding the strategic role of human resources especially nurses in making excellence is one of the value added features of successful healthcare

organization. Only successful organizations are able to delineate stimulants and barriers of creative performance of their nurses. Numerous antecedents and factors can stimulate nurses' creativity; however, knowledge sharing behavior exhibited by their leaders as well as the absorptive capacity of organizations to invest in novel knowledge sources and technology modalities are two factors responsible for the majority of creative ideation among nurses [4].

Knowledge sharing is a corner stone process as no one person cannot generate all the knowledge needed to carry out his/her everyday tasks [5]. Everyone must therefore acquire outside knowledge and experience [6]. According to Che et al. [5], individuals within organizations, including supervisors, can impart their knowledge and experience on others. Supervisors can also help their subordinates improve their work by imparting knowledge or useful information [7]. The value of knowledge and experience in creative performance has been demonstrated in the prior studies [8, 9]. Supervisor knowledge sharing behavior is regarded as prosocial behavior that is beneficial to nurses. When supervisors share their valuable knowledge, experts, and skills with nurses, they are likely to feel appreciated and learn this behavior [10]. Firms should choose individuals who frequently share their knowledge with others when staffing supervisory positions. Moreover, healthcare firms should encourage nursing supervisors as well as give supervisors a substantial amount of time and opportunities to share their knowledge with nurses [4].

Explicit knowledge and tacit knowledge are the two categories of knowledge [11]. Objective knowledge that can be expressed, codified, and conveyed using formal language is known as explicit knowledge. Tacit knowledge is described as subjective knowledge that is challenging to articulate, codify, and transfer [11]. Although it is challenging to convey tacit knowledge, supervisors can do so through interacting with, socializing with, and training their subordinates [12]. In addition, networking with others and face-to-face conversation can lead to information sharing [13]. Sharing information and experience with subordinates can be beneficial for supervisors. The ability to think creatively depends on knowledge [8, 14]. Supervisors can work with others to create and implement new ideas or procedures as well as exchange task-relevant ideas, knowledge, experience, and suggestions with subordinates [12]. Che et al. [5] asserted that employees' creative performance would be enhanced by learning from sources within organizations such as supervisors and leaders.

Absorptive capacity is the dynamic capacity that allows organization to create value, gain, and sustain a competitive advantage through the management of the external knowledge [15]. It is the ability of the organization to identify technological opportunities in its external environment and apply them to obtain a better performance [16]. Healthcare organizations can upgrade their absorptive capacity by mastering knowledge management skills, especially knowledge acquisition, learning, and assimilation systems. If these organizations need to shape their creativity strategies, they not only need to absorb new information from the environment but also use it internally [15].

Knowledge sharing behavior of supervisors and absorptive capacity are two concepts that are closely related. The relationship between them is interdependent and complementary. Knowledge sharing of supervisors can be seen as an antecedent of absorptive capacity because it provides the necessary knowledge for absorptive capacity to occur. On the other hand, absorptive capacity can be seen as an antecedent of knowledge sharing because it provides the necessary context for knowledge sharing to occur [17].

Koseoglu et al. [18] described creativity as the development of novel, useful products and processes. Creativity is essential for organizational innovation, performance, growth, and long-term survival. Every nurse has a creative mode, but it is frequently inhibited by internal and external variables including time, overly rigid control systems, and an excessive dependence on standard operating procedures [19]. Creativity is imperative for nursing practice as when there are no clear answers or courses of action, nurses can rely on their creativity to come up with new solutions and make decisions. In this context, the work of Zuber and Moody [20] highlighted that creativity in nursing care includes fluidity of mind and the creation and acceptance of new ideas for patient care in such a way that the new methods are simple, useful, efficient, affordable, and safe.

When it comes to creativity, knowledge sharing can benefit creativity through absorptive capacity and knowledge integration. Thuan [21] found that knowledge sharing was positively related to team creativity, fully mediated by both absorptive capacity and knowledge integration. In addition, cognitive team diversity played a moderating role in the relationship between knowledge sharing and organizational absorptive capacity, as well as in the relationship between knowledge sharing and knowledge integration [3].

1.1. Significance of the Study and Research Gap. Stimulating nurses' creativity is of paramount importance for healthcare organizations and nursing practice [1]. Recent studies stressed on the promising role of nurses' creativity toward buffering resources depletion and giving organization high magnetism power that enable it to attract patients and qualified cadres [2, 22]. This also strengthens organization in the pursuit of competitive advantage and sustainability [23]. Moreover, studying factors that stimulate creativity is highlighted in different scholars as recent required research direction due to its powerful role in transforming the conventional nursing practice and making it smart, flexible, green, evidence-based, patient-centered, and holistic practice [1]. Meanwhile, international council of nurses dedicates its efforts to shape nursing policy in the sustainable developmental era highlighting the importance of investment in nursing creativity [2]. Despite all these calls, nurses' creativity does not receive considerable attention in recent studies. The majority of studies that addressed creativity articulated around perspectives of nurses regarding their creativity. In addition, stimulants and barriers of nurses' creativity are not adequately explained with limited studies that shed the light on the role of different factors like

clinical practice environment [3], career development, job embeddedness [24], and polychronicity [25] on nurses' creativity in the Egyptian and international contexts.

The concepts of supervisor knowledge sharing behavior and absorptive capacity have gained high momentum recently in knowledge management literature [15]. Several studies examined their role in shaping innovation and employees' performance at different contexts like tourism [26], information technology agencies [21], public services settings [27], and petroleum companies [8]. Meanwhile, opinions of respected nursing authorities give consensus that supervisor knowledge sharing behavior and organizational absorptive capacity are important factors to build creativity among nurses [28]. However, these factors were not tested empirically in nursing context. To address this gap, our study aims to empirically examine the role of supervisor knowledge behavior and absorptive capacity toward nurses' creativity. Investigating the interplay among these factors could help nurse leaders to develop trusted strategies for cultivating creative work environment for nurses which ultimately improves quality of patient care and eradicate patient safety threats.

1.2. Theoretical Framework and Hypothesis Formulation.

This study combines organizational learning theory and organization knowledge management model developed by Vespo [29] to explain the relationship between knowledge sharing behavior, absorptive capacity, and nurses' creativity. According to organizational learning theory, organizational learning occurs through acquiring new knowledge shared from past experiences and absorbing new knowledge from outside organizations which could reinforce using absorptive capacity strategies [30]. Organizational learning theory believed that organizational learning is the behavioral process of organization employees to promote innovation and creative ideation using knowledge sources gained by sharing and absorbing [15]. In addition, the theory also assumed that fertilizing the land for creativity and innovation to grow require the organization to mix between both adaptive learning based on environmental change response and active learning based on self-motivation. In this respect, Vespo [29] uses the assumptions of organizational learning theory and develops simplified model illustrating organizational knowledge management. Accordingly, knowledge management starts with identifying new knowledge sources through knowledge sharing which in turn lead to elaboration through combining different skills with each other. The Result of this elaboration is in the first place the outcome itself, which may be creation or an innovation or an improvement of an existing service [29]. Our study uses the assumptions of organizational learning theory and the work of Vespo to conceptualize and predict the relationship between the three variables. Figure 1 shows our proposed conceptual framework illustrating the relationship between knowledge sharing behavior of supervisor, organizational absorptive capacity (independent variables), and nurses' creativity (dependent variable).

FIGURE 1: Conceptual model illustrating the relationship between study variables.

1.3. Study Hypotheses

- H1. There is a relationship between supervisor knowledge sharing behavior and nurses' creativity
- H2. There is a relationship between organizational absorptive capacity and nurses' creativity
- H3. Supervisor knowledge sharing behavior has positive effect on stimulating nurses' creativity
- H4. The level of organizational absorptive capacity has positive effect on stimulating nurses' creativity

2. Methods

2.1. *Aim.* The study aims to investigate the effect of supervisor knowledge sharing behavior and organizational absorptive capacity on nurses' creativity.

2.2. Research Question

- (i) To what extent nursing supervisors share their knowledge with nurses?
- (ii) What is the level of organizational absorptive capacity perceived by nurses?
- (iii) What is the level of creativity among nurses?
- (iv) Is there a relationship between supervisor knowledge sharing behavior and nurses' creativity?
- (v) Is there a relationship between the level of absorptive capacity of organization and nurses' creativity?

2.3. *Design.* A cross-sectional multicenter, correlational, and descriptive research study design was used.

2.4. *Study Settings.* This study was carried out at five hospitals in Alexandria, Egypt: the Alexandria Main University Hospital, the Gamal Abd-Nasser Hospital, the Sharq El Medina Hospital, the Al Gomhoreya Public Hospital, and the Mabaret Alasafra Hospital. These hospitals are affiliated to the University, the Health Insurance Organization, the General Secretary of Specialized Medical Centers, Ministry of Health and Population, and Private sectors, respectively. Each of the selected hospitals was selected as it is considered the largest capacitated one in terms of nurses' number and bed capacity. Moreover, these hospitals participate actively in "innovate Egypt" program that was launched by the

Egyptian government to ultimately connect educational services for enhancing healthcare-related knowledge with community requirements in different healthcare directions through empowering the next generation of Egyptian innovators that include different healthcare providers (e.g., nurses, physicians, technicians, and so on).

2.5. Study Participants and Sampling. A straightforward sampling by power analysis technique was used to pick a sample of 700 nurses ($n = 700$) from the total population of 1510 nurses in the chosen settings: 1510 total subjects, 95% confidence level, 5% margin of error, problem prevalence is 50%, and a maximum sample size of 700. It was determined that 20 individuals would be sufficient to conduct a reliable regression analysis because 20 participants were required for each study variable.

2.6. Study Measurements. Demographic data including age, gender, qualification, unit, current position, and years of experience were collected using personal and work-related data questionnaire.

2.7. Supervisor Knowledge Sharing Behavior. To assess supervisor knowledge sharing behavior, we developed a tool based on literature review. It consists of 11 items: five items adapted from Thuan [21] and six items adapted from Nifadkar et al. [31]. The items grouped into two dimensions, namely, supervisor explicit knowledge sharing behavior (8 items, Cronbach alpha, $\alpha = 0.766$) and supervisor tacit knowledge sharing behavior (3 items, $\alpha = 0.809$). Participants rated each item on a five-point scale (1 = strongly disagree to 5 = strongly agree). We calculated the average score for each dimension, and the total scale score (Cronbach alpha, $\alpha = 0.861$) was the average of the two dimensions; higher scores indicate that nursing supervisors have a high level of knowledge sharing behavior. Supervisors' levels of knowledge sharing were classified as follows: less than 50% for low level, 50% to less than 75% for moderate level, and 75% for high level.

2.8. Organizational Absorptive Capacity. We used the organizational absorptive capacity questionnaire for assessing absorptive capacity from the perspective of nurses [32]. This scale consists of ten items. We computed the average score for the total scale score using Cronbach alpha, $\alpha = 0.900$. Responses were measured on a five-point Likert scale ranging from 1 = strongly disagree to 5 = strongly agree. The overall score level ranges from 10 to 50. Higher scores indicate high level of absorptive capacity. The levels of absorptive capacity of organization were arranged as follows: less than 50% for low level, from 50% to less than 75% for moderate level, and $\geq 75\%$ for high level of absorptive capacity.

2.9. Nurses' Creativity. To assess nurses' creativity, we used the creativity self-assessment questionnaire [33]. It consists of 28 items. The items grouped into 4 dimensions, namely,

generating ideas (7 items, $\alpha = 0.779$), digging deeper into ideas (7 items, $\alpha = 0.736$), exploring ideas (7 items, $\alpha = 0.792$), and listening to the inner voice (7 items, $\alpha = 0.710$). This tool demonstrated acceptable reliability where Cronbach alpha, $\alpha = 0.73, 0.771$ in the studies of Adyasha and Duraipandian [34] and Naqvi et al. [35], respectively. We computed the average score for the total scale score (Cronbach alpha, $\alpha = 0.939$). Responses were measured on a five-point Likert scale ranging from 1 = strongly disagree to 5 = strongly agree. The overall score level ranges from 28 to 140. Higher scores indicate a high level of creativity. The levels of nurses' creativity were defined as follows: less than 50% for low creativity, from 50% to less than 75% for moderate creativity, and $\geq 75\%$ for high levels of creativity.

2.10. Study Tools Adaptation, Validity, and Reliability

2.10.1. Tools Translation. Tools were translated from English versions into Arabic versions (see Supplementary 1) using the back-to-back translation technique [36] to adapt to Egyptian culture, ensure accuracy, and eliminate any potential threats to the study's validity.

Following the translation of the tools, we employed various methods to evaluate their validity and reliability, such as following Steps 1–6 of DeVellis' [37] model for scale development (see Figure 2) in relation to the coding instrument created. Clarification of the construct and development of an item pool were informed by a review of the literature review [21, 31]. In addition, content validity, exploratory factor analysis (EFA), confirmatory factor analysis (CFA), corrected item-total correlations, and Cronbach's alpha were applied. We used IBM SPSS software package version 22.0 and AMOS version 23.0 for the analyses (see Supplementary 2).

2.10.2. Content Validity. A group of seven academics from the discipline includes three professors of information and data management and four professors of nursing administration. The panel identified word choice problems, typing errors, and punctuation errors. Several words were changed in response to their suggestions. In order to verify the accuracy and functionality of the instruments and determine the amount of time needed to complete study questionnaires, a pilot study with 70 nurses was also carried out and no modifications were made.

2.10.3. Construct Validity. Both exploratory factor analysis (EFA) and confirmatory factor analysis (CFA) were used to assess the construct validity of the translated tools.

Kaiser normalization was used in conjunction with Promax rotation to conduct an exploratory factor analysis (EFA). The objective of the EFA was to pinpoint the fundamental elements or dimensions that account for the variation in each questionnaire item's response.

The EFA of the supervisor knowledge sharing behavior questionnaire revealed a clear and consistent factor structure that reflected the two dimensions of the scale

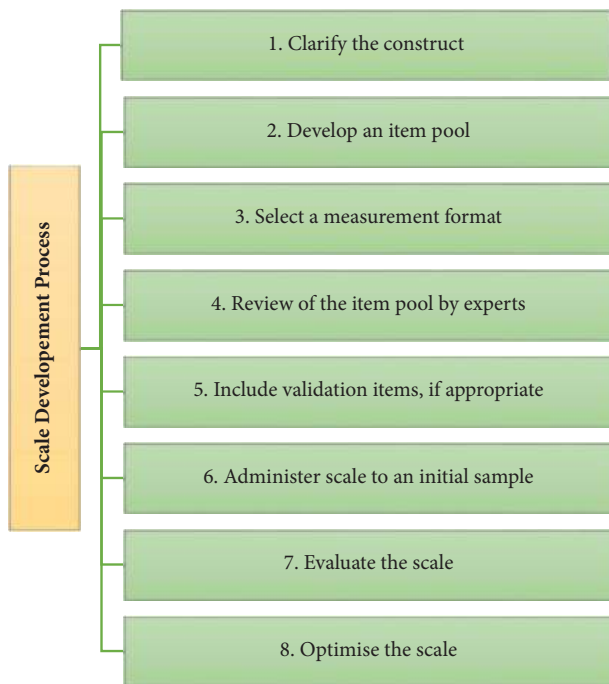

FIGURE 2: Steps in scale development [37].

with high boldface loadings for all items, ranging from 0.543 to 0.909 which means that the items strongly contribute to their factor. The Kaiser–Meyer–Olkin (KMO) measure of sampling adequacy was 0.703, which indicates the appropriateness of the data for factor analysis and that there is a high degree of common variance among the items.

The EFA of the absorptive capacity scale using Kaiser normalization revealed that there are two dominant factors that account for most of the variance in the responses. These factors have high loadings for all items, ranging from 0.617 to 0.747. This implies that it represents a general dimension of polychronic-monochronic tendency and that all items measure the same construct. The KMO value of 0.842 indicates that the data are very suitable for factor analysis, and that there is a high degree of common variance among the items.

The EFA of the nurses' creativity scale revealed a clear and consistent factor structure that reflected the four sections of the tool, with high loadings for all items on the corresponding factor, ranging from 0.522 to 0.756. This means that the items are more clearly nurses' creativity embeddedness. The KMO value of 0.853 indicates that the data are very suitable for factor analysis and that there is a high degree of common variance among the items.

2.10.4. Confirmatory Factor Analysis. CFA was done using structural equation modeling (SEM) for the mean and standard deviation of the three scales used in the study (supervisor knowledge sharing behavior, absorptive capacity, and nurses' creativity). The CFA aimed to test the fit of the factor structure derived from the EFA to the data. The CFA confirmed that the model fits the data very well

(comparative fit index (CFI) = 1.000, incremental fit index (IFI) = 1.000, root mean square error of approximation (RMSEA) = 0.117, Model $X^2 = 5.120$, and $p = 0.001^*$).

2.11. Reliability. The reliability of the tools was assessed using the corrected item-total correlations and internal consistency.

2.11.1. The Corrected Item-Total Correlations. The corrected item-total correlations of the supervisor knowledge sharing behavior questionnaire showed that all items were positively and significantly related to their respective sections and to the overall score of the survey, ranging from 0.576 to 0.905. The corrected item-total correlations of the absorptive capacity scale showed that all items were positively and significantly related to the scale, ranging from 0.628 to 0.763. The corrected item-total correlations of the nurses' creativity scale showed that all items were positively and significantly related to their respective sections and to the overall score of the tool, ranging from 0.536 to 0.827. This means that all items are positively related to their respective subscales and that they measure the same construct as the other items in the subscale.

2.11.2. Internal Consistency. Cronbach's alpha was used to measure the internal consistency of the tools. It is a measure of how well a set of items measures a single construct or dimension. It ranges from 0 to 1, with higher values indicating higher reliability and internal consistency. Cronbach's alpha values for the subscales of the supervisor knowledge sharing behavior ranged from 0.766 to 0.809 and 0.861 for the overall survey. Cronbach's alpha of absorptive capacity was 0.900. Cronbach's alpha values for all subscales of nurses' creativity scale ranged from 0.710 to 0.792, and the overall scale was 0.939. These results indicate acceptable reliability and internal consistency of the three study tools.

2.12. Data Collection. The administration of the hospitals officially approved the collection of data. By delivering the anonymous questionnaire (hand delivered), data were gathered over a three-month period, from the first of May 2022 to the end of July 2022. The questionnaire took around 25 minutes to complete and asked questions about participant demographics, supervisor knowledge sharing behavior, absorptive behavior, and creativity.

2.13. Data Analysis. Frequencies and percentages were utilized to illustrate the socio-demographic data; mean and standard deviation (SD) were employed to display continuous variables. The association between supervisor information sharing behavior, organizational absorptive capacity, and nursing creativity was examined using the Pearson correlation coefficient analysis (r). Inferential statistics (Pearson correlation coefficient and regression analysis (R^2)) were used to examine the study's findings. A 0.05 alpha error was used for all statistical calculations. The

mediating impact of career plateauing was investigated using a structural equation modeling approach. The moderator, organizational absorptive capacity, the independent variable, and the dependent variable, nurses' creativity, were examined by the researchers. All statistical analyses were performed using IBM SPSS Statistics and IBM SPSS AMOS versions 23 (Armonk, NY). The 0.05 level of statistical significance was used to determine the two-tailed nature of all given *p* values.

3. Results

Table 1 reveals that 47% of participants were within the age group 25–40 years with a mean score of 34.19 ± 10.16 . Furthermore, near to two-thirds of the participants were female (61.6%) with a Bachelor of Science Degree in Nursing (48.4%) followed by Diploma Degree in Nursing (30.6%) with 49.6% of participant with years of experience less than ten years, followed by 26.9% of them with more than 20 years of experience. In relation to the current working unit, near to one-third of the participants were working in ICU, followed by 20.7 of the participants were working in ER in the following healthcare settings as the majority of them (45.7%) were working at Alexandria Main University Hospital, followed by Gamal Abdel Nasser Hospital (18.3), and both hospitals were public sector, while 15.35 of participants were working at Mabaret Alsafra Hospital, which is related to the private health sector.

Table 2 shows that most of the study participants had a moderate perception level regarding their supervisor knowledge sharing behavior, their organizational behavior regarding absorptive capacity, and creativity (67.4%, 74.7%, and 80.9%), respectively. The mean score (\pm standard deviation) of the supervisor knowledge sharing behavior (possible score range: 1–5) was 3.66 ± 0.43 , and supervisor tacit knowledge sharing behavior had the highest mean domain score (3.91 ± 0.71). The mean score of absorptive capacity (possible score range: 1–5) was 3.62 ± 0.41 . As well as, the mean score of creativity (possible score range: 1–5) was 3.64 ± 0.35 , and generating ideas and digging deeper into idea domains had the highest mean scores (3.69 ± 0.48 and 3.69 ± 0.47 , respectively).

Table 3 shows that nurses' creativity was positively associated with supervisor knowledge sharing behavior and absorptive behavior ($r = 0.619$, p value < 0.001 , and $r = 0.545$, p value < 0.001 , respectively).

Figure 3 depicts the structured equation modeling's standardized regression weights (Chi-square = 1145.530; degree of freedom = 15; p value 0.001). Sharing of supervisory knowledge behavior explained 65% of the variance in organizational absorptive behavior and 87% of the variance in nurses' creativity, whereas absorptive capacity explained 55% of the variance in nurses' creativity. The lowest reliability estimates in the examined model were for the domains of digging deeper into ideas and listening to the inner voice: 0.54 (factor loading = 0.77, p value. 001) and 0.43 (factor loading = 0.75, p value 0.001), respectively. Sample size = 700. Chi-square = 1145.530. Degrees of freedom = 15. Probability level < 0.001 .

4. Discussion

Healthcare organizations should use knowledge sources and manage it in the manner that use lessons learned from the past experiences to build a robust resilient future and maintain competitiveness in turbulent environment. This future flourishes when innovation and creativity of healthcare providers especially nurses are emphasized. So, our study investigates the impact of supervisor knowledge sharing behavior and organizational absorptive capacity on nurses' creativity. It is hypothesized that supervisor knowledge sharing behavior and absorptive capacity have a significant role in stimulating nurses' creativity (the dependent variable). Our study revealed that supervisor knowledge sharing behavior and absorptive capacity are powerful determinants for nurses' creativity.

4.1. Supervisor Knowledge Sharing Behavior and Nurses' Creativity. Our study revealed a significant positive relationship between supervisor knowledge sharing behavior and nurses' creativity. This means that H1 of our study is accepted which give impression that sharing sources of knowledge and experiences by leaders could definitely

TABLE 2: Participants' levels of perception regarding the study variables (supervisor knowledge sharing behavior, organizational absorptive behavior, and their creativity).

Study variables	Mean score Mean \pm SD	Low (<50%)		Moderate (50%–<75%)		High (\geq 75%)	
		No.	%	No.	%	No.	%

Listening to the inner voice	3.68 \pm 0.40	20	2.9	492	70.3	188	26.9

stimulating nurses' creativity. This result is evident in our study since the majority of nurses had moderate perceived level regarding their creativity and, at the same time, had a moderate perceived level regarding the knowledge sharing behavior of their supervisors. This finding is also supported by results of regression analysis since supervisor knowledge sharing behavior accounts for 87% of variance in nurses' creativity which reflect that stimulating nurses' creativity requires a leader behavior that welcome sharing of previous experiences and dissemination of successful knowledge sources. Moreover, this reflects the high predicting power of supervisor knowledge sharing on shaping nursing creativity which means that H3 of our study is accepted. On other words, our study proved that both creative thinking and behavior among nurses could be flourished and augmented if their leaders share different sources of knowledge along with experiences in the workplace and make this sharing as pattern of improvement and communication.

This finding could be explained in the light of organizational learning theory since this theory believed that sharing of knowledge at different levels build a learning culture characterized by respecting different experiences and welcome ideas and suggestions [15]. The end result of this culture is innovation and creative ideation which is the case in our study. Also, one possible explanation of this relationship is that the knowledge sharing behavior of leaders could empower nurses in their workplace making them engaged which definitely stimulate their talents and ultimately foster the innovative and creative thinking which is the core philosophy of organization knowledge management model developed by Vespo [29]. Our finding concerning the correlation among supervisor knowledge sharing behavior and creativity is in line with the studies of Dong et al. [38], Hosseini et al. [39], Widyani et al. [40], and Revilla and Rodriguez-Prado [41]. These studies have agreed on the role of knowledge sharing among healthcare team in shaping the cognitive abilities of its members. Also, these studies found that the creative ability of staff is affected by the degree to which knowledge management process especially knowledge sharing is exercised in healthcare facility. In this context, the studies of Uyan and Şanal [12] and Kirpik and Çetin [42] found that knowledge sharing behavior in healthcare

organizations could boost ambidexterity which is a metaphor for creativity and innovation which could further support our finding.

Our study proved that knowledge sharing is the most affecting factor in nurses' creativity. Moreover, knowledge sharing is a prerequisite for better performance and competitiveness gained from the creative and innovative abilities of nurses. This empirical evidence supports the ideas of Rafique and Mahmood [43] and Shaari et al. [44], who stated that knowledge sharing fosters a cohesive environment in which employees share their field-related experience, novel ideas, and job-related knowledge with one another. They learned a lot from one another and became more creative as a result. Knowledge sharing assists healthcare professionals in developing various creative approaches to patient care, thereby improving their innovative capabilities and, as a result, their work performance. Furthermore, the study of El-Sayed et al. [45] clarified that knowledge sharing behavior adopted by collaborative leaders significantly foster nurses' innovative work behavior and fuel their creativity. Conversely, the studies of Thuan [21] and Ye et al. [14] found weak role of knowledge sharing toward employees' creativity. This contradictory from our study may be due to these studies conducted on employees working in different contexts that may do repetitive tasks with high routine where knowledge growth and development are not core necessity.

It is great to find that knowledge sharing behavior is adopted by supervisors and leaders in a wide scale in our study since more than two-thirds of nurses reported that their supervisors share different sources of knowledge with them. This finding is in line with the results of Widyani et al. [40], Magnier-Watanabe and Benton [46], and Maravilhas and Martins [47] who found knowledge sharing behavior is a hallmark that characterizes the attitudes of self-managed teams. Awad et al. [48] stressed that the majority of nurses were satisfied with the valuable support received from first line nurse managers. Also, the main source of support reported by nurses is knowledge and expertise sharing. In contrary, Sodeify et al. [49] and Senek et al. [50] clarified that nurses perceived low level of the supervisors' support and low tendency to share their expertise. This may be due to poor workplace conditions that also perceived by nurses in

TABLE 3: Correlation between supervisor knowledge sharing behavior, organizational absorptive behavior, and creativity.

these studies which affect their perceptions toward all positive workplace variables including support and knowledge sharing.

4.2. Organizational Absorptive Capacity and Nurses' Creativity. Our findings revealed significant positive relationship between absorptive capacity of organization and nurses' creativity. This means that H2 of our study is accepted which give impression that the high capacity of healthcare organization to absorb current and emerging internal and external knowledge sources is associated with high levels of nurses' creativity. This is supported by nurses' perceived levels of absorptive capacity and creativity since the majority of nurses have moderate perceived levels regarding the capacity of their organizations to absorb knowledge sources, and at the same time, they have moderate perceived levels regarding their creativity. Meanwhile, our study found that organizational absorptive capacity is a powerful antecedent for nurses' creativity since regression analysis revealed that absorptive capacity accounted for 55% of variance in nurses' creativity which means that our H4 is supported.

One possible explanation of this result is that absorptive capacity allows organizations to actively seek external sources of knowledge, such as collaboration with other firms, partnerships with research institutions, or participation in conferences. By accessing diverse knowledge, organizations are exposed to new perspectives, different ways of thinking, and alternative approaches. This exposure to diverse knowledge sparks new ideas, encourages innovation, and fuels creativity within the organization. In addition, absorptive capacity enables organizations to integrate external knowledge with their existing knowledge base. By bringing together different ideas, concepts, and perspectives, organizations can create novel combinations that often lead to innovative solutions and stimulate creativity. Our finding is the case in similar studies like Hameed et al. [51], Liu et al. [9], Asurakkody and Kim [52], and Motaghi et al. [53]. These studies found that absorptive capacity is a critical

determinant for nurses' creative and innovative behavior. Conversely, the studies of Maleski et al. [54] and Fulgence et al. [27] yielded that employees' performance including the creative abilities is not significantly affected by knowledge absorptive capacity. This contradiction with our finding may be the presence of confounding factors like employees' traits, work environment, and motivation in the linkage between creativity and absorptive capacity. These confounding factors may deter absorptive capacity from exerting its role toward creativity.

4.3. Supervisor Knowledge Sharing Behavior and Organizational Absorptive Capacity. Our study revealed significant positive correlation between supervisor knowledge sharing behavior and absorptive capacity. This correlation is supported in our study since the majority of nurses have moderate perceived level regarding the knowledge sharing behavior of their supervisors and at the same time they have moderate perceived level regarding the capacity of their organizations to absorb, assimilate, and utilize knowledge sources for fueling innovation and creativity. Moreover, our results depict that supervisor knowledge sharing behavior accounted for 65% of variance in the absorptive capacity of organizations. This gives impression that supervisor knowledge sharing behavior is critical pivotal factor in upgrading the absorptive capacity of organizations which is necessary to sustain innovation and creativity. Meanwhile, this implied that healthcare organization could build its innovation and creativity capacity if it cultivates a culture for knowledge sharing among top leaders and employees.

Our results in this point reflect the national efforts implemented by the Egyptian state to strengthen the Egyptian human being and this could explain the results yielded in our study. Nurses in the study settings are able to access to the different sources of knowledge installed in the Egyptian knowledge bank (EKB). Meanwhile, the General Authority for Health Accreditation and Regulation (GAHAR) makes it obligatory for health facilities to share and publish health-related data in order to be eligible to

universal health insurance schemes. Moreover, Internet access by healthcare providers becomes applicable and easy in the study settings after the inception of information literacy initiative taken by the Egyptian knowledge bank in collaboration with Ministry of Telecommunication. This finding is in line with the studies of Innis and Berta [55], Zhang et al. [17], and Motaghi et al. [53]. These studies reported a considerable credit for the absorptive capacity of the organizations that adopt knowledge sharing as way for improvement and sustainability.

4.4. Interplay between Supervisor Knowledge Sharing Behavior, Organizational Absorptive Capacity, and Nurses' Creativity. Our study revealed that absorptive capacity of organization could mediate the linkage between supervisor knowledge sharing behavior and nurses' creativity. This means nurses' creativity could ultimately be fostered if the organization builds high absorptive capacity in an environment where knowledge sharing is an absolute theme. This conclusion is consistent with Hameed et al's [51], who reported that absorptive capacity in the employability of knowledgeable workers works as a mediator between knowledge acquisition and innovation. In this context, Sancho-Zamora et al. [56], Cuevas-Vargas et al. [57], and Motaghi et al. [53] found the absorptive capacity of an organization is the key toward innovation and creativity in the presence of magnet features like knowledge sharing. All in all our study proved that in order to add value in any healthcare organization, creativity of nurses must be highlighted. Stimulating creativity requires open access for different sources of knowledge as well as enhancing the capacity to absorb different expertise and new knowledge elicited in a continuous basis.

5. Conclusion

Our study investigated the impact of supervisor knowledge sharing behavior and absorptive capacity toward nurses' creativity. It is concluded that supervisor knowledge sharing behavior and absorptive capacity play an important role in stimulating nurses' creativity, as supervisor knowledge sharing behavior accounted for 87% of variance in nurses' creativity and absorptive capacity accounted for 55%. Moreover, supervisor knowledge sharing behavior and absorptive capacity are powerful antecedents for nurses' creativity.

5.1. Implications of the Study. Based on the empirical evidence, our study provides some practical implications for nurses' managers, hospital administrations, and nurse educators. First, our study implied that modern management approaches must develop a systemic policy for knowledge management that provides a platform that maximizes individuals' capacity to learn and grow. Second, hospital directors, managers, and nursing leaders should play an important role in encouraging knowledge sharing by establishing a reward and incentive system for healthcare workers who share their knowledge with their

colleagues for mutual benefit and organizational development. Third, hospital executives must communicate the benefits of knowledge sharing to employees. They must encourage and provide the necessary support, assistance, and even resources for nurses to share knowledge because knowledge and ideas sharing improves creative behavior and capabilities in organizations. Fourth, nursing school administrators should focus on developing nursing students' critical thinking skills through challenging curricula that stimulate students' high cognitive domains of thinking, resulting in future creative nurses. Fifth, stimulants and barriers of creativity in nursing schools must be taken as priority in the recent context in order to graduate nurses able to cope with technology revolution repercussions. Sixth, nursing leaders must develop creativity pathway in which talents and successful proven experiences are considered and motivated. Seventh, recruitment policies must include measures to attract leaders with a high expertise and high tendency for knowledge sharing. Finally, the selection and placement process of leaders and nurses must include tests for examining the tendency toward knowledge sharing.

5.2. Research Strengths and Limitations. Our study offers new insights on stimulants of nurses' creativity. It is one of the first studies that shed the light on the interplay between knowledge sharing behavior, organizational absorptive capacity, and creativity in the nursing context. Our study adds to nursing literature through providing empirical evidence about the role of knowledge sharing behavior and organizational absorptive capacity on stimulating creativity among nurses. In addition, it gives strategies and measures for nurse managers to keep their organizations competitive and sustainable in the era of globalization and intense lobar competition through acting on the creativity of nurses. Our study is one of the initiatives geared toward achieving sustainable developmental goals worldwide. Our study has high reliability as it is a multicenter study that uses robust statistical methods to ensure the validity and reliability of the instruments used. However, there are some limitations that must be recognized. Because the current findings are based on self-reported data, they are susceptible to response bias and subjectivity.

Data Availability

The data and materials of the current study are not publicly available due to confidentiality reason but are available from the corresponding author on reasonable request.

Ethical Approval

The current study was approved by the Faculty of Nursing's Research Ethics Committee at Alexandria University (No: 83-9-2022). The administrative authority of the study setting gave written permission to conduct the study. All methods were carried out in accordance with relevant guidelines and regulations.

Consent

The first page of the questionnaire explained the purpose of the study, assured respondents that their responses would be voluntary and confidential, and stated that researchers would consider the completion and submission of the questionnaires as consent to participate. Informed consent was obtained from all the participants included in the study.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

All authors participated in the research idea, conceptualization, data collection, analysis, and preparation of the manuscript for publication.

Acknowledgments

The authors extend their appreciation to Princess Nourah bint Abdulrahman University Researchers Supporting Project number PNURSP2023R279, Princess Nourah bint Abdulrahman University, Riyadh, Saudi Arabia.

Background. Severe challenges in recruiting and retaining healthcare workers exist on a global level and are especially noticeable in elderly care services. Previous studies have not assessed how the attractiveness of a job is related to wellbeing at work among licensed practical nurses (LPNs) even though these professionals are vital in providing care to the elderly. **Objective.** The purpose of this study is to define factors that affect LPNs' attractiveness of work and wellbeing at work. **Design.** A cross-sectional survey study. **Participants.** A large-scale nationwide sample of 10 848 licensed practical nurses (LPNs) working in Finland. **Methods.** An online survey for LPNs working in Finland was conducted. Criteria for a good workplace (CFGW), measuring the attractiveness of work and wellbeing at work, were utilized. Descriptive and comparative analyses were performed. Cronbach's alpha values were tested to assess internal consistency ($\alpha = 0.739\text{--}0.915$). An ANOVA or *t*-test result which indicated a statistically significant between-group difference (which was in line with difference ≥ 0.1) was considered as both statistically significant and significant in practice. **Results.** The core group, LPNs' wellbeing at work ($m = 4.36$), is extremely important factor of attractiveness of work. Regarding the subgroups high quality of care ($m = 4.61$), reconciling of work and private life ($m = 4.59$) and well-functioning practices ($m = 4.55$) were most important. Well-functioning practices associated with several background variables, e.g., with working for full-time ($p \leq 0.001$, mean = 3.10) and age ($p < 0.001$). LPNs over 56 years old, especially, regard well-functioning practices important ($p = 3.17$). LPNs' who were 56 years old or older ($m = 3.12$) and those who had work experience 1 year or less ($m = 3.19$) stated rewarding work most important. **Conclusions.** The core group, wellbeing, is an exceptionally important for the LPNs attractiveness of work. The LPNs' wellbeing at work is supported by the quality of care and reconciliation of work and private life.

1. Background

The social and healthcare industry is facing severe challenges in recruiting and retaining a skilled workforce, and this is a global phenomenon. As such, there is a high demand for healthcare professionals, qualified registered nurses (RNs) and licensed practical nurses (LPNs), with this demand only

expected to increase [1, 2]. These workforce shortages particularly threaten elderly care services since LPNs and RNs are the largest professional groups in healthcare, representing over half of the global workforce [3]. The WHO estimates that there will be a global lack of 10 million qualified healthcare workers by 2030 [4]. As such, the healthcare industry needs 43 million additional healthcare

workers to achieve the targeted level of healthcare [5]. It is worrying that access to quality healthcare services, which is considered a basic human right, cannot be ensured for everyone, and immediate action is needed to ameliorate this lack of access to equal healthcare [1, 3].

The global demand for qualified nurses is growing rapidly due to several reasons, including population ageing. However, shortages appear when the demand for healthcare professionals exceeds the number of available employees [3]. Every country in the world is burdened by the growing size of the elderly population. For instance, the WHO estimates that “1 in 6 people in the world will be aged 60 years or over” by 2030. According to WHO’s ageing data portal, the amount of people 60 years and older will double to 2.1 billion by 2050 [6]. The greatest changes are expected for low- to middle-income countries around the world, e.g., countries in Middle Asia, South America, and West Africa [6, 7]. Healthcare systems are also burdened by challenges in replacing retiring employees and securing care for the elderly; this is clearly evident in modern welfare states such as Finland [8]. Furthermore, the COVID-19 pandemic highlighted the importance of healthcare personnel and their role in safeguarding the health of the population [9].

The impending healthcare crisis can be linked to the fact that many Organisation for Economic Co-operation and Development (OECD) member countries have not modelled the demand and supply for healthcare services up until 2025 [10]. It is also noteworthy that the definition of workforce shortage differs between countries, policies, and healthcare systems [1]. Typically, the financial and demand pressures associated with workforce shortages are characterized using criteria such as “vacancy fulfillment” or “volume of current vacant post” [11]. In addition, calculating the difference between the number of required healthcare professionals (demand) and the number of available qualified professionals (supply) is used as a policy contingent measure [1]. The occupation shortage lists published by governments also influence decision-making by, for example, the WHO and World Bank [12]. The already noted shortages in the workforce mean that countries must cooperate to create both a national system that meets the demand, as well as a resilient international network that ensures equal access to healthcare [1, 7].

The LPN role needs better recognition if healthcare systems are to overcome the nursing shortage [2]. The WHO has also noted that nursing professions, in general, require more appreciation to make the job desirable to future healthcare professionals [3]. Aiken et al. [13] concluded already in the year 2013 that without improvements in work environment nurse shortages are expected. Nurses’ dissatisfaction at work is associated with the quality of care as well [14]. Addressing nursing shortages requires empirical data about how LPNs perceive their role in health care and the attractiveness of LPNs’ work based on the long-term work satisfaction and motivation [15]. Moreover, promoting the wellbeing of the healthcare workforce is essential in retaining professionals in the industry. Nurses, working continuously with patients, have the best information for health care leaders in decision making to overcome critical workforce

challenges motivation [13]. Current work environment and role confusion does not support wellbeing of nursing workforce to the fullest potential [15, 16].

Evidence-based research, alongside concrete actions, about the attractiveness of healthcare work is needed to retain and attract qualified professionals to the industry [12]. Hence, it is important to focus on LPNs, who have a major role in caring for the elderly population. At present, there is a clear lack of data about a vital group of healthcare professionals, the LPNs. Although the discrepancy between the demand and supply of nurses is a global phenomenon, little research has focused on the factors which promote the attractiveness of the professional and wellbeing at work [3, 17]. Understanding the factors which affect the attractiveness of a profession and wellbeing at work are essential to workforce planning [3]; to this end, Roos et al. [18] recently performed a literature review to clarify these factors. The review produced data about the factors associated with the attractiveness of social and healthcare work from LPN perspective, which correspond well with WHO’s report “Health and care workforce in Europe: Time to act”; the authors of the report stressed that all European countries will face severe challenges in retaining healthcare professionals and outline 10 policies for strengthening the healthcare workforce [4, 18].

1.1. Theoretical Background. LPNs role as providers of care for the elderly has become increasingly important worldwide. The LPNs’ work and the role as a caregiver is emphasized in Finland, as well as with the number of employees. LPNs represent the largest group of healthcare professionals in Finland, with 89 820 LPNs registered in 2021 [19]. In the same year, registered nurses (RNs) were the second largest group of employees with 76 851 RNs in total [19]. LPNs work in various fields of social and healthcare, and especially the importance of their work is visible in long-term care settings and home care [15, 19].

In this study, a definition of licensed practical nurse (LPN) is used. The LPN profession is regulated by Finnish legislation and requires a specific education (Finnish National Agency for Education). Internationally, as described by the NCSBN, licensed practice/vocational nurses’ (LPN/VN) have a regulated education [20]. Globally, LPNs’ education has definitions, such as enrolled nurse (Australia), licensed practical nurses (Finland, USA), licensed vocational nurses (USA), and nurse associates (UK).

The demand for LPNs has rapidly grown, especially due to population ageing. According to analysis, there is shortage of 9 000 LPNs in the Finnish public sector [21]. The social and healthcare sector employed over 415 000 people in 2022, making it Finland’s largest industry [22]. By the year 2035, Finland will require over 200 000 new social and healthcare employees [23]. According to Official Statistics of Finland [22], the total number of elderly people over 75 years of age will grow rapidly, from 567 000 in 2021 to 855 000 by 2035. Finland, with a population of 5.6 million, will require a remarkably large amount of new healthcare personnel—this will require innovative strategies to ensure that the supply of workers sufficiently meets the demand.

The shortage of healthcare professionals has become a palpable problem. Already existing workforce shortages challenge nurse managers daily. Leaders in nursing are primarily responsible for the sustainable wellbeing of nursing personnel [24]. Challenges regarding the division of work with insufficient resources have a negative effect on the quality of care [15, 24]. In addition, citizens and family members have overcome worries about how general health care will be affected by these shortages [13, 17]. Strategies to resolve workforce shortages, including defining which factors promote the attractiveness of health care work, remain incomplete, yet under continuous development [1, 3, 13]. The WHO has called for more studies on the productivity of nursing professionals and the scope of practice of different professions, including LPNs, to improve the attractiveness of work [3].

Theoretical models to understand the fundamental concepts of employees' motivation, experiences, and work satisfaction have been developed at different fields of expertise. Most interestingly, the job characteristic model (JCM), the demand-control-support (DSC) model, or the theory of motivation explore and analyze the employees' experiences. The job characteristic model (JCM) implies on work characteristics (skill variety, task identity, task significance, autonomy, and feedback) and their impact on motivation, satisfaction, and performance [25]. The demand-control-support (DCS) model, instead, was developed to understand the relationship between job characteristics and employee health [26]. The theory of motivation [27] has been utilized in studies regarding healthcare workers job satisfaction, and particularly motivation and employees' attitude towards the work and work environment [28, 29]. The theory is typically applied, when investigating motivation related to work. The theory explains employees' job satisfaction/dissatisfaction to motivation. To understand the human resource experience in the context of nursing, the classic Herzberg's two-factor theory (originally developed in 1959), the theory of motivation is a well-justified framework in our study [27, 30].

There is insufficient evidence-based research into interventions for attracting and retaining healthcare workers [31]. In this study, we explore factors affecting the attractiveness of work and wellbeing at work from the LPN perspective. Furthermore, we gain insight into LPNs' work satisfaction to develop long-term work satisfaction and motivation. We explore the motivation-hygiene theory as a theoretical framework of this research to gain insight into both motivator factors and hygiene factors [27]. The theory implies that two sets of factors influence employees' motivation and work satisfaction, i.e., the motivator factors, which relate to the content of work (e.g., recognition, achievement, and responsibility) and the hygiene factors, which relate to the surrounding of work (e.g., working conditions, salary, and interpersonal relations) [27].

The theory of motivation explains that employee satisfaction, motivation, and commitment are primarily promoted by factors related to work content, such as recognition, opportunities for advancement, or responsibility [27]. Furthermore, the theory of motivation

argues that income is the most important factor in attracting professionals. However, this is not the only factor, as motivational factors related to work content and a long-term career (sense of personal achievement, promotion, and stimulating work) are also highly important [28]. Furthermore, possibilities for career progression and professional development opportunities support motivation in practice [15, 18, 32]. According to a survey distributed among Swedish mental health nursing staff's salary correlates with job satisfaction [33].

A recent study found that LPNs' intention to leave the nursing profession is correlated with both emotional exhaustion and high workload [34]. Other researchers found that the limited resources of healthcare systems mean that the division of work must be harmonized better [18]. In addition, nursing education should comprehensively describe different roles, while qualified professionals who have graduated should be afforded opportunities for continuous education [17, 35]. This would maintain a clear vision of the LPN role and hopefully improve employee retention [17]. Wellbeing at work is enhanced through active collaboration with educators and employers. Work satisfaction is improved by enabling flexible career paths and educational possibilities [36]. LPNs, for instance, have more limited opportunities for career progression and LPNs lack flexible career paths when compared to RNs [15, 35].

The WHO [36] introduced a model for workforce planning in nursing which stresses comprehensive development and understanding, with national demographical data considered a means to identify the core issues of work [36]. In line with the theory of motivation, to understand the factors affecting the attractiveness of LPNs work, these interventions should first cover roles of different professionals and also education and career options [27, 36]. Weaver et al. [15] discovered that the LPNs' and employers lack a clear vision of the LPNs' role. Furthermore, the LPNs work regularly "outside" their role, despite the regulations, due to situations in patient care [15, 18]. Challenges in delivering nursing care with insufficient human resources impacts the role of an LPN, as well as and may lead not only to a role confusion but also dissatisfaction in work-related well-being [13, 15]. An Australian literature review [17] revealed enablers and barriers to the recruitment and retention of enrolled nurses (ENs or global equivalents). A clear description of the role of an LPN affects positively to the retention and recruitment of nursing professionals [15, 17]. Confusion about the scope of practice and feelings of being undervalued negatively influence the LPNs wellbeing at work and retention instead [32]. Thus, evidence of how LPNs perceive their role is essential and important in retention of professionals [37].

Comprehensive workforce planning requires deep understanding of the core purpose of work, as well as a grasp of the current psychological and practical environment [1, 3]. Hence, healthcare professionals and nurse managers should clearly understand and state the roles of different nursing professions if care activities are to be efficiently carried out [15, 27]. Although LPNs' role is expanding, the LPNs experience role confusion and thus aspire recognition as an

important member of a care team [15]. Feeling empowered enhances wellbeing at work; for this reason, the role of an LPN must be clearly described in a way that does not merely repeat the legislation [15, 38, 39]. Unfortunately, not all of the possibilities of the LPN role are used in practice [15, 18]. A Finnish study [38] investigated LPNs', RNs', and managers' assessment of the activities of practical nurses. In line with the study of Weaver et al. [15], the results showed that other healthcare professionals need more information about the role of an LPN [38]. Healthcare leaders have the responsibility of clarifying and updating the scope and division of labor for the best outcome [15, 18, 38].

Nursing management and systematic workforce planning is crucial in retaining nursing professionals [40]. In addition, working conditions need to enable an adequate work-life balance since wellbeing at work deteriorates when the workload becomes a burden and/or there is not enough time to manage all of the necessary tasks [4, 13, 18]. Every healthcare organization is responsible for providing possibilities to all employees, as inefficient management narrows the possibilities to work in diverse and desired tasks [35]. This is important, as research has shown that an LPN is often considered second-level nursing position due to insufficient knowledge [18, 39]. Role clarification can maximize nursing professionals' capacity and capability; however, the scope of practice needs to be in line with organizational regulations and targets to improve the quality of patient care [15, 41]. A previous Australian study [42] attempted to improve the understanding of unclear professional roles by focusing on the scope of RNs' and enrolled nurses' (ENs) work. They found that the shortage of nursing professionals has transformed the LPN role to encompass more advanced nursing tasks [42]. More specifically, the current LPN role includes activities that were traditionally the responsibility of RNs, i.e., medication administration, care planning, and patient management [38, 42]. Clarification regarding the LPNs' expanding practical role is vital not only to improve quality of care but also for the wellbeing of the LPN [38]. This is not specific to LPNs, however, as other health care professionals also need more information about the LPN role [18]. Nursing management, which includes aspects of conflict management and dialogue with personnel, supports LPNs' organizational commitment [18, 43].

The division of healthcare professionals' work is also challenged by geographical reasons [44, 45]. The rural and remote areas of geographically vast countries, such as Finland, are characterized by insufficient access to healthcare services. Nursing managers face difficulties in recruiting and retaining nursing workforce due to geographical reasons and this will necessitate action plans to attract healthcare workers to rural areas [6, 45]. According to the WHO [6], national data on the size of the workforce are lacking. The growing demand for healthcare workers affords qualified professionals the freedom to choose countries with the most attractive salaries and workplaces and has led to rapid development in the international recruitment of health personnel [46]. A Canadian cross-sectional survey [45] examined intentions to leave among RNs, nurse practitioners (NPs), and LPNs; the results revealed that

organizational commitment enhanced LPNs' intention to stay, and this finding was especially relevant for rural areas. In rural areas, workforce planning is often challenging due to geographical limitations, and the healthcare system must ensure that rural professionals have similar opportunities as urban professionals [44]. This challenges leadership to find ways in ensuring that all employees, both in rural and urban areas, feel trusted and as a long-term part of the organization [37, 45]. Feeling of being trusted enhances psychological empowerment among LPNs working in elderly care [43].

Turnover among LPNs poses a major threat to elderly care [43]. Furthermore, a shortage in nursing professionals has become evident in long-term care facilities due to the increasing number of ageing residents [2]. Havaei et al. [44] demonstrated that a good work environment reduces turnover intentions among nursing professions. Furthermore, a healthy work environment is an initial factor in supporting and enhancing LPNs' organizational commitment [44]. In promoting the human resource experience, it is essential to study the factors that affect employee motivation and commitment to work [28]. Moreover, it is important to study, namely, the experiences of caregivers regarding the attractiveness of work and factors affecting attractiveness to ensure the adequacy of healthcare workforce [13].

2. Purpose and Aims of the Study

The purpose of this study is to define factors that affect LPNs' attractiveness of work and wellbeing at work. This study aims to examine the factors that affect the attractiveness of work and wellbeing at work from the LPN perspective by including both demographic (e.g., age, work experience) and attractiveness (e.g., well-functioning practices and participatory management) factors in the study.

3. Methods

In this cross-sectional study, LPNs who are registered members either of the following two unions: the Finnish Union of Qualified Social and Health Care Professionals (Tehy) and the Finnish Union of Practical Nurses (SuPer); they were emailed a link to an online survey ($n = 67\ 825$). The research utilized the checklist for Reporting of Internet E-Surveys for reporting the results [47, 48] and STROBE-checklist for cross-sectional studies [49].

3.1. Ethical Considerations. In accordance with the ethical principles of research involving human participants and the guidelines for human sciences set forth by the Finnish National Board on Research Integrity, an ethical review statement was not required in this study since information that could be used to identify a person was not collected [50]. As the research did not require a full ethical review, the University of Eastern Finland Committee on Research Ethics provided a description of the ethical review practices in Finland. Permission to use the CFGW in this study focused on LPNs was gained from a chairperson of the Finnish Nursing Association in January 2022. Participants were

given detailed information about the study prior to participation; the information document covered the aim, data collection methods, time required to complete the survey (10 min), data storage, and the researcher's (MR) contact information. Respondents were informed that submitting the survey form constitutes as an informed consent to participate in the study. Data were handled according to the EU's General Data Protection Regulation guidelines [51]. A privacy notice for scientific research was also given to respondents. In addition, all respondents were informed that participation was voluntary and responding to the survey is anonymous. Participants were not compensated for completing the survey [52, 53].

3.2. Sample and Sampling. Participants in this study were currently employed LPNs, who were registered members of the Union of Health and Social Care Professionals in Finland (Tehy) or the Finnish Union of Practical Nurses (SuPer). A large proportion of Finnish LPNs are registered members of the two trade unions for social and healthcare workers in Finland. A vast majority and, in our study, 90% ($n = 67\ 825$) of all Finnish LPNs ($n = 79\ 766$) employed in social and healthcare, are members either of the two trade unions [19].

To be included in this study, participants had to be licensed practical nurses (LPNs) with a vocational qualification in social and healthcare. In addition, participants had to be currently actively employed as an LPN in the social and healthcare field. Unemployed and nonworking LPNs were excluded. Other licensed health care professionals, e.g., registered nurses (RNs), were also excluded from this study. The eligibility of LPNs was filtered in advance via cooperation with the email registry holders (Tehy and SuPer). All eligible 67 825 LPNs were invited to participate online via e-mail. In total, 20 033 invitees opened the survey; 72% ($n = 14\ 312$) of those started filling the survey and 54% ($n = 10\ 848$) completed the entire survey.

3.3. Data Collection. Emails with a link to the online survey (in Finnish) and information about the study were sent to invitees' email addresses in the registries of the two previously described trade unions on May 10th, 2022. The online survey was accessible for two weeks (10.5.-25.5.2022). A reminder message was sent to all of the email addresses after one week. The questionnaire took about 10 minutes to complete. A total of 10 848 responses were received from LPNs and were included in the study.

3.4. Survey Instruments and Variables. The survey utilized the Criteria for a Good Workplace (CFGW) instrument and questions concerning background variables. CFGW is a structured 44-item questionnaire managing wellbeing at work, with a core group (wellbeing at work) and six subgroups, which are categorized into seven theme-based subgroups. The six subgroups are well-functioning practices, participatory management, rewarding work, development of expertise, quality of care and reconciling work, and private life (Figure 1).

The core group, wellbeing at work, includes all of the subgroups as an integral part of the LPN's wellbeing at work within the CFGW. As a core group, wellbeing at work, acts as a central group for wellbeing initiatives, the subgroups. Wellbeing at work is a representative group and implies that other six groups are divisions that fall under the representation of the main group. The subgroups are specialized units with 5–9 items each to describe their specific theme. A five-point Likert scale is used to indicate the level of importance or agreement (i.e., lower values indicate lower importance or agreement, while higher values indicate higher importance or agreement).

The CFGW allows comprehensive exploration of LPNs wellbeing at work, with the core group, and the subgroups addressing specific aspects for understanding the LPN's wellbeing at work and factors enhancing attractiveness of work. (Figure 1).

The CFGW has been developed and conducted bi-annually by the Finnish Nursing Association for its members (RNs) since 2010. The internal validity of the CFGW has been tested, although the result of the test of validation has not been published. In our study, the CFGW was modified in 2022 and the survey aimed at LPNs for the first time. In this study, we collected an online survey data to explore LPNs' wellbeing at work. We modified the questionnaire CFGW to assess LPNs' wellbeing at work and adapted the CFGW to be suitable for LPNs with the input of a group of specialists. We pilot tested the questionnaire on vocational social and healthcare students ($n = 13$). Proofreading of the questionnaire was completed in collaboration with a vocational teacher [54].

Concerning background variables, this survey included questions about the participant's gender, age, education, employment contract (full- or part-time), type of work shift, work experience in social and healthcare and in the current unit, sector of work, number of personnel, and work unit. The background data were later split into groups for statistical analysis. Age had six groups, each with a five-year interval and ranging from 25 to 65 years. Type of work shift had the following four groups: morning shift on weekdays and weekends; two-shift work; three-shift work; and only night shifts. Work experience in social and healthcare and in the current unit had the following seven groups: 1 year or less; 2–5 years; 6–10 years; 11–15 years; 16–20 years; 21–30 years; and 31 or more years. Sector of work consisted of two groups: public and private sector. Number of personnel had the following three groups: less than 10; 10–30; and more than 30.

The data were collected, and survey was presented to invitees using Webropol [55].

3.5. Statistical Analysis. A detailed plan for the statistical analysis was developed in collaboration with a statistician prior the starting of the study. The power analysis indicated that observing a difference of 0.1 between two-group averages would require both groups to have a sample size $n \geq 400$ (Figure 2). Consequently, only the groups with at least 400 observations were included in the data analysis

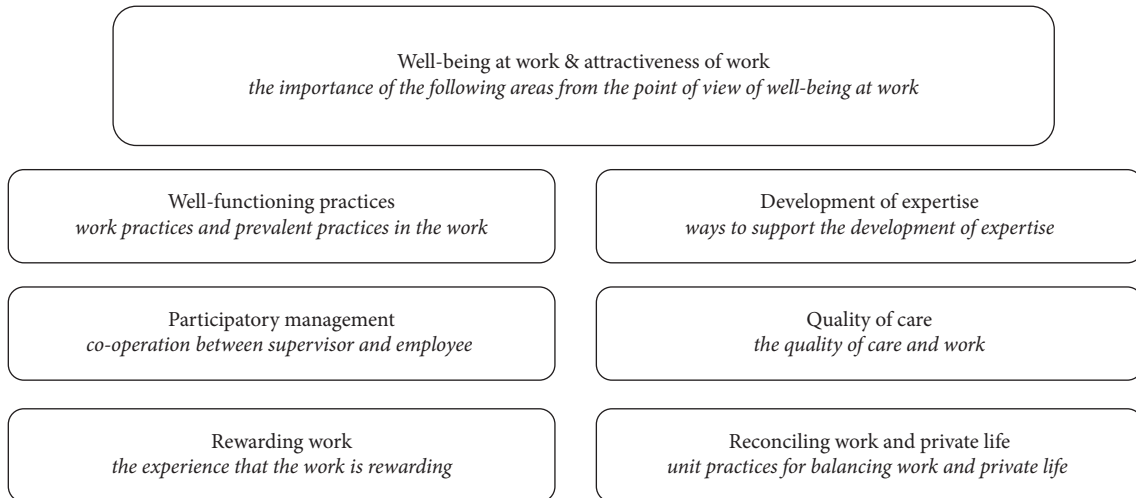

FIGURE 1: The core group and subgroups of the criteria for a good workplace (CFGW).

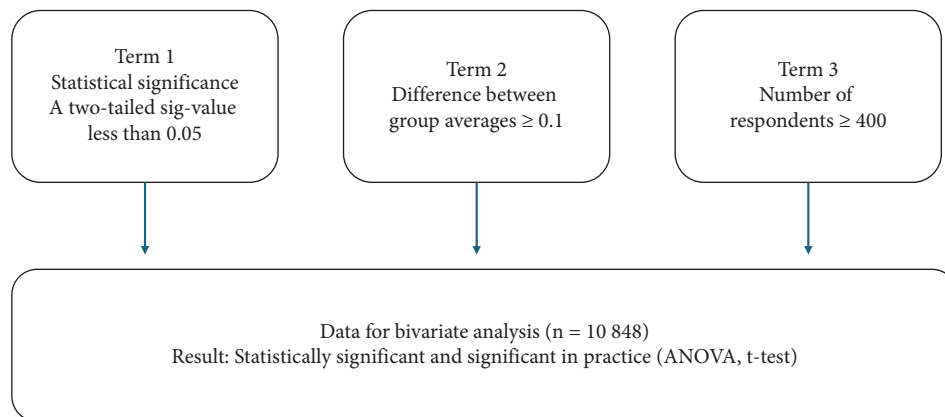

FIGURE 2: Terms of a result being statistically significant and significant in practice (sp) based on the initial power analysis.

regarding *t*-test, analysis of variance (ANOVA), and CFA factor scores. Following data collection, sum variables representing the arithmetic average, were calculated for each subtopic. The background and sum variables were detailed using descriptive statistics. The internal consistency of each subgroup was assessed by calculating Cronbach's alpha.

Confirmatory factor analysis (CFA) was conducted using AMOS software (IBM, Armonk, NY). The relationships between background variables and sum variables were studied using analysis of variance (ANOVA) and *t*-tests. Due to large number of observations ($n = 10\,848$), which can result in large amount of statistically significant results, we applied the concept of "significant in practice (sp)" to identify results that are not only statistically significant but also relevant to the study aims. The minimum difference regarding significance in practice (sp) in means was set at 0.1, determined after a discussion among the authors. Thus, an effect size of at least 0.125 was required for a result to be considered significant in practice if the *p* value is below threshold. An ANOVA or *t*-test result which indicated a statistically significant between-group difference (that was in line with difference ≥ 0.1) was considered as both statistically significant and significant in practice.

Descriptive statistics, including frequencies, percentages, mean values, and standard deviations, were used to describe the background variables. There were only four missing values out of 10 848 when calculating the sum variables, making imputation unnecessary. The normality of each sum variable was evaluated by assessing the mean value, standard deviation, skewness, and visual interpretation of histograms. All sum variables, except wellbeing at work, demonstrated a normal distribution. According to the central limit theorem, a sum of independent random variable is considered to normally distributed when the sample size is high [56, 57]. The central limit theorem's speed of convergence was evaluated using simulation for the wellbeing at work, and it was found out that 2000 observations is enough to make test statistics normally distributed.

Sum variables were calculated to study the attractiveness of work and wellbeing at work from the perspective of LPNs. Cronbach's alpha was calculated to determine whether all items grouped under a sum variable showed sufficient internal consistency. A Cronbach's alpha value over 0.70 is generally considered acceptable [58], with values in this study ranging from 0.739 to 0.915 (Table 1). No individual item had a Cronbach's alpha value exceeding that of the sum

TABLE 1: Descriptive statistics of the sum variables well-functioning practices, participatory management, rewarding work, development of expertise, quality of care, and reconciling work and private life, including the calculated Cronbach's alpha value.

<i>n</i> = 10 848	m (Sd)	Cronbach's alpha (*if item deleted)
Wellbeing at work and attractiveness of work: the importance of the following areas from the point of view of your wellbeing at work (a)	4.36 (0.64)	0.876
Well-functioning practices	4.55 (0.740)	*0.851

Quality of care	4.61 (0.713)	*0.851
Reconciling work and private life	4.59 (0.803)	*0.864
Well-functioning practices: work practices and prevalent practices in the work unit (b)	3.07 (0.84)	0.846
The goals and the core purpose for my work have been defined	4.00 (0.89)	*0.844
Work processes are regularly evaluated regularly together	2.97 (1.14)	*0.809
Personnel recruitment is based on the competence need of the work community	2.74 (1.18)	*0.816
The practices of high-quality student guidance have been agreed upon	2.98 (1.17)	*0.824
Existence of systematic activities that support wellbeing at work	2.54 (1.19)	*0.804
I give and receive feedback	3.18 (1.08)	*0.824
Participatory management: co-operation between supervisor and employee (b)	3.13 (1.00)	0.915
My supervisor has a clear understanding of what my work is	3.57 (1.23)	*0.907
As an employee, I am encouraged to participate in planning and decision-making	3.12 (1.22)	*0.901
Decision-making is open	2.79 (1.20)	*0.897
Problem situations are dealt with quickly	2.74 (1.23)	*0.899
The supervisor supports the renewal of working methods	3.26 (1.20)	*0.898
There are open and confidential relations between the supervisor and me (as an employee)	3.63 (1.22)	*0.902
Consistent rules are followed in my work unit; same rules for everyone at all times	2.81 (1.32)	*0.907
Rewarding work: the experience that the work is rewarding (b)	3.00 (0.83)	0.815
I can do my job well	3.46 (1.09)	*0.781
I feel that my work is respected	3.09 (1.17)	*0.758
I find work empowering (energy, dedication, and immersion in work)	3.02 (1.16)	*0.737
My work is meaningful even though I am sometimes stressed and tired	3.59 (1.05)	*0.763
The salary increases as the demands of the tasks increase	1.64 (0.97)	*0.838
Development of expertise: ways and means to support the development of expertise (b)	3.14 (0.79)	0.834
Orientation is systematic and sufficient	2.67 (1.12)	*0.812
Division of tasks is based on employee training (job title)	3.08 (1.18)	*0.821
The division of tasks is based on the skills of the employees	3.06 (1.14)	*0.812
I have the opportunity to develop my skills	3.35 (1.13)	*0.808
I use the latest researched and reliable information in my work	3.48 (0.99)	*0.818
I prepare for the development discussion in advance	3.44 (1.24)	*0.825
Development discussions are held regularly with the employee	3.06 (1.47)	*0.823
The most experienced employees act as mentors and transfer knowhow in the work community	3.23 (1.17)	*0.816
I get job guidance if necessary	2.93 (1.31)	*0.817
Quality of care: the quality of care and work (b)	3.37 (0.75)	0.773
I evaluate the patient's/client's treatment using existing quality criteria	3.59 (1.02)	*0.754
The number of personnel and professional structure correspond to the demands of the work	2.49 (1.21)	*0.744
The skills of practical nurses correspond to the demands of the work	3.66 (1.07)	*0.745
I use evidence-based treatment and work methods	3.73 (0.98)	*0.747
Treatment equipment and tools are up to date	3.40 (1.13)	*0.730
I can work in a manner that ensures patient safety	3.34 (1.14)	*0.717
Reconciling work and private life: unit practices for balancing work and private life (b)	3.34 (0.81)	0.739
I have enough time to do my work	2.94 (1.30)	*0.734
When planning working hours, individual needs are considered	3.24 (1.28)	*0.678
Transition to study, work rotation, and sabbatical leave, as well as part-time retirement, is possible	3.26 (1.15)	*0.680
Everyone has the right to family leave and to care for a sick child or loved one	3.89 (1.05)	*0.667
Fathers are also supported in using family leave	3.34 (0.99)	*0.705

a: level of importance (1 = not at all important, 5 = extremely important). b: level of agreement (1 = strongly disagree, 5 = strongly agree). *n* = amount of respondents. *m* = mean. *sd* = standard deviation. Cronbach's alpha: *if item deleted.

variable, so there was no reason to delete any items. One item, “the salary increases as the demands of the tasks increase” (item 24), would have resulted in a higher value for the sum variable if deleted ($\alpha = 0.84$ vs. $\alpha = 0.82$ if retained). Nevertheless, this item was retained in the survey since the sum variable already showed good internal consistency ($\alpha = 0.82$).

The statistical analysis yielded seven internally consistent sum variables for items of the CFGW. The sum variables describe different aspects of the attractiveness of work and wellbeing at work in social and health care, namely, wellbeing at work, well-functioning practices, participatory management, rewarding work, development of expertise, quality of care, and reconciling work and private life (Table 1). Regarding the bivariate associations, homoscedasticity of variances was tested using Levene’s test. If heteroscedasticity was detected, Welch’s ANOVA was applied; otherwise, traditional ANOVA was used. In these analyses, which were performed in IBM SPSS (version 27.0, IBM, Armonk, NY), the threshold for statistical significance was set as $p \leq 0.05$.

In addition, we calculated average interitem correlation, average item-total correlation, as well as split-half reliability and composite reliability. These quantities can be found in Appendix (Supplementary file 2).

4. Results

4.1. Demographic Characteristics of Licensed Practical Nurses (LPNs). The response rate was 16% ($n = 10\,848$). Majority of the respondents were women ($n = 10\,173$, 94%). The respondents’ ages were divided into six groups. Over half of the LPNs were over 45 years old (54%), while a quarter were over 55 years old (25%). In contrast, a minority of respondents were under 25 years old (5%). Most of the respondents had work experience of between 6–10 (22%) or 11–15 years (19%) in social and healthcare. Moreover, 27% of the LPNs had over 20 years of work experience in social and healthcare. It was most common for the respondents to have worked at the current unit for 2–5 years (32%), while one fifth of the respondents had worked at the current unit for less than one year (Table 2).

Most of the work units had between 10–30 employees (57%), while 17% of LPNs worked in smaller work units, with less than 10 employees. The participating LPNs mostly worked in enhanced service housing for the elderly (24%) or domiciliary care (17%), and three quarters of the respondents were employed by the public sector (74%). The rest of the LPNs (26%) were working in the private sector. Of the respondents, six out of seven (86%) were educated as a qualified LPN, while the rest (14%) had completed some other vocational education (e.g., basic nurse). Most of the participating LPNs were working full-time (81%), and it was most common to have work organized over two (38%) or three shifts (37%) (Table 2).

4.2. Results from Bivariate Associations and Analysis of Variance. Based on the analyses, three sum variables, namely, well-functioning practices, rewarding work, and development of expertise, were most often significantly associated with independent background variables. The results revealed that the core group and dependent variable, wellbeing at work ($m = 4.36$), including its six subgroups (well-functioning practices, participatory management, rewarding work, development of expertise, quality of care, and reconciling work and private life), are extremely important for LPNs’ perceptions of the attractiveness of work. Furthermore, subgroups quality of care and reconciliation of work and private life have the highest averages in wellbeing at work. (Table 1). Bivariate analyses, ANOVA, and *t*-tests were conducted to identify the variables that were independently associated with the CFGW sum scores. In this study, the presented statistically significant results are both statistically significant and meaningful in practice (mp) (Table 3 and Figure 2). Associations between the background and sum variables were assessed using bivariate analysis, analysis of variance (ANOVA), and *t*-tests. When only groups with 400 or more responses were included in the analyses, 44 of the 77 pairwise association tests demonstrated statistically significant associations that were also deemed significant in practice (Table 3 and Figure 2).

When evaluating the LPNs’ experience related to rewarding work, the LPNs evaluate work rather rewarding in other areas, except the salary. Furthermore, LPNs’ salary does not increase as the demands of the tasks increase ($m = 1.64$) (Table 1). Well-functioning practices need improvements according to the LPNs. Regular and joint evaluation of work processes could be improved ($m = 2.97$). Recruitment is not fully based on the competence need of the work ($m = 2.74$). Practices related to the high-quality student guidance have not been effectively agreed in the work unit ($m = 2.98$). Also, systematic activities, which support wellbeing at work, need improvement ($m = 2.54$). (Table 1). Furthermore, participatory management requires improvements in practice according to the results. LPNs strive for more open decision-making ($m = 2.79$). Furthermore, dealing effectively with problem situations requires improvements ($m = 2.74$). Consistency in following the rules needs enhancement in practice according to the results ($m = 2.81$). (Table 1). To support the LPNs’ development of expertise and empowerment, systematic and sufficient orientation is important ($m = 2.67$). Furthermore, LPNs’ work-related guidance is not sufficiently available for those in need ($m = 2.93$). The quality of care and work can be improved with corresponding better the number of personnel and professional structure to the demands of the work ($m = 2.49$).

All the following associations had the following *p* value: $p < 0.001$. Well-functioning practices associated with education, full-time work, type of work shift, age, work experience in social and healthcare and in the current unit, work

f = frequency, *basic nurse: professional title for licensed practical nurses before education reform during 1993.

unit, and professional pride. Rewarding work, on the other hand, was significantly associated with education, full-time work, work experience in social and healthcare and in the current unit, work unit, and professional pride. Furthermore, development of expertise was found to be significantly associated with education, full-time work, type of work shift, age, work experience in social and healthcare and in the current unit, number of personnel, work unit, and professional pride, while wellbeing at work was significantly associated with gender, age, and professional pride. (Table 3).

The independent variable full-time work demonstrated statistically significant associations with most of the sum variables (5 out of 7). LPNs who worked full-time were characterized by consistently higher averages across all the sum variables when compared to LPNs working part-time. For instance, LPNs who work full-time had significantly higher values for the sum variables of well-functioning practices ($m = 3.1$), participatory management ($m = 3.16$), rewarding work ($m = 2.99$), development of expertise ($m = 3.18$), and quality of care ($m = 3.4$) than LPNs working part-time. (Tables 1, 3). The LPNs working full-time evaluate the quality of care ($p \leq 0.001$, $m = 3.4$) as the most important aspect of work; rewarding work ($p \leq 0.001$) showed a statistically significant difference relative to responses from part-time workers but had the lowest average value ($m = 2.99$) (Table 3).

Age and work experience (both in social and healthcare as well as the current work unit) were associated with all the sum variables interestingly in a J-curve manner; an exception was well-being at work. Hence, people with only a few years of experience, as well as younger employees, show higher averages than people with 2–15 years of experience or between the ages of 25–55; this trend then reverses later, with the highest average values often seen for people who are nearing retirement. (Table 3).

Respondents with a vocational education other than a licensed practical nurse demonstrated systematically higher averages across all the sum variables when compared to LPNs. Among these respondents, the development of expertise was statistically significantly associated with the independent variable education ($p \leq 0.001$) and experienced as the most important aspect ($m = 3.28$). Work unit and all the sum variables, with the exception of wellbeing at work, demonstrated statistically significant associations. Furthermore, the results indicated that the opinions of the attractiveness of work were rather similar across all units. For instance, enhanced service housing and domiciliary care, which represented most of the respondents, showed similar results as the other units. The independent variable, number of personnel, was significantly associated with rewarding work ($p \leq 0.001$), quality of care ($p \leq 0.001$), and reconciling work and private life ($p \leq 0.001$). LPNs who worked in small units (less than 10 employees) demonstrated higher average values for the sum variables relative to LPNs working in larger units, which indicates higher satisfaction in smaller units (Table 3).

Interestingly, wellbeing at work showed exceptionally high averages ($m = 4.36$). This indicates that wellbeing at work is, in the opinion of LPNs, the most important aspect of attractiveness of work. (Table 1). The individual variables gender ($p \leq 0.001$) and age ($p \leq 0.001$) were significantly associated with wellbeing at work (Table 3). Furthermore, the subgroups' high quality of care and reconciliation of work and private life showed the highest average values (Table 3). The independent variable professional pride was significantly associated with all seven sum variables, the core- and subgroups. The LPNs who reported feeling professional pride, which was 77% of respondents, had higher average values for all seven sum variables when compared to LPNs who either reported not feeling professional pride or being unsure (Table 3).

5. Discussion

This study has identified factors which affect the attractiveness of work and wellbeing at work from the LPN perspective. Interestingly, we found out that wellbeing of the LPNs showed exceptionally high averages. This finding supports our study aims and indicates that wellbeing at work is, in the opinion of LPNs, the most important factor of attractive work.

LPNs' empowerment and feeling of rewarding work is vital in wellbeing at work in social and healthcare. Notably, according to the results, LPNs' wellbeing at work is the most important factor of attractive work. Furthermore, the results of this study show that nurse managers' actions in systematic supporting of the LPNs' wellbeing at work need improvement in practice. The individual variable age was significantly associated with wellbeing at work. This finding indicates interestingly that young and older LPNs have similarities in regarding wellbeing at work. Furthermore, the subgroups high quality of care and reconciliation of work and private life showed the highest average values.

According to the results of this study, improvements in salaries are an important element in enhancing the feeling of rewarding work for LPNs. A recent Taiwan study showed that high salary lowers the risk of turnover, especially among newly employed nurse aids [59]. Low salary is major reason for newly licensed registered nurses for leaving the current position as well [60]. Low salary enhances LPNs' dissatisfaction at work and creates a risk, as well as for the LPNs' retention in the workplace [17]. Salary is not merely the only factor, which increases LPNs' rewarding work. Instead, the results show that nursing managers should improve actively all areas of the LPNs' wellbeing at work in practice.

This study has clarified the subareas which most impact LPNs' perceptions of the attractiveness of work. LPNs experience the work rewarding in many areas as well. The LPNs' experience, for instance, that they have the possibility to do the work well and that their work is respected. The results imply that nursing managers should take active actions to maintain the LPNs' perceived feeling of being respected and further improve all areas of rewarding work in practice. In line with Loes and Tobin [43], feeling of being trusted enhances psychological empowerment among LPNs working in elderly care. The results support the fact that nursing managers should work actively and find ways to improve LPNs' salary to improve the attractiveness of work. "Out of the box" strategies, alongside with better salaries, to improve the work environment are essential in overcoming nursing shortages [61].

The WHO has stated that national healthcare systems must have sufficient capacity and quality [3]. However, equal healthcare coverage requires a qualified workforce that meets the demand for services [5]. LPNs' perceptions of the factors that contribute to the attractiveness of the professional has not previously been studied; this current research, a large-scale nationwide study, contributes to closing this knowledge gap

by including LPNs from various care settings, which is important as LPNs represent the largest group of professionals in elderly care in Finland. On an international level, the LPN role must be clarified, especially in the context of elderly care, to develop healthcare [34]. Previous studies have included a relatively small number of participants and are typically limited to RNs or specific contexts [13, 17]. A shortage of healthcare professionals is inevitable [1]. The WHO [3] outlines that major investments in healthcare systems are needed. Furthermore, it is important to consider that 90% of the nursing workforce is made up of women [3], as in our study. In addition, it is typical that nursing professionals earn salaries that are below the average wage of the country [3]. The results in this study also indicated that LPNs feel that their salaries are not in line with the tasks that they perform. According to the results, the LPNs' salary does not increase as the demands of work grow.

According to Herzberg's two-factor theory of motivation-hygiene, salary as one of the hygiene factors influences employees' dissatisfaction at work. An employee's motivation can be enhanced by factors called motivation factors, which are related to the content of work [27]. However, the reported results are not completely in accordance with the classic theory of motivation. Previous study, which was aimed at mental health nursing personnel, found a correlation between salary and job satisfaction [35]. In this study, according to the LPNs, all the factors which positively influence personal wellbeing are extremely important in work related attractiveness. In addition, Aiken et al. stated that personnel shortages can be tackled using simple interventions, such as career advancement possibilities and evidence-based human resource management [13]. Interestingly, LPNs evaluated that all aspects of wellbeing at work (e.g., well-functioning practices, rewarding work, and participatory management) are extremely important for their personal wellbeing, which is in line with Aiken et al. [13]. Furthermore, LPNs evaluated quality of care as the most important individual factor in this study.

The findings underline that actions which promote wellbeing at work are crucial to retaining healthcare professionals. The results agree with what was reported by Aiken et al., more specifically, widespread dissatisfaction among nurses regarding patient safety and nursing care. In addition, nurses from several countries, including Finland, only judged the quality of care as poor or fair [13]. The results from this study show that LPNs prioritize patient safety and high-quality care. Also, the results indicate the nurse managers to lead more effectively high-quality student guidance and orientation processes in practice. Previous research underlines that each healthcare role, including the LPN, should have a clearly defined scope of practice if a high-quality care is to be provided [15, 42].

Based on the results, the attractiveness of work was defined based on six work-related areas, namely, well-functioning practices, participatory management, rewarding work, development of expertise, quality of care, and reconciliation of work and private life. Together, these form a structural basis for the LPNs wellbeing and can be utilized in managing the wellbeing.

Interestingly, the youngest and oldest LPNs gave similar evaluations of which factors most affect wellbeing and attractiveness of work. These respondents also gave the highest averages for current wellbeing and attractiveness of work based on the assessed subareas. Especially, young and older LPNs are a valuable resource in managing the shortfall of healthcare personnel [15, 60]. Furthermore, investments in staffing in nursing homes improve the quality of care [13, 62]. Furthermore, the responses of inexperienced and experienced LPNs showed similar trends in this study. Also, LPNs working in small units reported higher average values than peers in larger work units. The LPNs' feeling of professional pride showed a positive association with all of the wellbeing subareas. Results indicate that improving LPNs' feeling of professional pride can significantly promote the attractiveness of work and have a positive effect on the retention. In addition, leaders in nursing should improve well-functioning practices by improving the evaluation of work processes together and regularly with the LPNs.

Although this study focused on the LPN perspective, the results can be generalized to other instances in which there is a shortage of healthcare professionals. The results provide evidence that the LPNs would support any actions by nurse leaders that would improve the quality of healthcare. A recent literature review by Roos et al. showed that the work-related attraction factors do exist and can be measured [18]. The present study, which focused on LPNs' perceptions, provided unique insight into LPNs' perceptions of work-related wellbeing and the attractiveness of their profession. The findings of our study underline the importance of wellbeing of the LPNs as highly supportive element in developing the attraction of work in social and healthcare.

6. Strengths and Limitations

This study and its results have several strengths and limitations. One significant strength is the detailed modification of the CFGW questionnaire by a group of specialists, ensuring its suitability for LPNs. In addition, we successfully involved LPNs on a large scale, which is notable compared to previous studies [34]. The CFGW questionnaire demonstrated acceptable internal consistency ($\alpha = 0.739\text{--}0.915$), supporting the reliability of our results [63]. In this study, we utilized the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) to improve the quality of the online survey [47].

Response rates for online surveys can vary widely from 25–35% [58], while our study reached merely 16% but the completion rate and participation rates were acceptable, 54% and 72%, respectively [47]. We succeeded to invite over 90% of the target population to our study and received 10 848 in total. Thus, the data have a significant amount and portion of LPNs, which allows us to study many aspects of the phenomenon of our interest. The results of this study have potential to be generalized in Finland and potentially in other countries with similar healthcare setting. Information about the nonrespondents is not available, and this weakens the generalizability of the results [64].

We consider the response rate (16%) to be eligible for assessing relationships between different variables in these data. When interpreting, for example, means, the reader should not take them as precise as they would be if we had much higher response rate. Instead, there may be bias in the means but that does not necessarily mean that there is bias in the relationships of variables. In this study the usage of sum variables, representing average of multiple items, does reduce overall bias. For example, if one item had some bias, it will not play large role in the sum variables. Furthermore, the bias in the relationships of different variables would be present only if nonresponse would occur highly associated differently with one category of a background variable. For example, if we want to know if male and female LPNs report their wellbeing at work to be on the same level on average, it is enough that willingness to participate is same for men and women with similar wellbeing at work.

To enhance the response rate, multiple approaches were included. First, the number of questionnaire items was considered when selecting an instrument. The modified questionnaire (CFGW) includes a moderate number (44 in total) in line with recommendations [47, 65]. Second, a reminder notification was sent to respondents after one week, which can positively influence the response rate [64, 66]. Respondents were also able to review and change their answers before submitting likely enhancing the participation rate [47, 65]. Furthermore, all the survey responses were completely anonymous; one limitation regarding the anonymity is that one respondent may provide duplicate responses if a respondent uses another browser. However, in online survey, this is very unlikely [47, 55]. To ensure that duplicate answers were minimized, an IP check setting was selected prior to sending out the first emails.

This survey was distributed in May, which is the first month of the vacation period in Finland and this could negatively influence the response rate. Furthermore, the LPNs who received the survey are registered members of either of the two main trade unions for nursing personnel in Finland and pay the membership fee, which could improve participation. The survey was distributed about two years after the start of the COVID-19 pandemic, which was a strong burden for healthcare personnel and their wellbeing at work [9]. As such, it could mean that personnel would be more open to sharing their assessments of work attractiveness and wellbeing. Furthermore, the two main nurses' trade unions and the municipal and welfare area employers had strong disagreements during the spring 2022 in Finland. This resulted in nurses' trade unions giving a large strike warning in March 2022, which included up to 40 000 RNs and LPNs [67, 68]. In response, the Finnish Ministry of Social Welfare and Health ratified a law in April to ensure immediate patient safety in light of the actions of trade unions [69]. These actions most likely affected LPNs' motivation to change the healthcare system in Finland, which was in crisis, and could be expected to have positively affected the response rate. However, we do not have similar national data regarding the LPNs, which strengthens the value of our findings.

The results of this study have potential to be generalized, with some restrictions, to social and healthcare settings in Nordic countries (Finland, Sweden, and Norway). The healthcare system is decentralized, predominantly tax based and publicly provided. Furthermore, the scope of practice and the division of healthcare personnel is rather similar in the Nordic areas [70]. LPNs are key participants of the nursing workforce in USA as well. The scope of practice and role of the LPNs needs more careful assessment in many states [15, 41]. Hence, the results of this study can possibly give valuable information for a better understanding of the essential role of the LPNs and the retention of the LPNs. In online surveys, the respondents are not selected through probability sampling, which has a negative effect of the generalizability of the results [64]. The results of this study are best applied among evidence-based practice of LPNs'. Furthermore, this study is replicable, which contributes to generalizability of the results [71].

7. Conclusions and Future Research

There is a gap in research concerning the attractiveness of the LPNs work and the wellbeing at work of an LPN. This study helped to bridge this gap by applying the instrument CFGW to examine LPNs' perceptions of the attractiveness of their work and wellbeing at work. The research revealed several factors which affect the attractiveness of the LPN role and wellbeing at work. Several independent variables showed significant associations with the dependent variables describing attractiveness of work and wellbeing. The participating LPNs shared that personal wellbeing is exceptionally important element regarding the attractiveness of work. LPNs' wellbeing was further supported by the quality of care and reconciliation of work and private life, for instance.

This research gives important information, especially for the leaders in nursing for a better understanding about the factors promoting the attractiveness of work and wellbeing of the LPNs. This information is vital regarding, for example, the retention of the LPNs. Actions aiming to develop the work-related environment requires collaboration with the healthcare personnel, including the LPNs. Participatory management is one of the key elements to be considered. Nurse managers play a crucial role in developing the work and wellbeing of the LPNs systematically and effectively. Current environment in evidence-based practice regarding the development of LPNs' work needs better characterization. To this end, the findings of this study suggest that statistical methods can be applied to quantitatively investigate the attractiveness of nursing and wellbeing of the LPNs. Furthermore, in this study, specific factors were identified in line with the core aim of this study, which was to define factors that affect LPNs' attractiveness of work and wellbeing at work. The results of this study give more insight into development of evidence-based practice in nursing and in the LPNs' work environment. In the future, it is

recommended to study the LPNs' attractiveness of work with qualitative methods to confirm the results.

Data Availability

The survey data of this study are not publicly available due to confidentiality reasons. In case of further inquiries regarding the availability of data, please contact the corresponding author.

Additional Points

What Is Already Known. (i) Shortages in the healthcare workforce represent a global threat that has particularly grave implications for elderly care services, as LPNs and RNs are the largest professional groups. (ii) There is a lack of data about a vital group of healthcare professionals, the LPNs. (iii) Although the discrepancy between the demand and supply of nurses is a global phenomenon, little research has focused on the factors which promote the attractiveness of the professional and wellbeing at work. *What This Paper Adds.* (i) This study has identified factors which affect the attractiveness of work and wellbeing at work from the LPNs' perspective. (ii) The attractiveness of work was defined based on six work-related areas, namely, well-functioning practices, participatory management, rewarding work, development of expertise, quality of care, and reconciliation of work and private life. Together, these form a structural basis for an LPN's wellbeing. (iii) Statistical methods were applied to assess wellbeing among LPNs, and the results can be used to improve wellbeing in practice in addressing nursing shortages.

Conflicts of Interest

The authors declare that they have no conflicts of interest. The author, Viinikainen S., works at the Union of Health and Social Care Professionals in Finland.

Acknowledgments

This research received funding from the Finnish Association of Nursing Research (HTTS), the Finnish Nursing Education Foundation, Finnish Nurses Association, and the Finnish Union of Practical Nurses. Open access funding was enabled and organized by FinELib 2023.

Aim. To explore and describe intensive care professional nurses' experiences caring for COVID-19 patients in private hospitals in Gauteng, South Africa. *Introduction.* Pandemics are unique forms of disasters characterised by adverse psychological symptoms and behaviours. Literature confirms a globally increased workload during pandemics, causing emotional exhaustion and poor concentration among healthcare workers. Moreover, high mortality rates are mentioned as a cause of moral distress and moral injury to healthcare workers. South Africa was unprepared for the COVID-19 pandemic, as evidenced by overcrowded hospitals, a lack of resources, and high mortality rates. *Materials and Methods.* A qualitative, phenomenological, exploratory, descriptive, and contextual research design was used. The five largest private hospitals from the same hospital group in Gauteng were chosen as they were admitting many COVID-19 patients. Fifteen participants were selected through purposeful sampling. Semistructured, in-depth, individual interviews were conducted and audio-recorded, and field notes were taken from April 2022 to December 2022. The interviews were transcribed verbatim and analysed using Giorgi's approach. *Results.* Three themes emerged: abrupt transition from normality to the COVID-19 pandemic; experienced isolation from family, community, and nursing management; and feelings of satisfaction and gratitude for teamwork and learning. *Conclusions.* It is essential for nurses' holistic care to be considered along with patients' holistic care. The findings in this study could drive healthcare institutions in South Africa to respond to nurses' health, care, and support needs. *Implication for Nursing Management.* Nursing management should consider shorter and fewer consecutive workdays for nurses to rest and restore their energy levels. Nurse management should also provide human caring by being visible to the nurses and communicating with them. Holistic self-care practices should be included in nurses' in-service training programmes.

1. Introduction

On 31 December 2019, the coronavirus disease 2019 (COVID-19) was reported to cause severe viral pneumonia in Wuhan, China [1]. The virus rapidly spread worldwide, resulting in a pandemic. COVID-19 is a complex respiratory disease that complicates acute respiratory distress syndrome (ARDS), and patients often require mechanical ventilation [2]. The transmission mode is human-to-human, and the virus is characterised by high transmission efficiency and the involvement of multiple organs [3].

South Africa's National Institute of Communicable Diseases (NICD) reported its first confirmed case on 5

March 2020 [4], and the president of South Africa declared a national disaster on 23 March 2020. The pandemic's rapid spread resulted in national lockdown restrictions on 27 March 2020. All citizens were forced to remain at home. Like other countries, healthcare workers in South Africa faced the unknown, highly contagious COVID-19 virus with inadequate resources and guidelines [5, 6]. An intensive care unit is mainly defined by highly trained nurses, doctors, and medical equipment that can assist in reversing organ dysfunction, such as mechanical ventilators and advanced physiological monitoring devices [7]. In South Africa, the training of the ICU nurse is regulated by R.212, and nurses must have the additional qualification "Medical Surgical:

Critical Care Nursing” from the South African Nursing Council (SANC) [8]; a critically ill patient requires the skills of critical thinking and clinical judgment underpinned by scientific, biomedical, and technological knowledge [9]. However, in this study, professional nurses were unexpectedly transferred from the wards to ICUs without knowledge and skills of critically ill patients’ care. Sufficient physical, emotional, and mental support is essential to promote nurses’ ability to care for patients [10]. Yet, healthcare workers were under enormous stress and were physically, emotionally, and mentally challenged during the pandemic.

Cotton and Iro [11] affirmed that the world was unprepared for this pandemic, as evidenced by overcrowded hospitals, high mortality rates, and staff shortages. Ulrich, Rushton, and Grady [12] agree that a general lack of institutional preparedness for the volume of COVID-19 patients within hospital systems left frontline nurses physically and emotionally susceptible to a persistent sense of guilt and anxiety. Al-Dossary, Alamri, and Albaqawi [13] also confirm that COVID-19 challenged nurses due to the novelty of the disease, and a lack of information and training accelerated the rate of hospital infections. The unavailability of guidelines was also significantly associated with anxiety among nurses [14] who faced an unexpected situation and had no experience and skill to deal with COVID-19 [15].

The World Health Organization [1] highlighted a global shortage of six million nursing positions, and combined with the staff shortages during the pandemic, quarantine also made nursing care difficult. In addition, many healthcare workers in South Africa were infected with COVID-19, placing more strain on the remaining healthcare workers [16]. Carter and Notter [17] confirm that COVID-19 placed unprecedented pressure on critical care services, stretching resources beyond capacity. Increasing the number of beds in intensive care units (ICUs) to accommodate critically ill COVID-19 patients resulted in a higher workload for nurses [18]. Moreover, increasing ICU beds resulted in a shortage of equipment such as ventilators and high-flow nasal machines, and nurses became part of the ethical decision-making process in this context, reflecting on criteria such as beneficence, non-maleficence, autonomy, and justice [19]. Eftekhar Ardebili et al. [20] indicated that participants reported a heavy workload, fast changes in the workplace, a loss of control over caregiving situations, feelings of helplessness, ineffectiveness in routine work, and the inadequacy of previous work experiences. Elhadi et al. [21] similarly indicated that a significant number of healthcare workers expressed low levels of awareness and preparedness regarding COVID-19, and their concern was that inadequate knowledge is a risk factor for disease transmission and can lead to low levels of care.

Mekonen et al. [14] pointed out that the unavailability of guidelines, fear of infecting family members, and having a chronic disease were significantly associated with nurses’ anxiety. Nursing managers also described their management approach during the pandemic as novel and complex, and nurses were losing trust in them [22]. This same view is supported by Sperling [23], who explains that nursing care is extraordinarily stressful and demanding due to rapid changes

in guidelines and regulations. Moreover, nurses’ fear and a lack of technical skills and knowledge about COVID-19 were significant coefficients in their mental health [24]. The inability to assist patients was also demotivating and frightening for nursing staff. Robertson, Maposa, Somaroo, and Johnson [25] claim that healthcare workers’ motivation and empathy are critical to effective and compassionate care. However, adverse mental health conditions were noted among healthcare workers exposed to COVID-19, and this affected their patient care. Witnessing unacceptable situations also causes individuals to react by blaming themselves, either for the choices they made or their inability to perform specific actions [26]. Moreover, inadequate knowledge in caring for patients with COVID-19 could result in moral injury, a form of psychological distress attributed to performing an action that contradicts one’s own moral and ethical code, resulting in guilt, shame, and anger [27]. South Africa does not have clinical resource organisations supporting nurses’ holistic care, such as the American Holistic Nurses Association, which encourages staff’s well-being.

During the pandemic, healthcare workers were left alone due to restrictions to control the spread of the virus and expected to deal with patients’ traumatic experiences and the unexpected loss of friends, family, and colleagues [28]. Said and El Shafel [29] also emphasise that inadequate emotional preparation among nurses dealing with death and dying is linked to occupational stressors. In addition, while working with COVID-19-positive patients, nurses wear heavy personal protective equipment (PPE) and often go six hours without using the bathroom, tolerating hunger and thirst. These working conditions affect the nurses’ physical, physiological, emotional, and psychological health [30], and the PPE is considered inadequate and not user-friendly [23].

The COVID-19 pandemic has consistently been documented as negatively affecting nurses worldwide since the outbreak’s start [31–33]. Several South African studies have explored nurses’ experiences caring for COVID-19 patients during the pandemic. However, these studies were conducted in contexts and healthcare institutions that differ from this study. Those studies were carried out in primary healthcare facilities [34–37], and other studies included all healthcare workers: nurses, medical doctors, and allied health professionals [38]. To fill this gap, this study explores the lived experiences of professional nurses caring for COVID-19 ICU patients in private hospitals in Gauteng, South Africa.

2. Materials and Methods

The authors followed a descriptive qualitative research method to explore professional nurses’ experiences caring for patients with COVID-19 in private hospitals in Gauteng, South Africa. The first author used the Consolidated Criteria for Reporting Qualitative Research (COREQ) guidelines in approaching and reporting on this qualitative study.

2.1. Study Design. A qualitative, exploratory, descriptive, and contextual research design was used in this study. In particular, we employed a phenomenological approach to

inquiry, focusing on understanding individuals' lived experiences and the meaning they attribute to those experiences. Phenomenology aims to provide a rich description of human experiences as they are perceived and understood by individuals [39]. Through in-depth, individual interviews, we aimed to understand participants' lived experiences and the meaning they ascribed to them. This approach offers a detailed exploration of participants' perspectives within their natural contexts. Data analysis involves reducing and organising data and extrapolating meaning [40, 41]. It is also defined as a dynamic process of weaving together emerging themes and identifying key ideas or units of meaning and material acquired from the literature [42]. Giorgi's analysis method was used to uncover the meaning of the phenomenon as experienced by individuals through the identification of essential themes [43] (see Table 1).

2.1.1. Settings. Data were collected at five private hospitals from the same private healthcare group. These private hospitals were chosen because they are the largest private hospitals in Gauteng and were admitting many COVID-19 patients during the pandemic because of their bed capacity. The distance between each hospital was eight to ten kilometres. The interview venue in each hospital was unique; boardrooms, clinical department offices, the night manager's office, and the infection control office were used for interviews. All five hospitals accommodated the first author in a way that ensured participants' privacy was protected and no disturbances occurred during interviews. Moreover, COVID-19 protocols were strictly followed during interviews, including wearing face masks and adhering to social distancing, and hand sanitisers were available in each interview room.

2.1.2. Participants, Sample, and Sampling. In this study, the population was all professional nurses caring for COVID-19 patients in a private hospital in Gauteng. In this study, the researcher (first author) used purposive sampling. Grove and Gray [40] define purposive sampling as recruiting participants based on their knowledge, experience, or views related to the intended study. This study's purposive, convenient sample was professional nurses caring for ICU COVID-19 patients in five private hospitals of the same hospital group in Gauteng ($N = 15$).

Inclusion criteria are the characteristics the participants must possess to be part of the target population [45]. This study's inclusion criteria were as follows: (a) all professional nurses in the chosen private hospitals caring for patients in COVID-19 ICUs during the pandemic; (b) the professional nurses had to be permanently employed at one of the five private hospitals, working day or night shifts in the COVID-19 ICUs; (c) participants had to be able to read and speak English; and (d) professional nurses who are working in the COVID-19 ICUs. Exclusion criteria are characteristics that restrict the population to a homogenous group of subjects [46]. This study's exclusion criteria were as follows: (a) professional nurses who did not work in the COVID-19 ICUs full time or those working as agency staff as they were often unavailable; (b) enrolled and auxiliary nurses working

in the COVID-19 ICUs and general units, as they work under the direct supervision of professional nurses, and they were not assigned to nurse critically ill patients; and (c) professional nurses working in the general COVID-19 wards.

The first researcher, who is a deputy nurse manager, conducted personal recruitment; the researcher got expertise to conduct a phenomenological study. The researcher met with the hospital management of all five hospitals separately to explain the intended study in detail. All five hospitals were happy to be chosen for the proposed study, and they all agreed that the interviews could be conducted during shifts. The deputy nurse managers of each hospital were chosen as gatekeepers, as they are the most involved with staff; this view is supported by Aaltonen and Kivijärvi [47], who agree gatekeepers are professionals or individuals engaged in everyday practice.

The gatekeepers play a key role in ensuring researchers gain access to potential participants and sites for research [48]. The researcher left information letters with the gatekeepers in each hospital to be distributed to all professional nurses who worked in COVID-19 units during the pandemic. Fifteen participants contacted the researcher voluntarily to indicate their willingness to participate in the study [44]. The researcher contacted the gatekeepers to arrange a suitable venue after the participants agreed upon an interview date and time. The researcher was aware of possible coercion due to her position of power, but participation was entirely voluntary. Participants were also not compensated for their participation.

The sample consisted of five male and ten female participants who voluntarily agreed to participate. Informed written consent was obtained from each participant. Participants' ages ranged from 27 to 45; the mean age was 27. All the participants were professional nurses, and three had post-basic diplomas in medical, surgical, and critical care nursing [9]. Their nursing experience ranged from one to ten years. Participants' demographic information is summarised in Table 2.

2.2. Data Collection. This study explored the experiences of professional nurses working in COVID-19 units in Gauteng, South Africa, from the beginning of the first wave until the end of the fifth wave. However, data were only collected from the end of the fourth wave (April 2022) to the fifth wave (December 2022). All the participants had been working in COVID-19 units since the pandemic's outbreak in the country. The first author thoroughly explained the purpose of the study to participants before obtaining their informed consent. The interviews were conducted between 10h00 and 11h00 with the permission of the nursing service managers after the doctors' rounds and participants' morning routine to avoid disruptions to care. The gatekeepers also arranged for clinical facilitators to help, if needed, during the participants' interviews.

The researcher conducted semistructured individual interviews that lasted 45 to 60 minutes, using various communication skills to gather rich information, and recorded information using an audio recorder, observation skills, and field notes. The researcher gained experience in

TABLE 1: Themes, subthemes, and quotes from participants [44].

Subthemes	Categories	Quotations
<i>Theme 1: abrupt transition from normality to the COVID-19 pandemic</i>	Rapid changes in working structure, COVID-19 policies, and more responsibilities	Participant 7: "We felt that management was failing us, changing protocols many times but not coming to us to hear our problems"
	Participants were overworked due to a shortage of staff	Participant 2: "We were not prepared; we did not know the signs and symptoms of it and how it spread from one person to another. We were all scared, and we were overworked"
(1.1) Participants felt overwhelmed, overworked, physically and mentally exhausted, and faced high mortality rates	Participants faced moral distress and moral injury	Participant 8: "... shortage of staff affected us negatively. Patients were left with us; no visitors were allowed. Most of the staff members were infected. Nursing three patients and sometimes you find us that you are the only one who is ICU trained. Most of the staff never nurse a ventilated patient" Participant 1 shared his sadness: "We worked ten days or more straight shift to cover the ward"
	Participants witnessed an increased death rate	Participant 4: "We are still not recovered emotionally from seeing lots of people dying. We have lost so many patients"
	The extra burden of patient care led to self-neglect, and nurses sacrificed their own holistic needs	Participant 2: "We were in the ward for 6 hrs. In that six hour we couldn't eat, or drink anything. We were sweating to the point that we were thirsty. We kept on working because our patients were very sick"
<i>Theme 2: experienced isolation from family, community, and nursing management</i>	Participants sacrificed seeing their families and friends and suffered loneliness	Participant 3: "You arrived at home after a hectic day, you are tired physically and emotionally, you can't share with your family because you are scared that you might infect them, you isolate yourself"
(2.1) Participants experienced stigma from the community and isolation from family	Participants experienced stigma from the community	Participant 5: "... when I am off. I will stay in my flat because people in our building were assuming that if you are a nurse, you got Covid. You can see the way they were looking at me and suddenly avoiding me"
(2.2) Participants mentioned a lack of support from nursing management	Participants shared that nursing management did not physically or emotionally support them during extremely challenging times	Participant 4: "Nursing management was not even coming inside just to say thank you. Only people from outside on TVs and radios that were acknowledging our hard working, it is very sad"
<i>Theme 3: feelings of satisfaction and gratitude for teamwork and learning</i>	Participants experienced very positive team support	Participant 7: "Jaa, we were good team there were some instances when we talk about the incidents that happened and how to improve ourselves. Yes, and after talking we were feeling better. We were praying every morning before starting the routine and it was helping"
(3.1) Participants expressed that COVID-19 gave them learning opportunities and empowered them to mature professionally	Participants shared their joy when patients recovered	Participant 1: "I have learned a lot. After so much that I have learned, I want to do a degree in Nursing. Nursing COVID-19 patients has encouraged me to study more. I have realized that I need more knowledge"
(3.2) Participants expressed feelings of satisfaction	Participants shared their joy when patients recovered	Participant 4: "It was hectic, but we were grateful if we extubate a patient and see them recovering well, it was very pleasing. Discharging patient home was a bonus, we will be so excited. Patients will phone us and update them about their progress, we were also doing the follow up, they were concerned about us. They were so grateful"

TABLE 2: Summary of participants' demographic information [44].

Participant	Gender	Age	Qualification	Post-basic qualification	Years of experience as a professional nurse	Department working prior to COVID-19
1	Male	27	Professional nurse		1	Surgical ward
2	Female	29	Professional nurse		1	Medical ward
3	Male	41	Professional nurse		4	Orthopaedic ward
4	Female	33	Professional nurse		10	Oncology
5	Female	29	Professional nurse		2	Surgical
6	Female	45	Professional nurse		4	High care unit
7	Female	31	Professional nurse	“Diploma in Medical Surgical: Critical Care Nursing” (SANC, 1993: R.212), March 2017	6	Intensive care unit
8	Female	38	Professional nurse		3	Surgical ward
9	Female	29	Professional nurse		3	Medical ward
10	Male	45	Professional nurse	“Diploma in Medical Surgical: Critical Care Nursing” (SANC, 1993: R.212), March 2017	10	Intensive care unit
11	Female	32	Professional nurse		3	Orthopaedic ward
12	Male	41	Professional nurse		1	High care unit
13	Male	28	Professional nurse		3	Surgical ward
14	Female	45	Professional nurse		6	Medical ward
15	Female	31	Professional nurse	“Diploma in Medical Surgical: Critical Care Nursing” (SANC, 1993: R.212), March 2017	8	Intensive care unit

qualitative research during her master's degree study, and she gained expertise in phenomenological studies. The first interview was conducted in the presence of the second researcher, who has extensive research knowledge in qualitative research, a professor in nursing science. This interview was regarded as a pilot interview to determine the central question's effectiveness in gathering the required information based on the study's objective. The central open-ended question was as follows: "How is it for you to care for COVID-19-positive patients?" The pilot interview was successful, provided rich data, and was added as part of the data analysed for the main study. Each interview was transcribed verbatim on the day it was conducted and sent to the research supervisor for review. Data saturation was attained with the 15th interview, and the independent coder confirmed this saturation.

2.3. Data Analysis. Data analysis involves reducing and organising data and extrapolating meaning [49, 50]. To obtain a sense of the whole, the analysis starts by reading and rereading the data, looking at themes, emotions, and the unexpected, considering the overall picture [35]. Data were analysed for meaning using Giorgi's [43] approach, which involved the following steps: (a) the first author read the complete transcripts to get a sense of the whole and bracketed her preconceived knowledge and ideas regarding the phenomenon under study to focus on professional nurses' perspectives. The information was obtained and transcribed from in-depth individual interviews, audio recordings, and field notes. (b) The first author went back to the beginning of the transcriptions and reread them. This time, every time she experienced a transition in meaning within the participant's attitude, she made a mark on the transcription. These parts are called "meaning units." (c) The authors transformed the data—still in the subject's words—into expressions that were more direct impressions of what the participant said. (d) The direct and psychologically more sensitive expressions were then reviewed, and with the help of free imaginative variation, an essential structure of the experience was formed. (e) The essential structure was then used to help clarify and interpret the raw data of the research.

The first author compiled, reanalysed, and interpreted the results. Data were manually coded using coloured pens to categorise the findings, identify significant patterns in all the interviews, and finally draw meaning. A discussion was held with the second author, and agreement was reached regarding the themes and subthemes that emerged, as differences only related to terminology and the phrasing of sentences. In May 2023, the first author also telephonically contacted the participants to confirm whether the data analysis was a true reflection of their meaning. None of the participants requested changes to the themes/subthemes.

2.4. Trustworthiness. Trustworthiness measures refer to the concepts adapted and promoted by Lincoln and Guba [51] to the essential framework for evaluating trustworthiness in qualitative research. Denzin and Lincoln [52] discuss the

trustworthiness criteria: 1. credibility: (a) prolonged engagement was adhered to as data collection started on 23 April 2022 and was completed on 14 December 2022. (b) Triangulation occurred by the first author using multiple sources of data collection, including in-depth, individual interviews, observations, and field notes. (c) Peer debriefing with the research supervisor, a professor in nursing science with extensive knowledge in qualitative research studies, also ensued. The supervisor reviewed and challenged the analysis to promote the rigour and credibility of the data analysis. (d) Member checking: collected data were verified with the participants, who confirmed that the findings reflected their feelings and experiences. 2. Transferability: (a) purposive sampling was used, and a description of the participants' demographic profile and the setting was provided. (b) The research methodology was described in detail. 3. Dependability was heightened in the discussion of the results. 4. Confirmability: adequate and relevant references were used, and there are retrievable, well-organised collected data.

In addition, the first author wrote reflexive notes, indicating a lot of introspection and internal examination to explore her feelings, experiences, and biases, which were bracketed to enhance objectivity. As defined by Polit and Beck [53], bracketing is a method some qualitative researchers used to reduce potential taints caused by preconceptions. This study reminded the researcher of her experiences of being infected with COVID-19, and she found it challenging not to discuss these experiences with participants but to pause, take a drink of water, and refocus on the participant.

2.5. Ethical Approval Details. The study was approved by the Faculty of Health Sciences of the University of Johannesburg's Higher Degrees Committee (HDC-01-96-2021), the Faculty of Health Sciences Ethics Committee (REC-1252-2021), and the research committee of a private hospital group where the participants were employed (UNIV-2021-0054).

3. Results

The sample consisted of five male and ten female professional nurses aged 27 to 45; the mean age was 27. Three main themes emerged, and these were further subdivided into subthemes. The narrative that follows describes the qualitative themes and offers quotations demonstrating how professional nurses' physical, mental, emotional, and social health was affected during the pandemic.

3.1. Theme 1: Abrupt Transition from Normality to the COVID-19 Pandemic. Participants described the COVID-19 as overwhelmed, overworked, physically and mentally exhausted, and faced high mortality rates, leaving them feeling overwhelmed and overworked. Professional nurses' unexpected transfers from general wards to ICUs to care for very sick patients also created significant frustration for ICU professional nurses. They had to teach their colleagues from the general wards how to nurse very sick patients on ventilators. Moreover, professional nurses from the general wards were frustrated because they had to learn fast.

3.1.1. Subtheme 1.1: Participants Felt Overwhelmed, Overworked, Physically and Mentally Exhausted, and Faced High Mortality Rates. The participants also mentioned that there was enormous pressure on them as they did not know about COVID-19. Participants feared possible errors and were held accountable even though they were not the primary nurses because professional nurses with a lack of ICU experience from the general wards were working under their direct supervision. In normal situations, the shift leader supervises and supports the team to ensure safe patient care. The shift leader is thus held accountable for the team and their actions. Participant 5 shared: "Nurses from the ward didn't know how to nurse very sick patients on the high flow machines, Continuous positive airway pressure (CPAP) machines and ventilators. We had to teach them quickly the basic things like trouble shooting when ventilator alarms and the most important things, not to ignore the alarms. The patients were very sick, more pressure on us. They were working under direct supervision of us; we were responsible and accountable for their patients and our patients." During the pandemic, no one was assigned to shift leading, and ICU staff already taking care of more than three critically ill patients at a time were simultaneously responsible for staff from the general ward assigned next to them.

The shortage of nurses resulted in prolonged shifts and increased professional nurses' duties. Extended shifts led to extreme physical and mental exhaustion. Participant 8 said: "shortage of staff affected us negatively. Most of the staff members were infected. Nursing three patients and sometimes you find us that you are the only one who is ICU trained, accountability is on your shoulders." Participant 1 shared his sadness: "We worked ten days or more straights shift to cover the units. There was a time where I had to look after four High care patients alone due to shortage of staff." Participant 11 mentioned a similar experience: "Yes it was hell. We planned that we would eat before going in and use the bathroom as we know that we will wait for 6 hours to drink, eat or use the bathroom. Going out and leaving your patients with your colleague who is already battling with more than 5 patients was not easy. We opted to go and eat quickly and come back, not to spend an hour break."

Participants were unhappy with the rapid changes in the COVID-19 policies. "We felt that management was failing us, changing protocols many times but not coming to us to hear our problems" (Participant 7). Participant 4 mentioned the same challenge: "Management were changing protocols daily or twice a day, sometimes we were not getting those communications only after work when you switch on your phones you will get lots of forwarded messages from our unit manager, received from the management."

Participants witnessed many deaths and suffered moral distress, which resulted in moral injury. Participant 3 reportedly experienced significant distress as a result of the multiple deaths they faced during the pandemic: "second wave was bad in that most people were dying, arriving at home, you just have to bath and sleep. When you are sleeping, your mind is still going through all what happened during the day, you cannot sleep. Most of us were depressed due to lots of

death." Participant 9 said: "You hear your colleague crying after being called to the phone, just to tell her that somebody in their family died. She will cry and go out for 30 minutes and come back to look after her patients. It was a norm that you will attend the funeral to only your immediate family, not the uncles or cousins. It was bad. I am from extended family; we are too close to uncles and cousins, but we couldn't bury them."

Participants also indicated that the extra burden of patient care led to self-neglect, and they had to sacrifice their own holistic needs. Participants put the patients first and neglected their basic needs; they had to wear protective gear for up to six hours at a time due to the shortage of PPE and staff. Consequently, participants were facing dehydration and discomfort. Participant 2 explained: "we were in the ward for 6 hrs. In that six hours we could not eat, or drink anything. We were sweating to the point that we were thirsty. We kept on working because our patients were very sick."

3.2. Theme 2: Experienced Isolation from Family, Community, and Nursing Management

3.2.1. Subtheme 2.1: Participants Experienced Stigma from the Community and Isolation from Family. The participants indicated that their relationships with friends, families, and the community changed during the pandemic. Some community members labelled them as having COVID-19. The participants said they were isolated and often avoided. Participant 5 shared: "...when I am off, I will stay in my flat because people in our building were assuming that if you are a nurse, you got Covid. You can see the way they were looking at me and suddenly avoiding me." A similar perception of social isolation was shared by Participant 2: "I have lost my cousin, my uncle's son. I couldn't go and bury him. After a week, his wife died as well, and I couldn't go and bury her. We were so close; we were like twins. Same age as me. So, my uncle is angry with me, he even told my parents that I must not come to his house. I am from the rural area, people there will never understand."

3.2.2. Subtheme 2.2: Participants Experienced Isolation and a Lack of Support from Nursing Management. Most participants felt management should have done more to provide sufficient PPE to protect the staff. They also concurred that the information should have been more consistent and clearer. The participants mentioned that news of the deaths of colleagues caused them tremendous psychological harm, and management did not comfort them. This increased their fear that they were facing the danger alone, and they worried that it might happen to them. Many participants ultimately mentioned a lack of support from management during the interviews. Participant 4 said: "There was a shortage of PPE as the hospital was getting full. Zapping of gowns and N95. We were not even sure if they are 100% safe. We felt the hospital is gambling with our lives, moreover they were not even coming inside just to say thank you. Only people from outside on TVs and radios that were acknowledging our hard working. It is very sad."

3.3. Theme 3: Feelings of Satisfaction and Gratitude for Teamwork and Learning

3.3.1. Subtheme 3.1: Participants Expressed That COVID-19 Gave Them Learning Opportunities and Empowered Them to Mature Professionally. The regular ICU staff described being grateful for the support they received from colleagues from other departments. Similarly, nurses who were transferred to the ICU shared their gratitude for the support from the ICU nurses. Participants mentioned that their resilience was enhanced by shouldering the COVID-19 burden with their colleagues. Participant 5 explained: “. . . it was not easy, but we were a good team of nurses and doctors. We supported one another. We told ourselves that we need to be there for our patient.”

3.3.2. Subtheme 3.2: Participants Expressed Feelings of Satisfaction. The participants expressed their pleasure at seeing patients recover and return home; it was a moment of joy for them. This was often described as a victory over the disease and gave the professional nurses hope for other patients and the strength to continue their work. Additionally, the participating nurses described many emotional moments, for example, when patients could communicate with their relatives for the first time in weeks. Participant 10 reflected: “It was hectic, but we were grateful if we extubate a patient and see them recovering well, it was very pleasing. Discharging patient home was a bonus, we will be so excited. Patients will phone us and update them about their progress, we were also doing the follow up, they were concerned about us. They were so grateful.”

Themes, subthemes, and participants’ quotes are summarised in Table 1.

4. Discussion

The results of this study revealed that professional nurses experienced posttraumatic stress due to multiple stressors such as a shortage of staff, inadequate knowledge of COVID-19, high mortality rate, isolation from family, and stigma from the community. Moreover, a lack of support from nursing management was emphasised. The participants shared their negative experiences linked to physical and mental exhaustion, sleepless nights, fear, depression, and a lack of holistic self-care practices. Although the nurses mentioned some negative experiences, they expressed satisfaction and gratitude for their team’s efforts (Table 1, [48]).

Professional nurses described the COVID-19 pandemic as an abrupt transition from normality to the COVID-19 pandemic. It was an unexpected chaotic disruption in the care of patients due to the overflowing of patients in the hospitals despite a gross shortage of staff. Moreover, most of these COVID-19 patients were critically ill in the ICUs. This resulted in rapid changes in working structure and more responsibilities as the professional nurses with a lack of knowledge and skills in nursing a critically ill patient were moved from the wards to the ICUs. The South African Nursing Council Competencies for Critical Care Nurses’ Nursing Act (Act No. 33 of 2005) [9] suggests that patient care in ICUs should be comprehensive

critical care. Nursing practice in South Africa is governed by the R767 regulations, which outline the acts and omissions for which the SANC can take disciplinary action (Nursing Act No. 33 of 2005) [54], such as failing to maintain a patient’s health status. The nurse-to-patient ratio in the ICUs is 1 : 1; however, in this study, the professional nurses mentioned that they were nursing three critically ill patients. Participants shared that they worked ten days or more straight shifts to cover the unit, which is against the South Africa Basic Conditions of Employment Act [55], which states that an employer may not require or permit an employee to work more than 45 hours in any week.

Professional nurses mentioned that they were overwhelmed, overworked, and physically and mentally exhausted. Similar findings were mentioned by Yunitri, Chu, Kang, Jen, Pien, Tsai, Kamil, and Chou [56] that hospitals and clinics overcrowded with COVID-19 patients left health professionals with no time for rest, impacting their psychological well-being. This is asserted by Liu et al. [57] that intensive work during the COVID-19 pandemic drained healthcare providers physically and emotionally. Alquwez [58] mentioned that as nurses deal with a terrible pandemic and exhausting work experiences, well-being at work is critical and needs to be emphasised. Inocian, Cruz, Saeed Alshehry, Alshamlani, Ignacio, and Tumala [59] also mentioned that nurses’ work experiences and work conditions during this pandemic adversely affected their professional quality of life. Although the South African Nursing Council’s (SANC) Nurses Rights [60] states that nurses have the right to a safe working environment that is compatible with efficient patient care and is equipped with at least the minimum physical, material, and personnel requirements; however, the working environment was not physically and mentally safe for the participants in this study.

During the interviews, professional nurses expressed frustration and stress regarding the frequent changes in COVID-19 protocols and policies. Catania et al. [61] wrote that the main challenges their participants raised were the constant change in care management guidelines and treatment protocols, which resulted in nurses providing care in uncertain conditions. LoGiudice and Bartos [62] also shared that the nurses in their study expressed that their stress was heightened because their hospital’s protocols changed daily. There was a lot of confusion from the administration with changing guidelines, directions, and endless questions. Persistent changes in protocols and policies were also mentioned by Firozskouhi et al. [63], stating that despite nurses’ crucial role in public health in critical situations such as pandemics, they face certain obstacles in managing events when there are no predefined guidelines or protocols. Irrespective of the frustrations and confusions due to unclear, inconsistent guidelines, professional nurses are obliged to adhere to the South African Nursing Council’s (SANC) Code of Ethics [64], which states that nurses are required to demonstrate the art of nurturing by both applying professional competencies and positive emotions.

Professional nurses faced moral distress and moral injury due to high mortality rate. The participants expressed that they were mentally affected due to the high mortality rate, and some could not sleep as a result. Their distress was also related to patients dying alone due to the visitor restrictions that were imposed during the pandemic. Lake et al. [65] reported that the most distressing situations for professional nurses included caring for patients dying without family present. Robinson and Stinson [65] similarly concurred that their participants were stressed at seeing patients dying without their loved ones by their side. Patients with COVID-19 faced lonely deaths, and family members were not allowed to be present with their loved ones [66]. Castaldo Lusignani Papini Eleuteri and Matarese [67] stated that nurses consequently suffered emotionally and felt inadequate to respond to the needs of many dying patients during the COVID-19 pandemic. Several studies concluded that posttraumatic stress disorder is a major concern in health institutions [68]. Spilg et al. [69] concurred that healthcare workers caring for COVID-19 patients showed signs of severe moral distress, anxiety, and depression. Hossain and Clatty [70] stated that the stress nurses face would create moral distress and have a lasting impact; this is why the term “moral injury” is most suited in the context of COVID-19. This view is supported by Al Maqbali [71], who claims nurses experienced sleep disturbance related to increases in stress, anxiety, depression, high workloads, fear, pressure, and helplessness during the pandemic; to care responsibly for patients, especially as they practice in settings with more complex needs, nurses need to feel healthy, well, and supported. In this study, the participants were not offered any form of psychoemotional support.

Participants also indicated that the extra burden of patient care led to self-neglect, and they had to sacrifice their holistic needs. Participants’ needs were compromised, and they shared that they kept working in unfavourable conditions without eating or drinking for extended periods. During the interviews, the professional nurses shared that they were wearing their PPE for up to six hours before they could go out for a break, leading to sweating and itching. The South African Government’s Batho Pele Principles, 1977 [72], “putting other people first,” and the South African Nursing Council’s (SANC) Pledge of Service [73] were applied by professional nurses during the COVID-19 pandemic, putting patients first and neglecting their basic needs. Abiakam, Worsley, Jayabal, Mitchell, Jones, Fletcher, Spratt, and Bader [74] indicated that wearing PPE for more than four consecutive hours led to redness of the cheeks, dry mouth, redness of the nose bridge, and redness of the ears due to N95 masks, dryness of the mouth when wearing surgical masks, skin dryness, sweating, and redness from wearing gloves, headaches from wearing goggles/face shields, and sweating when wearing overalls or a gown. Harris, McLeod, and Titler [75] similarly stated that the lack of breaks, including meal and bathroom breaks, affected their participants’ physical health. Wearing PPE for a long time exposed nurses to physical health complications such as pressure injuries, dermatitis, dehydration, and headaches [76, 77].

Every employer shall provide and maintain, as far as is reasonably practicable, a working environment that is safe and without risk to the health of his employees, according to Occupational Health and Safety Act 85 of 1993 [78].

Professional nurses experienced social isolation from their family and friends. Professional nurses shared that they had a fear of transmitting the virus to them and decided to isolate themselves to protect families and friends. However, it was negatively affecting their mental well-being. Many nurses felt social rejection, the closeness of the relationship, a sense of social rejection, and a high level of loneliness and depression [79]. Many nurses had quarantined themselves from their families and others to prevent the risk of transmission, which had exacerbated their feelings of anxiety, stress, and social isolation [80]. Çelik et al. [81] also revealed that nurses felt pain because the pandemic process had separated them from their families and children.

Isolation from the community affected the professional nurses’ mental well-being negatively. Some professional nurses indicated that their relationships with friends, families, and community changed during the pandemic. Much of this was related to the fear of transmitting the virus to them, and some community members were labelling them as having COVID-19. Nurses who cared for patients diagnosed with COVID-19 experienced stigma and were labelled “COVID nurses” [82]. Asa et al. [83] shared that nurses were distressed due to stigma and discrimination against nursing COVID-19 patients. Ramaci et al. [84] also indicated that during the COVID-19 pandemic, healthcare workers were facing stigma, resulting in psychological distress. In South Africa, a nurturing of humanism called “Ubuntu,” meaning a human being is a human being through the otherness of other human beings, is supported throughout the country. However, this study revealed that the community did not support nurses during the pandemic.

Moreover, most participants mentioned a lack of support from nursing management and their invisibility during these extremely challenging times. Participants expressed that they were facing the danger of the new virus alone, and nursing management was not visible. Dawood, Tomita, and Ramlall [85] highlighted high levels of depression, anxiety, and stress, combined with poor perceptions of employer support, illustrating the need to identify and address this population’s psychosocial support needs. During pandemics, healthcare organisations should maintain clear, fluid, and regular communication with nursing staff, which could help increase staff members’ confidence and sense of control [86]. It was also confirmed by Joo and Liu [87] that nurses did not receive adequate support from hospitals and the healthcare system and lacked the necessary protective equipment, such as masks and hand sanitiser, to ensure the safety of healthcare workers. AL-Abrow et al. [88] suggested that there is an excellent need for managerial interventions, for example, support, appreciation, and recognition, to help healthcare workers feel valued in their work. Inadequate leadership support was also attributed to a lack of support for the healthcare team, including inadequate staffing and

supplies [89]. Managers should thus respond appropriately to decrease nurses' COVID-19-related phobias by educating, counselling, or providing psychotherapy and work-life balance strategies.

Participants expressed the feelings of satisfaction and gratitude for teamwork and learning. This view is consistent with other studies, reflecting that healthcare workers' ability to support their colleagues creates a growth environment [90]. Veitch and Richardson [91] pointed out that coworker support benefits nurses' mental well-being during times of crisis. Nurses often put the team's needs before their own and hold a cultural ideal of team loyalty; they often work even when sick so they do not let the team down [92].

Participants mentioned that COVID-19 empowered them to mature professionally. In this study, professional nurses demonstrated resiliency and professionalism. Participants verbalised that they had grown professionally and learned a lot; this finding is consistent with Molala and Downing's [93] findings that their participants were eager to learn and achieve professional growth despite the challenges of working in a new environment. Although the provision of care led to physical and psychological distress among nurses, based on their commitment and professional obligations, this new experience also led to personal satisfaction [94]. Clinical nurses gained significant experience during the pandemic, positively affecting their readiness for future pandemics [95]. Alcalá-Albert et al. [96] also shared that their participants mentioned that clinical practice provided them with additional caregiving knowledge and techniques that were previously unknown to them. LoGiudice and Bartos [67] concurred that their participants experienced professional growth during the COVID-19 pandemic and felt they could deal with difficult situations.

When patients survived and were discharged, feelings of satisfaction felt like an achievement for professional nurses. Additionally, the participating nurses described many emotional moments, such as when patients could communicate with their relatives for the first time in weeks. Positive feelings when patients recover are embedded in Watson's theory as one of the Caritas, humanistic-altruistic value systems. Positive experiences were also mentioned by Taheri-Ezbarami et al. [97], who determined that caring for patients with COVID-19 satisfied nurses' needs, such as altruism and love for others, and it ultimately led to the formation of a sense of satisfaction in providing care.

5. Conclusions

This study revealed that psychosocial, mental, and physical care are paramount to professional nurses' ability to deliver holistic care to themselves and their patients. The authors hope this study's findings will help healthcare organisations develop new strategies and policies to support and prepare nurses for future pandemics and outbreaks. Moreover, professional nurses' holistic self-care should ultimately be

facilitated in nursing. Unfortunately, South Africa does not have clinical resource organisations that support nurses' holistic care, such as the American Holistic Nurses Association, which supports the well-being of nurses. The authors hope the nurses' voices will be heard, and awareness of the need to promote their mental health will be created. This information could drive healthcare institutions to plan for future pandemics and respond to nurses' health, care, and support needs [98].

6. Implication of the Study

To make nurses feel valued in their jobs, nursing management must provide support, appreciation, and recognition. It is recommended that nursing management consider shorter and fewer consecutive workdays for nurses so they can rest and restore their energy levels. Nursing management should provide human caring by being visible to the nurses and communicating with them continuously. Holistic self-care should be included in nurses' in-service training programmes. It is also essential that health institutions offer well-being and mental health support to their employees.

7. Recommendations for Future Research

Using the findings of this study, a quantitative study could be conducted to generate a questionnaire and distribute it to public and private hospitals; these findings could emphasise the need to support nurses' well-being. The study concurred on the need for a model to facilitate nurses' holistic care; this can lead to improved patient care and quality of life for nurses.

8. Study Limitations

Fifteen nurses were recruited from five private hospitals but none from state hospitals for this study. Therefore, the findings cannot be generalised to other populations. The study was conducted from the end of the fourth wave to the end of the fifth wave of the pandemic; if it had been conducted during the first wave, more experiences might have been shared as they happened. The first author is a deputy nurse manager, and although the study was not conducted in the hospital where she works, it is the same hospital group; thus, participants might not have felt comfortable sharing some of their experiences. Nursing categories such as enrolled and auxiliary nurses were excluded, limiting the overview of nurses' experiences during COVID-19.

Data Availability

The data used to support the findings of this study are available from the corresponding author upon reasonable request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Introduction. Little is known about how shifting hospital visitor restrictions issued by national health authorities were communicated, managed, and adapted by hospital charge nurses during the COVID-19 pandemic. **Aims.** To describe the shifting visitor restrictions and the passing on of restrictions from the national authority level to charge nurses and secondly describe charge nurses' management of the restrictions and their challenges when enforcing them. **Methods.** The study consisted of a document analysis and a cross-sectional survey including open-ended questions. Descriptive statistics and qualitative content analysis were used. The survey was distributed online to 88 charge nurses in somatic units in a Danish university hospital from March 2020 to April 2021. **Results.** Restrictions were communicated from national authority level in an effective administrative cascade. The charge nurses led their enforcement in each unit. In total, 71 charge nurses (81%) responded to the survey. For 70%, the wording of the restrictions was clear, while 31% found them challenging to handle. On a weekly or daily basis, 68% of the charge nurses deviated from the restrictions. They identified both upsides and downsides to the absence of relatives. Communication, collaboration, and leadership were experienced as key tools in the ongoing processes of adapting to shifting restrictions. **Conclusion.** During this severe health crisis, essential information was passed on through well-defined management levels in an effective communication pathway. Charge nurses and their professional values were challenged when balancing shifting national restrictions against individual needs of patients and relatives. **Implications for Nursing Management.** Charge nurses serve as vital intermediaries between national authorities and frontline nursing practice in managing shifting visitor restrictions during a pandemic. Their experiences can contribute to further qualifying nurse managers' considerations when designing family-centred hospital visitor policies for the future. Also, they may strengthen the handling of future sudden major organizational changes.

1. Background

In hospitals around the world, the Coronavirus Disease 2019 (COVID-19) pandemic caused by the Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) has led to visitor restrictions to prevent the spread of the virus. Internationally, healthcare organizations have implemented policies and guidelines to restrict visitors' access to hospitals.

Hospital visitor restrictions have been a source of suffering and distress for all parties involved [1–6]. The absence of relatives is one of the most commonly identified factors that increase inpatients' anxiety when hospitalised with COVID-19 [3]. Furthermore, feelings of social isolation from close relatives and a lack of psychosocial support have been reported among COVID-19 inpatients [7]. For family members of both COVID-19 patients and other hospitalised patients, worry, anxiety, and uncertainty are common, and they have reported an increased need for information from care providers during the pandemic [8]. Relatives play an important role for individuals suffering from acute or chronic illness for shorter or longer periods of time, and the informal caregiving provided by relatives has been described as the backbone of care provision [9]. In addition to offering their affection and support, relatives sometimes take on more demanding tasks or responsibilities related to the nursing care, treatment, or rehabilitation of their loved one [10, 11], highlighting relatives' roles as important partners in many areas of patient care.

Prior to the pandemic, Danish hospitals generally had liberal visiting policies, acknowledging the ties between patients and their relatives and the important supportive role of relatives during hospitalisation and beyond. Consequently, in 2018, the board of directors at the 850-bed Aarhus University Hospital, where the present study was conducted, announced the end of fixed visiting hours. Therefore, when visitor restrictions were imposed upon all Danish hospitals in March 2020, this represented a historic break with a strong tradition among Danish healthcare professionals (HCPs) of welcoming and involving patients' relatives. During the pandemic, the restrictions have been loosened and tightened several times, challenging HCPs to stay updated and to deal with the implications of these restrictions for patients, relatives, and staff. At times, enforcing the shifting restrictions has been a challenging task for frontline nurses [12].

To manage the restrictions, charge nurses have played a vital role in this process. In a Danish study, hospital charge nurses with formal management education and leaders with more than five years of experience more effectively managed the COVID-19 situation [13]. However, shifting visitor restrictions during the pandemic may have complicated charge nurses' management efforts. Therefore, we aimed firstly to describe how the shifting visitor restrictions were passed on from the national authority level to the charge nurses in a university hospital and secondly to describe the charge nurses' efforts to manage the shifting restrictions in bed wards and outpatient clinics and their challenges doing so.

2. Design and Methods

2.1. Design. The study was conducted in two parts, according to its aims. Part 1 was a document analysis describing the shifting visitor restrictions in the process from decision making to their operationalisation in clinical practice. Part 2 was a cross-sectional survey exploring charge nurses' efforts to manage the shifting restrictions and their challenges doing so. We followed the CROSS guidelines for surveys [14].

2.2. Methods

2.2.1. Part 1: Document Analysis. The document analysis was inspired by the guidelines for document analyses (CARDA), including recommendations for description of the data collection procedure and a data analysis [15].

(1) Legislative Context. In a Danish legislative context, the Danish Ministry of Health determines the overall regulatory and supervisory functions of national healthcare, while the five Danish regions are primarily responsible for the administration of Danish public hospitals [16, 17]. The Danish Epidemic Act, which dates to the plague epidemic in 1665, authorizes the Ministry of Health to issue restrictions to prevent infectious diseases from spreading in or outside of Denmark [18]. Under this act, managing pandemics was considered a public area of responsibility and applied to the entire population [19]. The Epidemic Act takes precedence over all other national legislation, except the Danish Constitution [20, 21].

(2) Data Collection. A comprehensive collection of publicly available electronic documents was retrieved by the researchers HM and TWV between March 2020 and June 2021. The data comprised various sources, including public health policy documents, institutional formal letters, and minutes of meetings of the regional council and hospital administration. The data were retrieved from national authorities, hospital websites, intranet pages, and institutional instructions and files. To ensure the thoroughness of the document collection, the process was extended to references and attachments associated with the primary materials. Six key words were used in the search for documents: Visitor restrictions, hospital visitor restrictions, relative, coronavirus, COVID-19, SARS-CoV-2, and pandemic. All documents containing instructions or orders regarding restricting relatives' access to public and private hospitals were included in the analysis.

(3) Data Analysis. The analysis procedures involved systematic reviewing of all collected data sources. To describe the information paths among authorities and hospital organizations in the enforcement of the visiting restrictions, a systematic content analysis of the documents was conducted in two phases [22]. The initial phase aimed to describe the information cascade in the decision-making processes related to hospital visitation

restrictions. This included identifying the individuals or organizations responsible for determining, authoring, and managing the restrictions, as well as the recipients to whom these directives were forwarded and again passed on to finally be implemented in practice. The second phase of the content analysis focused on tracking changes and developments over time regarding the visitor restrictions, focusing on how they were clarified, loosened, or tightened in both the first and second waves of the pandemic.

2.2.2. Part 2: Cross-Sectional Survey

(1) *Questionnaire Development and Validation.* Based on relevant literature and experience, the five authors developed a questionnaire. Besides questions about background characteristics of the respondents, the questionnaire included five multiple-choice questions:

- (1) How did you as leader get information about current visitor restrictions? (7 options)
- (2) How did you pass on the information about visitor restriction to your staff? (5 options)
- (3) How clear was the wording of the visitor restrictions to understand? (3-point Likert scale)
- (4) How did you as leader experience handling the visitor restrictions in practice? (3-point Likert scale)
- (5) How often have you deviated from visitor restrictions paying regard to patients and their relatives? (5-point Likert scale)

Also, the questionnaire included three open-ended questions allowing charge nurses to elaborate on selected aspects of their experiences or highlight important issues that were not otherwise addressed in the study:

- (a) Did you have any doubts about visitor restrictions, and if so, how were you able to clarify your doubts?
- (b) As charge nurse, is there anything you would do differently if a similar situation should occur in the future?
- (c) Is there anything else you would like to add?

The questionnaire was validated by cognitive interviewing [23] of four charge nurses representing the target group. They were asked individually to complete the questionnaire with one of the authors by their side. By using the think aloud principles [24], the charge nurses were asked about their understanding of the questions, considerations about the answers, and the relevance of the questions. The charge nurses found that some questions could be answered differently, depending on whether they were thinking about the first or second wave of the pandemic. Therefore, three of the multiple-choice questions were divided into sections concerning the first and second waves, respectively. In addition, some questions were revised for clarification. The

revised questionnaire was then converted into an electronic version, which again was pretested by two charge nurses; no further revision was needed. After adjusting the visual layout, a final version to be used in the study was accepted.

(2) *Study Population and Sampling.* In April and May 2021, the electronic questionnaire was emailed to 88 charge nurses in the hospital's somatic wards, including bed wards, outpatient clinics, short-term units, same-day surgery units, intensive care units, and mixed units. To further create attention to the survey, when launching it, the authors also announced the survey through their hospital networks. After two weeks, a reminder was emailed to those nurses who had still not responded. The online survey was created using Research Electronic Data Capture (REDCap), a safe software database for research studies, which does not allow answering the questionnaire twice [25].

(3) Analysis of Survey Data

Quantitative Data. The quantitative data were transferred from REDCap to Stata version 17.0 (StataCorp LLC, College Station, TX). The charge nurses' characteristics were analyzed using simple descriptive statistics. Each of the five multiple-choice questions was calculated as percentages. No imputations were made on missing data.

Qualitative Data. The qualitative analysis of the responses to the three open-ended questions was inspired by Graneheim and Lundman's content analysis method [26]. Initially, the responses were read several times by all the authors, to get an overall understanding of the data, while making individual notes of impressions and first analytic ideas. Next, authors ASÅ, TWV, and GSR developed initial codes by systematically identifying and labelling meaning units from the text that seemed to capture key aspects. Concurrently, they identified categories in the data and summarized illustrative analytic points. The qualitative data collected through the electronically administered questionnaire did not allow us the possibility to go back and ask the respondents to elaborate on their comments. Consequently, the focus of the analysis was primarily on a manifest level (what the text says) rather than on a latent level (what the text talks about). For each of the three open-ended questions, the analytic process was repeated. During the entire process of analysis, attention was paid to the fundamental importance of researcher reflexivity, i.e., a researcher's critical self-reflection about her or his own personal background, preferences and preconceptions, and their influence on the study [27]. To further strengthen reflexivity and increase the credibility of the findings, in the final steps of the process, authors HM and MG were involved for new rounds of reflective discussions until consensus among all authors was reached on the final description of the findings [28].

2.3. Ethics. The study was approved by the board of directors at Aarhus University Hospital. According to the Danish Ethical Committee Law § 14, subsection 2, ethical approval by the Central Denmark Region Committees on Health Research Ethics or by the Danish Committee on Health Research Ethics was not required for this type of study. Written permission to e-mail the questionnaire to the departments' charge nurses was obtained from the senior nurse manager in each hospital department. Information about the study, voluntary participation, and anonymity was provided in the initial e-mail to the charge nurses as well as in the introductory text of the questionnaire. Completing the survey was considered consent to participation. When completing the survey in REDCap, all participant information was anonymised, preventing any direct or indirect identification of individual participants. The study was conducted according to the principles of the Declaration of Helsinki [29].

3. Results

3.1. Part 1: Document Analysis. The Epidemic Act was the legal framework for Denmark's lockdown, which was proclaimed on 18 March 2020 by the Danish Prime Minister. The comprehensive societal restrictions were based on a precautionary approach to prevent the spread of the virus [30]. The document analysis showed that, when changes were decided by the Ministry of Health, restrictions were carried into effect via an administrative cascade (Figure 1).

The Danish Patient Safety Authority instructed the Regional Councils in the five Danish regions to issue orders to restrict relatives' access to public and private hospitals. From the Regional Councils, the restrictions were passed on to hospitals' boards of directors and from there to all hospital heads of department. They, in turn, communicated the restrictions to their charge nurses. At the endpoint of the administrative cascade, frontline healthcare professionals carried the restrictions into effect in their clinical practice. In addition, hospital administrations took steps to continuously update the regional and hospital-based electronic guidelines on visitor restrictions and to post information about restrictions on the hospital's web page.

The visitor restrictions were clarified, loosened, or tightened eight times between March 2020 and April 2021 (Figure 2), reflecting the fluctuating infection rates. In March 2020, in the early days of the first wave, Denmark went into lockdown, which led to a strict no-visiting policy at the hospitals. One month later, this general protective measure was clarified by defining the term "close relative" as family in a straight line or, according to a specific assessment, a close relative. Furthermore, the term "minors" was defined as a child under the age of 18. Also, if a patient suffered from cognitive impairment, it was considered a critical reason for still allowing family visits.

Due to a decrease in infection rates in June 2020, two relatives were allowed to visit all patients, and in July, all restrictions were lifted. In cases of future local increases in infection rates, temporary restrictions applying to the affected regions only could be issued. Due to a local increase in

the infection rate in August 2020, only one visitor per patient was allowed at our hospital. One month later, the local infection rate was acceptable, and consequently, the visitor restrictions were lifted. Still, all visitors were instructed to wear a face mask during their entire hospital visit. In November 2020, the second wave hit Denmark, and once again the visitor restrictions were tightened, allowing visits from one close relative only. The high infection rates faded three months later, and visitors were once more allowed in hospitals. However, hospital-based restrictions could still be issued if the physical surroundings of a ward or unit did not allow for keeping a two-meter social distance.

3.2. Part 2: Cross-Sectional Survey. Out of 88 charge nurses, 71 responded, yielding a response rate of 81%. Nearly all the responding charge nurses were women, and more than half were 50 years or older. They were employed in 29 different departments and primarily from bed wards. Nearly 50% of the charge nurses had more than 10 years of experience as a nurse (Table 1).

3.2.1. Multiple-Choice Questions. During the first and second wave, most often the charge nurses were informed about the current visitor restrictions by the hospital board of directors, their head of department, by regional electronic guidelines, and from the hospital intranet (Table 2). Overall, this information was passed on to the staff at daily meetings and through newsletters and work e-mails. During the first wave, 68% of the charge nurses found the wording of the visitor restrictions clear or very clear and during the second wave it was 86%. One-third of the charge nurses found it challenging to handle the restrictions in practice. During the first wave, 68% of the charge nurses stated that they deviated from the restrictions weekly, or even daily, and during the second wave, it was 74%. No differences in the pattern of responses were found between the first and second waves of the COVID-19 pandemic.

3.2.2. Open-Ended Questions. The qualitative findings complement the results described in Table 2. One of the charge nurses reflected, "We were creating the path while running," and this specific quote summarizes a wide range of the charge nurses' experiences during the hospital's visitor restrictions, as summarized below.

The charge nurses' doubts about the restrictions were mostly related to insecurity about how best to apply the general restrictions in the specific clinical setting of their unit. During the first wave of the pandemic, they gradually realized that there was room to manoeuvre with supplementary professional considerations to safely deviate from the general restrictions in specific patients' cases. Handling restrictions challenged relations and collaborations both within and outside the ward and required substantial communication efforts from the charge nurses.

Being prepared was a subject commonly mentioned by the charge nurses, in terms of thinking ahead and using virtual and written materials to support communication

Visitor restrictions	Clarifications	Loosening	Loosening	Local tightening	Local loosening	Tightening	Loosening
No visitors allowed in hospitals. Exceptions: 1. Close relatives of the critically ill. 2. Parents of minors. 3. Giving birth. 4. Other heavy-weighted reasons for an urgent visit.	1. Close relatives were defined. 2. 'Minors' were defined. 3. Other heavy-weighted reasons were clarified.	1. Possibility of visits in outdoor areas. 2. One or two designated visitors indoor. 3. Possibility for the patient to participate in home visits.	1. Visits to patients can be made without any restrictions 2. The Danish Agency for Patient Safety is given the opportunity to issue temporary local restrictions.	1. One visitor per patient. 2. Children and young people allowed up to two visitors. 3. All visitors must wear masks.	1. No visitor restrictions and no requirements for masks (loosening from the Danish Agency for Patient Safety to the Region).	1. Visit of one close relative defined as family in straight line (permission for the Region to issue deviations). 2. Up to two relatives of children.	1. Visits could be made without any restrictions beside wearing masks. 2. The two-meter distance requirement could lead to local tightening on the number of visitors.

with patients and relatives. In addition, providing more context-specific information on restrictions was a suggestion for reducing conflicts with relatives. The importance of leadership was evident for the charge nurses, and some highlighted values such as trust, human relations, and common sense in the process of making decisions about visiting.

During the pandemic, it became a basic condition for charge nurses to handle varying visitation restrictions. A clear and concrete information flow was vitally important, and when the information was delayed or not well-synchronised with information given to the public, it caused confusion and disturbances among staff. The charge nurses described how restrictions had both upsides and

downsides for both staff and patients. Furthermore, the physical surroundings of the wards limited the possibilities for deviating from restrictions.

4. Discussion

Restrictions were communicated in an effective administrative cascade from the Danish Ministry of Health and further on to charge nurses, who led their implementation in each hospital unit. The majority found the wording of the restrictions clear, while one-third found them challenging to handle. Both upsides and downsides to the absence of relatives were identified. To balance the needs of patients, relatives, and staff against the need to prevent the spread of the virus, the charge nurses gradually developed ways to deviate from the restrictions. Communication, collaboration, and leadership were experienced as key tools in the processes of adapting shifting restrictions.

4.1. Information Pathways and Communication. The study showed that the information pathway through the Danish healthcare system was considered transparent and coherent

during the first year of the pandemic. Along the way, eight shifts in visitor restrictions were made. According to the Organization for Economic Cooperation and Development (OECD), in the OECD Digital Government Index 2023, Denmark was ranked second-best among 38 countries [31]. Also, in the Digital Economy and Society Index 2021, published by the European Commission, Denmark was ranked first [32], indicating a solid digital infrastructure in public governance and that digital skills are generally high among the Danish population. This probably laid the groundwork for the effective digital communication cascade from national guidelines to frontline nursing practices in our hospital. In the current study, the charge nurses found the wording of the visitor restrictions clear, or even very clear. In contrast, Harrison et al. conducted a study scanning policy documents and websites describing COVID-19 adult inpatient visitor restrictions at 70 American medical centres [33]. They found that the information was unclear, inconsistent across the centres, and lacked important details. However, even if the Danish charge nurses generally found the wording of the shifting restriction policies clear, enforcing them was still a complex task when confronted with patients and relatives who perhaps were not informed

to the same degree of detail. The charge nurses suggested that should another pandemic occur, the Danish public should be better informed that differing physical surroundings in hospital units would allow differing levels of restrictions.

The importance of communication in handling and implementing the visitor restrictions cannot be overstated. Effective communication is critical to managing any crisis or public health emergency, and COVID-19 has been no exception. In the current study, one-third of the charge nurses found it challenging to manage the visitor restrictions in practice. As shown in Tables 3–5, several challenges were related to communication in the unit and the hospital organization as well as with patients and relatives. In another Danish study, hospital charge nurses with formal management education and leaders with more than five years of experience more effectively managed the COVID-19 situation [13]. In the current study, testing a possible association between years of experience as a charge nurse and their perceptions of the challenges related to managing the shifting visitor restrictions could provide valuable insights. However, the limited sample size of 71 charge nurses precluded such analysis. Therefore, larger studies are needed to investigate this relation.

Leadership has been defined as "... the process of influencing others to understand and agree about what needs to be done and how to do it, and the process of facilitating individual and collective efforts to accomplish shared objectives" [34]. One of the key components in leadership is clear and timely communication. As healthcare environments are complex webs of people and resources, communication processes need to extend upwards and laterally within the organization [35]. Simonovich and colleagues described the importance of effective communication in nursing practice across three levels during the pandemic: organizational leadership, unit leadership, and nurse-to-nurse communication [36]. Furthermore, during the pandemic, the important communication with patients and relatives about the shifting restrictions and their implications for the practice in each unit represented a fourth level of communication. Complex examples of communication-related to all four levels are reflected in the current study. As illustrated, handling the restrictions challenged relations and collaborations both within and outside the ward and required substantial communication efforts from the charge nurses. It is one of many examples that the COVID-19 crisis has presented exceptional challenges for charge nurses.

4.2. Managing Shifting Visitor Restrictions. In Denmark during the pandemic, the approach to restrictions changed from being general to more specific and local. When hospitals were allowed to welcome visitors again, it was up to each department to decide the number of visitors allowed, according to their social distancing requirements. At the beginning of the pandemic, from March through May 2020, no visitors were allowed access to the hospitals. In the US, visitor restrictions were more local. Harrison et al. reported that, across 70 medical

centres, visitor restrictions varied during a similar period [33]. Seventeen percent did not allow any visitors, and 73% allowed one visitor while the last 10% did not describe the number of visitors allowed. For hospitalised patients with COVID-19, 63% of the centres outlined visitor policies different than those for patients without COVID-19. In contrast, the visitor restrictions in Denmark applied to all hospitalised patients, whether suffering from COVID-19 or not. However, the consistency in visitor restrictions in Denmark was probably due to the size of the Danish healthcare system compared to the American system.

Almost all charge nurses in our study deviated from the restrictions in force. Deviations from the restrictions were wide-ranging in our study, even in an international context. The efficiency of the digital communication cascade from national guidelines to frontline nursing combined with charge nurses' communication and leadership practices may have allowed for a high level of flexibility in managing the visitor restrictions in the individual units. We found the charge nurses deviated from the restrictions to allow relatives of both hospitalised adults and child patients to visit. Across 23 states in the US, exceptions to visitor restriction policies during the COVID-19 pandemic were found in 63 out of 65 hospitals [37]. Setting-specific exceptions included paediatrics, obstetrics/gynaecology, emergency departments, behavioural health, inpatient rehabilitation, surgery, and outpatient clinics. In paediatric units across 36 hospitals in the US, 97% of the units allowed at least one visitor, which underlines how parents are considered the most essential partners in the care of a child [38]. In our study, the charge nurses described exceptions in similar types of settings and further added geriatric wards and intensive care units. Similar results were found in a study of Scandinavian intensive care units [39]. Furthermore, across the different settings, the charge nurses identified patients suffering from a variety of cognitive deficits as one group of patients in particular need of support from their relatives, both when hospitalised and during outpatient treatment. This is an indication that, most likely, all types of clinical settings experienced how the support and involvement of relatives was needed in a wide range of patient pathways; this requires a continued postpandemic nursing focus.

From a societal perspective, deviating from the restrictions to meet complex needs of patients and relatives could be seen as an admirable act of compassion. On the other hand, if deviating could increase the risk of spreading the virus, it could also be seen as a risky practice opposing the general and organizational policies and jeopardizing the health of patients, relatives, and staff. When judging the charge nurses' practice, the relatively low level of total cumulated COVID-19-related deaths in Denmark of 143 per 100,000 people [40] should be considered. Furthermore, as highlighted above, the charge nurses "were creating the path while running." During the first wave, when knowledge about the disease increased and more protective equipment became available, they gradually learned there could be room to manoeuvre to safely deviate from the restrictions in specific patients' cases.

TABLE 3: Summary of findings from open-ended question 1.

Open-ended question 1: Did you have any doubts about the visitor restrictions, and if so, how were you able to clarify your doubts?	
Category	Illustrative analytic points
Identifying particularly critical situations	(i) Doubts occurred in particularly critical situations related to the care of, for example, dying patients, patients suffering from cognitive deficits, the critically ill, parents of a child or adolescent patient, or young siblings. Also, when staff had to discuss critical treatment issues with a patient, the charge nurses would have preferred relatives to be present. (ii) During the pandemic, increased knowledge of the disease and the availability of more protective equipment allowed charge nurses to safely deviate from the restrictions in certain patients' cases
Clarifying doubts through communication	(i) The charge nurses discussed uncertainties with their heads of department, fellow managers, ward staff, patients and relatives, the hospital hygiene team, or the hospital's corona hotline (ii) Clarifying doubts was time consuming
Leadership and collaboration	(i) Sometimes the restrictions were managed with variations, causing confusion and frustration among patients, relatives, and staff, such as when a patient was transferred from one ward, department, or hospital to another. This was a challenge to the relationships between staff and patients or relatives and to the collaborations among units, departments, and/or hospitals. (ii) The charge nurses found some nurses fully capable of making decisions about deviating from the general restrictions, and they seemed comfortable doing so. Other charge nurses experienced that the nurses wanted the charge nurse to make the decision about visiting in each patient's case, to feel protected by her authority.

TABLE 4: Summary of findings from open-ended question 2.

Open-ended question 2: As a charge nurse, is there anything you would do differently, if a similar situation should occur in the future?	
Category	Illustrative analytic points
Being prepared	(i) The evolving pandemic and the rapidly changing guidelines made the charge nurses feel a step behind things, as leaders. Thus, in a future situation, they wanted to be better at thinking through and planning different scenarios, so they could be ahead of things and reduce stress. (ii) The charge nurses would have liked to be better prepared for virtual communication with relatives, including having the relevant electronic equipment at their disposal (iii) Further use of posters and information pamphlets explaining the restrictions in specific contexts, such as single/multi-bed rooms, intensive care units, wards, or outpatient clinics would have been helpful
Enforcing precise communication and transparent leadership	(i) Some charge nurses reported that it would have been nice if it had been made more clear to the public that the physical surroundings differ among wards, and consequently wards need to have differing restrictions. Highlighting this information might have reduced conflicts with relatives who did not understand the restrictions. (ii) Some charge nurses wondered if an information dissemination task force would have been helpful (iii) To avoid unnecessary issues related to interpreting and acting upon the restrictions, the charge nurses described the need for transparent leadership and communication in the organization, both upwards and downwards
Worrying less when deviating from visitor restrictions	(i) The charge nurses had accepted that, when applying visitor restrictions, "one size does not fit all." After some time, they worried less about making compromises when balancing rules and humanity. (ii) Some of the charge nurses suggested trusting the frontline nurses' professional assessments more and using common sense for the sake of the patients

4.3. *Supporting Patients and Relatives.* Our findings show that, during the serious health crisis of the pandemic, acknowledging the value of family bonds and the role of relatives has been an incentive for the charge nurses to prioritise relatives' presence or to facilitate alternative means

of communication. Thus, national restrictions do not seem to capture the complexity at the individual level. Moral distress can occur if an individual is unable to act in accordance with their moral judgment owing to external barriers [41]. The charge nurses reported frequently

TABLE 5: Summary of findings from open-ended question 3.

Open-ended question 3: Is there anything else you would like to add?	
Category	Illustrative analytic points
Delays in the information flow	(i) Information from the hospital's administrators should be clear and concrete, directing fast production of ward-based guidelines (ii) Although charge nurses learned to live with delays in the information flow, it caused anxiety among patients, relatives, and staff, with the latter often having to cope with disturbances that might have been avoided
Upsides and downsides to the absence of relatives	(i) When relatives were not allowed access to the wards, they did not interfere with staff in the timing of their professional work (ii) Relatives' absence left the ward environment more tranquil for both patients and staff, which was described as a relief (iii) Relatives' absence allowed the patients to rest and recover more (iv) Normally, relatives represent a valuable supplementary resource in everyday nurse-patient collaborations, as many things are not possible if the relatives cannot participate (v) When adhering strictly to the restrictions, it was difficult for staff to be confronted with the sadness and powerlessness of patients and relatives
The continued managing of social distance requirements	(i) Even when restrictions were loosened, the requirements regarding social distancing still applied, challenging the arrangement of the physical surroundings of the wards

deviating from the national restrictions as they sought to weigh the interests of the individual patient and his or her relatives against the existing visitor restrictions. Other studies have reported high levels of moral distress among staff witnessing the suffering of patients and relatives who were separated [2]. Obviously, hospitals must ensure the safety of both patients and staff, and the more visitors allowed in the hospital, the more difficult social distancing becomes [42]; however, Valley et al. question whether no-visitor policies are essential for infection prevention at all, and to what extent restricted visitation might unintentionally foster poor patient health outcomes [43].

If visitors are allowed during a pandemic, hospital units need resources to provide personal protective equipment for visitors, and to patients and staff [44]. In Denmark, protective equipment supplies were scarce during the first wave, and staff were not yet fully trained to apply them, likely causing a general reluctance to allow relatives to visit. However, the charge nurses gradually realized there was room to manoeuvre in specific patient cases, if doing so was expected to significantly improve the quality of care. Downar and Kekewich proposed that healthcare organizations adopt a new end-of-life visitor policy that reduces restrictions overall without necessarily putting patients, staff, and family members at an increased risk of COVID-19 transmission [45]. Selman et al. also have recommended advanced care planning that includes regular communication with family members, accurate information provision, support of virtual communication, and enabling family members to say goodbye in person where possible [46]. In the current study, this was what the charge nurses did when adjusting the national restrictions to the local context of their units.

Recent literature on total visitor prohibitions at hospitals during the COVID-19 pandemic describes how palliative care patients, critically ill patients, children, and cognitively impaired patients need alternatives to the support provided

by relatives accompanying outpatients to hospital appointments, or when visiting inpatients. Kuntz et al. found that the efficient application of telemedicine for family e-meetings can be feasible and effective for decision making related to dying patients and their families [47]. Selman et al. also recommend applying digital communication strategies to meet the needs of patients and relatives [46]. In a study from an American intensive care unit, a dedicated facilitator helped schedule calls and coordinate virtual communications to reduce the frustrations for patients, family, and HCPs [48]. In our study, the charge nurses would have liked to have been better prepared for virtual communication with relatives, including having the relevant electronic equipment at their disposal. Similar findings have been reported from China [44]. We believe that now, that the pandemic is over, digital communication tools will still be useful to further facilitate the participation of relatives in important hospital conversations if the relative lives far away from the hospital or perhaps is at work at the scheduled time of the conversation.

The charge nurses described how the absence of relatives shed light upon both downsides and upsides to relatives' absence. They also realized that "one size does not fit all." In the years to come, perhaps these experiences from the pandemic will inspire hospitals with open visiting policies to develop more differentiated visiting policies, welcoming relatives' presence in some units and perhaps limiting their presence in others, to better protect the patients' interests. Nurses may play an important role in balancing the needs of individual patients with the needs of visitors [49]. Nurses' role as a gatekeeper in a flexible visitation practice has also been described in a study of intensive care units [50]. To promote a family-centred approach, it is essential to involve patients and relatives in the process of designing the hospital visiting policies of the future.

4.4. Strengths and Limitations. This study has certain limitations. In a document analysis, the selection of documents relies on existing information and may introduce bias as certain materials may be more readily available. Also, the documents may lack the context necessary for a comprehensive understanding [51]. However, the Danish authorities and hospitals constantly updated the population with the most recent announcements. The continuous updating could have brought some difficulties accessing previous information on visitor restrictions that had been adjusted or even changed.

The survey allowed us to collect data from 81% of the hospital's charge nurses. Still, nonresponse bias could occur as the sample did not represent the entire group of charge nurses [52]. As it is a single-site study, the results from the survey cannot be considered representative of all charge nurses in Denmark. Still, as the study was carried out in the largest hospital in the country, the data most likely show some general tendencies. However, the results of the survey may not be generalisable to other situations or settings beyond the research context [53].

The questionnaire was developed for the current study as no existing questionnaire was available. Several initiatives were taken to test the quality of the questionnaire, including double testing of the content of the questions, wording, and layout with several charge nurses, ensuring face validity of the questionnaire [54, 55]. The charge nurses' validation feedback encouraged the authors to include all types of units, especially outpatient clinics and same-day surgery units, which created a more complete dataset. Using face-to-face interviews instead of the electronic questionnaire may have provided more detailed data and in-depth elaboration on the open-ended questions. However, considering the fluctuating infection rates during the study period, this method was not considered feasible. The questionnaire was distributed 14 months after the first wave of the pandemic struck in Denmark. Charge nurses' recollections about the first wave may have induced a systematic error blurred by experiences and behaviours from the second wave causing recall bias [56]. However, the charge nurses seemed to have distinct memories from each of the two waves.

5. Conclusion

In Denmark, during the first year of the pandemic, hospital visitor restrictions gradually changed from general to becoming more locally and individually adjusted. A well-organized digital public healthcare information cascade supported the process. Although the information about visitor restrictions was passed through several management levels in the Danish healthcare system, the information generally reached the charge nurses quite effectively.

The charge nurses were informed primarily through other levels of the hospital organization. Even if they generally found the wording of the visitor restrictions clear, one-third found them challenging to handle in practice. Enforcing the restrictions challenged relations and collaborations within and outside the units and required substantial communication efforts from the charge nurses.

When making decisions about visiting, trust, human relations, and common sense were highlighted as important leadership values.

The charge nurses played a significant role in balancing the needs of patients, relatives, and staff while managing visitor restrictions during the COVID-19 pandemic. When the charge nurses had to balance general restrictions against the individual needs of patients and relatives, professional nursing values were challenged, and the pandemic has shed light upon downsides as well as upsides to the absence of relatives. Increased knowledge of the disease and the availability of more protective equipment enabled the charge nurses, through professional considerations, to gradually deviate more from the general restrictions in specific patients' cases. Seven out of ten charge nurses deviated from the restrictions weekly or daily.

6. Implications for Nurse Managers

In some cases, separation of patients and their closest relative is a paramount burden. When charge nurses deviate from visitor restrictions during a pandemic for the sake of patients and closest relatives, the consequences can extend beyond the immediate healthcare setting with positive as well as potentially negative implications for both the individuals involved and the healthcare institution. The charge nurses' experiences from the pandemic can contribute to further qualifying nurse managers' considerations when designing family-centred hospital visitor policies for the future. Also, they may strengthen the handling of future sudden major organizational changes. Charge nurses require support from both society and hospital managers during a pandemic with visitor restrictions to effectively navigate the challenges they face. This support may come in various forms, including emotional assistance, resource allocation, clear communication strategies, and recognition for their vital role in maintaining healthcare delivery.

Data Availability

The data underlying this article can be shared on reasonable request to the corresponding author.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

All authors contributed substantially to designing the study, collecting and analyzing the data, preparing the manuscript, and approving the final version for submission.

Acknowledgments

The authors thank the charge nurses who took the time to respond to the survey during a busy working day. As no external funding was provided, we also thank our heads of department for facilitating the study.

Aim. To develop a scale for measuring nurse's perceived work environment during the public health emergencies (PHEs) and assess its reliability and validity. **Background.** Although there is extensive research on instruments for measuring nursing work environments in regular healthcare settings, there is a lack of specific scales tailored to address the unique work conditions experienced by nurses during PHEs. **Design.** This study employed a cross-sectional design for psychometric evaluation and adhered to the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) statement. **Methods.** A self-report scale, the Chinese Nursing Work Environment Scale for Public Health Emergencies (C-NWE-PHE), was developed, integrating situational characteristics. Data on demographics, adapted scale scores, and subjective evaluations of nursing management performance were collected from 1156 nurses through online surveys conducted between January 2023 and March 2023. Confirmatory factor analysis, Pearson correlations, and Cronbach's alpha analyses were conducted to evaluate the psychometric properties of the scale. **Results.** The adapted C-NWE-PHE scale comprised 28 items organized into five subscales: Workforce and Deployment Support, Leadership and Emergency Management, Autonomy and Empowerment, Teamwork and Collaboration, and Logistics and Humanistic Care. Structural equation modelling showed satisfactory factor loadings for each subscale and a good model fit, confirming construct validity. The content validity and reliability of the total scale were confirmed. **Conclusion.** This study provides empirical evidence for understanding and assessing the nursing work environment during PHEs with a psychometrically sound scale. **Implications for Nursing Management.** The C-NWE-PHE scale, along with its five identified constructs, provides a nuanced comprehension of working conditions amid PHEs. Implementing this scale could foster specific enhancements, support nurse retention efforts, and enhance the effectiveness of responses during challenging emergency situations.

1. Introduction

The COVID-19 pandemic has sparked widespread discussions regarding the burnout and psychological well-being of nurses [1–3]. These issues have had a significant impact on nurses' commitment to the nursing profession and their contributions to fighting against public health emergencies (PHEs) [1, 4]. Nurses worldwide have reported experiencing

a poor work environment during the pandemic, resulting in negative work outcomes, low job satisfaction, and increased turnover intentions [5, 6]. Numerous studies have provided compelling evidence that establishing a healthy work environment is an effective strategy for mitigating job burnout, retaining nurses, and promoting sustainable development [7–9]. Given the urgency of the matter, it is vital to explore the concept, core components, and assessment tools to guide

investments in establishing supportive environments at the organizational level [5, 7, 10–13]. These initiatives should be specifically tailored to crisis management contexts and encompass generalizable managerial strategies to enhance nurses' contributions to respond to future PHEs.

Public health emergencies (PHEs) are characterized by their causes and events that pose a threat to overwhelm routine capabilities due to their scale, timing, or unpredictability [14]. The recent COVID-19 pandemic serves as a prime example of a PHE that requires international attention and emergency response [10, 12]. PHEs have underscored the importance of specific working conditions, policies, health regulations, and operational practices in effectively addressing the challenges [15]. Measures taken by various countries, such as establishing designated hospitals, mobile cabin hospitals, and temporary treatment centres, have played pivotal roles in strengthening healthcare system capacity and capabilities during the COVID-19 pandemic [15–17]. Alongside expanding functional capabilities, there have been suggestions for enabling multisectoral organizational strategies and mobilizing human resources to enforce health security capacities worldwide [15, 18]. However, these measures have also introduced additional complexities for organizations, particularly in terms of ensuring nurse engagement, supporting their well-being, and fostering sustained commitments. To prepare healthcare systems for PHEs, it is important to optimize the work environment, improve the work performance, and enhance the well-being of nurses.

The nursing work environment is a multidimensional concept that significantly influences nursing practice and patient outcomes [19]. Researchers have labelled its concept domains differently, such as work values, nurse satisfaction, perceived productivity, organizational traits, autonomy, control, collaborative relationships, patient-centred care, and organizational support, etc. [20–22]. Nurses' perceptions of their working environments during the COVID-19 pandemic have been extensively explored through qualitative interviews, revealing significant challenges such as increased workload, safety concerns, emotional stress and burnout, inadequate resources, and professional and personal sacrifices [3, 23–25]. Nurses have made remarkable displays of resilience and adaptive capacity, with factors like camaraderie, recognition, and appreciation playing a vital role in mitigating the impact on their well-being [26, 27]. To enhance working conditions and prioritize initiatives, practical actions should be taken, such as ensuring staff adequacy, competence, empowerment, and equitable distribution [27–30]. Additionally, the six Pathways to Excellence Standards, which include shared decision-making, leadership, safety, quality, well-being, and professional development, were developed and implemented [27]. However, there is still a need for a comprehensive understanding of how emergency response and managerial strategies affect the practice environment and nurse outcomes during PHEs [27, 31, 32]. Effective measures that incorporate accountability-oriented evaluations can enable external comparisons and internal efforts for improvement [14]. To gain deeper insights into the work environment during

PHEs, quantitative approaches are necessary, providing a solid foundation for assessments and understanding their impact on nurse performance, thereby informing strategies to improve nursing practice and outcomes.

Previous literature reviews on measuring work environments have highlighted that existing questionnaires primarily focus on general hospital settings and evaluate physical environments within healthcare facilities [20, 33]. However, emerging evidence in the COVID-19 era underscores significant differences in nurses' needs and essential support resources, encompassing logistics, emotional well-being, patient care, teamwork, and protective trainings, all crucial elements contributing to a healthy work environment [4, 34, 35]. Moreover, recent studies have demonstrated a noteworthy link between nurses' perceptions of work conditions and job outcomes, including their perceived workload, staffing adequacy, leadership, and overall organizational performance [35–37]. Initial investigations into suitable staffing solutions and their impact on the work environment, utilizing the practice environment index in acute care settings, revealed potential predictive relationships between these variables [4, 38]. As of now, there remains a lack of a specific scale for measuring and assessing work environments in emergency situations related to PHEs. To address this gap, it is practical to adapt a self-reported assessment tool based on previous evidence in measuring nurses' work environment in normal healthcare settings, thereby enhancing domain specificity and addressing situational phenomena [39, 40]. Through modifications in item wording, the scale can be refined to align with the situational context, and further validity evidence can be gathered, typically through confirmatory factor analysis [39]. This strategy allows for the adaptation of an established assessment tool, providing deeper insights into the dynamics of the work environment, particularly within the context of PHEs.

In an effort to comprehensively assess the nursing work environment and provide insights on a global scale, a meticulously developed Chinese Nursing Work Environment (C-NWE) scale was selected for adaptation. Originating in 2010, this scale was constructed based on the principles of the person-environment fit theory and contextual factors. It amalgamated crucial elements from widely used assessments, including the professional practice environment, nursing work index-revised, and practice environment index. After evaluating empirical data within the Chinese context, researchers noticed that the job-demands resources theory, centred on external influences, didn't fully capture nurses' work environment perceptions. Consequently, the C-NWE underwent refinement, integrating the theory of harmony management to enhance the understanding of individual resources, person-environment interactions, and value alignment within the scale. Initially, a 47-item scale was developed [22], aligning with global efforts exploring nursing work environment traits while integrating the influence of nurses' individual values and empowerments on their work environment [41, 42]. For greater usability, the C-NWE was further condensed into a 26-item scale using rigorous statistical methodologies and employed in

a national survey covering eight economic regions [43]. This extensive survey gathered data from 19,000 nurses across 31 provinces in mainland China [9, 43], demonstrating robust psychometric properties and considerable efficiency. The 26-item version retained elements such as professional development, clinical autonomy, salary and welfare, recognition of value, while further refining aspects related to staffing adequacy, support and care, and nurse-physician relationships, thereby improving the reflective nature of person-environment interactions. These foundational constructs provide a solid theoretical framework for the current study, guiding the analysis of data pertaining to nurses' perceived work environment during the COVID-19 pandemic.

This study seeks to address the complexities of the nursing work environment concept, especially within the context of PHEs and organizational strategies geared towards effective responses to such crises. The primary objective is to construct a dependable scale for assessing nurses' perceptions of their work environment during PHEs. Validating this scale through empirical survey data will establish a robust framework for understanding the underlying theoretical concepts. This comprehension could facilitate targeted improvements in the nursing work environment, ultimately bolstering nurse retention rates and promoting well-prepared and efficient responses to future PHEs on a global scale.

2. Materials and Methods

2.1. Design. Following Heggstad's practical guideline [39], we implemented a systematic approach to adapt a measurement scale within the situational context of the items, known as scale adaptation. The initial phase aimed to generate the scale items and accurately measure the underlying construct in the target situation. Subsequently, in the second phase, we focused on reporting supporting validity evidence specifically among nurses who had experienced an appropriate level of crisis exposure. The study findings were reported in accordance with the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) statement [44].

2.2. Scale Adaptation

2.2.1. Item Generation. The C-NWE underwent a comprehensive redesign to cater specifically to the unique challenges posed by PHEs, resulting in the creation of the C-NWE-PHE (Chinese Nursing Work Environment Scale for Public Health Emergencies). The refinement was necessitated by the need to distinguish between a typical hospital nursing work environment and the specific demands of organizational traits for responding to an event of PHE. To thoroughly understand the situational context, an integrative literature review on nurses' experiences during the COVID-19 pandemic was conducted (unpublished), incorporating expert views and identifying the core competencies of nursing professionals in public health emergencies [45]. Specific items were generated from qualitative data obtained through semistructured interviews, enabling

a secondary analysis of 17 nurse managers' experiences with crisis exposure to identify scale constructs. The goal of this process was to adapt the content of the C-NWE scale to accurately reflect emergency-specific traits and working conditions [39]. The generated 28 items were then theoretically categorized into five factors using thematic induction. The research team sought the expertise of nine researchers knowledgeable in nurses' response to PHEs and seven experts to thoroughly review and enhance the alignment between the research instrument and the contextual factors. As a result, a 28-item C-NWE-PHE scale was used for validation research. The scale response options and scoring rules in the current study remained consistent with the 26-item C-NWE scale, ranging from strongly disagree to strongly agree.

2.2.2. Content Validity Verification. A panel of seven experts, consisting of five nursing professors (senior clinical scientists) and two clinical nursing deputies, was invited to evaluate the content validity of the C-NWE-PHE scale. The Delphi survey included the original 26-item C-NWE scale and an overview of its subscales, the 28-item C-NWE-PHE, and an assessment form for content equivalence. Each expert was asked to rate the relevance of each item using a scale ranging from 1 (not relevant) to 5 (very relevant and succinct). Additionally, the experts were requested to provide demographic information, such as their education level, working experience, research areas, and familiarity with the scale's topic, via e-mail. The response rate was 100%, with all experts returning the evaluation surveys. To ensure the reliability of the assessment, three coefficients were calculated: the expert familiarity coefficient (Cs) and expert judgment coefficient (Ca), which yielded values of 0.91 and 0.94, respectively. Moreover, the expert authority coefficient (Cr) was determined to be 0.93, exceeding the threshold of 0.7, indicating an acceptable level of agreement among the experts [46]. Based on the experts' feedback and assessments, the research team conducted a rigorous comparison and discussion of the results to achieve consensus and identify any necessary revisions. Subsequently, an initial version of the C-NWE-PHE scale was developed for a preliminary survey among nurses.

2.2.3. Preliminary Survey. Following the cognitive validity assessment approach [40], a trained investigator invited and recruited 10 nurses who were actively serving on the frontline during the COVID-19 pandemic. These nurses were requested to evaluate the scale from a cognitive standpoint, offering detailed feedback on the comprehensibility of the scale items, relevance to their perceived work environment, and the convenience of the distribution platform employed for data collection. It took approximately 14 minutes to complete the survey.

2.3. Scale Validation. The validation process commenced with workshop discussions and was carried out in a scale-specific manner. Adhering to practice recommendations

[39], we ensured the verification of the scale by employing a fixed set of items, a predetermined response scale, and carefully crafted instructions. We sought responses from nurses with first-hand working experience to ensure the relevance and validity of the scale. The implementation protocol for survey distribution underwent refinement through three rounds of workshops, each involving 10 members. This process resulted in a rigorous validation approach that aligns with the research objectives.

2.3.1. Participants. Using purposive sampling approach, a skilled investigator facilitated the recruitment process and identified eligible nurses who met the following criteria: (1) registered nurses employed full-time in Shanghai tertiary hospitals, (2) possessing at least one year of work experience in current hospitals, (3) having prior experience with and exposure to public health emergencies such as the COVID-19 pandemic, earthquakes, Ebola, SARS, etc., and (4) expressing willingness to participate in the survey.

2.3.2. Instruments. The C-NWE-PHE scale, along with a demographic questionnaire and four subjective questions, was employed to assess the work environment and performance of nursing management from the perspective of nurses. The demographic questionnaire collected information on age, religion, education level, job position, job tenure, workplace, and frontline experiences of eligible nurses. The 28-item C-NWE-PHE scale was presented in a digital format, requiring respondents to rate workplace characteristics on a 6-point scale ranging from 1 (strongly disagree) to 6 (strongly agree), consisting with the rating approach of the original 26-item C-NWE scale.

2.3.3. Data Collection. Between January 2023 and March 2023, a user-friendly digital platform called Chao Xing was utilized for data collection. Chao Xing operates as a mobile learning system, comprising platform and application terminals. It includes features such as a community announcement board and a survey or evaluation mode, accessible through individual user accounts and passwords. This period followed the strict lockdown in Shanghai city experienced by nurses from April 2022 to June 2022, as well as subsequent policy changes. The data collection process was facilitated by a collaborative effort involving three investigators and one data engineer who designed a logically structured digital survey. Each user was permitted to complete only one survey, identified through IP and account authentication. The survey, including a digital survey link, inclusion criteria, and participant consent, was distributed to 12 affiliated hospitals nurses but anonymously to their nursing managers to avoid report bias. To ensure the integrity of the study, researchers maintained a blind approach to the data collection process.

2.4. Data Analysis. Data management was conducted using Excel, and analysis was performed using SPSS 28.0 and SAS Studio software. Two-tailed tests were conducted with

a significance level set at $P < 0.05$. Descriptive analysis was utilized to report the mean and standard deviation (SD) for continuous variables and percentage frequency for categorical variables. Scale validation was conducted following the COSMIN (Consensus-based Standards for the selection of health status Measurement Instruments) checklist [47]. Content validity, including face validity, was evaluated based on expert ratings using the item-level content validity index (I-CVI) and the average scale-level content validity index (S-CVI/Ave). Construct validity was assessed through confirmatory factor analysis (CFA) using structural equation modelling (SEM). Criterion validity was examined by calculating Pearson's correlation coefficients to assess the relationship between C-NWE-PHE scores and quantitative data on the overall assessments of nursing management performance. Reliability analysis included testing the homogeneity of items using Cronbach's alpha, and test-retest reliability was assessed using the intraclass correlation coefficient (ICC) with a two-way mixed-effects model and a consistency definition [48].

2.5. Ethical Considerations. This study was performed in accordance with the Declaration of Helsinki. Ethical approval was obtained from the ethics committee of a university-affiliated hospital (Approval No. RA-2022-397), and the investigation protocol involving 12 affiliated hospitals was approved by the ethics committee of a university (Approval No. SJUPN-HY-202304-3-KS1). All participants gave written informed consent through a digital platform before their inclusion in the study.

3. Results

3.1. Characteristics of the Study Participants. Out of the 3000 nurses invited from 12 tertiary hospitals, a total of 1156 nurses participated and 1059 nurses (91.61%) provided valid responses for the data analysis. As shown in Table 1, the average working experience of the participants was 9.2 years. Most of the participants were female (86.8%) and held primary job positions (82.8%). Most nurses were required to work at least 5 hours per day (60.0%) and fewer than 5 days per week (75.2%). The two most common workplaces were designated hospitals (32.6%) and Fangcang shelters (29.7%).

3.2. Description of the C-NWE-PHE. Figure 1 illustrates the internal structure of the C-NWE-PHE scale, comprising a five-factor solution, which underwent validation by the expert panel and tested through CFA. Drawing from the qualitative interview data and its conceptual interpretation, the key component of each item was presented. Each factor consisted of a varying number of items, ranging from four to six.

The five identified subscales were named in alignment with a comprehensive understanding of the nursing work environment as follows: Workforce and Deployment Support ($F1$), Leadership and Emergency Management ($F2$), Autonomy and Empowerment ($F3$), Teamwork and Collaboration ($F4$), and Logistics and Humanistic Care

TABLE 1: Characteristics of the participants ($n = 1059$).

Characteristics	Participants (n)	(%)
Years of experience (mean, SD)		(9.2, 7.7)
Sex		
Female	919	86.8
Male	140	13.2
Title level		
Primary	877	82.8
Intermediate	169	16.0
Deputy senior or above	13	1.2
Workload		
0–4 hours per day	382	36.1
5–8 hours per day	576	54.4
9–12 hours per day	97	9.2
13 hours and above per day	4	0.4
Workdays		
≤5 days per week	796	75.2
>5 days per week	263	24.8
Workplace (ever and current)		
Local residence community	112	10.6
Fangcang shelter	315	29.7
Public health centre	61	5.8
Designated hospital	345	32.6
Customs airport	20	1.9
Hainan province	176	16.6
Wuhan city	27	2.5
Other places	200	18.9

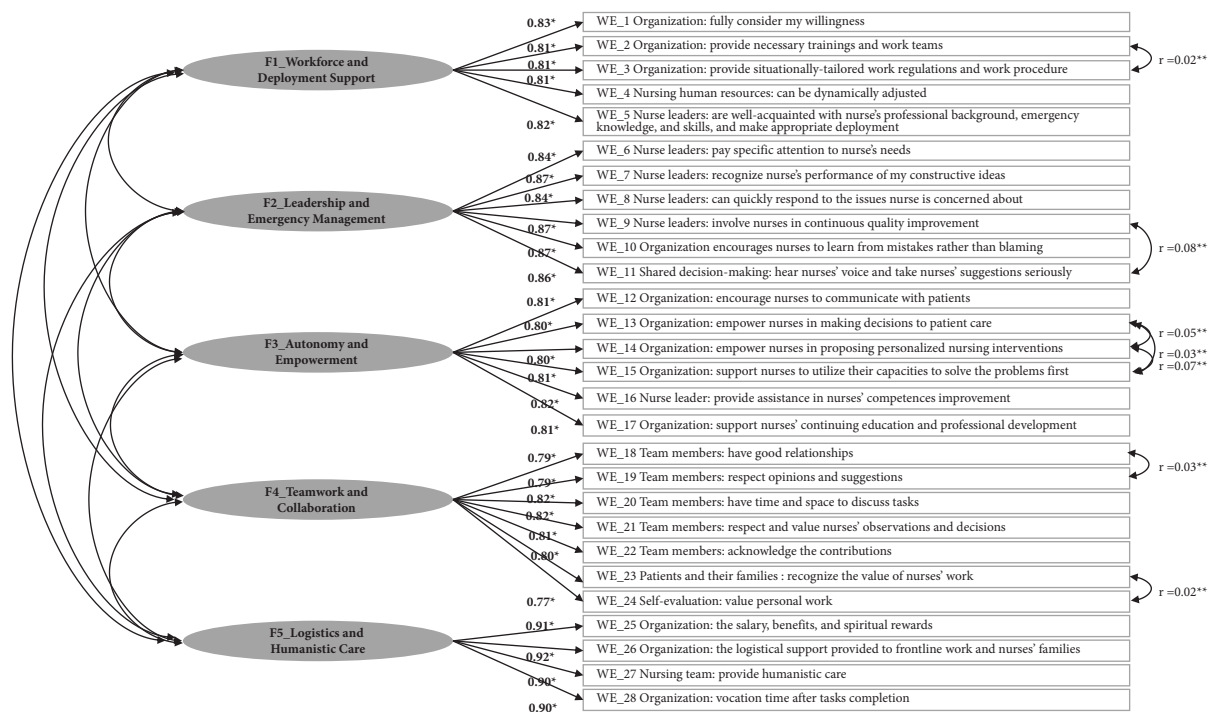

FIGURE 1: Construct of the Chinese nursing work environment scale for public health emergencies. * denotes the factor loading of each item within the corresponding theoretical factor; ** denotes the covariance parameters identified and added to the model.

(F5). Applying the SEM method, the factor loadings of items to each subscale were found to be 0.81–0.83 for F1, 0.84–0.87 for F2, 0.80–0.82 for F3, 0.77–0.82 for F4, and 0.90–0.92 for F5. All subscale scores demonstrated

significant loadings on the first higher-order factor (loadings > 0.49), indicating that the C-NWE-PHE scale effectively measures the various constructs of the nursing work environment during a PHE.

3.3. Content Validity. In comparison to the 26-item C-NWE scale, two additional items were added to the 28-item C-NWE-PHE scale: “The organization and the nursing team can fully consider my willingness to participate in emergency rescue work” and “Nursing team can provide situationally tailored work regulations and work procedures.” The C-NWE-PHE scale was validated by a 7-expert panel, showing a good I-CVI range of 0.85 to 1.00 and an overall S-CVI/Ave of 0.93. Notably, 13 items with an I-CVI of 0.85 exceeded the suggested standard of 0.83, requiring only minor revisions based on the experts’ detailed suggestions. For instance, the term “doctors” in all items of the original scale was changed to “team members,” and “salary” was expanded to include salary, benefits, and spiritual rewards in the PHE context.

3.4. Construct Validity. The model validation was based on a hypothesized five-factor solution. Initially, a model with no covariance between any pair of items was tested. Using Lagrange Multiplier (LM) statistics and residual analysis, specific covariance parameters were identified and added to the model, resulting in an enhanced fit. The identified item pairs, along with their respective correlations and significance levels, were as follows: items 2 and 3 ($r=0.02$, $P < 0.001$), items 9 and 11 ($r=0.08$, $P < 0.001$), items 13 and 14 ($r=0.05$, $P < 0.001$), items 13 and 15 ($r=0.03$, $P < 0.001$), items 14 and 15 ($r=0.07$, $P < 0.001$), items 18 and 19 ($r=0.03$, $P < 0.001$), and items 23 and 24 ($r=0.02$, $P < 0.001$).

Figure 1 displays the fit indices of the a priori theorized factor model, yielding the following results: $\chi^2(333) = 1822.480$, $P < 0.001$, with a χ^2/df ratio of 5.47. The comparative fit index (CFI) was 0.97, the Tucker–Lewis index (TLI) was 0.97, the root mean square error of approximation (RMSEA) was 0.07, the standardized root mean square residual (SRMR) was 0.02, the goodness-of-fit index (GFI) was 0.97, and the adjusted goodness-of-fit index (AGFI) was 0.86. These findings indicate that the model demonstrated a reasonably good fit to the data.

3.5. Reliability. Table 2 illustrates the standardized Cronbach’s alpha coefficients for the total score, indicating a high internal consistency, with a coefficient of 0.99 based on 28 items. Cronbach’s alpha coefficient for the subscales ranged from 0.96 to 0.98. Additionally, the test-retest reliability, assessed among 22 nurses over a two-week period, yielded a coefficient of 0.97.

4. Discussion

This study presents an exploration into the characteristics of the nursing work environment during the COVID-19 pandemic, along with initial evidence regarding the psychometric properties of scores on the C-NWE-PHE scale. The refined items of the scale were validated through expert consultation, rigorously tested using the SEM method, and further supported by score validity and reliability analysis. In comparison to the original 26-item C-NWE subscale

designed for stable hospital settings, the C-NWE-PHE subscale identifies distinct characteristics that reflect the dynamic, challenging, uncertain, and unpredictable environments nurses encountered during the PHE. The identified characteristics include Workforce and Deployment Support, Leadership and Emergency Management, Autonomy and Empowerment, Teamwork and Collaboration, and Logistics and Humanistic Care. These concepts emerged from frontline experiences and were consistently observed among nurses throughout the testing process.

4.1. The Factor Structure of the C-NWE-PHE. The structure and characteristics identified in the C-NWE-PHE scale align with the multifaceted definition of the nursing work environment and conceptualize the situational factors specific to PHE contexts that is resource-limited and changeable rather than static and are closely associated with PHE preparedness and response [11, 12, 21, 27, 49]. Moreover, the study revealed robust relationships among the five elements of the nursing work environment, with association coefficients ranging from 0.85 to 0.97. This finding is consistent with previous research that explored the interconnectedness of these elements as challenges, opportunities, and managerial strategies for frontline environments, supporting nurses and promoting organizational performance [50, 51]. The significance of workforce support and effective leadership within the healthcare system is aligned with the achievement of resilience [52].

The Workforce and Deployment Support prioritizes both workforce capacity and allocation practices concerning deployed human resources and necessary work teams. It encompasses the work regulations and procedures for supporting nurses, making institutional support a crucial aspect of nurses’ perception of a safe work environment. A key focus is on the willingness and suitability of allocating and deploying nurses to ensure optimal staffing and operational effectiveness, also as observed during the response to the Ebola outbreak [53]. This finding is highly relevant in the lessons gleaned from the COVID-19 pandemic, particularly regarding public health governance. It underscores the importance of coordinating service delivery, cultivating sustainable health workforces that leverage a diverse range of skills, establishing training pipelines, and implementing effective operating procedures at the organizational, regional, and national strategy levels [16, 18, 54]. Amid varied conditions encountered during the PHEs, witnessed across different countries, the utilization of nursing staff becomes crucial for coping with nursing shortages [6, 29, 37, 55]. This necessitates proactive measures and preparedness efforts, such as educationally prepared and deployment mechanisms, to address challenges that may arise due to administrative processes and the need for clear job descriptions and maintaining work-life balance [30, 56, 57].

The Leadership and Emergency Management subscale focuses on elements that nurses value in nurse leaders’ efforts to foster a shared governance environment. This involves ensuring that leaders are accessible and facilitate collaborative decision-making, creating opportunities for

TABLE 2: Correlations among C-NWE-PHE subscales ($n = 1059$).

Subscales	F1	F2	F3	F4	F5	Alpha
F1 workforce and deployment support	1					0.97
F2 leadership and emergency management	0.94	1				0.97
F3 autonomy and empowerment	0.93	0.96	1			0.97
F4 teamwork and collaboration	0.93	0.92	0.97	1		0.98
F5 logistics and humanistic care	0.85	0.87	0.87	0.88	1	0.96
Overall scale	—	—	—	—	—	0.99

nurses' voices, ideas, and suggestions to be involved and considered. During the pandemic, nursing leadership demonstrated high visibility and responsiveness towards the needs, concerns, suggestions, and contributions expressed by nurses [52, 58]. It is crucial to implement robust measures that unite and motivate nurses, ensuring that their voices are not only heard and respected but also acted upon [59, 60]. This approach to leadership is based on agile and transformative leadership styles, which are more effective in nursing culture compared to a command-and-control style [61]. Furthermore, nursing leadership that extends to higher levels within organizations, health systems, and governments can result in increased resource allocation to support frontline nurses in their work [62]. The significance of effective leadership at all levels of healthcare governance cannot be underestimated, as it plays a critical role in promoting a supportive and responsive work environment for nurses during challenging times like a PHE, as recognized across international experiences [11, 32, 55].

The Autonomy and Empowerment factor ensures that nurses are equipped with the necessary competence to deliver high-quality care to patients while also prioritizing their personal safety. This factor involves providing nurses with ample support for professional learning, recognizing the significant importance of training and reskilling programs, especially during emergency responses [63]. In contrast to the conventional approach of fostering a positive practice environment through ongoing professional development, the empowerment and facilitation of nurses' professional growth during times of crisis take a different approach, with an emphasis on appropriate education tailored for a "fit-for-purpose" workforce rather than lifelong learning [64]. This targeted focus on acquiring specific skills and knowledge required to handle critical situations equips nurses to confront challenges with confidence and leverage their expertise in acting and performing patient care effectively.

The factor of Teamwork and Collaboration plays a central role in the performance of healthcare organizations, involving not only healthcare professionals but also other members of the team. Effective teamwork and collaboration contribute to improved patient outcomes, streamlined workflow, and increased job satisfaction among nurses [65], particularly in demanding and time-sensitive emergency response situations [66]. Nurses play a crucial role in the healthcare team, and their contributions are closely tied to the establishment of effective communication and efficient cooperation with other healthcare workers [67]. When nurses feel appreciated and their expertise is acknowledged, it fosters a positive and supportive working environment,

which can ultimately lead to better patient care and organization performance. While these factors are commonly emphasized in describing the work environment in hospital settings, they become even more critical during emergency responses, where the traditional up and down hierarchy and status lines may be less emphasized [68]. By fostering a culture of teamwork and collaboration, healthcare organizations can create an environment that values the contributions of each team member and promotes open communication, mutual respect, and effective coordination [69, 70].

The factor of Logistics and Humanistic care within the organizational traits encompasses the provision of both physical and psychosocial support. Previous experiences and views of frontline healthcare workers during past pandemics have underscored the significance of adequate physical support, managing high workloads, handling long shifts, promoting adequate rest and recovery, and fostering positive relationships with the surroundings [71]. In this context, nurses expected additional benefits and spiritual rewards, beyond their regular salaries, as recognition for their dedicated contributions and extraordinary efforts made during these challenging times. Additionally, the demanding nature of frontline work has led nurses to desire adequate vacation time after fulfilling emergency tasks. Consistent with this, a review illustrated that organizations incorporated logistics support for nurses by ensuring the availability of personal protective equipment, adequate food and supplies, and also extending this support to the families of frontline workers to alleviate their concerns and provide a sense of security [72]. In addition to logistics support, emphasizing humanistic care for nurses has become a common practice to enhance their psychological well-being [73]. Nurse leaders who offer emotional support and empathy can significantly impact the overall morale and resilience of the nursing workforce [60, 74]. Empirical evidence from cross-sectional surveys indicates that nurses who perceive higher levels of organizational and social support, and demonstrate resilience, are more likely to report lower levels of anxiety related [75].

4.2. The Validity and Reliability of the C-NEW-PHE. The scale adaptation of the C-NWE was rigorously conducted following Heggstad's practical guideline and within the specific situational context of PHEs. An initial set of items was created based on the experiences of nurse managers in establishing a healthy work environment during the COVID-19 pandemic, taking into account the essential

dimensions derived from previous descriptions of work environments in normal hospital settings, specifically considering the Chinese context [9, 22, 42, 43]. The scale items and construct were identified through collaboration with a research team and several nine-researcher workshops. Moreover, a Delphi expert panel method was employed to ensure content validity, resulting in acceptable I-CVI scores ranging from 0.85 to 1.00 and satisfactory S-CVI/Ave of 0.93, which affirms a strong agreement among experts regarding the relevance of the items and the scale's adequate content validity [76]. To further validate these items, the preliminary survey was conducted with nurses, confirming the suitability of the revised items.

During the development process, the internal consistency reliabilities and factor loadings of the assumed dimensions demonstrated satisfactory results. The scale validation of the C-NWE-PHE was performed by CFA using the SEM method, showing how relationships amongst items in the measure and the dimensions are consistent with the conceptual framework depicting the organizational traits of the work environment. The C-NWE-PHE exhibited a distinct factorial structure compared to both the original C-NWE scale and other existing instruments with varying content [20]. To further validate the scale's structure and model fits, future research should involve testing the C-NWE-PHE in various PHE events and across international healthcare organizations.

4.3. Limitations and Strengths. The generalizability of this study may be limited due to the sampling population, as it represents the first attempt to quantitatively assess workplace characteristics related to PHEs. Furthermore, the data collected from nurses relied on self-report measures, which can introduce response bias or social desirability bias. However, to address this limitation, we included data from nurse managers, validated the measures with experts, and conducted tests using the nurses' data. Additionally, as the primary aim was scale validation, a cross-sectional design was employed, which does not allow for establishing causal relationships between the work environment, nurses' characteristics, and nurses' outcomes. Further research is needed to explore their correlations with the performance of nursing management. It is worth noting that this study possesses several strengths, such as a rigorous scale adaptation process, a large sample size, multicenter data collection, comprehensive analysis, and a significant contribution to the field of nursing work environment during public health emergencies. The findings provide valuable evidence for understanding and assessing the work environment in such contexts, serving as a foundation for future research and improvement strategies in nursing practice.

4.4. Implications for Nursing Management. The theoretical constructs of the C-NWE-PHE scale provide valuable insights into nurses' perceptions of the nursing work environment during the PHEs, demonstrating robust validity and reliability. It can be potentially utilized in

cross-sectional studies, prospective assessments of organizational traits, and interventional research. Future studies should not only concentrate on addressing acute burnout and reducing turnover intentions among nurses but should also prioritize the development and implementation of strategies that foster a healthy working environment conducive to nurses' well-being. To advance our understanding of the different constructs within the work environment and effectively implement improvements, concrete efforts and clear directions are needed for global applicability, including comparative studies across various workplaces to identify successful managerial measures. Further research aiming to pinpoint specific areas of improvement and interventions that target key factors such as workload management, professional development, leadership support, and collaboration can be designed. By considering the dynamic nature of the nursing work environment in PHE settings and understanding its interrelated components, healthcare organizations can better prepare for and respond to emergencies effectively.

5. Conclusions

This study employed a rigorous scale adaptation process that incorporated qualitative data, expert collaboration, and statistical analysis. Through this comprehensive approach, the reliability and validity of the C-NWE-PHE scale for assessing the work environment in the context of PHEs were ensured. Recognizing that the nursing workforce is an indispensable part of the health system and contributes to the resilience of organizations, it is imperative to invest in research and initiatives that foster a positive and supportive work environment for nurses.

Aims. To test whether emotional intelligence plays a mediating role in the process by which moral sensitivity affects nurses' ability to communicate with angry patients. **Background.** Hospital workplace violence is a global problem that disrupts the normal work order of healthcare, undermines trust between nurses and patients, and threatens the physical and mental health of nurses. Improving nurses' ability to communicate with angry patients to identify and diffuse patients' anger is critical to reducing the nurse-patient conflict and avoiding violence in the hospital workplace. **Methods.** The data were collected in China. A sample of 212 nurses completed measures of moral sensitivity, emotional intelligence, and the ability to communicate with angry patients. Structural equation modeling was used to test the study's hypothesis. **Results.** Our results suggest that nurses' emotional intelligence mediates the relationship between nurses' moral sensitivity and nurses' ability to communicate with angry patients, with a positive correlation between nurses' moral sensitivity, emotional intelligence, and ability to communicate with angry patients. **Conclusions.** The findings showed that nurses' moral sensitivity indirectly influenced nurses' ability to communicate with angry patients by directly influencing emotional intelligence. This study provides a theoretical and methodological approach to mitigate nurse-patient conflict and reduce violence in the hospital workplace through a moral perspective. **Implications for Nursing Management.** Nursing managers should pay attention to the moral sensitivity and emotional intelligence of nurses and promote their moral development and emotional intelligence by strengthening moral education in hospitals, utilizing emotional intelligence training courses and narrative nursing, ultimately promoting nurses' ability to communicate with angry patients, further contributing to the reduction of nurse-patient conflict, avoiding violence in the hospital workplace, building a safer hospital environment, promoting the overall development of nurses, and contributing to the development of global health and wellness.

1. Introduction

Workplace violence in hospitals continues to be a global problem that disrupts the normal work order of healthcare, undermines trust between nurses and patients, leads to nurses' emotional exhaustion and resignation, and even threatens the lives of nurses [1–3]. Anger, as an innate human emotion, is a precursor to the deterioration of all kinds of interpersonal relationships [4]. The accumulating anger of patients is a direct factor and trigger for eventual

nurse-patient conflict and hospital workplace violence. Therefore, the key to resolving nurse-patient conflict and preventing violence in the hospital workplace lies in timely and accurate identification of patients' anger, understanding the cause of their anger, and effectively communicating with them [5]. Nurses are most closely related to patients and serve as the "outpost" of hospital violence. It has been shown that there is a negative correlation between nurses' communication ability and medical disputes and nurse-patient conflicts [6]. In other words, the higher the communication

ability of nurses, the fewer nurse-patient conflicts, and the lower the likelihood of hospital workplace violence [7]. At the same time, the nurse's emotions as an individual also need to be seen when considering the nurse's communication with an angry patient. Nurses who fail to control their emotions often respond to difficult-to-communicate patients with anger and frustration [8]. But nurses with high emotional intelligence can successfully resolve conflicts and contradictions from angry patients [9–11]. Therefore, it can be seen that not only does the nurse's communication ability play a role, but their level of emotional intelligence also influences the outcome of handling nurse-patient conflicts. Research has also proven that nurses' communication ability is related to moral sensitivity [12]. The higher the nurses' moral sensitivity, the greater the ability to detect patients' problems in the clinical environment, and the better the nurses' communication ability [13]. Thus, this issue cannot be viewed in isolation; when considering nurses' ability to communicate with angry patients, we must comprehensively consider both their moral sensitivity and emotional intelligence. This study takes a moral psychology perspective to explore whether moral sensitivity affects nurses' ability to communicate with angry patients through direct or indirect pathways. The findings of this study will provide nursing managers with new perspectives and approaches to resolving the problem of medical conflicts and hospital workplace violence.

2. Literature Review and Hypotheses

2.1. The Concepts of Moral Sensitivity, Emotional Intelligence, and the Ability to Communicate with Angry Patients. Moral sensitivity is the ability to recognize ethical issues and be aware of the consequences of ethical decisions [14]. Nurses' moral sensitivity is defined as their understanding of patients' vulnerability, their ability to identify potential conflicts, and their capacity to accurately infer patient issues while being aware of the consequences of patient decisions [15]. This enables nurses to make favorable decisions for patients.

Emotional intelligence refers to the ability to recognize, control, and utilize one's own emotions and the emotions of others [16].

The ability to communicate with angry patients refers to nurses' capacity to recognize the patient's anger early, identify the cause of the anger, and diffuse it through effective communication skills [17]. In developing the scale, Chen argued that nurses' ability to communicate with an angry patient encompasses four areas: the nurse's recognition of the patient's anger, exploration of the cause of the patient's anger, the nurse's personal preparedness, and communication skills.

2.2. Studies on Moral Sensitivity and Emotional Intelligence. A strong positive correlation exists between the moral reasoning ability of nurse leaders and their emotional intelligence [18]. Similarly, a study pointed out that emotional intelligence is an important variable in ethical decision-

making [19]. Further research into the moral sensitivity and emotional intelligence of nurses by Kim found a positive correlation between nurses' emotional intelligence and moral sensitivity in a study conducted among Korean nurses [15]. Emotional intelligence and moral sensitivity play crucial roles in influencing nurses' ethical decision-making [20]. Furthermore, higher levels of moral sensitivity, emotional intelligence, and work engagement in nurses contribute to improved interpersonal relationships [21]. Moral sensitivity and emotional intelligence are recognized as key elements influencing interpersonal relationships.

2.3. Studies on Moral Sensitivity and the Ability to Communicate with Angry Patients. The communication of bad information to patients or families poses an ethical challenge, leading to extensive research on moral sensitivity in this context. Studies have demonstrated that nurses' moral sensitivity affects their communication ability with patients and their families [22, 23]. Nurses with high levels of moral sensitivity tend to perform better in delivering adverse events reports to patients and families, engaging in honest and safe communication [24]. A high level of moral sensitivity enables nurses to be more attuned to the physical and psychological conditions of patients and actively seek verbal or nonverbal approaches to problem-solving [25].

2.4. Studies on Emotional Intelligence and the Ability to Communicate with Angry Patients. Emotional intelligence is recognized as a vital foundation of nurses' conflict resolution abilities. Studies have demonstrated that emotional intelligence as one important component of nurses' personality traits can predict various coping strategies for dealing with conflict [9, 26]. Moreover, emotional intelligence significantly impacts the frequency of workplace violence experienced by nurses. Research has also revealed that emotional intelligence catalyzes improved communication, effectively addressing workplace violence through enhanced communication skills [10]. Emotional intelligence influences nurses' communication style and determines the quality of patient-nurse interactions. Consequently, researchers recommend enhancing the level of emotional intelligence among nurses to improve the quality and safety of patient care [27].

2.5. Conceptual Model. This study utilized the social cognitive theory to establish a conceptual model that examines the relationship between nurses' moral sensitivity, emotional intelligence, and their ability to communicate with angry patients [28]. According to the social cognitive theory, individuals learn and develop their behaviors through continuous interactions between personal factors, environmental factors, and behavioral factors. In this study, nurses' moral sensitivity and emotional intelligence are considered as personal factors, the mood of angry patients as an environmental factor, and nurse-patient communication ability is considered as a behavioral factor. Based on the conceptual model, the following hypotheses were proposed:

- (1) There is a correlation between nurses' moral sensitivity, emotional intelligence, and ability to communicate with angry patients.
- (2) Nurses' moral sensitivity can directly and positively influence nurses' emotional intelligence.
- (3) Nurses' moral sensitivity can directly and positively influence nurses' ability to communicate with angry patients.
- (4) Nurses' emotional intelligence can directly and positively influence nurses' ability to communicate with angry patients.
- (5) Nurses' moral sensitivity can indirectly influence nurses' ability to communicate with angry patients by affecting nurses' emotional intelligence.

3. Methods

3.1. Aims. This study aimed to describe the levels of moral sensitivity, emotional intelligence, and communication ability with angry patients among nurses, and to test whether emotional intelligence plays a mediating role in the process by which moral sensitivity affects nurses' ability to communicate with angry patients.

3.2. Design. This study used a cross-sectional research design and correlation analyses to examine the mediating role of emotional intelligence in the relationship between moral sensitivity and nurses' ability to communicate with angry patients. To determine the relationship between these variables, responses from participants were gathered through an online survey. The language used in the questionnaire was Chinese.

3.3. Participants. Nurses who participated met the following inclusion criteria: (a) having worked for one year and above in the current hospital; and (b) willing to participate in the study. The minimum sample size for structural equation modeling (SEM) is 200 [29]. According to the statistician's recommendations, 5 to 10 times the maximum number of items in the study scale was calculated to determine the sample size in this range [30, 31]. Using the Monte Carlo method [32] based on simulation techniques, it was determined that the minimum sample size required to achieve the desired level of statistical power (80%) was 90 cases. In this study, we recruited 212 participants. The statistical power level for the sample size of 212 cases obtained in this study was 91%. Exclusion criteria were those who did not complete the scale and selected the same answer for all of them, and those who were away from clinical work for more than three months for various reasons before the start of the study. Nurses participating in the study were drawn from a tertiary public hospital in Zhengzhou, Henan Province, China, using a systematic sampling method.

3.4. Variable Measurements

3.4.1. Moral Sensitivity. The Moral Sensitivity Questionnaire was developed by Lützné and revised in 2006 [33]. It was translated and culturally adapted by Huang to make the MSQ-R more appropriate for Chinese nurses [34]. The Chinese version of the MSQ-R consists of two dimensions, Moral Burden (4 items) and Moral Responsibility (5 items), and is scored on a 6-point Likert-type scale ranging from 1 "totally disagree" to 6 "totally agree." Scores range from 9 to 54, with higher scores indicating higher levels of moral sensitivity, with a total score of <32 indicating low sensitivity, 32–43 indicating moderate sensitivity, and >43 indicating high sensitivity. The Cronbach's α of this scale in this study is 0.896.

3.4.2. Emotional Intelligence. The Emotional Intelligence Scale was developed in 2002 [35]. In 2010, Wang translated the scale into Chinese and administered it to university students, civil servants, and corporate employees using the Chinese version. The scale consists of four dimensions: Self-Emotional Assessment (4 items), Emotional Assessment of Others (4 items), Emotional Control (4 items), and Emotional Application (4 items). Using a 7-point Likert scale (1 = "I totally disagree" to 7 = "I totally agree"), the scale scores range from 7 to 112, with higher scores indicating higher emotional intelligence. The Cronbach's α of this scale in this study is 0.964.

3.4.3. Nurse's Communication Ability with Angry Patients Scale (NCAAPS). Developed by Chen in 2021 in China, the NCAAPS consists of 4 dimensions: anger perception (3 items), cause exploration (6 items), self-preparation (7 items), and communication skills (3 items) [17]. The options were assigned from "Strongly Disagree" to "Strongly Agree" on a scale of 1–5, with higher scores indicating better communication skills in angry situations, with a maximum score of 95. The Cronbach's α of this scale in this study is 0.934.

3.5. Data Analysis. The data was analysed using SPSS and AMOS software. First, SPSS was used to filter and remove invalid questionnaires. The total number of participants who chose the same answers for all questions was five, and the total number of participants who did not fill in some of the answers was three. These invalid questionnaires were removed as recommended by existing studies [36]. Descriptive statistics were used to describe general characteristics. Relationships between all dimensions were assessed by Pearson correlation analysis. Validating factor analysis was used to test the applicability of the AMOS measurement model, followed by structural equation modeling to verify the relationship between moral sensitivity, emotional intelligence, and nurses' ability to communicate with angry patients. The mediating role of emotional intelligence was also tested.

3.6. *Ethical Considerations.* Before the investigation, the study was approved by the university ethics committee (approval number: 2023-109) and by the hospital nursing department. Nurses volunteered to participate in this study and could quit at any time. The electronic questionnaire was completed anonymously.

4. Results

4.1. *Participants' Sociodemographic Characteristics.* The demographic characteristics of the participants are shown in Table 1. The majority of participants were female (69.3%) and married (80.2%). The mean age of the participants was 35.35 years (SD = 7.51) and the mean number of years worked was 14.82 years (SD = 9.26). The general information characteristics of the sample drawn were generally consistent with those of previously studied Chinese nurses [37].

4.2. *Moral Sensitivity, Emotional Intelligence, and Nurses' Ability to Communicate with Angry Patients and the Association between the Variables.* Descriptive statistics for the key variables are shown in Table 2, with a total mean score of 46.62 (SD = 7.55) for moral sensitivity, 92.92 (SD = 15.42) for emotional intelligence, and 81.64 (SD = 11.62) for the nurses' ability to communicate with angry patients. As shown in the correlation matrix in Table 2, moral sensitivity was significantly positively correlated with emotional intelligence ($r = 0.544$, $p < 0.001$) and also with nurses' ability to communicate with angry patients ($r = 0.734$, $p < 0.001$). The nurses' emotional intelligence was also significantly positively correlated with nurses' ability to communicate with angry patients ($r = 0.627$, $p < 0.001$).

4.3. *Structural Equation Model.* Using moral sensitivity as the independent variable, the nurses' ability to communicate with angry patients as the dependent variable, and emotional intelligence as the mediating variable, a structural equation model plot was created using AMOS. The model fit indices $X^2/df = 2.125 (< 3)$, RMSEA = 0.06 (< 0.08), CFI = 0.986 (> 0.9), IFI = 0.986 (> 0.9), GFI = 0.943 (> 0.9), and TLI = 0.981 (> 0.9), were all within acceptable limits, indicating that the structural model fitted well (Figure 1).

4.4. *The Mediating Effect Analysis.* As shown in Table 3, moral sensitivity has a direct positive effect on both emotional intelligence ($\beta = 0.61$, $p < 0.001$) and the nurse's ability to communicate with angry patients ($\beta = 0.69$, $p < 0.001$). Emotional intelligence directly and positively influenced nurses' ability to communicate with angry patients ($\beta = 0.25$, $p < 0.001$). Moral sensitivity also positively influences nurses' communication skills with angry patients indirectly through emotional intelligence ($\beta = 0.15$, $p < 0.001$). The findings suggest that nurses' moral sensitivity indirectly affects nurses' ability to communicate with angry patients by directly influencing nurses' emotional intelligence.

Emotional intelligence played a mediating role in the influence of moral sensitivity on nurses' ability to communicate with angry patients.

5. Discussion

Social cognitive theory suggests that human activity is determined by the interaction of three factors: the external environment in which the individual lives, individual cognition and other individual characteristics, and individual behavior [28]. When a person is placed in an environment, not only does the environment have an impact on the individual's behavior, but the individual's cognition and individual characteristics also play a significant role in the individual's behavior. Based on the background of social cognitive theory, this study aims to examine and clarify the relationship between nurses' moral sensitivity, emotional intelligence, and their ability to communicate with angry patients. Additionally, it seeks to explore the mechanisms through which nurses' moral sensitivity influences their ability to communicate with angry patients. The main finding of this study highlights the significant mediating role of nurses' emotional intelligence between their moral sensitivity and their ability to communicate with angry patients. Moreover, a strong positive correlation is observed between nurses' emotional intelligence and their moral sensitivity. These findings are consistent with hypotheses based on social cognitive theory.

5.1. Moral Sensitivity Influences Nurses' Ability to Communicate with Angry Patients through the Mediating Role of Emotional Intelligence

5.1.1. *Moral Sensitivity Directly Affects Nurses' Ability to Communicate with Angry Patients.* This study discovered a significant positive correlation between nurses' moral sensitivity and their ability to communicate with angry patients. The findings of this study indicate that higher levels of moral sensitivity in nurses are associated with better communication abilities when interacting with angry patients and a reduced likelihood of nurse-patient conflict. These findings align with previous studies that have also highlighted the relationship between nurses' communication abilities and moral sensitivity [26, 38].

This study further revealed that nurses with a heightened awareness of their moral responsibility exhibited better assessment of the emotional state of angry patients, their own emotions, emotional preparedness, and emotional control (Table 2). Additionally, nurses with high levels of moral sensitivity demonstrated increased sensitivity to potential nurse-patient conflicts in clinical settings, enabling them to detect the accumulation of anger in patients more effectively and promptly (Table 2). Furthermore, nurses with high moral sensitivity displayed a greater awareness of their moral responsibilities and burdens, leading them to proactively address communication issues with angry patients (Table 2).

TABLE 1: Sociodemographic characteristics of participants ($n = 212$).

Nurse characteristics	Mean (SD)	N (%)
Gender		
Male		65 (30.7)
Female		147 (69.3)
Age	35.35 (7.51)	
20~30		62 (29.2)
31~40		81 (38.2)
>40		69 (32.6)
Years in nursing	14.82 (9.26)	
1~5		47 (22.2)
6~10		47 (22.2)
11~20		64 (30.2)
>20		54 (25.4)
Professional title		
Junior		94 (44.3)
Intermediate		87 (41.1)
Senior		31 (14.6)
Education level		
Secondary vocational		18 (8.5)
Associate degree		57 (26.9)
Bachelor's degree		126 (59.4)
Master's degree or above		11 (5.2)
Marital status		
Married		170 (80.2)
Single		39 (18.4)
Other (divorce/widowed)		3 (1.4)

5.1.2. Emotional Intelligence Mediates the Relationship between Moral Sensitivity and the Nurses' Ability to Communicate with Angry Patients. We can find that from this study, moral sensitivity has a positive impact on nurses' ability to communicate with angry patients, and emotional intelligence plays a mediating role between these two factors; nurses' moral sensitivity indirectly influences their ability to communicate with angry patients by directly influencing their emotional intelligence.

Nurses with high moral sensitivity are adept at identifying moral issues by gathering information from their environment. When they become aware of ethical dilemmas, their emotional intelligence is activated, allowing them to integrate their own emotions with those of others, ultimately leading to problem-solving behaviors. Moral sensitivity provides cognitive material and cues, while emotional intelligence integrates them. Through the use of emotional intelligence, nurses can identify patients' anger and mobilize their emotional intelligence to explore the underlying causes, evoke positive emotions within themselves, and employ effective communication skills to defuse the patients' anger. In this way, nurses' emotional intelligence serves as a bridge between moral sensitivity and their ability to communicate with angry patients.

5.2. Practical Implications

5.2.1. Promotions of Nurses' Moral Sensitivity. Reflecting on existing research, the overarching goal of studies on nurse ethics and nurse ethics education is to foster nurses' moral

consciousness. This aims to ensure that nurses adhere to ethical principles in clinical practice and make decisions that maximize patient benefits in complex healthcare scenarios. The cultivation of nurses' moral sensitivity is crucial in this regard.

To enhance nurses' moral sensitivity, managers can establish a moral education platform for nurses through interdisciplinary collaboration, including integration with humanities and social science disciplines. This integration serves to promote nurses' moral sensitivity and incorporate it into their professional practice. A panel consisting of nursing researchers, humanities and social science researchers, and other relevant stakeholders can be convened to determine the course content based on existing literature on moral sensitivity in nursing and theoretical models of moral sensitivity.

The course can be structured in two phases. In the first phase, nurses receive lectures on the theoretical aspects of the moral sensitivity course. The second phase adopts a discussion and questioning approach, encouraging nurses to raise questions and engage in moral discussions regarding potential issues that may arise in clinical settings. This interactive approach encourages nurses to actively explore and analyse moral dilemmas, thereby further developing their moral sensitivity [39]. Kant, in his work "On Pedagogy," emphasizes that the ultimate goal of education is to enable individuals to transition from "heteronomy" to "self-discipline" [40, 41]. In other words, the ideal moral development of nurses entails the transformation of external moral constraints into internal moral principles. Successful

moral education for nurses empowers them to transcend their previous moral selves and attain a higher level of moral sensitivity. In complex clinical settings, nurses can utilize their moral sensitivity to identify potential patient issues and engage in altruistic behavior instinctively. This is because nurses have internalized morality, enabling them to act based on self-discipline rather than external constraints.

5.2.2. Improvements of Nurses' Emotional Intelligence. Nursing managers should indeed prioritize the development of nurses' emotional intelligence, as nurses with poor emotional regulation may struggle with complex moral choices and experience heightened negative emotions in the face of ongoing moral stress. To address this, training courses on emotional intelligence can be conducted to provide nurses with education on emotional recognition, emotional control, and communication skills. These courses

should aim to enhance nurses' understanding of emotional intelligence by explaining its theories and theoretical models.

The course also can be designed to improve nurses' emotional intelligence through interactive activities such as self-reporting, role-playing, and group debriefing. Nurses can be randomly divided into small groups and assigned various clinical cases for discussion. Each group can then use a PowerPoint presentation to analyse the emotional aspects of the case, including the emotions of both the nurse and the patient, identify any inappropriate emotional responses from the nurse, and suggest measures to address the case. Incorporating emotional intelligence assessment into the evaluation criteria for nurses' abilities and performance is also recommended.

Furthermore, nursing managers can consider utilizing narrative medicine and narrative care to enhance nurses' emotional intelligence. These approaches involve utilizing

storytelling and reflective practices to promote self-awareness and empathy, thereby improving emotional intelligence. Establishing relevant departments within hospitals to provide support and assistance in enhancing nurses' emotional intelligence can further contribute to their development in this area.

5.2.3. Training on Nurses' Ability to Communicate with Angry Patients, Reduce the Occurrence of Workplace Violence. To train nurses on communicating emotions with angry patients, firstly, nurses must learn to identify patients' anger in a timely and accurate manner. They can improve their ability to identify patients' anger by reading relevant books, pictures and videos, and sharing good communicational cases. Nursing managers can also incorporate existing research, such as psychological sociology, to develop models of patients' anger changes and set up relevant training and courses in hospitals to improve nurses' ability to communicate with angry patients.

6. Limitations

This study explored the relationship between nurses' moral sensitivity, emotional intelligence, and ability to communicate with angry patients. However, this study sampled some nurses in China and the findings may not be completely representative of other countries. Future researchers will need to further expand the sample participants for the study. Additional variables could be considered for future studies to explore the role that other variables play in the relationship between nurses' moral sensitivity, emotional intelligence, and ability to communicate with angry patients.

7. Conclusions

This study aimed to explore the relationship between nurses' moral sensitivity, emotional intelligence, and ability to communicate with angry patients. The findings showed that there was a positive relationship between nurses' moral sensitivity, emotional intelligence, and ability to communicate with angry patients, and that emotional intelligence mediated the relationship between moral sensitivity and ability to communicate with angry patients. Nurses' moral sensitivity indirectly influenced nurses' ability to communicate with angry patients by directly influencing emotional intelligence. This study provides new perspectives and methods for alleviating nurse-patient conflict and resolving hospital violence [42].

Data Availability

The datasets generated during and/or analysed during the current study are available from the corresponding author on reasonable request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

In this study, GSY and W XK made substantial contributions to conception and design, or acquisition of data, or analysis and interpretation of data; ZZ X Involved in drafting the manuscript or revising it critically for important intellectual content; ZQJ and PX gave final approval of the version to be published. Each author should have participated sufficiently in the work to take public responsibility for appropriate portions of the content. LCX and KDD agreed to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved.

Acknowledgments

The authors would like to thank all the participants involved in this research for their time and contributions. This research was supported by the Henan Provincial Education Science Planning Project (Study on the Educational Practice of Enhancing Medical Students' Humanistic Literacy through Narrative Medicine: 2023YB0012).

Background. The relationship among comfort, perceived social support, and hope should still be further explored. Clarifying the relationship between the aforementioned variables can enable clinical staff to implement tailored and effective intervention strategies for enhancing the management and quality of care of patients with ischemic stroke. **Aim.** This study aims to investigate the relationship between comfort, perceived social support, and hope in hospitalized patients with acute ischemic stroke and to explore the mediating effect of perceived social support on comfort and hope. **Methods.** A correlational cross-sectional study was performed using an online questionnaire. The study was conducted from January to August 2023 among 572 patients with acute ischemic stroke, and finally 534 valid questionnaires were included in the analysis. The general information questionnaire, Modified Barthel Index, Shortened General Comfort Questionnaire, Perceived Social Support Scale, and Herth Hope Index were utilized for investigation. Mediation analysis was performed by structural equation modelling. Indirect effects were evaluated through bootstrapping. Data analysis was performed using the statistical program packages, namely, SPSS 29.0 and AMOS 24.0. **Results.** The comfort, perceived social support, and hope scores of patients with acute ischemic stroke were 94.1 (11.92), 72.74 (10.26), and 40.55 (4.99), respectively. The participants' hope was positively related to comfort ($r = 0.531$, $p < 0.001$) and perceived social support ($r = 0.589$, $p < 0.001$). Perceived social support exerts a partial mediating role between comfort and hope, and the mediating effect was 0.159 (95% CI [0.117, 0.210]), accounting for 25.0% of the total effect. **Conclusion.** We reported that comfort—directly and indirectly—exerts a positive impact on hope. Particularly, perceived social support enhances the impact of comfort on hope; perceived social support mediates the relationship between comfort and hope. Clinical staff should correctly understand the relationship among the three variables; they should effects targeted strategies to enhance patient comfort and social support, thereby increasing the hope level among ischemic stroke patients and bolstering confidence in disease management. **Implications for Nursing Management.** This study demonstrates that comfort and perceived social support serve as protective factors for hope among ischemic stroke patients. This observation provides evidence supporting the optimization of management for ischemic stroke patients from the perspectives of the cognitive adaptation theory and comfort theory. The findings of this study contribute to a more optimal understanding among clinical caregivers regarding the mechanisms underlying the relationship between comfort, social support, and hope, and it facilitates the adoption of effective intervention strategies for promoting the psychological management of ischemic stroke patients and enhancing patient care quality.

1. Introduction

Stroke is the second leading cause of death and the third leading cause of disability worldwide, and exhibits high morbidity, disability, and mortality [1]. There are more than

2 million new cases of stroke in China every year, and stroke is the first leading cause of death and disability in adults [2]. Acute ischemic stroke (AIS) accounts for 60% to 80% of all strokes [3]. Stroke often exhibits an acute onset and rapid progression [4]. Due to its severity, unpredictability, and

uncontrollability, patients become prone to neurological dysfunction, hemiplegia, anxiety and depression, and other physical and mental symptoms [5, 6]. They exhibit increased negative emotions and negative attitudes toward the disease and a crucially reduced hope level [7]. Patients require comfort to alleviate the psychological distress occasioned by these symptoms, as well as hope to treat the illness [8]. Hope can enable patients to rebuild personal confidence and can make patients believe that a positive, realistic, and expected life goal can be achieved [9]. As an internal strength of psychology, it can enable patients to overcome difficulties, relieve pain, and enhance confidence in overcoming the disease. The recovery of self-care ability in patients with acute ischemic stroke is a lengthy process that requires patients to be full of hope and to accept their condition and exhibit active psychological recovery to obtain more optimal results [10]. However, patients hope is influenced by many aspects, such as occupation, education level, and psychological status [11, 12]. The crucial factor is the patient's feeling about the disease (i.e., comfort and perceived social support), which is the source and motivation of hope [7, 13].

Comfort is a pleasant experience, a desired state of satisfaction, and a feeling of positivity and strength in one's ability to cope with crisis and challenge [14]. Enhanced comfort after therapeutic interventions may increase hope and confidence and facilitate healing [15]. Long-term cognitive comfort indicates that life is not dynamic, which can easily lead to cognitive habits, thereby creating a scenario in which individuals fall into cognitive comfort zones and, thus, lose interest in life [16]. Patients with acute ischemic stroke often exhibit emotional, concentration, and fatigue problems, which generally transition from a state of cognitive stress to a state of cognitive relaxation and may fall into a cognitive comfort zone [17]. How to enable them to make decisions that can facilitate life- and cognitive environment-related changes is a novel experience and challenge for the mechanism of patients with acute ischemic stroke. Kolcaba defines comfort as "The immediate experience of being strengthened by having needs for relief, ease, and transcendence met in four contexts: physical, psychospiritual, sociocultural, and environmental, and it is so much more than the absence of pain" [18]. The patient relieved physical, psychological, and environmental discomfort; achieved spiritual comfort; and was treated as an individual with feelings, thoughts, values, and dignity [19]. Thus, comfort can promote patients with acute ischemic stroke to be able to express their emotions, identify the meaning and value of life, build confidence in the treatment of disease, and establish hope for survival and the future [20].

We examine perceived social support in the context of the transition to building hope, utilizing cognitive adaptation theory as a framework for conceptualizing resilience [21]. Social support enables individuals to feel loved, valued, and respected and includes family, friends, and other social supports [22]. It can also help individuals aspire to health, rebuild trust with others, and begin to integrate into social groups [23]. Optimal social support can provide individuals with trust to relieve stress, prevent anxiety, induce strength, and motivation in others to persevere and enhance personal

hope and confidence in the future. In addition, studies have confirmed that there is a positive correlation between the comfort and hope felt by patients [24]. However, the relationship among comfort, perceived social support, and hope and their functional paths are unclear and should be further explored. From the perspective of the development of the positive psychology of hope, this study explores the influence path and structural causal relationship of comfort and perceived social support on the level of hope. Thus, it provides an entry point of psychological intervention for patients to actively participate in disease rehabilitation after increasing their hope and treatment confidence.

2. Methods

2.1. Study Design. This was a cross-sectional study and inferential analysis from West China Hospital, Sichuan University in Chengdu, Sichuan Province, China. This descriptive correlation study was designed to examine the relationship among comfort, perceived social support, and hope in hospitalized patients with acute ischemic stroke. A convenience sample was utilized to select patients from January to August 2023.

The sample size calculation method intended for this study was based on a total of 52 items across three scales, with the sample size being 10–15 times the total number of items [25, 26]. Considering potential incomplete data collection from patients, we increased the sample size by 10%, leading to a final calculated sample size of 572 cases. Questionnaires were distributed to a total of 572 patients who participated in this study, and surveys with invalid data and missing data were eliminated. Thirteen individuals who provided incomplete responses and 25 individuals who completed poor-quality questionnaires were excluded. Finally, a total of 534 valid questionnaires were included in the analysis, with an effective recovery rate of 93.4%.

2.2. Inclusion and Exclusion Criteria. The inclusion criteria were as follows: (1) age over 18 years; (2) AIS diagnosis made by neurologists and confirmed using computed tomography (CT) or magnetic resonance imaging (MRI); (3) consciousness and cognition were normal; and (4) patients could provide consent and were willing to cooperate with questionnaire completion.

The exclusion criteria were as follows: (1) incomplete clinical data; (2) previous history of other central nervous system diseases; (3) severe cardiac dysfunction, pulmonary dysfunction, liver dysfunction, or renal dysfunction; (4) acute embolism of the external cerebral artery; and (5) pregnancy.

2.3. Instruments

- (1) General information questionnaire. The general information questionnaire was utilized to collect demographic information: gender, age, level of education, marital status, provider payments, and comorbidity.

- (2) Shortened General Comfort Questionnaire (GCQ) [27]. This Likert 6 self-rating scale has 28 items; transcendence is addressed in four domains, namely, physical, psychospiritual, sociocultural, and environmental; and higher scores indicate better comfort. Examples of items relating to the four domains include, "I have a poor appetite" (physical), "My beliefs give me peace of mind" (psychospiritual), "My friends remember me with their cards and phone calls" (sociocultural), and "These surroundings are pleasant" (environmental). Negatively worded items are reverse scored. The GCQ exhibited a Cronbach's α of 0.88. The Chinese version exhibited reliability, with a Cronbach's α of 0.892 [28].
- (3) Perceived Social Support Scale (PSSS) [29]. The scale consists of support from family and friends and has 12 items; each item was scored on a 7-point Likert scale ranging from 1 (very strongly disagree) to 7 (very strongly agree), with a higher total score indicating a higher level of social support. The Chinese PSSS has been utilized among Chinese patients and has exhibited satisfactory reliability. Cronbach's α of the scale was calculated to be 0.962 [29].
- (4) Herth Hope Index (HHI) [9]. The scale is a 12-item summated rating scale designed as an individual measure of hope. Participants are asked to rate each item using a 4-point Likert response format. The internal consistency of the HHI in ill adults has been acceptable [30]. Cronbach's α coefficients for total HHI scores were 0.84 for stroke survivors [10].

2.4. Data Collection. The questionnaire was uploaded to the Questionnaire Star platform, an online crowdsourcing platform, and the survey was, subsequently, conducted through the WeChat app. The purpose and significance of the investigation were fully explained to the patients by the investigators. The survey was completed only after signing the informed consent form. Otherwise, they could not complete the questionnaire. The completed scales were immediately collected and initially reviewed by the investigator. If any omission was identified, the questionnaire was to be completed on the spot and checked again. Data were treated as invalid if subjects suddenly felt discomfort, leading them to not complete all questions. Incomplete and semifinished questionnaire data were eliminated and recorded and finally reviewed by two researchers for accuracy.

2.5. Ethical Considerations. The authors confirm adherence to ethical guidelines and obtained ethical approval (from the institutional review board). This study was performed in accordance with the ethical principles of the 1964 Declaration of Helsinki and it was approved by the Ethics Committee of West China Hospital, Sichuan University (No: 2022[1969]).

2.6. Statistical Analysis. Data analysis was conducted using the statistical program packages SPSS 29.0 and AMOS 24.0. In the descriptive statistics, the mean, standard deviation, frequency, and percentage were reported. Pearson correlation was utilized to analyze the correlation between variables. AMOS24.0 established a structural equation model (SEM) of the mediating role of perceived social support between comfort and hope. Comfort and perceived social support are the independent variables, and hope is the result variable. Moreover, subscale scores are utilized as the indicators for the latent factor. The maximum likelihood estimation method was utilized to estimate the model parameters, and the nonparametric percentile bootstrap method of bias correction was utilized to calculate the confidence interval of the effect. Bootstrapping was utilized to verify the mediation effect, with a duplicate sample size of 2000. If the 95% CI (confidence interval) of the indirect effect did not include zero, the mediation effect was proved to be significant [31]. We adopted many common indexes to evaluate the model in the current study, including the chi-square ratio to degrees of freedom (χ^2/df), root mean square error of approximation (RMSEA), goodness-of-fit index (GFI), normed fit index (NFI), incremental fit index (IFI), Tucker-Lewis index (TLI), and comparative fit index (CFI). If a model is acceptable, the χ^2/df should be less than 5, and other indexes should be greater than 0.90 [32]. A p value <0.05 was considered to be statistically significant.

3. Results

The mean age of the sample was 62.15 ± 15.03 years, including 369 males. The general characteristics of the patients are depicted in Table 1.

Correlation analysis was performed to verify the relationship between comfort, perceived social support, and hope. Consequently, as illustrated in Table 2, there were bivariate correlations between the subfactors of the main variables. The participants' hope was positively related to comfort ($r=0.531$, $p<0.001$) and perceived social support ($r=0.589$, $p<0.001$). The participants' perceived social support was also positively related to comfort ($r=0.383$, $p<0.001$). All relevant subcategories were positively associated with one another. In addition, most of the coefficients were below 0.80 (i.e., the standard for multicollinearity), indicating that there is no apparent multicollinearity problem [33].

To further explore the effects of comfort and perceived social support on Hope in patients with acute ischemic stroke, we tested for the mediating effects of perceived social support on comfort and hope. According to the research conducted by Wen and Fan [34], we tested this mediating model and constructed the structural equation model (SEM) using AMOS software. We modified the model by adding residual correlation according to the significant results of the initial model parameters and the model correction index provided by AMOS [35]. Herein, 3 model revisions were performed. The results of the SEM analysis indicated that this model was acceptable, $\chi^2/df = 1.722$, RMSEA = 0.037

TABLE 1: General characteristics ($N = 534$).

Variable	Category	<i>n</i> (%)
Gender	Male	369 (69.1)
	Female	165 (30.9)
Level of education	Primary school or below	163 (30.5)
	Junior	128 (24.0)
	Senior	101 (18.9)
	College degree or above	142 (26.6)
Marital status	Unmarried	18 (3.4)
	Married	469 (87.8)
	Widowed or divorced	47 (8.8)
Provider payments	Medical insurance	493 (92.3)
	Self-paying medical	41 (7.7)
Comorbidity	Hypertension	335 (62.7)
	Diabetes mellitus	179 (33.6)
	Hyperlipidemia	64 (12.0)
	Heart disease	146 (27.3)
	Atherosclerosis	156 (29.2)

(95% *CI*: 0.020, 0.052), *GFI* = 0.978, *NFI* = 0.984, *IFI* = 0.993, *TLI* = 0.991, *CFI* = 0.993. The final structural equation model was depicted in Figure 1.

The mediation effect was tested using the bootstrap method with bootstrap samples of 2,000 (Table 3). The results indicated that the bootstrap 95% confidence intervals of the direct and indirect effects of comfort on hope did not contain 0. This observation indicated that perceived social support exerts a partial mediating role between comfort and Hope, and the mediating effect was 0.159 (95% *CI* [0.117, 0.210]), accounting for 25.0% of the total effect.

4. Discussion

Due to the characteristics of a high recurrence rate and high disability rate of stroke, most patients worry or even fear the future prognosis of the disease when treating it [36]. This study revealed that the score of hope in patients with acute ischemic stroke was 40.55 (4.99), which was slightly higher than that of 37.7 (4.46) in previous studies [10], which may be rationalized as follows: with the continuous progress of medical technology in recent years, an increasing number of treatment options have emerged, and the treatment effect of acute ischemic stroke may now be considerably enhanced compared with previous eras. This study mainly included hospitalized patients who were conscious, stable, and able to cooperate with the questionnaire, and most of these patients exhibited more optimal treatment outcomes than those with severe diseases. This observation indicates that we should consider the physical symptoms and signs in the acute stage, create a favorable communication environment and health education, and offer patients care and emotional support. Medical practitioners should, in turn, eliminate their negative emotions, help patients with a more positive and healthy mentality cope with the troubles occasioned by the disease, and promote the enhancement of the hope level in stroke patients.

The results of this study indicate that the comfort of patients with acute ischemic stroke is positively correlated with hope. Herein, the subjects are ischemic stroke patients,

who are primarily elderly males. They generally exhibit a lower overall level of education, and more than half of these patients have one or more accompanying chronic illnesses. These patients face physiological, psychological, and environmental challenges amid the symptoms of the disease and emotional distress [37, 38]. The results of this study indicate that comfort serves as both a preceding variable and a critical intervention variable, aligning broadly with previous research outcomes [39, 40]. Changes in comfort levels impact patients' confidence in disease treatment and their expectations for future life [41]. More comfort and encouragement from healthcare professionals can assist patients in alleviating emotions and in prompting them to step out of their comfort zones [41]; thus, patients can face the challenges posed by the disease with a more positive attitude, which is beneficial for altering cognitive states, aiding in physical and mental recovery, and ultimately increasing hope for rehabilitation. This indicates that the effect of symptom relief is more prominent by evaluating the comprehensive state of patients and, subsequently, formulating and implementing various discomfort relief measures according to the needs and state of patients [42]. The relief of symptoms contributes to the relief of negative emotions and the improvement of the quality of life [43]. In this process, the patient's recovery confidence also increases, which can be reflected in the improvement of the hope level.

Perceived social support reflects the individual's emotional experience and satisfaction, accompanied by a feeling of being respected and supported in society, which is closely related to the individual's subjective feelings [44]. The results of this study revealed that perceived social support can significantly positively predict the level of hope, thereby indicating that higher levels of perceived social support are associated with higher levels of hope. Patients with higher perceived social support were more likely to establish favorable relationships with others, such as family and social relationships [45]. When individuals perceive more peer support, they promote the development of peer relationships, which makes individuals more likely to stimulate

internal motivation and seek effective methods of addressing challenges when handling setbacks and pressure situations as a means of improving their hope level [46]. The surrounding environment of patients with acute ischemic stroke changes when they are admitted to the hospital with a sudden illness. They are more sensitive to interpersonal relationships around them and are more likely to exhibit favorable social relationships and reduce the occurrence of bad emotions such as depression when they receive objective supportive behaviors or support resources from others [47, 48]. When patients feel a more optimal interpersonal relationship, they may enhance their expectations for the future, set goals, and believe that they can achieve them, thereby improving their hope level.

The results of this study revealed that perceived social support exerts a partial mediating role in the effect of comfort on hope. The comfort of patients with acute ischemic stroke exerts a direct effect on hope, and it, simultaneously, exerts an indirect effect on hope through perceived social support. According to the buffering effect model of social support, favorable social support can enable patients with high stress to avoid or suffer fewer adverse effects occasioned by stressful events [49]. When patients with acute ischemic stroke are faced with disability occasioned by their disease, various dysfunctions can lead to great stress [50]. These physical and psychological pains all appear suddenly with the disease [51]. However, when patients are in a more comfortable atmosphere, they feel more social support from family, friends, and other aspects.

Thus, the adverse impact of the disease on psychology can be weakened, and the patients can begin to actively cope with life and face the disease and have more confidence and hope for the treatment of the disease. This observation indicates that medical staff should not only consider the physical and psychological comfort of patients with acute conditions but also consider the impact of perceived social support on patients. The hope level of patients should be simultaneously enhanced from two aspects. Based on the path analysis of the mediating effect, the corresponding intervention plan was formulated to create a comfortable treatment process for patients and provide social support in many aspects. We can encourage patients to actively seek the help of family or friends to relieve economic or emotional pressure, reduce negative emotions, and finally face the disease and life with hope.

5. Conclusions

We reported that comfort, directly and indirectly, has a positive impact on hope. Particularly, perceived social support enhances the impact of comfort on hope; perceived social support mediates the relationship between comfort and hope. Clinical staff should correctly understand the relationship among the three variables, taking targeted strategies to enhance patient comfort and social support, thereby increasing the hope level among ischemic stroke patients and bolstering confidence in disease management.

6. Limitations

Due to the limited region and energy, this study adopted a cross-sectional survey, and the research object was obtained from a tertiary hospital; therefore, because the sample representativeness was limited, readers should be cautious when applying the findings to patients from other countries or different cultural backgrounds. Further studies should be conducted to expand the sample size and study population; thus, the conclusions of this study can be verified. Personalized interventions can also be formulated from the aspects of comfort and social support to increase the hope of patients.

Abbreviations

AIS:	Acute ischemic stroke
SEM:	Structural equation model
χ^2 :	Chi-square value
df:	Degrees of freedom
χ^2/df :	Ratio of the chi-square to degrees of freedom
RMSEA:	Root mean square error of approximation
GFI:	Goodness-of-fit index
NFI:	Normed fit index
IFI:	Incremental fit index
TLL:	Tucker–Lewis index
CFI:	Comparative fit index.

Aims. To explore the mediating effect of cognitive load on the relationship between self-efficacy and task load among intensive care unit (ICU) nurses. **Background.** Studies related to ICU nurses' self-efficacy, cognitive load, and task load are noteworthy but limited. **Methods.** A total of 253 ICU nurses from three tertiary hospitals in Beijing were recruited and investigated by the Chinese version of the National Aeronautics and Space Administration-Task Load Index (NASA-TLX), General Self-Efficacy Scale (GSES), and an instrument for Measuring Different Types of Cognitive Load (MDT-CL) scales. SPSS 25.0 was used for Pearson correlation analysis and multiple linear regression analysis and mediation effect analysis using Model 4 in PROCESS (5,000 resamples). **Results.** Mediation analysis indicated that a partial mediating effect of extraneous cognitive load between self-efficacy and task load among ICU nurses was -0.707 (95% CI: $-0.940, -0.504$), accounting for 51.64% of the total effect. **Conclusion.** This study suggests that enhancing ICU nurses' self-efficacy can be a potential strategy to decrease extraneous cognitive load and task load. **Implications for Nursing Management.** Nursing administrators should actively implement intervention strategies based on influencing the task load pathway of ICU nurses to ensure they can provide safe and high-quality nursing services.

1. Introduction

The demand for nursing services is constantly increasing, and nurses are the most direct personnel to provide nursing care to patients, especially in intensive care units (ICUs) where nursing activities are characterized by extremely demanding workloads [1, 2]. ICU nurses need to possess the ability to make clinical decisions quickly, handle complex changes in patient conditions, and use special equipment. The complexity and urgency of the ICU environment often expose nurses to high-level mental task loads [1, 3]. Paula et al. [3] investigated 111 ICU nurses and 100% indicated a medium to high level of mental task load. Nursing administrators and researchers are paying more attention to the task load of nursing care. High-level task loads among ICU nurses can lead to physical and psychological problems, such as the increased risk of anxiety and depression, higher

occupational fatigue and turnover rate, missed nursing care, and increased nursing errors [4, 5]. For example, Boehm and colleagues surveyed 268 ICU nurses and found that for every additional point increase in task load (rated on a scale of 0–10), adherence to bundle interventions among ICU nurses decreased by 53% [4].

Studies have shown that self-efficacy and cognitive load were related to an individual's mental task load [6–8]. Self-efficacy is defined as the level of belief in one's ability to complete a heavy workload successfully [9]. Cognitive load is defined as the total amount of cognitive resources that a person requires to process cognitive tasks [10] and is composed of intrinsic, extraneous, and germane cognitive load [11]. Intrinsic cognitive load is defined as the demand for working memory in processing information elements and their interactions in related tasks [12]. Extraneous cognitive load is generated by inappropriate activity

presentation rather than the task itself [12]. Germane cognitive load increases schema construction, therefore promoting the execution of the task [12, 13]. Broad evidence has shown that self-efficacy also affects an individual's cognitive load [14, 15]. Jiang et al. [14] reported that self-efficacy in English reading among students is negatively related to intrinsic cognitive load. However, the mediating effect of cognitive load between self-efficacy and task load is unclear. Therefore, the study aimed to investigate the mediator effects of cognitive load on the association between self-efficacy and task load of ICU nurses.

2. Materials and Methods

2.1. Study Design and Samples. A cross-sectional questionnaire study design was conducted with convenience sampling at three tertiary hospitals between February and June 2023.

Registered nurses were eligible for the study if they consented to participate in this study. Nurses were excluded if they (a) had less than 1 year of intensive care experience, (b) currently did not work full-time in the ICU, and (c) had long leave with pay, such as sick or prenatal leave. A simple structural equation model (SEM) was used to analyze the relationship among self-efficacy, cognitive load, and task load, and a minimum of 200 patients was required to run the model as suggested by Shah and Goldstein [16].

2.2. Instruments. The questionnaire consisted of four parts: (a) demographic information; (b) the Chinese National Aeronautics and Space Administration-Task Load Index (NASA-TLX); (c) the Chinese General Self-Efficacy Scale (GSES); and (d) an instrument for Measuring Different Types of Cognitive Load (MDT-CL). Cronbach's α coefficient for the combined questionnaires was 0.732, indicating that the Chinese version of the NASA-TLX, GSES, and MDT-CL had acceptable reliability for ICU nurses.

2.3. Demographic Information. Demographic information included age, gender, education level, marital status, number of children, living situation, years of ICU working experience, professional title, number of night shifts per month, and number of patients cared for during the whole shift.

2.4. National Aeronautics and Space Administration-Task Load Index. The NASA-TLX was used to assess task load and was developed by Hart [17] and was translated into Chinese by Liling Liang and colleagues [18]. The NASA-TLX has 6 items: mental demand, physical demand, temporal demand, performance, effort, and frustration. Each item is scored on a Likert scale from 0 (low load) to 20 (high load), and the total score ranges from 0 to 120, with higher scores indicating a higher level of task load. The retest reliability of the scale was 0.806, and Cronbach's α coefficient was 0.707 [18]. Content validity in the Chinese version of NASA-TLX was 0.900, and the split-half

reliability was 0.808 [19]. The Chinese version of NASA-TLX has good consistency between each item and validity.

2.5. General Self-Efficacy Scale. The GSES was developed by Schwarzer [9] and was translated into Chinese version by Caikang Wang et al. [20]. The GSES consists of 10 items, and each item is scored on a 4-point Likert scale ranging from 1 ("not at all true") to 4 ("exactly true"). Example items are "If you try hard, you can always accomplish a task efficiently" and "Even objected by others, you still can manage to get what you want." A single score for the GSES is computed using the total score of all items. A higher total score indicates a higher level of self-efficacy. The Chinese version of the GSES has shown good reliability and validity for Chinese adults [20, 21]. Cronbach's α coefficient was 0.870, retest reliability was 0.830 ($P < 0.001$), and split-half reliability was 0.820 ($n = 401$, $P < 0.001$) [20].

2.6. An Instrument for Measuring Different Types of Cognitive Load. The MDT-CL was used to assess three types of cognitive load. The MDT-CL was developed by Leppink and colleagues [12] and was translated into Chinese version by Zhang et al. [13]. A ten-item questionnaire was presented for the measurement of intrinsic cognitive load (items 1, 2, and 3), extraneous cognitive load (items 4, 5, and 6), and germane cognitive load (items 7, 8, 9, and 10). Example items are "The intensive care activity/activities presented in daily usual care was/were very complex" for intrinsic cognitive load, "The instructions and/or explanations in daily usual care during implementing intensive care activity/activities were very unclear" for extraneous cognitive load, and "Daily usual care enhanced my understanding of the intensive care activity/activities covered" for germane cognitive load. Each item scores from 0 ("not at all") to 10 ("completely"), the higher the score, the higher the cognitive load. The Chinese version MDT-CL has good reliability and validity, and Cronbach's α was 0.818; Cronbach's α in measurement of intrinsic, extraneous, and germane cognitive load was 0.879, 0.878, and 0.946, respectively [13].

2.7. Data Collection. Before the study commencement, the investigators received research training about how to use standardized instruments to ensure the collected data were consistent and accurate. Data collectors recruited ICU nurses based on the inclusion and exclusion criteria, and the aim and procedure of the study were fully explained to all eligible nurses before the recruitment. This survey was conducted anonymously, utilizing online responses via mobile phones. To ensure the accuracy and effectiveness of the questionnaire, any questions related to the study were answered by the investigators during the completion of the questionnaire. All of the questions refer to the daily nursing activity that just finished. For instance, "The nursing activity presented in daily usual care that I perceived as very complex," "The instructions and/or explanations in daily usual care were, in terms of clinical application, very

ineffective,” and “Daily usual care enhanced my knowledge and understanding of nursing.” After completing the questionnaire, all data were entered into a database by two researchers who conducted extensive error and validity checks. The quality of the questionnaires was checked, and any questionnaires with identical answers or missing answers to more than two-thirds of the questions were excluded.

2.8. Informed Consent and Ethical Considerations. The institutional review board of the university approved this study (approval number: Z2019SY021). Written informed consent was obtained from all ICU nurses after the investigators introduced the study procedures in detail. The eligible ICU nurses had the right to withdraw from the study at any time without any harmful consequences.

2.9. Data Analysis. The SPSS version 25.0 (SPSS Inc., Chicago, IL) was used for data analyses, cases with missing data in self-efficacy, cognitive load, and task load, or with missing covariates (age, gender, educational level, and years of ICU working experience) >35% were excluded from the final analysis, and others were processed using multiple imputations if the missing is in random [22]. Continuous variables were described as means and standard deviation (SD) for normal and medians and inter-quartile range for abnormally distributed data. The relationship among self-efficacy, cognitive load (intrinsic, extraneous, and germane cognitive load), and task load (dichotomous variable) was verified using the Pearson correlation test. Finally, the significant factors ($P < 0.05$) were selected to enter a multiple linear regression analysis. The standardization coefficient (β) and standard error (SE) were used to express the strength of the association. Finally, all significant variables that were identified by the multivariate linear regression were entered into the structural equation model (SEM). Harman’s single-factor test was used to examine common method variance with self-report measures [23]. Model 4 test in PROCESS in SPSS (an add-on for SPSS) was used for mediation analysis of task load, self-efficacy, and cognitive load [24]. The bootstrap method with a 95% bias-corrected confidence interval (CI) was used to test the significance of the mediation effect. The statistical significance was set at $P < 0.05$, with two-tailed testing.

3. Results

3.1. General Characteristics of the Participants. A total of 265 questionnaires were distributed, and 253 (95.47%) valid questionnaires were returned. The average age was 32.91 years (SD = 6.30; range between 21 and 52 years), and 65.3% are female (Table 1). The mean years of ICU working experience were 9.81 years (SD = 5.18), and most of the ICU nurses (86.6%) reported working night shifts.

3.2. Correlation among Major Variables. The ICU nurses showed high levels of task load with an overall NASA-TLX score of 86.49 ± 15.05 , and 42.69% (108/253) of ICU nurses had a high-level task load (overall NASA-TLX score ≥ 90). The score of each item was as follows: mental demand (15.17 ± 3.30), physical demand (16.87 ± 2.97), temporal demand (15.46 ± 3.32), performance (16.01 ± 2.92), effort (11.47 ± 5.96), and frustration (11.49 ± 5.47).

As shown in Table 2, statistically significant differences were observed between task load and self-efficacy ($r = -0.437$, $P < 0.001$), task load and intrinsic cognitive load ($r = 0.373$, $P < 0.001$), and task load and extraneous cognitive load ($r = 0.636$, $P < 0.001$). However, no significant differences were found between task load and germane cognitive load ($r = -0.051$, $P > 0.05$).

3.3. Factors Affecting Task Load. The self-efficacy, intrinsic cognitive load, and extraneous cognitive load were entered into regression analysis with enter forwards selection due to these factors being statistically related to task load. As shown in Table 3, after adjusting covariates (age, gender, educational level, and years of ICU working experience), the results indicated that only self-efficacy ($\beta' = -0.202$, $P < 0.001$) and extraneous cognitive load ($\beta' = -0.520$, $P < 0.001$) were statistically explained task load.

3.4. Structural Model. Harman's single-factor test showed that the cumulative variance interpretation was 28.26%, which is lower than the critical standard of 40% [25], illustrating that common method variance was not significant in this study.

Figure 1 shows the mediation model.

The direct and indirect effects of the model are summarized in Table 4. The results showed that self-efficacy significantly predicted extraneous cognitive load ($a = -0.728$, $SE = 0.102$, $P < 0.001$), extraneous cognitive load was shown to be a significant predictor of task load ($b = 0.971$, $SE = 0.093$, $P < 0.001$), and self-efficacy also had a direct effect on task load ($c' = -0.662$, $SE = 0.163$, $P < 0.001$). The bias-corrected percentile Bootstrap method test showed that extraneous cognitive load partially mediated the relationship between self-efficacy and task load ($a * b = -0.707$, 95% CI: -0.940 , -0.504 ; $SE = 0.112$; $P < 0.001$). The mediation effect accounted for 51.64% of the total effect.

4. Discussion

In this cross-sectional design study, 253 ICU nurses were investigated to explore the mediator effects of cognitive load between self-efficacy and task load. We found that 42.69% of ICU nurses had high levels task load, and correlations analysis reported self-efficacy was negatively related to task load, but intrinsic and extraneous cognitive load were positively related to task load. However, after adjusting covariates in multiple linear regression analysis, only self-efficacy and extraneous cognitive load were statistically explained task load. A three-factor mediation model was

constructed and tested, and the relationships between self-efficacy and task load were partially mediated by extraneous cognitive load among ICU nurses, accounting for 51.64% of the total effect. The findings imply that even though the perceived task load of ICU nurses was affected by both poor self-efficacy and high-level extraneous cognitive load from daily intensive care activities, the influence of self-efficacy can be increased if extraneous cognitive load declines. Therefore, early assessment of self-efficacy and cognitive load for ICU nurses may benefit from targeted prevention strategies.

The partially mediating role of extraneous cognitive load between overall self-efficacy and task load of ICU nurses was confirmed in our study. In other words, an individual's self-efficacy not only has a direct effect on task load but also has an indirect effect through extraneous cognitive load. ICU nurses with high-level self-efficacy are always able to cope with unexpected issues and come up with solving strategies [26, 27]. These abilities weaken the high level of the extraneous cognitive load caused by unclear instructions for nursing activities in daily nursing practice, thereby reducing the task load in terms of mental demand, physical demand, temporal demand, performance, effort, and frustration for ICU nurses. Highlighting the meaningfulness of high-level self-efficacy and low-level extraneous cognitive load might contribute to a decreased perceived task load.

Regarding the relationship between self-efficacy and perceived task load among ICU nurses, it has been found that high levels of self-efficacy were associated with lower levels of task load. The findings from this study were confirmed by other studies [7, 8]. Cayupe et al. [7] recruited 300 primary school teachers to examine the mediating role of job satisfaction between self-efficacy, life satisfaction, workload, and overall life satisfaction. They also found that self-efficacy was negatively related to workload ($r = -0.43$). In addition, Molero et al. [8] investigated 1307 nurses in a cross-sectional study and reported that workload had a significant negative relationship with perceived self-efficacy ($r = -0.07$; $P < 0.01$).

It is likely because ICU nurses with high-level of self-efficacy are more capable of coping with the workload brought on by the high-intensity working environment. They are more likely to adopt proactive strategies to alleviate challenges from intensive tasks, such as participating in education programs, flexibly adjusting resource allocation, generating effective work plans, and time management strategies, and having good team cooperation ability; these strategies could help ICU nurses alleviated the perceived task load [28–30]. Therefore, the nursing administrator should provide job support to increase self-efficacy among ICU nurses, which would empower and motivate them to cope with an intensive task load.

Our study also examined the correlation between extraneous cognitive load and task load, indicating that the high level of extraneous cognitive load from unclear instructions in daily intensive care activities was positively related to higher perceived task load. Nasirizad and colleagues [31] conducted a cross-sectional study among 105 ICU nurses. They confirmed a significant relationship between cognitive and task load ($P < 0.001$). Based on the Cognitive Load Theory (CLT),

TABLE 2: Descriptive statistics and correlations of the study variables ($N = 253$).

	1	2	3	4	5
(1) Self-efficacy	1.000				
(2) Intrinsic cognitive load	-0.332**	1.000

FIGURE 1: Mediation model of extraneous cognitive load on the relationship between self-efficacy and task load of ICU nurses. Note: All coefficients are significant ($P < 0.001$).

TABLE 4: Effect analysis of extraneous cognitive load as a mediator between self-efficacy and task load in ICU nurses ($N = 253$).

Effect	Path	β	Bias-corrected 95% CI	SE	t -value	P value
Direct effect	Self-efficacy \rightarrow task load	-0.662 (c')	-0.984, -0.341	0.163	-4.057	<0.001
Indirect effect	Self-efficacy \rightarrow extraneous cognitive load	-0.728 (a)	-0.929, -0.527	0.102	-7.144	<0.001
	Extraneous cognitive load \rightarrow task load	0.971 (b)	0.788, 1.154	0.093	10.467	<0.001
Total effect	Self-efficacy \rightarrow task load	-1.369	-1.721, -1.018	0.178	-7.681	<0.001

Note. Adjusting for covariates, including age, gender, educational level, and years of ICU working experience.

the human cognitive resources are limited, and once the cognitive resources required for the cognitive tasks to be processed exceed the total cognitive resources of human beings, cognitive load increases and results in unsatisfactory task performance [10]. The extraneous cognitive load can be derived from suboptimal presentation methods and unclear instruction of activities [12]. Therefore, nursing administrators should identify and modify the factors that increase the extraneous cognitive load in nursing practice, for example, by simplifying nursing processes and improving collaboration mechanisms. In addition, administrators can introduce appropriate information technology-assisted tools, such as intelligent devices, to improve the presentation mode of interventions, provide decision support, and alleviate the nurse's extraneous cognitive load [32, 33].

4.1. Limitations and Future Research. This study has several limitations. First, the ICU nurses were recruited from three tertiary hospitals in one region, which limits the generalisability of the study findings to different populations and regions. In the future, expanding the sample collection is recommended to identify differences between region levels. Second, the nature of the cross-sectional study limited the possibility of drawing causal relationships among the variables. To gain a better understanding of the relationship between self-efficacy, cognitive load, and task load in ICU nurses, prospective longitudinal studies were recommended to confirm causal relationships in the future. Finally, the investigated variables in this study were collected by self-report questionnaires, which may lead to recall bias. For future studies, objective

measurements of task load, such as pupil diameter, heart rate variability (HRV), and electroencephalography (EEG), are recommended [34, 35].

5. Conclusions

In this cross-sectional study, we concluded that self-efficacy and lower extraneous cognitive load could help defend against the adverse impact of increased task load among ICU nurses. Self-efficacy influences the task load, and extraneous cognitive load partially mediates the correlation. Therefore, nursing managers should strengthen the assessment and monitoring of self-efficacy and cognitive load in ICU nurses and tailor effective support strategies to reduce task load. To sum up, self-efficacy is a crucial resource in the ICU nursing work environment with positive impacts on well-being (e.g., reducing physical demand and frustration).

6. Implications for Nursing Management

Given that self-efficacy has beneficial consequences for nurses' cognitive load and task load, interventions directed at three factors can be carried out. Nursing administrators need to pay attention to the measurement of nurses' self-efficacy, cognitive load, and task load, focus on the presentation of nursing activities and other factors that may affect the source of task load for ICU nurses, and provide targeted intervention measures. For example, nursing administrators should promote the development of strong cooperation among nursing teams (e.g., gratitude for the help and mutual appreciation) to work together in high-pressure and complex ICU work environments. These effective strategies for enhancing self-efficacy and improving the cognitive load of nurses can help them to reduce work burden and pressure, thereby improving their job satisfaction, physical and mental health, and work performance.

Aim. To examine the effectiveness of mobile health application-based interventions on mortality, hospitalization rate, self-care, and quality of life in people with heart failure. **Background.** Mobile health application-based interventions are reported to potentially help people with heart failure improve health-related clinical outcomes. However, evidence on the effects of mobile health application-based interventions on mortality, hospitalization, self-care, and quality of life remains inconclusive and limited. **Methods.** A systematic literature search was conducted in six databases (MEDLINE, CINAHL Plus with Full Text, PsycINFO, Web of Science, EMBASE, and CENTRAL) to identify relevant studies from inception to 21 October 2023. Two authors independently extracted the data and assessed the risk of bias using the Cochrane risk-of-bias tool. The meta-analysis was conducted in Review Manager (version 5.4) and the statistical software R 4.3.3. Sensitivity analysis and subgroup analysis were also performed. The certainty of the evidence was evaluated by the GRADE approach. **Results.** Twenty-four studies involving 2886 participants were identified in this review. The pooled analysis showed that mobile health application-based interventions had statistically significant beneficial effects on reducing heart failure-related hospitalization (RR = 0.72, 95% CI 0.57 to 0.91, $p = 0.01$) and improving quality of life (SMD = 0.46, 95% CI 0.09 to 0.83, $p = 0.02$), but had no statistically significant effects on all-cause mortality (RR = 0.90, 95% CI 0.66 to 1.25, $p = 0.47$), cardiovascular mortality (RR = 0.87, 95% CI 0.59 to 1.26, $p = 0.24$), all-cause hospitalization (RR = 0.74, 95% CI 0.39 to 1.42, $p = 0.29$), or self-care (MD = -2.42, 95% CI -15.07 to 10.24, $p = 0.64$). Subgroup analyses indicated that intervention duration and monitoring frequency may influence the effects of mobile health application-based interventions on quality of life. **Conclusions.** Mobile health application-based interventions were effective at reducing heart failure-related hospitalization and improving quality of life in people with heart failure. More well-designed randomized controlled trials are needed to strengthen the evidence. **Implications for Nursing Management.** Mobile health application-based interventions may have benefits for improving heart failure-related hospitalization and quality of life. More rigorous studies are warranted to confirm the effects of mobile health application-based interventions for people with heart failure.

1. Introduction

Heart failure is considered a global health care problem since it is associated with a high hospitalization rate, increased mortality, and impaired quality of life, leading to a heavy economic burden on global health care systems [1, 2]. Current guidelines suggest that continuous medical therapy and patient self-care play a core role in improving the prognosis of heart failure [3]. Self-care in heart failure refers to the specific health behaviors that patients perform to manage their disease and promote health [4]; these behaviors typically include daily weight monitoring, symptom

recognition, medication adherence, lifestyle changes, and regular follow-up [3]. Appropriate treatment adherence and optimal self-care have positive effects on patients' outcomes (e.g., decreased mortality and improved quality of life) [5, 6]. Despite the proven benefits of self-care, people with heart failure exhibit poor self-care behaviors [7–9]. Only 42% of patients persistently undertake good self-care behavior [9]. Studies have shown that unmet needs for disease knowledge and limited access to healthcare providers are the main barriers to self-care for people with heart failure [10, 11].

Recent advances in information technology have offered opportunities to address and resolve self-care barriers for

people with heart failure. Mobile health (mHealth) is defined as the use of mobile devices (e.g., smartphones, tablets, personal digital assistants—PDAs, and other mobile devices) to deliver health care services outside of hospital settings [12]. Mobile application is one of the typical and popular delivery methods for mHealth worldwide [13]. Interventions based on mobile health applications have the potential to educate one on one at any convenient time and place, collect real-time data, track heart failure signs and symptoms, and provide quick health advice [14, 15]. Previous trials demonstrated that mobile applications can promote patient adherence to medication, self-monitoring of symptoms, and healthy lifestyles, which contribute to lower rehospitalization rates and improved quality of life [15–17]. Although the potential of mobile health application-based interventions has been well established in recent years, the effectiveness of such interventions for people with heart failure is mixed [18–20]. For example, Jiang et al. [17] reported that smartphone application use could improve self-care and quality of life among people with heart failure, while no effect on self-care was found in another article [20].

Several systematic reviews have assessed the effects of mobile health application-based interventions on people with heart failure. Kitsiou et al. [21] revealed that mobile health interventions (such as mobile applications, text messages, and remote mobile monitoring) were effective at reducing mortality and heart failure-related hospitalizations. Son et al. [22] reported that mobile phone-based interventions, including voice calls, telemonitoring, short messaging services, and mobile applications, could reduce the length of hospital stay for people with heart failure. However, these reviews combined various mHealth interventions in one study instead of focusing on specific application-based interventions [21–23], which may confound the true effects of application-based interventions. One review tested the effect of mobile applications, but the participants were mixed patients with various cardiovascular diseases (i.e., hypertension, heart failure, stroke, and cardiac rehabilitation populations) and not categorizing for heart failure [24]. Athilingam and Jenkins [25] qualitatively synthesized the effects of mobile phone application interventions and found inconsistent effects on self-care management. In their review, the randomized controlled trials (RCTs), pilot RCTs, and prepost intervention design trials were included. One recent systematic review examined the effectiveness of mobile health applications on mortality, hospitalization rate, and quality of life, but the applications were limited to telemonitoring applications, and applications with no remote monitoring functionality were not included [26]. Additionally, this review did not assess the effects on self-care and only included articles published between 2000 and 2021. Alves Leite de Barros et al. [13] conducted a review on the effects of mobile health applications on people, focusing on medication adherence, but the authors did not evaluate mortality, hospitalization, self-care, or quality of life. Thus, existing reviews cannot provide sufficient evidence on the effects of mobile health application-based interventions on mortality, hospitalization, self-care, and quality of life in people with heart failure.

Moreover, as the field of information technology has advanced, there has been rapid growth in mobile application intervention research. There shall be more rigorous data synthesis to inform the effects of mobile health application-based interventions to guide heart failure management. Therefore, this systematic review aims to quantitatively analyze the evidence of mobile health application-based interventions to determine its pooled effects on mortality, hospitalization rate, self-care, and quality of life for people with heart failure.

2. Methods

This systematic review and meta-analysis were registered in the International Prospective Register of Systematic Reviews (PROSPERO protocol number: CRD42023492005) and reported according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. A Measurement Tool to Assess Systematic Review 2 (AMSTAR2) was followed to ensure the quality of this review [27].

2.1. Literature Search. A comprehensive search was performed from inception to 21 October 2023 across six electronic databases: MEDLINE, CINAHL Plus with Full Text, PsycINFO, Web of Science, EMBASE, and CENTRAL. The search strategy used a combination of medical subject headings (MeSH) and text words, such as “heart failure,” “cardiac failure,” “mobile applications,” “mobile health,” and “smartphone.” Appropriate Boolean operators were used to combine these MeSH terms and text words to retrieve all relevant studies. The limiters were English language articles. A manual search through the reference lists of the included articles and previously published relevant reviews was also conducted to retrieve any additional studies. The detailed search strategy is presented in Supplementary Material Table S1.

2.2. Inclusion and Exclusion Criteria. The articles were included if they met the following PICOS criteria: (1) population: adults diagnosed with heart failure; (2) intervention: any mobile health applications used either as a standalone or combined with other delivery modes, such as telephone calls, text messages, or telemonitoring. The applications offer an interface through any kind of mobile device, for example, a smartphone, tablet computer, or PDA; (3) comparison: usual care, standard care, routine care, waitlist control or health education without mobile application; (4) studies including at least one of the following outcomes: mortality, hospitalization rate, self-care, or quality of life; and (5) study design: RCTs or pilot RCTs.

The exclusion criteria were as follows: (1) mixed participants with various chronic diseases or general cardiac disorders (e.g., hypertension, coronary heart disease, and atrial fibrillation) but not categorizing for heart failure; (2) primary intervention were telephone calls, videoconferences, e-mail, online social networking, or any other mobile intervention without applications; (3) comparisons were

made between different applications in both the intervention group and control group; (4) applications as a control group compared to other mobile technology-based interventions, such as automated telemonitoring devices; (5) incomplete studies, such as study protocols or incomplete data; and (6) conference abstracts, book chapter reviews, or editorials.

2.3. Study Selection and Data Extraction. The results of the literature search were exported to EndNote x9 software. After removing duplicates, two authors independently screened the titles and abstracts of the studies based on the inclusion and exclusion criteria. Then, full-text assessment of potentially relevant studies was conducted by the same two authors to select the eligible studies to be included in this review. Any disagreements were discussed with a third reviewer to reach a consensus.

Data from the included studies were independently extracted by two authors using predesigned data collection forms guided by the Cochrane Handbook [28]. The extracted data included author, year, country, sample size, sample characteristics (e.g., age, gender), intervention characteristics (e.g., key component, frequency and duration, mobile device, and delivery personnel), control characteristics, outcomes and measurement tools, and grants. The corresponding authors were contacted by e-mail for missing information when the data were incomplete. Disagreements were resolved by discussion with a third reviewer.

2.4. Quality and Evidence Assessment. Two authors assessed the methodological quality of the included studies using the Cochrane Risk-of-Bias Tool [29]. Disagreements were resolved by discussion with a third reviewer. This risk tool includes seven domains: random sequence generation (selection bias), allocation concealment (selection bias), blinding of participants and personnel (performance bias), blinding of outcome assessment (detection bias), incomplete outcome data (attrition bias), selective reporting (reporting bias), and other bias. Each domain was rated as having a low risk of bias, a high risk of bias, or an unclear risk of bias. The certainty of evidence was independently evaluated by two reviewers using the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) approach [30], which classified the certainty of the evidence into four classes (high, moderate, low, or very low) from five aspects (risk of bias, inconsistency, indirectness, imprecision, and publication bias). The Grading of Recommendations Assessment, Development, and Evaluation Profiler Guideline Development Tool (GRADEpro GDT) was applied to develop the GRADE evidence profile.

2.5. Data Synthesis and Analysis. A descriptive synthesis was performed to describe the characteristics of the included studies. All the statistical analyses for the meta-analysis were performed with Review Manager 5.4 and the statistical software R 4.3.3. Binary outcomes were calculated by the risk ratio (RR) with 95% confidence intervals (CIs) using the Mantel-Haenszel method, and statistically significant RRs

were translated into numbers needed to treat (NNT) to determine clinical relevance. For continuous data measured using the same tools, mean differences (MDs) with 95% CIs were used to determine the effects of the intervention. For continuous data measured using different tools, standardized mean differences (SMDs) with 95% CIs were computed using the generic inverse variance method [28]. The effect size was evaluated by Cohen's *d* (0.20–0.49 indicated a small effect, 0.50–0.79 a moderate effect and ≥ 0.80 a large effect) [31]. The overall effect was determined using Z-statistics with $p < 0.05$.

A random-effects model with restricted maximum likelihood estimation was used based on the clinical and methodological heterogeneity across the included studies [32, 33]. The Knapp-Hartung adjustments were conducted for 95% CIs of pooled effect sizes to reduce the risk of false positives. The 95% prediction intervals (PIs) were also calculated [34]. The statistical heterogeneity of the included studies was assessed using the I^2 statistic and Cochran's *Q* test. I^2 values of 0% to 40%, 30% to 60%, 50% to 90%, or 75% to 100% indicated unimportant, moderate, substantial, or considerable heterogeneity, respectively [28]. Possible sources of heterogeneity between studies were explored by subgroup analyses (i.e., duration of intervention, mobile device, frequency of monitoring, and delivery personnel). For studies with a multi-arm profile, the relevance to this review scope was assessed to create a single pairwise comparison for the main analysis according to the Cochrane Handbook [28]. When the studies reported the medians and interquartile ranges, the means and standard deviations were estimated following the recommendations of McGrath et al. [35]. A sensitivity analysis was performed by excluding one study at a time to test the robustness and reliability of the pooled results [36]. Egger's regression test and funnel plots were used to detect potential publication bias.

3. Results

3.1. Study Selection. The PRISMA flowchart of the literature search and selection process is shown in Figure 1. A total of 4208 records were retrieved from electronic databases, and 8 records were searched manually through the reference lists of the included articles and previously published relevant reviews. After removing duplicates and screening for titles and abstracts, 79 studies remained for full-text assessment. Finally, 24 studies met the inclusion criteria and were included in this review.

3.2. Characteristics of the Included Studies. The characteristics of the included studies are shown in the Supplementary Material Table S2. A total of 2886 individuals with heart failure were involved from 24 studies, with sample sizes ranging from 18 to 710. Twenty-three studies [14–16, 18–20, 37–53] were two-arm trials, and one was a three-arm trial [17]. All the studies were published between 2009 and 2023, and 62.5% (15/24) of the studies were published after 2020. The studies were conducted in Europe ($n = 10$), North America ($n = 6$), Asia ($n = 6$), Oceania

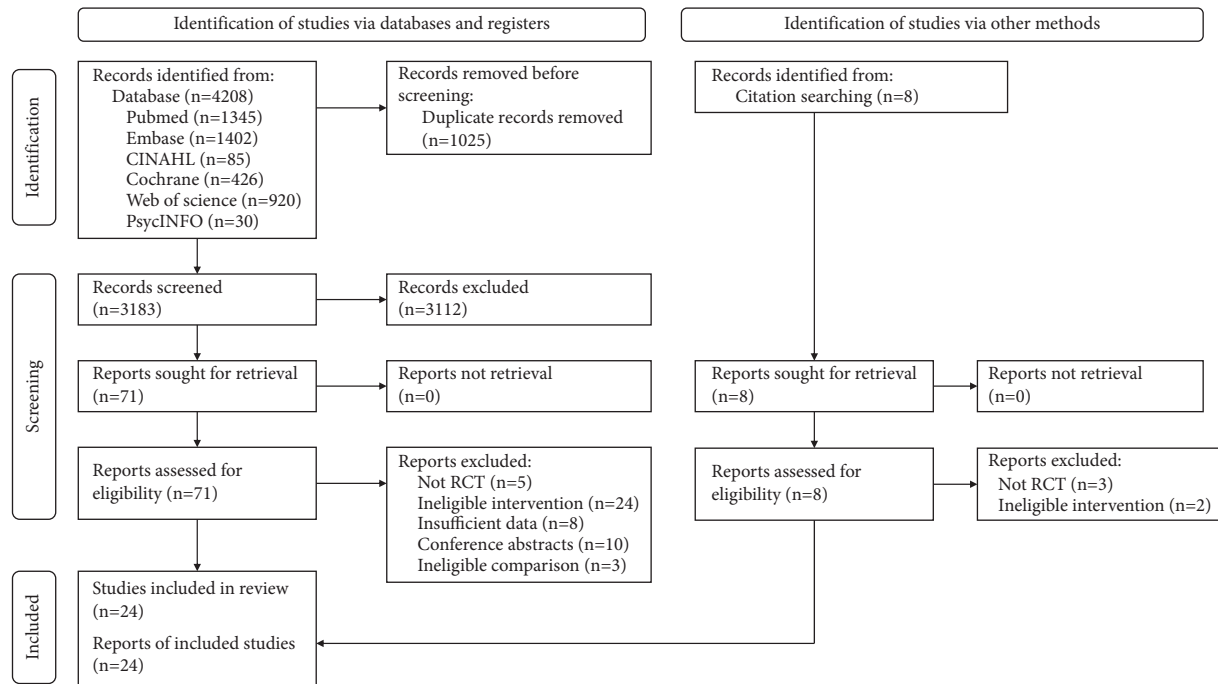

FIGURE 1: PRISMA flow diagram.

($n=1$), and South America ($n=1$). The mean age of the participants ranged from 50.0 to 79.9 years, and the percentage of female participants ranged from 7% to 69.8%. Twenty-three studies involving 2855 participants reported the New York Heart Association (NYHA) classification (a classification system used to assess functional exercise capacity and symptom severity of patients), and approximately 50% presented with NYHA class III or IV. Left ventricle ejection fraction (LVEF) was described in 19 studies, 13 of which reported a reduced ejection fraction $\leq 40\%$.

3.3. Characteristics of Interventions and Comparators. Five studies delivered interventions via basic mobile phones, 11 studies via smartphones, 6 studies via tablets, and 2 studies via the PDA. All the studies conducted the interventions in participants' homes. The interventions were implemented by different personnel, including physicians, clinicians, cardiologists, or geriatricians, in 8 studies; nurses in 8 trials; multidisciplinary care teams in 5 studies; and study coordinators in 1 study. Two studies did not report any information about the personnel.

3.3.1. Key Features of the Mobile Application-Based Interventions. The functionalities provided by the applications varied among studies. The seven key features of the applications included (1) reminders and notifications (i.e., reminding the participants to use the application, perform self-monitoring, or take medicine); (2) self-monitoring and assessment (i.e., conducting self-monitoring and recording vital parameters and symptoms, such as blood pressure, heart rate, and weight); (3) goal-setting (i.e., setting up

a tailored goal for participants, such as physical activity); (4) health education (i.e., providing health information or resources related to heart failure); (5) feedback and alerts (i.e., providing clinician feedback and alerts based on physiological and symptom information); (6) tele-coaching (i.e., providing personalized recommendations and modifying the treatment); and (7) social interaction (i.e., access to chat rooms, discussion forums, and interactions with companions and professionals). The details of the interventions are summarized in the Supplementary Material Table S2.

Reminders and notifications: fifteen studies used applications that offered reminders and notifications. Visual or audible reminders or push notifications were sent to patients to remind them to take measurements (e.g., weight and blood pressure), answer the questionnaire (e.g., symptom assessment), or use the application.

Self-monitoring and assessment: all but one study [19] used applications with self-monitoring and assessment features. In 13 of these studies, physiological data (e.g., weight and heart rate) were automatically sent to mobile devices via wireless Bluetooth or wearable technology. Seven studies recorded the measurement values manually. Three studies did not report whether the measurements were manually recorded or automatically recorded. The most frequently monitored parameters across studies were weight ($n=20$), blood pressure ($n=13$), heart failure symptoms ($n=12$), and heart rate ($n=7$).

Goal-setting: three studies used applications that had goal-setting. Saleh et al. [15] set up a weekly goal for physical activity via the mobile health applications. Clays et al. [48] and Wita et al. [16] developed personalized physical exercise schemes or individualized care plans based on patient parameter trends.

Health education: thirteen studies used applications that offered health information and resources in various formats (e.g., text, photos, videos, question, and answer games). Health information involves various aspects of heart failure, such as pathophysiology, symptoms, symptom management, lifestyle, treatment, and self-care behavior.

Feedback and alerts: twenty studies used applications with feedback and alert features. Participants received feedback and alerts via e-mail, messages, calls or screen color classification (e.g., Red Zone) [44] when the reported vital parameters were outside the target range or when symptoms indicated possible worsening of heart failure. Feedbacks or alerts were generated based on medical staff assessments (delayed) [46, 50] or automatically generated by machines (immediate) [20, 41].

Tele-coaching: eight studies used applications with a tele-coaching feature. The tele-coaching included a clinical consultation, therapy modification (e.g., an extra dose of diuretic), an early office visit, and exercise prescription adjustment.

Social interaction: four studies used applications that allowed interactions. Among these studies, one study allowed patients to share their behavioral progression and daily goal achievement with their companions [15], and all four studies provided chat rooms or discussion forums for interactions between patients and professionals.

3.3.2. Dosage (Duration and Frequency) of Mobile Application-Based Interventions. The duration of the mobile health application-based interventions varied among the included studies, ranging from 4 weeks to 24 months. Seven studies had the duration of mobile application-based interventions for 3 months. Six studies implemented the mobile application-based interventions for 6 months. Two studies reported the duration of the interventions for 12 weeks, two for 12 months, and two for 24 months. The remaining studies had the duration of mobile application-based interventions for 4 weeks, 6 weeks, 45 days, 8 weeks, or 240 days. The follow-up period ranged from 30 days to 2 years. Nineteen studies had daily self-monitoring for blood pressure, heart rate, weight, or symptoms. Three studies had weekly monitoring for the ECG. Twelve studies provided real time feedback or alerts. Further details are shown in the Supplementary Material Table S2.

3.3.3. Empowerment Strategies. Eight studies [14, 15, 17, 19, 20, 44, 46, 51] incorporated empowerment strategies and behavior change strategies in the applications. Cichosz et al. [46] reported that the core concept of the intervention was patient empowerment, achieved by increasing patients' coping capabilities through self-monitoring. Saleh et al. [15] used the Theory of Planned Behavior to guide interventions and empower patients with the ability to perform physical activity. Johnson et al. [51], Athilingam et al. [44], and Kiyarosta et al. [14] reported that daily prompts or encouragement messages were sent to the

patients in the intervention group. Another three studies [17, 19, 20] demonstrated that patients were motivated to engage in self-management behavior through various types of education information or daily messages. One study [48] embedded psychological support in applications, which included cognitive behavioral interventions and mindfulness exercises based on a weekly plan.

The control conditions, including usual care ($n=17$), standard care ($n=6$), and waitlist control ($n=1$), varied across the included studies. The contents of the controls mainly included standard pharmacological treatment, provision of information, and outpatient follow-up.

3.4. Characteristics of the Study Outcomes. Study outcomes were measured using validated scales. Self-care was measured using two different scales, including the Self-Care of Heart Failure Index (SCHFI) and European Heart Failure Self-care Behavior Scale (EHFScB). Quality of life was measured using the Minnesota Living with Heart Failure Questionnaire (MLHFQ), Kansas City Cardiomyopathy Questionnaire (KCCQ), 36-item Short-form Health Survey (SF-36), or EuroQoL Five-Dimension. Nineteen studies reported outcomes of self-care or quality of life at baseline and follow-up, and one study provided change data from baseline to follow-up [48].

3.5. Risk of Bias and Certainty of Evidence. The risk of bias assessment for the 24 studies is presented in Figure 2. Sixteen studies provided details about random sequence generation, and 13 studies provided detailed information regarding allocation concealment, indicating a low risk of selection bias. Due to the nature of the mobile health application-based intervention, it was not feasible to blind the participants and personnels; thus, all studies were rated as high risk for performance bias. Blinding of outcome assessors was not achieved in 3 studies and was not clearly described in 16 studies, leading to a high or unclear risk of detection bias. Three studies were considered to be at high risk for attrition bias because the dropout rate was more than 20%, and intention-to-treat analyses were not performed. Eight studies were considered to have an unclear risk of reporting bias due to the lack of a published or registered protocol. The certainty of the evidence ranged from very low to moderate for different outcomes (Supplementary Material Table S3). The degrading factors mainly originated from the risk of bias, considerable heterogeneity, and small sample size.

3.6. Intervention Effects

3.6.1. All-Cause Mortality. Eight studies provided data regarding all-cause mortality, and the pooled results showed that mobile health application-based interventions had no statistically significant effect on all-cause mortality (RR = 0.90, 95% CI 0.66 to 1.25, $p = 0.47$, moderate-certainty evidence; Figure 3(a) and Supplementary Material Table S3), with no evidence of heterogeneity ($I^2 = 0\%$, $p = 0.62$).

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Blinding of participants and personnel (performance bias)	Blinding of outcome assessment (detection bias)	Incomplete outcome data (attrition bias)	Selective reporting (reporting bias)	Other bias

FIGURE 2: Risk of bias summary.

3.6.2. *Cardiovascular Mortality.* Three studies reported cardiovascular mortality as an outcome, and the pooled results showed that mobile health application-based

interventions had no statistically significant effect on cardiovascular mortality (RR=0.87, 95% CI 0.59 to 1.26, $p = 0.24$, moderate-certainty evidence; Figure 3(b) and Supplementary Material Table S3), with no evidence of heterogeneity ($I^2 = 0\%$, $p = 0.82$).

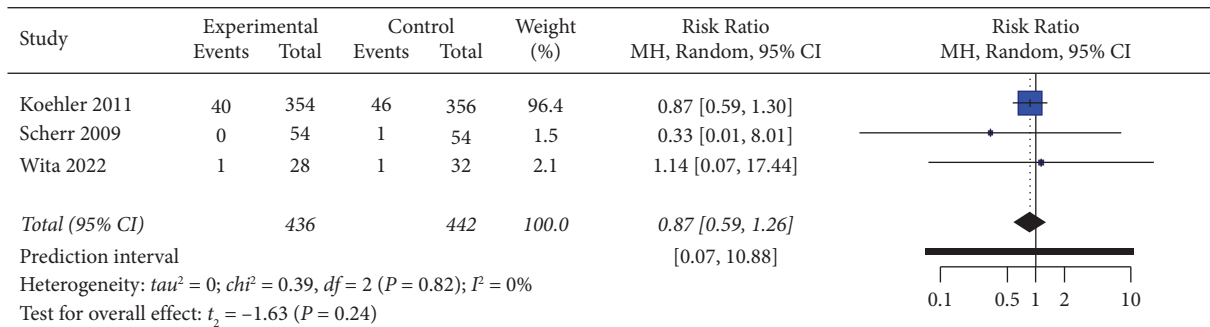

3.6.3. *All-Cause Hospitalization.* Seven studies assessed the effectiveness of mobile health application-based interventions for all-cause hospitalization, but only six studies were included in the meta-analysis. The excluded studies [39] reported the means and standard deviations instead of the numbers and percentages. The pooled results indicated that mobile health application-based interventions had no statistically significant effect on all-cause hospitalization (RR=0.74, 95% CI 0.39 to 1.42, $p = 0.29$, low-certainty evidence; Figure 3(c) and Supplementary Material Table S3), with statistically significant heterogeneity ($I^2 = 82\%$, $p < 0.01$). Seto et al. [39] reported no group differences in all-cause hospitalization.

3.6.4. *Heart Failure-Related Hospitalization.* Thirteen studies reported heart failure-related hospitalization. One study [17] was excluded from the meta-analysis because it reported the median hospitalization duration rather than the number and percentage of patients. The pooled results showed that mobile health application-based interventions significantly reduced heart failure-related hospitalization (RR=0.72, 95% CI 0.57 to 0.91, $p = 0.01$, low-certainty evidence; Figure 3(d) and Supplementary Material Table S3), with unimportant heterogeneity ($I^2 = 22\%$, $p = 0.22$). This effect size corresponds to an NNT of 14, indicating that one hospitalization from heart failure could be expectantly averted for every 14 people treated. The sensitivity analysis showed that the pooled result was not altered after removing the included studies one by one, indicating the robustness of the result.

3.6.5. *Self-Care.* Twelve studies assessed the effectiveness of mobile health application-based interventions for self-care. Six studies using the SCHFI reported scores for each subscale (i.e., self-care maintenance, self-care management, and self-care confidence) instead of the total score. Six studies used EHFS_{CB} to evaluate self-care. Higher SCHFI scores represented better self-care, while higher EHFS_{CB} scores indicated worse self-care. Additionally, the score of SCHFI was commonly presented in the subdimension rather than the total score. Thus, the effectiveness of self-care was separately combined based on different tools. The pooled results demonstrated that mobile health application-based intervention had no statistically significant effect on self-care maintenance (MD = 6.04, 95% CI -3.14 to 15.21, $p = 0.15$, low-certainty evidence; Figure 4(a) and Supplementary Material Table S3), self-care management (MD = 8.94, 95% CI -6.79 to 24.66, $p = 0.19$, very low-certainty evidence; Figure 4(b) and Supplementary Material Table S3), or self-care confidence (MD = 5.29, 95% CI -5.90 to 16.48, $p = 0.28$, low-certainty evidence; Figure 4(c) and Supplementary

Material Table S3) when measured using the SCHFI. Furthermore, the pooled results showed no statistically significant effects on overall self-care when measured using the EHFS_{CB} (MD = -2.42, 95% CI -15.07 to 10.24, $p = 0.64$, low-certainty evidence; Figure 4(d) and Supplementary Material Table S3).

3.6.6. Quality of Life. Fourteen studies evaluated the effectiveness of mobile health application-based interventions on quality of life. Twelve studies used one tool to measure quality of life, with six using the MLHFQ, three using the KCCQ, two using the SF-36, and one using the EuroQoL Five-Dimension. Two studies used two tools (the SF-36 and MLHFQ [45] and the SF-36 and KCCQ [46]) to evaluate quality of life. For these two studies, the MLHFQ or KCCQ score were used to perform the meta-analysis instead of the SF-36 because the SF-36 score was presented subdimensionally rather than as the total score. Among the 14 studies measuring quality of life, one study [51] was excluded from the meta-analysis due to incomplete data. Because lower scores on the MLHFQ indicate better quality of life, while higher scores on other tools indicate better quality of life, the changes in quality of life using MLHFQ were recalculated in the present study using the baseline score minus the final score based on the Cochrane Handbook [28] and a previous meta-analysis [54] to obtain a consistent explanation of the scale scores. The pooled results showed that mobile health application-based interventions had a small but statistically significant effect on improving quality of life (SMD = 0.46, 95% CI 0.09 to 0.83, $p = 0.02$, low-certainty evidence; Figure 5 and Supplementary Material Table S3), with substantial heterogeneity ($I^2 = 93\%$, $p < 0.01$). The sensitivity analysis demonstrated that the pooled result was opposite

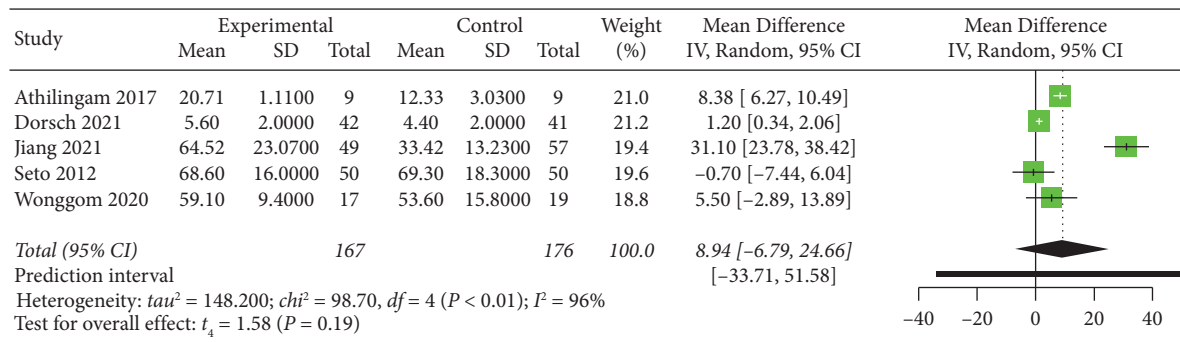

after removing the study [18], probably because the baseline quality of life in this study was lower than that in other studies.

3.6.7. Subgroup Analysis. A series of subgroup analyses were conducted based on the duration of intervention (<6 months, 6–12 months, or ≥ 12 months), mobile device (smartphone, mobile phone, or others), frequency of monitoring (daily or not daily), and delivery personnel (multidisciplinary team, not multidisciplinary team, or not specified). For the self-care subscales from the SCHFI (self-care maintenance and self-care confidence) and overall self-care from the EHFS_{CB}, the effect sizes among subgroups were similar, and no significant subgroup differences ($Q = 0.00$ – 2.83 , $p = 0.24$ – 0.98) were found except for different mobile devices for overall self-care ($Q = 8.39$, $p = 0.02$) (Figure 4 and Supplementary Material Table S4). No subgroup analysis was performed for self-care management (subscale of the SCHFI) due to the small number of studies included [55].

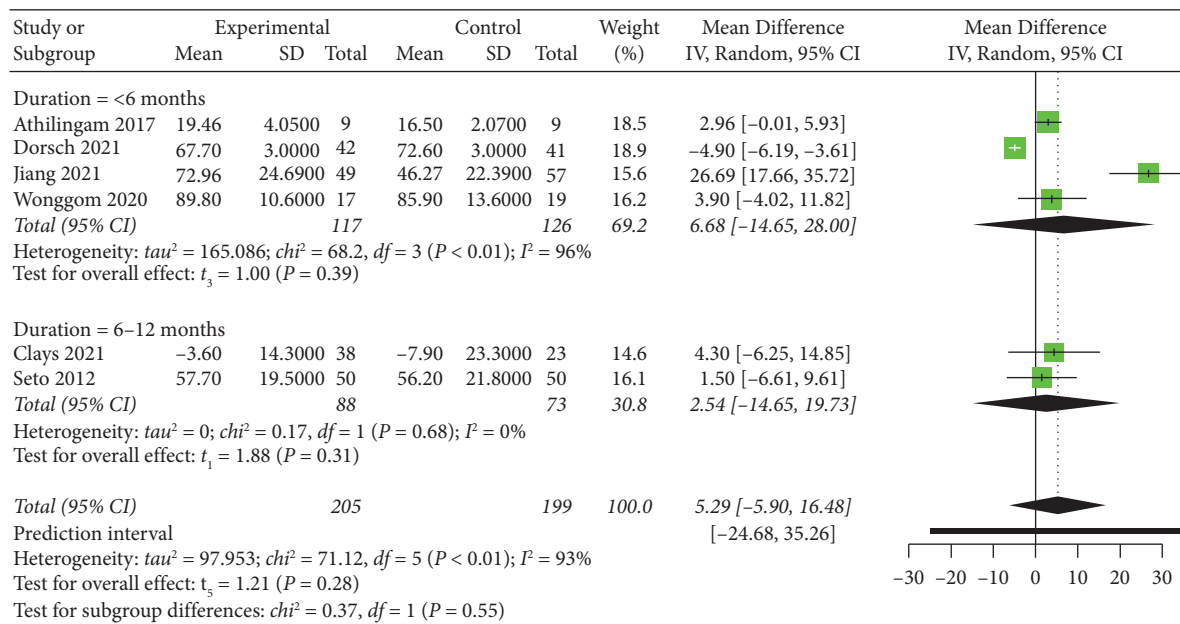

For quality of life, the results showed that mobile health application-based interventions were effective for improving quality of life when the duration of the intervention was between 6 and 12 months (SMD = 0.23, 95% CI 0.05 to 0.41, $p = 0.03$); however, no statistically significant effect occurred when the intervention duration was less than 6 months (SMD = 0.43, 95% CI -0.13 to 1.00, $p = 0.11$) or more than 12 months (SMD = 0.85, 95% CI -7.40 to 9.10, $p = 0.41$) (Figure 5). Nevertheless, the subgroup effect was not statistically significant ($Q = 1.58$, $p = 0.45$). According to the subgroup analysis of the frequency of monitoring, mobile health application-based interventions had a significant effect on quality of life when physiological data were

FIGURE 5: Forest plot of the effect of mobile health application-based interventions on quality of life.

monitored daily (SMD = 0.47, 95% CI 0.02 to 0.92, $p = 0.04$); however, no statistically significant effect was found when physiological data were not monitored daily (SMD = 0.40, 95% CI -2.26 to 3.05, $p = 0.31$) (Supplementary Material Table S4). No subgroup differences were detected ($Q = 0.06$, $p = 0.80$).

3.6.8. Publication Bias. Egger's regression intercept indicated that publication bias in quality of life was not statistically significant ($p = 0.054$). However, publication bias was found for heart failure-related hospitalization according to Egger's regression intercept ($p = 0.004$). Funnel plots of heart failure-related hospitalization and quality of life are presented in Supplementary Material Figures S1 and S2, respectively. Funnel plots for all-cause mortality, cardiovascular mortality, all-cause hospitalization, and self-care were not generated due to the small number of studies [28].

4. Discussion

This systematic review and meta-analysis summarized evidence from 24 studies involving 2886 participants to identify the effects of mobile health application-based interventions among people with heart failure. The pooled results showed that mobile health application-based interventions had beneficial effects on reducing heart failure-related hospitalization and improving quality of life but had no statistically significant effect on all-cause mortality, cardiovascular mortality, all-cause hospitalization, or self-care.

The results indicated that application-based interventions could not reduce mortality or all-cause hospitalization. These findings are consistent with previous reviews [26], which revealed no statistically significant positive effect of mobile telemonitoring applications on mortality in people with heart failure. Similarly, a review focused on mobile phone-based interventions for managing heart failure revealed that such interventions were not effective at reducing all-cause mortality or all-cause hospitalization [22]. One possible reason could be that almost all interventions included in this review monitored indices specific to heart failure (e.g., weight and heart failure symptoms), which may limit the possibility of identifying exacerbations related to other chronic conditions (e.g., diabetes and chronic obstructive pulmonary disease) and other cardiovascular diseases (e.g., ventricular arrhythmias) [21]. Another possible explanation is that more than half of the participants were older adults who had a high risk of comorbidity [56], prompting hospitalization because of another disease instead of heart failure.

The findings suggested that the application-based interventions may have benefits for reducing heart failure-related hospitalization, which was in line with the findings of a previous study [49]. Most of the included studies in this review had the feature of self-monitoring and feedback. Self-monitoring of physiological data (e.g., weight, blood pressure, and heart rate) and heart failure symptoms allows healthcare providers to track patients' health information and provide timely suggestions and knowledge about disease

[49, 50], which helps patients take early action to delay the worsening of heart failure, resulting in decreased failure-related hospitalization. However, these findings should be interpreted with caution. First, the certainty of evidence was low, and the included studies had varied risks of bias. Second, publication bias was detected for the outcome of heart failure-related hospitalization, which may overestimate the effectiveness of application-based interventions.

The results of the meta-analysis indicated that the effects of application-based interventions on self-care were not observed, whether measured with the SCHFI or EHFScB. These findings are supported by those of Wonggom et al. [19], who reported that the use of application-based interventions had no statistically significant effect on self-care maintenance or self-care confidence. However, these findings were inconsistent with those of a previous review by Zhang et al. [57]. A possible explanation for this difference is that nearly half of the included studies in this review did not provide additional health education resources, which may have limited the improvement of heart failure-related knowledge and skills and was less likely to cause statistically significant impacts on self-care. Nevertheless, almost all the included studies in Zhang et al.'s [57] review provided self-management guidance for chronic heart failure, resulting in improved self-care. Hence, our results suggest that health education can be embedded in applications in addition to tele-monitoring features and offers much more visual and vivid education, for example, videos, questions and answer games [50]. In addition, the studies included in this review rarely used empowerment strategies or behavior change theories, which may have resulted in a nonsignificant effect on self-care behavior in the present review, as incorporating empowerment strategies and behavior change theories into interventions is more effective than not incorporating such strategies [58]. Therefore, future studies should be developed based on empowerment strategies and behavior change theories.

Despite the apparent heterogeneity, this review revealed a statistically significant effect of mobile health application-based interventions on improving quality of life. Similarly, Zhang et al. [57] reported that electronic health interventions, such as application-based interventions, effectively increase quality of life in people with chronic heart failure. However, our findings are inconsistent with those of Son et al. [22] and Kitsiou et al. [21]. These differences may be because previous reviews included various mobile health technologies, such as voice call interventions and short message services, while the current review limited the intervention to mobile applications. Moreover, the most frequent intervention was voice calls in Son et al.'s study, which lacked an interface for telemonitoring interactions [26]. Self-monitoring, reminders, and feedback were the common features of our included studies; these features make it easy for patients to receive immediate support from healthcare professionals, eventually leading to improved quality of life. Subgroup analysis revealed that the effect on quality of life was observed when patients received mobile health application-based interventions for 6–12 months or when self-monitoring was conducted daily. However, the subgroup effect was not statistically significant, which might

be due to uneven distributions of studies and participants across subgroups [59]. This result should be interpreted with caution because of the small number of long-term studies (two to three trials), the heterogeneity of the interventions, and the low certainty of the evidence. Hence, further rigorous trials are warranted to draw highly robust conclusions.

Notably, when delivering mobile health application-based interventions for people with heart failure, the acceptance and simplicity of use of the applications need to be considered [60], especially for elderly patients and people with limited digital literacy [61]. The characteristics of applications may reduce patient engagement and increase the attrition rate, which in turn affects intervention effectiveness [61].

4.1. Limitations. This systematic review has several limitations. First, the methodological qualities of the included studies were not optimal, and all studies showed performance bias due to the nature of the interventions. Second, there was substantial heterogeneity between studies due to differences in sample sizes, intervention characteristics (e.g., application features, duration and frequency of monitoring), participant characteristics, and assessment tools. Therefore, the results of the current study must be interpreted with caution. Third, the included studies were mostly conducted in developed countries, which may limit the generalizability of our results. Fourth, only English-language studies were included, which may result in possible publication bias. Finally, cautions should be taken when using the evidence, as the overall GRADE evidence was very low to moderate.

4.2. Implications. This systematic review provides a quantitative synthesis of the effects of mobile health application-based interventions on mortality, hospitalization, self-care, and quality of life. The findings suggest that the use of mobile health application-based interventions can be considered a useful strategy for managing heart failure. Given the prevalence of smartphone ownership [62], mobile applications are a viable option for patients to obtain medical suggestions and support. Existing studies that involve application-based interventions differ in terms of delivery devices, personnel, key features of the application, durations, and outcome measures [18, 20]. Therefore, the optimal component of mobile health application-based interventions should be examined in the future based on patient characteristics and multicultural contexts. Only eight out of 24 studies used empowerment strategies and behavior change theories. Hence, additional theory-guided trials are warranted to determine the impact of mobile health application-based interventions on self-care. Due to the complexity of heart failure, a multidisciplinary team is recommended for delivery application-based interventions.

5. Conclusions

This systematic review and meta-analysis showed that mobile health application-based interventions are effective at reducing heart failure-related hospitalization and improving quality of life. Evidence was not conclusive for

mortality, self-care, and all-cause hospitalization. The effects on quality of life may vary among the different durations of the interventions and frequency of monitoring. Hence, well-designed randomized controlled trials are needed to explore the optimal duration of intervention and strengthen the current evidence.

The COVID-19 pandemic has exacerbated the difficulties nurses face, resulting in higher turnover rates and workforce shortages. This study investigated the relationships between nurses' moral distress, burnout, and turnover intention during the last stage of the COVID-19 pandemic. It also explored the coping strategies nurses use to mitigate moral distress. Utilizing a mixed-method approach, this study analyzed data from 307 nurses caring for patients with COVID-19 in acute care hospitals through an online survey conducted in November 2022. Our data analysis encompassed quantitative methods, including descriptive statistics and path analysis, using a generalized structural equation model. For the qualitative aspect, we examined open-ended responses from 246 nurses using inductive content analysis. The quantitative findings revealed that nurses' moral distress had a significant direct effect on turnover intention. In addition, burnout significantly mediated the relationship between moral distress and turnover intention. Qualitative analyses contextualized the relationships uncovered in the quantitative analyses. The qualitative analysis identified various positive and negative coping strategies. Positive strategies included a commitment to minimize COVID-19 transmission risks, adopting a holistic approach amidst the challenges posed by the pandemic, voicing concerns for patient safety, engaging in continuous learning, and prioritizing self-care. Conversely, negative strategies involved adopting avoidance behaviors stemming from feelings of powerlessness and adopting a passive approach to one's role. Notably, some participants shifted from positive to negative coping strategies because of institutional barriers and challenges. The findings underscore the importance for hospital administrators and nurse managers to acknowledge the impact of the pandemic-related challenges encountered by nurses and recognize the link among moral distress, burnout, and turnover intention. It highlights the essential role of organizational and managerial support in fostering effective coping strategies among nurses to address moral distress.

1. Introduction

The COVID-19 pandemic has significantly heightened the challenges faced by nurses, resulting in increased turnover rates and looming concerns about workforce shortages [1, 2]. The Organisation for Economic Co-operation and Development reported that a substantial number of nurses considered leaving their positions during and after the pandemic [3]. Furthermore, the International Council of

Nurses predicted a global shortage of up to 130,000 nurses, largely due to the pandemic [4]. Understanding the factors driving nurses' turnover intention is crucial to curtail these shortages. Traditional factors influencing nurse turnover include unfavorable work environments, unsupportive organizational cultures, high work demands, and insufficient social support [5, 6]. However, the pandemic has introduced novel concerns, such as COVID-19 fear, safety inadequacies, direct patient care challenges, personal infection risks, and

moral distress [7]. Furthermore, moral distress, driven by pandemic-specific ethical dilemmas, has played a central role in nurses' contemplation of leaving their positions or professions.

Moral distress is an emotional reaction that arises when individuals are unable to act ethically owing to external constraints [8]. The global COVID-19 pandemic presented nurses with myriad of challenges, intensifying their experience of moral distress [9, 10]. Amid the pandemic, nurses were required to shoulder dual responsibilities—attending to basic patient needs and delivering specialized nursing care, especially as isolated COVID-19 patients lacked dedicated caregivers [10, 11]. The scarcity of personal protective equipment (PPE) endangered the direct care of COVID-19 patients [9]. These collective challenges heightened nurses' moral distress during the pandemic [9, 10, 12], fuelling their intention to depart from their nursing roles [7]. Previous research has identified the experience of moral distress among nurses during the COVID-19 pandemic as a significant contributor to turnover intention among nurses in Romania [13] and the US [14].

While previous studies have emphasized the impact of moral distress on nurses' intentions to leave [13–16], the underlying mechanisms explaining its nature remain ambiguous. Consistent findings suggest a correlation between chronic moral distress and the development of burnout [17, 18]. Facing recurring ethically distressing situations can result in nurses experiencing burnout symptoms such as exhaustion, cynicism, and decreased self-efficacy [19]. Exhaustion often stems from overwhelming workloads and when combined with perceptions of unfairness and a lack of rewards, a cynical perspective can develop [20]. Cynicism, which refers to psychological withdrawal from work, directly increases the propensity for turnover intention [20]. Given that the pandemic exacerbated moral distress through the intensified workloads and situations that undermined patients' quality of care and healthcare professionals' safety [10, 12, 18], it is plausible that this could precipitate burnout [17, 18]. Thus, we postulated that burnout could be a mediating factor in the relationship between moral distress and nurses' turnover intention.

Given the importance of moral distress on nurses' turnover intention, several studies have explored coping techniques. Most recommendations have focused on addressing the symptoms of moral distress through activities such as meditation, ensuring adequate sleep, listening to music [21], personal reflection, and informal conversations with colleagues [10, 22, 23]. However, these self-care strategies often align more with alleviating post-traumatic stress disorder symptoms than moral distress [24] and limited evidence supports their effectiveness in the context of moral distress. Furthermore, emphasizing these coping techniques may inadvertently frame moral distress as a challenge for individuals, implying that personal resilience is the primary solution. Considering the unique pressures of the COVID-19 pandemic, nurses might have utilized alternative coping strategies beyond the standard self-care approaches highlighted in prior studies. However, the strategies that nurses could have embraced to counteract

moral distress during the pandemic remain underexplored, underscoring a critical gap in understanding and clarifying the need for further investigation into this area.

This study had the following three primary objectives: (1) to examine the relationship between moral distress and nurses' turnover intention; (2) to investigate whether burnout mediated this relationship; and (3) to identify the coping strategies employed by nurses to mitigate moral distress in the Korean healthcare context.

2. Materials and Methods

2.1. Study Design. This study used a concurrent mixed-methods design. Using an online survey, quantitative and qualitative data were simultaneously collected. This study was conducted as a part of the Global Consortium of Nursing and Midwifery Study, a multinational research consortium comprising 75 countries. For this study, we focused exclusively on data collected from Korean nurses, as only Korean dataset included items on moral distress.

2.2. Participants. Nurses who provided direct care to COVID-19 inpatients in acute care hospitals were invited to participate. Nurses with managerial roles were excluded because they do not provide direct care to patients in Korean hospitals. A total of 310 nurses completed the online survey, but data from three participants were excluded because they responded to all survey items with the same option number. Therefore, data from 307 nurses were analyzed. The ideal sample size for path analysis was at least 20 participants per variable [25]. Given that our study utilizes eight variables in path analysis, a minimum of 160 participants is required to ensure adequate statistical power and reliability of the results. Therefore, the sample size was deemed sufficient for this study.

2.3. Data Collection. In November 2022, data were collected from two Korean hospitals that experienced a significant influx of COVID-19 patient admissions. We collaborated with the nursing department of each hospital to facilitate participant recruitment. The nursing departments assisted in sending invitation emails containing secure links to an online survey, specifically to nurses caring for COVID-19 patients. Given that in Korea, only specific hospitals were designated as COVID-19 hospitals with designated isolation beds to contain the spread of the virus [26], we employed a snowball sampling method to augment our sample size and ensure its adequacy.

2.4. Measurements

2.4.1. Demographic Characteristics. Participants' demographic information, including age, gender, educational level, hospital tenure, and monthly income, was collected.

2.4.2. Moral Distress. Moral distress was measured using the COVID-19 Moral Distress Scale (COVID-MDS) [27]. The scale comprises 12 items across the following three domains:

team/system (six items), patient (three items), and COVID-19 (three items). These domains capture the various sources of moral distress that nurses may experience while caring for COVID-19 patients [27].

After receiving approval from the original tool developers, the instrument was translated into Korean, following the translation guidelines of the Agency for Healthcare Research and Quality [28]. First, two bilingual nurses translated the scale into Korean. Subsequently, a nursing professor and three nurses with more than five years of nursing experience reviewed the translated items for their accuracy and appropriateness. A panel of five experts independently rated the relevance and accuracy of the translated items. The standard four-point Content Validity Index (CVI) rating scale, from 1 (not relevant) to 4 (highly relevant), was used to evaluate the conceptual relevance of each item, and the accuracy of the translation was answered as either yes or no [29]. Modified kappa statistics, which adjusted for chance agreement for CVI, were used to assess the relevance and accuracy of the translation [30]. The item-level CVI (I-CVI) for relevance was 1.0 for all 12 items. The modified kappa and the translation I-CVI (TI-CVI) were 0.76–1.0 and 0.80–1.0, respectively, indicating that the COVID-MDS is relevant for measuring moral distress in Korean nurse population [30]. Based on the results of the cognitive interviews with six nurses, the instrument was further refined and finalized. Subsequently, a confirmatory factor analysis (CFA) was performed on the data from 307 participants, and the results supported the three-factor model of the COVID-MDS. The CFA fit indices yielded favorable results, with a χ^2 (51) of 62.96, root mean square error of approximation of 0.03, standardized root mean square residual of 0.06, comparative fit index of 0.99, and Tucker–Lewis index of 0.99.

In line with the instructions provided by the tool developers [27], each item on the COVID-MDS was scored by multiplying the frequency ranging from 0 (never) to 3 (often) and the intensity ranging from 0 (no distress) to 3 (severe distress). This calculation yielded item scores ranging from 0 to 9. The total COVID-MDS score was calculated as the mean value for all the items' scores, with a higher value indicating a higher moral distress. The Cronbach's alpha value was 0.90 in the original study of the instrument [27] and the value was 0.90 in the present study.

2.4.3. Burnout. Burnout was assessed using a single-item measure adapted from the Mini-Z Instrument, developed by Linzer et al. [31]. This measure has been validated against the Maslach Burnout Inventory [32], indicating good validity [31]. Responses were scored on a 5-point scale ranging from 1 (no symptoms of burnout) to 5 (completely burned out). Consistent with previous studies [33], scores over 2 were considered indicative of burnout.

2.4.4. Turnover Intention. Turnover intention was measured using a single-item question that asked nurses whether they were considering leaving their current job within the next year. The response options provided were no, maybe, or yes.

In line with previous research [34], we recategorized the responses as a binary variable as follows: 0 (no turnover intention) and 1 (turnover intention, including those who answered either maybe or yes).

2.4.5. Strategies to Mitigate Moral Distress. Participants were asked to answer an open-ended question regarding the strategies they employed to alleviate moral distress while caring for COVID-19 patients. The question was presented as a free-text response, allowing the participants to provide as much detail as they wished. Since online surveys that incorporated open-ended questions were shown to be a suitable method for collecting qualitative data during the COVID-19 pandemic given their flexibility and accessibility [11], we utilized this method.

2.5. Ethical Considerations. This study received ethical approval from the Institutional Review Board of Yonsei University Health System (#4-2022-0675). The online survey introduction page provided participants with information about the purpose of the study, eligibility criteria, study duration, and the estimated time required to complete the survey. Participation in the study was voluntary, and participants had the freedom to withdraw at any point without any consequences. Written informed consent was adapted to the online format of our survey. At the beginning of the survey, participants encountered mandatory consent checkboxes. By selecting these checkboxes, participants indicated their informed consent to participate in this study. As a token of appreciation for their participation, all participants were offered a gift card worth approximately US\$12.

2.6. Data Analysis. For the quantitative data, descriptive statistics were employed to examine the sample characteristics and key study variables. Path analysis was conducted using generalized structural equation modeling (GSEM), controlling for covariates, to investigate the mediating effect of burnout on the relationship between moral distress and turnover intention. Given that GSEM is suitable for path analyses involving binary variables [35], we chose this analytical method because burnout and turnover intention are binary variables. Bootstrapping based on 5,000 replications was performed to test the significance of direct and indirect effects [36]. All statistical analyses were performed using STATA 16.0 with the statistical significance level set at 0.05.

For the qualitative data analysis, we adopted the inductive content analysis method proposed by Graneheim and Lundman [37]. Of the 307 survey participants, 246 responded to the open-ended questions, yielding a dataset of free-text data from 246 participants. The analysis was conducted by three trained coders, who engaged in iterative discussions to address any discrepancies and ensure consistency in the coding process. Prior to commencing the analysis, all coders thoroughly familiarized themselves with the participants' responses by carefully reading through the data. In total, 344 meaning units were identified from the

responses. Subsequently, the coders condensed the meaning units and independently assigned codes to them. Through ongoing discussions and comparison of coding outcomes, any discrepancies in coding were resolved through consensus among the coders. Similar codes were grouped into subcategories, which were then merged to form major categories. This meticulous process was employed to uphold the rigor and quality of the data analysis, ensuring reliability and validity of the findings.

3. Results

3.1. Description of the Participants. A total of 307 nurses who had cared for COVID-19 patients participated in this study. The majority of participants ($n = 289$, 94.1%) were female, with an average age of 32.1 (SD = 6.5) years. Most participants held a bachelor's degree ($n = 245$, 79.8%) and their mean length of hospital tenure was 89.4 (SD = 66.2) months. More than half of the participants ($n = 174$, 56.7%) reported experiencing burnout, and 41.4% ($n = 127$) reported an intention to leave their current jobs (Table 1).

3.2. Moral Distress. Table 2 illustrates the scores for the moral distress subdomains and the summary scores. The summary score of moral distress was 3.0 (SD = 1.8), with the COVID-19 domain (mean = 3.3, SD = 2.3) exhibiting the highest score among the three domains. Nurses reported experiencing the highest levels of moral distress when assigned an unsafe number of patients. This was followed by caring for COVID-19 patients who presented with a transmission risk and caring for patients who had to be hospitalized without their family members.

3.3. The Relationships between Moral Distress, Burnout, and Turnover Intention. Figure 1 illustrates the associations between moral distress and turnover intention through burnout, while accounting for participants' age, gender, educational level, hospital tenure, and monthly income. Moral distress was positively associated with burnout (coefficient = 0.30, $p < 0.001$) and turnover intention (coefficient = 0.15, $p < 0.01$). Burnout was significantly related to turnover intention (coefficient = 1.28, $p < 0.001$). In addition, burnout significantly mediated the relationship between moral distress and turnover intention (OR = 1.47, 95% bias-corrected CI = 1.13–1.92).

3.4. Coping Strategies to Mitigate Moral Distress. The qualitative data analysis yielded three main categories and eight subcategories regarding nurses' moral distress coping strategies (Table 3). The three main categories were positive, negative, and shifting from positive to negative coping strategies. The first category, positive-coping strategies, encompasses five subcategories that highlighted the proactive strategies employed by nurses to address moral distress and foster personal growth. The second category, negative-coping strategies, consisted of two subcategories that clarified the passive and negative ways in which nurses

TABLE 1: General characteristics of the study participants ($N = 307$).

Variables	Mean (SD)	n (%)
Age (years)	32.1 (6.5)	
Gender		
Male		18 (5.9)
Female		289 (94.1)
Educational level		
Associate's degree		38 (12.4)
Bachelor's degree		245 (79.8)
Master's degree		24 (7.8)
Hospital tenure (months)	89.4 (66.2)	
Monthly income (10,000 Korean won)	379.9 (94.4)	
Burnout		
Yes		174 (56.7)
No		133 (43.3)
Turnover intention		
Yes		127 (41.4)
No		180 (58.6)

Note. SD: standard deviation.

coped with moral distress. The third category, shifting from positive to negative coping strategies, describes how some nurses initially utilized positive coping strategies, but subsequently shifted towards negative ones.

3.4.1. Positive-Coping Strategies

(1) Being Committed to Minimizing COVID-19 Transmission Risks. Nurses adhered to stringent protocols and measures to alleviate moral distress stemming from the potential transmission risks inherent in caring for COVID-19 patients. They strictly adhered to institutional policies by properly wearing PPE and actively adhering to the quarantine guidelines. The participants strictly prohibited contact between patients to prevent transmission and took precautions to avoid personal contamination.

"I strictly followed the quarantine guidelines to ensure both our patients and we remained shielded from infection." (P57)

"I've been trying my best to prevent virus transmission and avoid contamination." (P179)

(2) Adopting a Holistic Approach Amidst COVID-19 Challenges. Several nurses stated that they tried to provide more comprehensive care for their patients by meeting patients' needs, focusing on patient education, and referring to patients' relevant resources to mitigate their moral distress. Participants noted that they attempted to provide nursing care that addressed the unique needs of each patient. Some participants stated that they carefully assessed each patient's symptoms and focused on the fundamental nursing care that they might not usually provide, such as oral hygiene and eye care. Notably, COVID-19 patients experienced isolation without the presence of family caregivers, and nurses took on the responsibility of frequently monitoring and assisting patients with their personal hygiene and safety. Many

TABLE 2: COVID-19-related moral distress.

Domain	Frequency Mean (SD)	Intensity Mean (SD)	Multiplied score Mean (SD)
Patient domain	1.4 (0.9)	1.4 (1.0)	2.4 (2.0)
Being asked to provide and continue aggressive and potentially futile treatments when I believe it is not in the best interest of the patient	1.6 (0.8)	1.5 (1.0)	2.7 (2.5)
Witnessing orders for unnecessary or inappropriate care that do not adequately address patient needs	1.2 (0.8)	1.2 (1.0)	2.0 (2.3)
Providing care to patients who have not been adequately informed or included in decisions regarding their own care	1.5 (0.9)	1.4 (1.0)	2.6 (2.4)
Team/system domain	1.7 (0.9)	1.5 (1.0)	3.1 (2.0)
Experiencing poor communication between members of the care team that adversely affects patient care	1.7 (0.7)	1.6 (0.9)	3.0 (2.4)
Being assigned an unsafe number of patients to care for at once considering the acuity level for each patient assigned to me	2.1 (0.8)	1.9 (0.9)	4.4 (3.0)
Attempting to deliver a high standard of care with limited time, supplies, and resources	1.7 (0.9)	1.5 (1.0)	3.1 (2.8)
Using technology and documentation that burdens me and compromises patient care	1.6 (0.8)	1.5 (0.9)	2.8 (2.5)
Witnessing or experiencing uncivil behavior among members of the care team	1.8 (0.9)	1.6 (1.0)	3.2 (2.9)
Witnessing a lack of respect among the healthcare team for patients from vulnerable populations or minority groups	1.1 (0.9)	1.1 (1.1)	1.8 (2.3)
COVID-19 domain	1.8 (0.9)	1.5 (1.0)	3.3 (2.3)
Caring for patients who must experience hospitalization without family presence	2.1 (0.8)	1.6 (0.9)	3.7 (2.7)
Caring for patients who die during a hospitalization without family and/or clergy present	1.3 (1.0)	1.3 (1.1)	2.4 (2.7)
Caring for COVID-19 patients that presents a transmission risk to you or your family/household	2.0 (0.9)	1.7 (1.0)	3.8 (2.9)
Summary score	1.6 (0.9)	1.5 (1.0)	3.0 (1.8)

Note. SD: standard deviation.

FIGURE 1: Results of path analysis using generalized structural equation modelling. Age, gender, educational level, hospital tenure, and monthly income were adjusted for in the model, and results were bootstrapped with 5,000 repetitions. The unstandardized coefficients were used to express the correlation between variables. The direct and indirect effects are presented as odds ratios at the bottom of the figure. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.

Positive-coping strategies	Being committed to minimizing COVID-19 transmission risks
	Adopting a holistic approach amidst COVID-19 challenges
	Voicing concerns for patient safety
	Continuous learning
	Engaging in self-care
Negative-coping strategies	Adopting avoidance behaviors due to feelings of powerlessness Becoming passive in one's role
Shifting from positive- to negative-coping strategies	—

respondents also stated that they educated or counseled patients and their family members frequently to help enhance their understanding of their health status and the

treatment journey. One nurse shared her practice of providing daily briefings to patients to ensure that they were informed about their treatment progress. Another nurse

shared that when patients decided whether to continue life-sustaining treatment, she explained the details of each treatment to help them make informed decisions. In addition, some nurses actively directed patients to resources, connecting those with financial constraints to hospital aid programs or even seeking extra assistance for their patients who could not afford necessary treatments.

"I completed other tasks as quickly as possible and devoted time to basic nursing care for patients, including position change, oral care, eye care, and lung care." (P279)

"I made an effort to explain both the current physical condition and the purposes of treatments to patients. I aimed to briefly summarize the patients' progress of each day and share any improvements with them and their caregivers." (P124)

"When a patient refused treatment due to financial constraints, I sought ways to assist the patient." (P59)

(3) *Voicing Concerns for Patient Safety.* Nurses noted that they advocated for patient safety by voicing their concerns to supervisors or physicians to alleviate their moral distress. They proactively approached their supervisors, urging an increase in the number of nurses assigned to units to enhance the quality of nursing care. These nurses recognized the detrimental effects of nursing shortages on patient outcomes and emphasized the importance of adequate staffing to maintain high-quality care. In addition, nurses took it upon themselves to clarify and question physicians' orders that appeared inappropriate or lacked sufficient evidence supporting their effectiveness. They recommended alternative approaches and advocated for better decision-making to ensure their patients' best interests. One nurse saw a patient suffer immensely from an unnecessary and improper prescription and spoke to both a resident and attending physician, urging a change in prescription practices.

"I asked my manager to increase the number of nurses working in our department to ensure our patients received safer care." (P167)

"The most harrowing experience for me was witnessing a cancer patient, already terminally ill, die without dignity. Despite his decision to refuse life-sustaining treatment, the patient had to suffer because his physician prescribed numerous tests for him and did not prescribe the appropriate pain meds. I have become more vocal, ensuring my opinions and concerns are heard, even if it means addressing an attending physician directly." (P149)

(4) *Continuous Learning.* Participants strongly emphasized the importance of continuous learning to adapt to the challenges posed by the emergence of a new disease and to provide evidence-based care to their patients. They sought educational seminars and training opportunities, recognizing the importance of staying updated and informed in

their practice. Some participants elected to go further with their continuous learning by pursuing graduate education to deepen their clinical knowledge and professional development.

"I always study to find the latest evidence for my practice." (P305)

"Due to frequent reassignments to units where I was tasked with unfamiliar work, I felt the need for comprehensive knowledge, prompting my decision to attend a graduate nursing program." (P84)

(5) *Engaging in Self-Care.* The participants sought strategies to relax and maintain their emotional wellbeing. Prayer, meditation, and deep breathing were commonly identified for managing stress. Some nurses described seeking professional help from psychiatrists and psychologists to cope with the stress and emotional demands of their work. Nurses reported that support from family and friends also helped reduce moral distress.

"I used relaxation therapy, such as deep breathing and meditation." (P76)

"I talked to a psychiatrist to reduce my moral distress." (P158)

3.4.2. Negative-Coping Strategies

(1) *Adopting Avoidance Behaviors due to Feelings of Powerlessness.* Some nurses expressed feelings of powerlessness when confronted with morally distressing situations, leading them to use avoidance as a coping mechanism. They believed that, as nurses, they lacked the authority to effect meaningful changes and felt that their opinions would be disregarded by hospital managers. Consequently, the nurses would rationalize their inaction in morally distressing situations and attempt to distance themselves from such experiences by striving to forget or suppress them.

"In practice, there is nothing a nurse can do to solve the problems. Even when we voice our concerns, they tend to be overlooked, making us feel that our opinions hold no weight." (P197)

"I believed that, as a nurse, I lacked the authority to bring about real change, so I tried to avoid those distressing moments." (P106)

(2) *Becoming Passive in One's Role.* Some participants adopted a passive approach to work in response to stressful situations. They described feeling discouraged from taking proactive measures because they believed that the hospital did not value or accept their proactive attitude. Consequently, these participants limited themselves to completing only the assigned tasks without engaging in critical thinking

or going beyond their assigned responsibilities. In addition, they shared instances in which they ignored minor patient demands, considering them too burdensome or requiring excessive effort. Consequently, these participants adopted a formal, business-like approach when interacting with patients and focused solely on completing the basic and necessary tasks.

"I began to just stick to my assigned tasks without taking on any unnecessary duties." (P207)

"I only spoke when it was absolutely necessary." (P260)

"Given the overwhelming workload, I felt I could not change my situation, so I often overlooked patients' minor requests." (P241)

3.4.3. Shifting from Positive- to Negative-Coping Strategies.

Some participants reported a shift in their approach to managing their moral distress. Initially, they attempted to employ positive strategies such as referring patients to external support services and reporting inappropriate situations to their supervisors; however, their ability to effectively address moral distress was hindered after encountering challenges and obstacles within their institutions. The experience of encountering obstacles and a lack of organizational support profoundly impacted the nurses, leading to a sense of resignation, which resulted in their decision to leave their current job in some cases.

"Initially, I believed it was part of my role to seek external resources for patient recovery. But without any support, compensation, encouragement, or rewards, and even facing criticism for taking an initiative, I eventually stopped putting in the extra effort." (P16)

"I used to communicate my concerns to my manager or report them to the relevant department, but in the end, I decided to leave this job." (P96)

4. Discussion

To the best of our knowledge, this is the first study to examine the relationship among moral distress, burnout, and turnover intention among nurses and investigate the coping strategies that were employed to mitigate this distress within the Korean healthcare context using a mixed-methods approach. Our quantitative analyses revealed a significant association between higher levels of moral distress and increased turnover intention among nurses. Also, burnout was identified as a mediator in this relationship. Moreover, our qualitative analysis identified the various coping strategies nurses used to manage moral distress.

During the COVID-19 pandemic, nurses faced challenging situations leading to significant moral distress, as underscored by our findings and corroborated in a US study [38]. Both studies identified the increased patient care volume and potential infection risk to the nurses' families as the primary contributors to this distress. The global PPE shortage could have intensified this distress, leaving many

nurses unprotected, consequently heightening their anxiety [9, 10, 21, 38]. When planning for future pandemic response implementation, healthcare organizations must ensure adequate PPE supplies, enforce stringent safety measures [10, 38], and provide clearly communicated policies and guidelines [38] to minimize the risk of nurses experiencing avoidable moral distress.

Our findings build on previous research [13–16] and demonstrated a direct association between nurses' moral distress and turnover intention. Nursing professionals often derive motivation from the intrinsic value of their roles, commitment, and passion for patients [39]. However, when they encounter situations that conflict with their ethical practices, their professional satisfaction diminishes, leading to increased turnover intentions [40]. This issue became particularly apparent during the COVID-19 pandemic when nurses confronted moral distress due to barriers hindering high-quality care [10]. A prior study demonstrated that during the pandemic, nurses experienced higher levels of stress, leading to an increased intention to leave their positions, compared to prepandemic times [41]. In addition, consistent with previous findings [17, 18, 42], we also found that burnout significantly mediated the relationship between moral distress and turnover intention, which aligns with the moral distress model [43], positing that unresolved moral distress heightens burnout, further increasing their inclination to leave the nursing profession. Thus, effectively addressing moral distress can be a strategy for reducing burnout and nurse turnover [13].

Our qualitative analysis revealed a range of coping strategies that nurses adopted in situations causing them moral distress, ranging from positive to potentially negative approaches. In line with previous research [10, 21–23], we found that nurses engaged in self-care practices, such as prayer and meditation, to manage their distress. Positive-coping strategies in our study were marked by a proactive commitment to patient care. This commitment is evident in their strict adherence to infection prevention guidelines, reflecting their dedication to the safety and their patients' welfare. Moreover, nurses frequently exceeded their standard duties to ensure that patients experienced personalized care in the absence of family caregivers as they recognized the isolating circumstances of COVID-19 hospitalizations. They also actively voiced concerns about enhancing the quality of patient care. This deep commitment might be attributed to the unique emotional challenges posed by the COVID-19 pandemic, as suggested by Ahokas and Hemberg [44].

However, recognizing the negative-coping strategies driven by feelings of powerlessness and a lack of organizational and managerial support is equally important. Our findings revealed that nurses shifted from positive- to negative-coping strategies when they felt inadequate organizational support, underscoring the importance of organizational and managerial support. These insights emphasize the urgency for hospital administrators and nurse managers to genuinely value frontline nurses' feedback. Previous research has emphasized the significance of administrative support [45], suggesting that nurse managers should

establish clear policies and guidelines to promptly address nurses' concerns [38]. In addition, addressing the issue of moral distress during meetings can demonstrate to nursing staff that their wellbeing is a priority for their managers [44]. Moreover, nurse managers' inclusive leadership can be instrumental in supporting nurses experiencing moral distress because such leaders foster open communication, value diverse perspectives, and prioritize shared decision-making [46].

The findings also help conceptually delineate avoidable and unavoidable moral distress when implementing a pandemic response. Avoidable moral distress is associated with the structural and organizational factors related to implementing a pandemic response. These would include, but are not limited to, resource management, communication patterns, nurse staffing and managerial leadership and how organizational culture sets the tone for pandemic response implementation [47]. We theorize that avoidable moral distress is more likely to contribute to burnout because structural and organizational factors are perceived as being controllable and addressable than those associated with unknowns.

Unavoidable moral distress is that associated with the unknowns and uncertainties of working during a pandemic, such as the nature of the disease, its effects on patients and their caregivers, evolving treatments, and other factors [10]. Unavoidable moral distress is where resilience and coping strategies may play a stronger role in mitigating the stressors of working during a pandemic, along with perceived mental health and social support of nurses working on the frontlines of pandemics [10, 48, 49]. Conceptually distinguishing between the factors driving moral distress as experienced by nurses working the frontlines of pandemics is important for optimizing interventions and support services for them. It may further help develop our understanding of the drivers of turnover as well. Thus, there is a need for further research in this area.

This study had several limitations. First, we used a cross-sectional design; therefore, the causal relationships among the study variables cannot be determined. Second, the data were collected using self-reported questionnaires; thus, there might have been a potential desirability bias because some participants could have hesitated to provide honest answers to certain questions [50]. Third, the study only included nurses working in Korean acute care hospitals, which may not be generalized to other healthcare settings. Finally, although the open-ended questions allowed us to identify the coping strategies used by nurses, contextual information regarding the pre- and postapplication of these strategies was not collected. Therefore, future qualitative studies using alternative methods, such as in-depth interviews, could provide detailed and insightful responses from the participants.

5. Conclusions

During the COVID-19 pandemic, the immense challenges faced by healthcare professionals, particularly nurses, were undeniable. This study investigated the challenges faced by

nurses in Korea, highlighting the impact of moral distress on turnover intention, with burnout as a significant mediator. The unique aspects of pandemic care exacerbated moral distress, prompting nurses to adopt various coping strategies. Although some of these strategies were constructive, a shift from positive to negative mechanisms was evident in the absence of organizational and managerial support, highlighting the importance of robust institutional support. Our findings could provide valuable insights into leadership practices during future crises.

Data Availability

The data used to support the findings of this study are not available because the participants did not provide written consent for their data to be shared publicly.

Background. With projected nursing shortages, an aging workforce, and the imminent retirement of nurse leaders, nursing leadership shortages are a concern. While several studies have indicated the interest of nurses in pursuing leadership positions, limited research has focused on examining the influence of the leadership practice environment on nurses' motivation to lead. **Aim.** The aims of the study were to (1) assess the relationship between the leadership environment and the motivation of nurses to lead and (2) determine whether there are particular aspects of the leadership environment that influence motivation to lead. **Methods.** A cross-sectional research design was used to collect data from 435 nurses working in 16 public and private hospitals in Oman. Leadership Environment Scale and Motivation to Lead Scale were used to assess participants' perceived leadership environment and their motivation to engage in formal leadership roles, respectively. Multivariate linear regression was used to assess the relationship between the perceived leadership environment and the motivation of nurses to undertake leadership roles. **Findings.** Nurses reported a mean scale value of 3.208 out of 5 (SD = 0.467) for their motivation to lead, which exceeds the midpoint, indicating a strong motivation to engage in formal leadership roles. Nurses reported a mean score of 3.194 out of 4 (SD = 0.661), which exceeds the midpoint, suggesting a favorable perception of leadership environment. The findings showed a significant relationship between the leadership environment and nurses' motivation to lead. Specifically, self-organization ($\beta = 0.185$, $p = 0.001$, CI = 0.086–0.378), agents ($\beta = 0.221$, $p = 0.002$, CI = 0.124–0.474), and transformative exchange ($\beta = 0.100$, $p = 0.037$, CI = 0.101–0.142) were characteristics of the leadership environment that were associated with greater motivation to engage in leadership. **Conclusion.** This study emphasizes the importance of cultivating a supportive leadership environment as a potential strategy to attract nurses to assume formal nursing leadership roles. **Implications for Nursing Management.** Strategies to improve nurses' motivation to lead in a complex healthcare environment include improving nurses' active involvement in their organization, creating a collegial supportive and mentoring leadership culture, and improving transformative exchange by supporting career and educational advancement.

1. Introduction

Nursing leadership is a critical factor that influences healthcare quality, patient outcomes, and organizational success. Effective nurse leaders guide teams, create positive work environments, and contribute to increased job satisfaction among nurses [1]. The role of nurse leaders is particularly crucial in addressing contemporary healthcare challenges and ensuring the resilience of nursing teams [2, 3]. Nurses' involvement in leadership positions within the healthcare system is a dynamic and evolving aspect which is crucial to delivering quality patient care and contributing to the overall effectiveness of healthcare organizations [4]. Traditionally, nurses have been at the forefront of direct patient care. However, there is a growing recognition of the need for nurses' active participation in leadership roles to address the complexities of modern healthcare [5, 6]. The involvement of nurses in leadership positions contributes to improving decision-making processes, enhancing coordination among healthcare teams, and fostering positive work environments [7]. Furthermore, as healthcare systems face challenges such as nursing shortages and increased demands, the active engagement of nurses in leadership positions becomes even more critical [8, 9].

Previous research on motivation to lead in the healthcare sector highlights the turnover intention of current nurse leaders [10, 11] and a persistent shortage of nurses' willingness to step into formal leadership roles [12, 13]. This scarcity is a critical concern given the acknowledged importance of motivating nurse leaders in achieving organizational goals and improving patient outcomes [1]. Upon closer examination, organizational variables emerged as significant contributors to nurses' hesitancy in embracing formal leadership roles. Issues such as inadequate leadership preparation, limited growth opportunities, and unsupportive work conditions emerged as crucial determinants impacting motivation to lead [14, 15]. This underscores the role played by the organizational context in shaping individuals' motivation to assume leadership responsibilities.

Recent research by Labrague et al. [9] shows a positive correlation between nurse confidence and desire to lead when working with authentic leaders. This emphasizes the influential role of the leadership environment on motivation to lead. In Oman, nearly 70% of millennial nurses expressed an intention for career advancement in assuming nursing leadership responsibilities [16]. Currently, in Oman, there are 21,288 registered nurses and a significant proportion are expatriates [17]. Fostering a culture that encourages nurses to assume leadership roles becomes essential to build a resilient and adaptable nursing workforce [17]. Understanding the factors that motivate nurses to assume leadership responsibilities is a critical step in tailoring interventions and support systems that align with the unique challenges and dynamics of the Oman health system.

Although several studies investigated the factors that contribute to nurses' motivation to lead [9, 13, 14, 18], limited evidence exists on the influence of the leadership environment. Therefore, the aim of this study was to

examine the influence of leadership environment on nurses' motivation to lead. The study hypothesis is that there is a significant relationship between leadership environment and nurses' motivation to engage in leadership roles. In addition, the study intended to determine whether there are particular aspects of the leadership environment that influence motivation to lead. A unique contribution of this study is the use of complexity leadership theory, which contributes to the limited empirical research in this area. It also facilitates a better understanding of the complex relationship between nurses' motivations to assume leadership roles and specific dimensions of the leadership environment.

2. Theoretical Framework

The current study was guided by the complexity leadership theory. Complexity science posits that a system is more aptly described as a complex adaptive system (CAS), where the structure is nonhierarchical and nonlinear [19, 20]. People, objects, or processes (known as agents) have widespread impact on the system and from the system outward. Leadership culture is the feature that makes the difference and determines the impact of agents [5, 21].

In a CAS, the leaders (sometimes nurse managers, directors, or chief nursing officers) create the space to work (known as containers) so that several outcomes can be achieved simultaneously. The process in a CAS is therefore nonlinear. The advantage of a nonlinear system is the allowance for self-organization that supports shared governance and decision making. In any level in a CAS, accountability particularly resides in shared power and decision making [21]. People, in a CAS, bring different perspectives and resources to relationship exchanges where each exchange has the potential to transform the other agent [22]. These exchanges support the emergence of new or unexpected ideas, structures, or patterns of work. People, when in relationship and involved in transformative exchanges, are also changed in the process of coevolution [21]. Most healthcare systems, within which nurses work, have the attributes of a CAS.

A person motivated to lead does so within a system or context. The leadership context or leadership environment is important to identify, as some of the aspects of that environment can be modified to foster nurses' feelings of support and, therefore, a desire to lead. According to the CAS, those aspects are self-organization, agents, shared governance and decision making, emergence, transformative exchanges, different perspectives, and coevolution [23].

The seven CAS aspects of the work environment, mentioned above, have relatedness to the constructs of motivation (assuming more or higher-order responsibilities and advancement in organization positions) and leadership (involvement in and influence in decision making). The framework shows a unidirectional impact (Figure 1). Motivation to lead occurs within the context or leadership environment. This is the same as nurse leaders setting the space/container for self-organization, engaging agents (in the process of motivation), and allowing transformative exchanges between agents with different perspectives. What follows is the emergence of coevolution that can also become

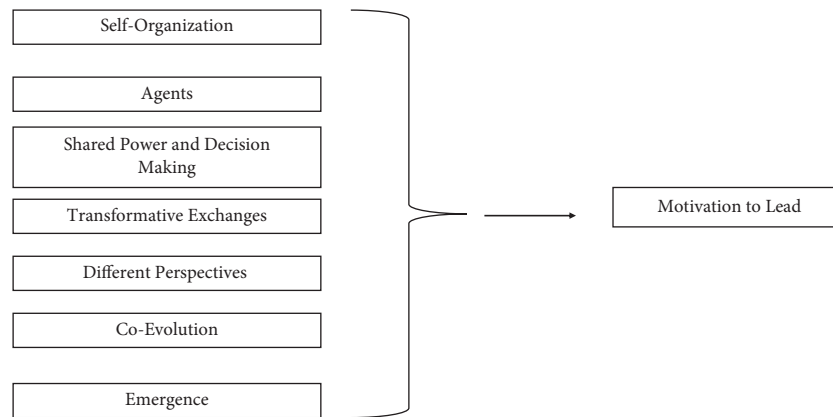

FIGURE 1: Theoretical framework.

shared power and decision making, hallmarks of leading. Since the research aim was to delineate the pertinent aspects of the leadership environment that are related to willingness to lead, the complexity leadership theory was chosen over other leadership theories or styles. The LENS as a measure will provide details of the environment that can be enhanced or mitigated in order for more nurses to be willing to lead. Other measures of leadership do not completely apply to the context or environment within which nurses lead.

3. Materials and Methods

3.1. Study Design and Setting. A cross-sectional design was used. Self-reported data were collected from staff nurses working in 15 acute care public and private hospitals in the Sultanate of Oman. The hospitals were distributed over different geographical areas of Oman, making the sample highly representative of the nursing workforce working in the acute care setting in Oman.

3.2. Study Sample. A convenience sampling technique was adopted to gather data from registered nurses working in public and private hospitals in the Sultanate of Oman. The use of convenience sampling might have created sampling bias. To reduce it, the study utilized a national sample by including hospitals from different governorates of Oman.

The inclusion criteria were registered staff nurses providing bedside care, holding a minimum diploma in nursing, being licensed, and having at least one year of experience in their current unit, and able to read and write English language. Unit managers were excluded from the study as they are in a leadership position, which negates the main purpose of the study. The estimated sample size of the study was 540 participants based on the G-Power priori sample size calculator [24]. A statistical power of 80%, 10 predictors, a small effect size, and a probability level of 0.05 were used to calculate this sample. The survey was distributed to 540 nurses, where a total of 435 nurses participated, resulting in an 80.6% response rate.

3.3. Study Instruments. Data were collected using a paper-based survey. All study instruments were administered in English. The study instruments consisted of three sections:

sociodemographic information, the Leadership Environment Scale, and the Motivation to Lead Scale. The sociodemographic section includes questions about the age, sex, years of work experience, education level, nationality, and previous leadership experience and training.

The perceived leadership environment was measured using the 16-item Leadership Environment Scale (LENS) [23]. The scale assesses nurses' perceptions of nurses about seven domains of the leadership environment including (1) self-organization, which is defined as the creation of self-organizing systems (by individuals or groups) through feedback, self-reference, and effective information use; (2) agent, which is defined as a person, object, or process that has an impact on a system at a local and global level, and these agents provide insights into the structure of a complex adaptive system; (3) shared power and decision making, which are the key components of a self-organizing system that ideally occur at the point where actions are to be executed and accountability is expected; (4) emergence, which is defined as an unexpected idea, structure, or pattern that arises without any prior warning or preparation; (5) transformative exchanges, which refer to a series of interdependent connections within a complex adaptive system where information and resources are shared in such a way that each agent involved is altered as a result of the exchange; (6) different perspectives, which are defined as differences that affect both the work and relationships within a system; and (7) coevolution, which is defined as the mutual change that occurs between them when they are in relationship [23]. As one agent adapts and mirrors, another agent also changes. These domains were adopted from the key features of complexity leadership theory [21]. Responses were rated using a 4-point Likert scale in which 1 refers to strongly disagree and 4 refers to strongly agree. Higher scores indicate a more favorable perception of the leadership environment. The scale is valid and reliable with Cronbach's alpha of 0.91 [23]. In the current study sample, Cronbach's alpha was 0.81.

Nurses' motivation to engage in formal leadership roles was measured using the 3-item Motivation to Lead Scale (MTL) [25]. Responses were rated using a 5-point Likert scale in which 1 refers to strongly disagree and 5 refers to strongly agree. Higher scores indicate a greater motivation to

engage in formal leadership roles. The scale is valid and reliable with Cronbach's alpha of 0.78 [16]. In the current study sample, Cronbach's alpha was 0.88.

All of the data were collected using a self-reported method. To reduce the possibility of the response bias, all data were collected anonymously with no identification.

3.4. Ethical Considerations and Data Collection Procedure.

Prior to data collection, ethical approval was obtained from the Oman Ministry of Health Research and Studies Approval Committee (MoH/CSR/22/26226). The recruited hospitals also provided administrative permission to collect the data. Written informed consent was obtained from the study participants.

Participants received a package containing an information sheet, an informed consent form, a survey, and an envelope. This information sheet provided information about the study's aims, procedure, the time required to complete the survey, assurances of voluntary participation and confidentiality, and contact information for the principal investigator for additional clarifications or information if needed. To facilitate the deposit of completed surveys, drop boxes were located in nursing stations. Data were collected over five months, between August 2022 and February 2023.

3.5. Data Analysis. The Statistical Package for the Social Sciences (SPSS)[®] version 23 was used to analyze the data. Descriptive statistics of frequencies, standard deviations, and means were used to describe the study sample. Multivariate linear regression was used to examine the relationship between the leadership environment and nurses' motivation to lead, controlling for the sociodemographic and work characteristics of the participants. The significance level was established at $p < 0.05$. No missing data were reported and no sensitivity analyses were conducted.

4. Results

A total of 435 nurses participated in the study. The sample was predominantly female (87.4%), with an average age of 43.85 years ($SD = 6.549$) and 11.40 years of work experience ($SD = 6.652$). Of the 435 participants, more than half were expatriate (51.3%), and 56.1% held a diploma in nursing. The majority of the sample had no previous leadership experience or received leadership training (66.7% and 70.8%), respectively (Table 1).

4.1. Perception of Leadership Environment and Motivation to Lead. The mean scale value for LENS was 3.194 out of 4 ($SD = 0.661$). Across the seven leadership environment domains, nurses perceived emergence followed by the transformative exchange as the highest. Nurses perceived self-organization as the lowest available feature of their leadership environment in which nurses reported lack of time to participate actively in changing their work setting (Table 2).

TABLE 1: Sample characteristics ($N = 435$).

Variables	Mean	SD
Age	34.853	6.549
Years of experience	11.396	6.652
	<i>n</i>	%

Yes, and it was adequate	96	22.1
Yes, but it was not adequate	31	7.1

*Included nurses working in multispecialty units, outpatient clinics, and cath lab.

The mean scale value for MTL was 3.208 out of 5 ($SD = 0.467$). The findings also revealed that most of the study participants (85.1%) reported a desire to advance their career and assume greater responsibility. Additionally, 83.5% indicated an intention to assume different responsibilities in their current roles and 83.5% intend to advance to positions that involve more decision making (Table 3).

4.2. Relationship between Leadership Environment and Motivation to Lead. A multivariate regression model was conducted to assess the relationship between nurses' perception of the current leadership environment and the reported motivation to engage in leadership roles controlling for age, years of experience, nationality, level of education, type of working unit and hospitals, previous leadership training, and experiences (Table 4). After testing for multicollinearity, no evidence of multicollinearity was observed.

The findings demonstrated a significant relationship between leadership environment and nurses' motivation to engage in leadership roles controlling for other covariates, supporting the study hypothesis. In addition, the study

TABLE 2: Descriptive summary and responses on Leadership Environment Scale.

Item	Mean	SD
Leadership Environment Scale*	3.194	0.661
Self-organization	3.135	0.503
I have time to actively participate in efforts to change practice in my work setting	3.064	0.599

I take time to reflect on my work and career	3.156	0.582

*Scale composite score.

intended to determine whether there are particular aspects of the leadership environment that influence motivation to lead. Findings demonstrated that self-organization ($\beta = 0.185$, $p = 0.001$, $CI = 0.086-0.378$), agents ($\beta = 0.221$, $p = 0.002$, $CI = 0.124-0.474$), and transformative exchange ($\beta = 0.100$, $p = 0.037$, $CI = 0.101-0.142$) were specific elements of the leadership environment associated with higher motivation to engage in leadership. The overall R^2 of the model was 0.38, which reflects that the model was successful in explaining 38% of the variance in nurses' motivation to lead the score.

5. Discussion

This study examined the relationship between leadership environment and nurses' motivation to lead. The mean score obtained on the LENS suggests that nurses perceive their leadership environment positively. In other words, they likely view their leadership as supportive, effective, and conducive to their professional growth and well-being. This result is encouraging given that a favorable leadership environment is critical for the overall success and well-being of an organization [26]. When leaders create an atmosphere of trust, respect, and support, employees are more likely to feel satisfied and engaged in their job [27]. Moreover, a favorable leadership environment fosters a culture of collaboration and open communication, where ideas are freely exchanged, and innovation is encouraged [28, 29]. This, in turn, leads to higher levels of productivity and better organizational outcomes [30].

The mean score on the MTL, which exceeds the mid-point, suggests a strong desire or motivation among people to pursue formal nursing leadership roles in the future. Across the MTL items, 85.1% of the participants expressed a desire to advance in the nursing career and assume more responsibilities. This aligns with Labrague et al.'s [16] findings where 70% of nurses shared a similar aspiration for career advancement. This result implies that there is a notable readiness and eagerness among nurses to embrace formal nursing leadership roles, potentially contributing to the cultivation of future nursing leaders and the advancement of nursing practice and healthcare delivery. The overarching endorsement of career advancement among nurses in the present study emphasized the necessity of structural empowerment for upward mobility in leadership and highlighted the crucial role of the work environment in fostering nurses' willingness to assume leadership roles.

The results of the multiple regression analysis showed a positive relationship between leadership environment at work and nurses' motivation to lead. To our knowledge, this study was the first to explore the specific features within the leadership environment that strongly influence nurses' motivation to undertake leadership roles. Hence, this study provided the necessary information to optimize organizational efforts and drive meaningful improvements in leadership development. Nevertheless, the results from the current study suggested that when nurses perceive their work environment as supportive, conducive to growth and development, and characterized by effective leadership, they are more likely to be motivated to pursue leadership roles in

TABLE 3: Response on the Motivation to Lead Scale.

MTL items	Strongly disagree <i>n</i> (%)	Disagree <i>n</i> (%)	Neither <i>n</i> (%)	Agree <i>n</i> (%)	Strongly agree <i>n</i> (%)
(1) I desire career advancement to assume more responsibility	5 (1.1%)	11 (2.5%)	49 (11.3%)	277 (63.7%)	93 (21.4%)
(2) I would like to take on different responsibilities compared to those my job position requires	1 (0.2%)	22 (5.1%)	49 (11.3%)	274 (63%)	89 (20.5%)
(3) I would like to advance in organizational positions that require greater involvement and influence in organizational decision-making processes	1 (0.2%)	19 (4.4%)	52 (12%)	263 (60.5%)	100 (23%)

MTL: Motivation to Lead Scale. $p < 0.05$.

the nursing profession. In other words, a more favorable and empowering work environment, where leadership is perceived positively, can serve as a catalyst for fostering nurses' aspirations and intentions to take on leadership responsibilities. Previous studies have shown that with a desirable work environment, nurses are provided with management and leadership advancement, engagement, coaching, mentoring, leadership modeling, and adequate structural resources, which all contributed to increase their willingness to engage in leadership tasks [9, 11, 31]. Positive work environments can increase the intention of nurses to lead, as well as enhance their professional development. This finding was reported in previous research that suggested that a favorable work environment is positively associated with the leadership career advancement [9, 13, 32]. Overall, this finding underscores the importance of cultivating a nurturing and supportive organizational culture. This can inspire nurses to develop their leadership potential, which ultimately contributes to the advancement of nursing practice and the delivery of quality patient care.

A significant contribution of the present study lies in its ability to link the results to Ross et al.'s conceptual framework, framing the results through the seven dimensions of the LENS. The framework was proposed to describe the leadership environment experienced by nurses in their practice settings. While the LENS respondents were direct care nurses from Oregon in the USA, the current study respondents were direct care nurses from Oman. Oregon nurses were on average 10 years older and there was a 10% higher number of nurses with baccalaureate degrees [23]. However, the percentage of nurse respondents in both countries who reported they were female was the same. These similarities made drawing conclusions about the work

environment and its effect on the leadership environment very sensible. In fact, the findings of the current study support the notion that, regardless of the cultural difference between different countries, the workplace environment is still a critical factor that influences the leadership environment among direct care nurses. It is important to acknowledge that the leadership environment between the two countries is different. For example, the findings of the current study suggested that nurses identified emergence, closely followed by transformative exchanges, as the highest features of the leadership environment. This differs from the results from LENS study in Oregon, where the highest endorsement was for coevolution, emphasizing mutual benefit in working with others.

The specific domains of the leadership environment that significantly influenced nurses' motivation to lead were self-organization, agents, and transformative exchanges. These domains are malleable and can be influenced by relationships and system supports, as indicated by the two-factor solution proposed by Ross et al. [23]. Self-organization is oriented towards the individual and how they can foster relationships within their organization. Nurses in the current study rated self-organization as the least obvious feature of the leadership environment. A similar finding was reported by Ross et al. [23]. According to the complexity theory, self-organizing systems emerge through the ability to be self-directed and effective utilization of available resources and information [5, 23]. This indicates the need to provide nurses with adequate knowledge, skills, resources, and authority to be actively involved in decision making and organizational change.

Agents are codependent on their relationship with each other, people, processes, and perspectives, specifically

mentorship, understanding of different perspectives, and modeling leadership, and they can influence systems at a distance, such as seen in the butterfly effect (a hallmark of the CAS). Transformative exchanges are the currency that the health system uses to influence locally and at a distance. Transformative exchanges are used in self-organization between agents within the system. These exchanges show nurses the support they have from their supervisor and the system, as well as how the system supports their educational advancement into potential leadership roles [21]. In order to improve the transformative exchange within healthcare settings, it is important to foster a culture of continuous learning and mentorship, by current nurse leaders. Encouraging ongoing professional development and providing mentoring opportunities can contribute significantly to the growth of potential leaders.

Motivation to lead is a multifaceted construct influenced by a variety of factors [14, 15]. Given that only 38% of the variance in motivation to lead was explained by the leadership environment, there may be other significant elements contributing to this outcome. High workloads and inadequate staffing are crucial factors that can lead to burnout, work dissatisfaction, and reduced motivation to take on additional leadership responsibilities [13, 16, 33, 34]. Educational background and professional development opportunities also play a significant role; nurses with higher education levels and access to continuous learning may be more inclined to pursue leadership roles [16]. Personal characteristics, such as leadership self-efficacy, career aspirations, and individual interest in leadership, further impact motivation [7, 16, 35]. Moreover, the presence of structural elements such as professional advancement opportunities, robust leadership and managerial support, and sufficient hospital resources may profoundly influence nurses' confidence in their leadership abilities and, consequently, their inclination to assume leadership roles [7, 15, 16]. These confounding factors suggest that a multifaceted approach is necessary to fully understand and enhance nurses' motivation to lead. Hence, future research should be conducted to take these elements into account and provide a more comprehensive understanding of what drives nurses to assume leadership roles.

5.1. Implications for Nursing Management. The most important implications of this study are that leaders should be aware of the importance of the leadership environment to front-line leaders, as well as their capacity to influence and create such environment. According to this study, emergence and transformational exchanges dominate the leadership environment, indicating that establishing a positive team culture is key to creating a desirable work environment. In addition, by investing in succession planning and mentorship programs, nurse leaders can ensure a smooth transition of leadership roles and sustain the continuity of effective leadership within the nursing workforce [29]. The findings of this study point to the importance of changing the leadership environment. Even though previous studies by Cziraki et al. [7] and Mascia et al. [25] found that self-efficacy was a significant factor in MTL, the environment

within which leaders develop and lead may trump self-efficacy or any demographic factors. In the leadership environment, agents, self-organization, and transformative exchanges are the strongest domains that can influence motivation to lead.

The other implications that can be linked to the findings of the current study are that nurse managers are to take the lead in changing the environment within their sphere of influence and setting the container or creating the space, so nurses not only cope with stress and change but also can fulfil their potential as leaders. To achieve this, nurse leaders are strongly recommended to implement the following strategies. First, as an agent, the nurse leaders are required to create the space and set the container within which all the work of developing new nurse leaders will occur. Second, nurse leaders identify candidates for leadership development who are known to have diverse perspectives. Third, create, in conjunction with the leadership candidate, pertinent resources to support the development of leadership skills. Fourth, provide opportunities for self-organization and transformative exchanges while staying in relationship.

Lastly, it is important to periodically assess the leadership environment, especially before any planned changes within the work environment. This baseline assessment can provide better insight into the change in the work environment and its relationship to the leadership environment at the unit and institutional levels.

5.2. Study Limitations and Future Research. Because the study used a cross-sectional design, the causal relationship between leadership environment and nurses' motivation to lead was limited. Additionally, the sample included nurses working in acute care hospitals; therefore, the generalizability of the study findings to other types of hospitals could be limited. Future study utilizing a longitudinal design including nurses from diverse hospitals such as general primary, tertiary, and acute care hospitals, assessing nurses' perception of their leadership environment and motivation to lead are recommended. Suggestions for future research also include conducting a longitudinal interventional study measuring the LENS prior to educational enhancement on leadership development and mentorship and three to six months after the intervention.

6. Conclusions

The study findings highlight the critical need to foster a nurturing and supportive organizational culture that motivates nurses to explore and expand their leadership capabilities. By doing so, organizations can significantly advance nursing practice and enhance the quality of patient care they provide. Recognizing aspects of self-organization, agent dynamics, and transformative interactions within the healthcare system presents a strategic approach to nurturing nurses' motivation to assume leadership roles, fostering a positive work culture, and improving the overall leadership environment in healthcare settings. While this study was conducted specifically within the context of Oman, the

implications of fostering a supportive nurse practice environment are broadly relevant to healthcare systems globally. Healthcare organizations worldwide can benefit from these insights by investing in leadership development and creating a culture that supports nurses, ultimately leading to improved patient outcomes and enhanced nursing practice.

Aim: This study examines the interrelationship between medical staff's sense of medical care policy alienation (SPA) and their subjective career success and the potential mediating roles of occupational calling (OC) and job satisfaction.

Background: Medical staff's pivotal role in medical care policy implementation outcomes underscores their approach to career success, which affects work efficiency, and willingness to implement medical care policy. Effective policy is anticipated to be positively and rationally implemented, fostering favorable perceptions and career success among policy executors such as medical staff. However, limited research examines the relationship between career outcomes and medical staff's SPA.

Methods: A cross-sectional study conducted from May to June 2023 collected data from 521 medical staff in 14 hospitals in northern, western, and southern China through questionnaire surveys. The questionnaire measured their SPA, OC, job satisfaction, and career success. A chain multiple mediation model was constructed to explore SPA's relationship with medical staff's OC and job satisfaction, resulting in less career success, and whether work overload moderated this relationship.

Results: Medical staff's SPA was negatively related to career success via a chain mediation mechanism involving OC and job satisfaction. Work overload did not moderate SPA's negative association with OC; however, it moderated its association with job satisfaction. High workload intensified SPA's association with job satisfaction, increasing the mediating effect on career success compared to those with lower workloads.

Conclusion: Medical staff's SPA was significantly negatively related to career success, reflected in a weakened OC, and decreased job satisfaction. Work overload somewhat moderated the relationship between SPA and job satisfaction. Policymakers and medical stakeholders should emphasize improved communication between medical institutions and staff, which is essential for crafting and disseminating medical care policies. Medical care policy implementation should be enhanced in diverse Chinese contexts to enrich the understanding of medical policy management.

Keywords: career success; job satisfaction; medical care policy alienation; medical staff; occupational calling; work overload

1. Introduction

Career success substantially influences medical staff's occupational outcomes, work efficiency, and willingness to implement medical care policies. It also supports them in managing challenges during the process of medical care policy implementation [1–3]. While effective social policy, such as medical care policy, is expected to be well-designed

in terms of its original intent and rationality, it should also foster positive perceptions and attitudes among policy executors, such as medical staff, toward its implementation [4].

From the perspective of the social psychological motivation behind frontline policy executors' implementation of social policy, Tummers et al. [5] introduced the concept of "policy alienation" among policy executors (such as medical staff). This concept refers to a general cognitive state of

psychological disconnection from the policy program implemented by a public professional who regularly interacts directly with clients [5]. Scientists then utilized this concept to assess the extent to which policy implementation outcomes might be affected by policy executors' subjective sense of policy alienation while seeking possibilities to improve policy implementation performance [3]. Studies have found that the policy alienation of policy executors not only affects their willingness to implement social policies [6] but also affects their job performance, work efficiency [3, 7], and general well-being [8].

However, existing research has not sufficiently explored the mechanism by which policy alienation impacts the career success of policy executors, such as medical staff [8], nor has it analyzed the conditions under which policy alienation has an impact on them [9]. The literature has also overlooked the potential impact that medical care policies may have on the career success and work management of medical staff.

Therefore, it is crucial to introduce effective and innovative medical care policies globally and to continue with medical care policy reforms. Equally important is ensuring the successful implementation of these policies by local policy executors, such as medical staff, as this contributes to their career success and work efficiency [10, 11]. To address this research gap and contribute to the existing literature, this study proposes a theoretical moderated chain mediation model that includes the variables of occupational calling (OC), job satisfaction, sense of medical care policy alienation (SPA), career success, and work overload. It is important to note that this research model remains theoretical, and the available data do not permit the testing of the processes involved.

This study defines OC as the pursuit of a meaningful and prosocial career driven by an external force, characterized by a transcendent passion to use one's talent to fulfill a particular life role, thereby deriving a sense of purpose as a primary source of motivation [12, 13]. Job satisfaction refers to the assessment of the favorability of a job, typically reflecting an individual's overall evaluative judgment about their job [14, 15]. SPA refers to a multidimensional construct that encompasses residents' perceptions of a disconnect from medical care policy. Career success is defined as an individual's subjective evaluation of their career accomplishments [1, 16]. Work overload refers to the excessive demands placed on an individual due to the performance requirements of their job [17, 18].

The control variables include respondents' demographic information, such as gender, age, educational level, and marital status. This study also controls for the level of the medical institution at which medical staff work, their professional titles, and whether they have management responsibilities. It also controls for medical staff's health status, using the presence of chronic diseases as a proxy indicator of health condition.

This study contributes to the literature by addressing a critical gap in career development research; it expands the scope of "career success" studies within the context of medical staff, broadening the research concerning medical staff work management. It also offers a deeper

understanding of the mechanisms by which SPA may undermine medical staff's experience of career success. It highlights that the SPA of medical staff may be higher in cases where they face work overload, thereby providing insights into work patterns that could improve their work efficiency.

1.1. Research Hypotheses. This study proposes six hypotheses based on moderating and mediating analyses, grounded in relevant literature. First, as society advances in the information age, the trend toward organizational flattening becomes more obvious, blurring traditional occupational hierarchies [19–21]. Coupled with the development of the platform economy, promotions and salary increases, traditionally used as core indicators to measure objective career success, are increasingly being questioned in academia [22–24]. Some scholars argue that objective career success cannot be used as the only indicator of a person's career performance [4]. By contrast, subjective career success has gradually been recognized in academic discourse as an important indicator of individual career performance [25, 26]. Subjective career success "capture(s) individuals' subjective judgments about their career attainments" [1] and is often defined as the accumulated positive work and psychological outcomes resulting from one's work experiences [27]. Nevertheless, a sense of policy alienation can negatively impact the career success of medical staff. This is because, on the one hand, medical staff with high SPA are more inclined to doubt the value of medical policies for patients and society [27]. Since their work goals are to support patients in recovery, it is difficult for them to integrate medical policy resources into their work when experiencing high levels of SPA, hindering their career success. Subsequently, medical staff with high SPA often feel disconnected from medical care policy formulation, implementation, or reform, which can lead them to perceive that medical policy cannot support them with work-related challenges. Thus, they experience decreased work efficacy and weaker work management, resulting in difficulties in achieving career success [28]. Furthermore, medical staff with high SPA are more likely to doubt the feasibility of implementing a given medical care; however, as frontline policy executors, medical staff should trust in the implementation of medical care policies. This dilemma can cause psychological conflicts for medical staff, requiring them to spend more psychological resources dealing with these conflicts, thereby depleting the psychological resources necessary for work, and resulting in lower career success possibilities [29]. Based on this analysis, we propose the following hypothesis:

Hypothesis 1. SPA is significantly negatively related to the career success of medical staff.

Second, based on existing literature, we argue that SPA can weaken an individual's OC. First, medical staff with high SPA are inclined to doubt the practical value of medical policies for residents and society as a whole [7, 30], which may hinder their OC [31]. In addition, medical staff with

high SPA tend to perceive that they have minimal influence over medical policy formulation and implementation [5, 32]; consequently, their sense of purpose to fulfill their prosocial role at work could be weakened, resulting in a low level of OC. In addition, medical staff with high SPA may believe that medical care policy cannot be implemented efficiently for those with medical care needs, which may also lead to doubts about promoting the greater good [31, 32].

OC has a significant positive impact on career success. Individuals with strong OC are highly motivated at work, which often results in better work performance, a higher likelihood of career success, and high work efficiency [33, 34]. They are less likely to give up when encountering workplace challenges, increasing the probability of career success [35, 36]. Additionally, they may regard work as a means of achieving both external and internal work-related goals, such as earning a living and personal satisfaction and fulfillment of work values, respectively [37, 38]. Therefore, individuals with high OC may be better at balancing the external and internal goals that lead to career success. Based on this analysis, we propose the second hypothesis:

Hypothesis 2. OC mediates the association between SPA and career success of medical staff.

Third, we argue that SPA is significantly negatively related to the job satisfaction of medical staff because they tend to think of medical care policy as having little value [39]. This devaluation of policy implementation can diminish their sense of purpose and fulfillment as policy executors, leading to lower job satisfaction. This study also assumed that high SPA might lead to feelings of self-worthlessness in medical policy implementation, resulting in a weak perception of mastery and autonomy in their work [8, 40]; consequently, medical staff may experience less career success. Organizational behavior research has also suggested a correlation between job satisfaction and career success [1, 3]. Based on the above analysis, this study proposes its third hypothesis.

Hypothesis 3. Job satisfaction mediates the association between SPA and the career success of medical staff.

Fourth, this study argues that both OC and job satisfaction, which are interrelated, mediate the relationship between SPA and career success and that the medical staff's OC is positively associated with job satisfaction level. We assume that medical staff with strong OC gain high job satisfaction because of their consistent engagement in work values and long-term development goals [37, 41]. Moreover, medical staff with high OC can more easily identify their work as not only a means to make a living but also to contribute to the greater good, fostering a sense of accomplishment and leading to increased job satisfaction [33, 42]. In addition, this study proposes that medical staff with strong OC are inclined to believe that their work is aligned with societal needs, which connects them to broader humanistic goals, evokes positive emotions, and increases their job satisfaction and work efficiency [31, 43]. Based on the above analysis and considering the association between SPA and OC and that between job satisfaction and career success, we propose the fourth hypothesis.

Hypothesis 4. OC and job satisfaction mediate the relationship between SPA and career success among medical staff.

Fifth, many studies have found that SPA has negatively relationship with work performance, with outcomes such as reduced trust in government, decreased willingness to implement policies, and increased job burnout [8, 44]. However, the literature has not explored the conditions under which SPA might exacerbate work and career consequences for employees nor the extent to which possible interventions could mitigate these effects. Therefore, this study proposes that workload moderates the association between SPA and the outcome variables.

For example, compared to a normal workload, overloaded medical staff experience more negative emotions [45]. SPA might amplify these negative emotions, further undermining their work status and experience and weakening their job satisfaction and OC. Furthermore, when medical staff are overloaded, they may have less time to communicate with patients [46], exhibit impatience with patients [47], or foster a mutually distrustful climate between doctors and patients. These outcomes can lead to more serious consequences if medical staff are also experiencing strong SPA. Based on the above analysis, we propose the fifth and sixth hypotheses of this study.

Hypothesis 5. Workload moderates the relationship between SPA on OC for medical staff; in cases where medical staff experience work overload, SPA has a stronger negative relationship with OC.

Hypothesis 6. Workload moderates the relationship between SPA and job satisfaction for medical staff; in cases where medical staff experience work overload, SPA has a stronger negative relationship with job satisfaction.

The theoretical mediational model of this study is presented in Figure 1.

Hypotheses: (i) SPA has a significant negative impact on the career success of medical staff; (ii) OC mediates the association between SPA and career success among medical staff; (iii) job satisfaction mediates the association between SPA and the career success of medical staff; (iv) OC and job satisfaction mediate the relationship between SPA and career success among medical staff; (v) workload moderates the impact of SPA on OC for medical staff: in cases where medical staff experience work overload, SPA has a stronger negative impact on OC; and (vi) workload moderates the impact of SPA on job satisfaction for medical staff; in cases where medical staff experience work overload, SPA has a stronger negative impact on job satisfaction.

2. Materials and Methods

2.1. Research Design. We conducted a cross-sectional study to collect sample data from May to June 2023. The sample consisted of medical staff from 14 hospitals in four cities in northern (Changchun City), western (Chengdu City), and southern China (Shangrao City and Hefei City). These 14 hospitals are classified as secondary and tertiary hospitals in

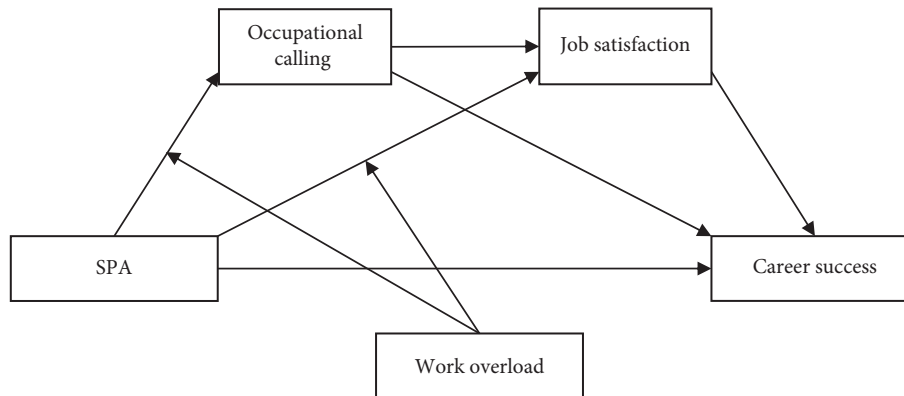

FIGURE 1: Theoretical model. SPA: sense of medical care policy alienation.

China according to the Chinese hospital management regulations [48]. Hospitals in China can be roughly divided into three levels based on their size, number of professional staff, and medical care resources available to patients [49]. First-level hospitals are grassroots hospitals that provide services to patients, focusing on disease prevention, rehabilitation, and healthcare services, which are considered basic medical services in primary healthcare institutions. Secondary and tertiary hospitals play a significant role in providing more advanced medical care, with patients accessing the majority of medical care resources at these institutions [48]. Therefore, in this study, medical staff from six secondary and eight tertiary hospitals were interviewed after obtaining consent from the hospital manager and medical staff participants.

2.2. Sample and Procedure

2.2.1. Inclusion and Exclusion Criteria. The inclusion criteria in this study were (1) working full-time in the hospital, (2) having no less than 3 years of medical work experience, (3) being 60 years old or younger, and (4) voluntarily participating in the survey after understanding the purpose of the research and signing an informed consent form. The exclusion criteria were (1) medical staff working in first-level hospitals in China, because their work content and patients are quite different from those in secondary and tertiary hospitals [48, 49], (2) part-time medical staff and medical staff rehired after retirement, and (3) medical staff with less than 3 years of full-time work experience.

2.3. Sampling Technique. To analyze the mediating effect, the required sample size depends on various factors, including model complexity, number of indicators, method used to estimate the mediating effect, and power value [50, 51]. For the model with two mediating variables, the sample size recommended in the literature is between 221 and 1000, with a median of 352 [52]. We used the sample size recommended in the literature (352) and the average value (393) from Sim, Kim, and Suh [52] simulation analysis (433) as our reference for this study. Given that we surveyed professional medical staff, we expected the questionnaire return rate to be low and

the proportion of invalid questionnaires high. To ensure at least 393 valid questionnaires, we multiplied this number by 1.5 and then rounded up to the closest integer, resulting in a distribution of 600 questionnaires. The actual questionnaire return rate and proportion of valid questionnaires exceeded our expectations, with 521 valid questionnaires. The sample of this study came from 14 hospitals in North (Changchun City), West (Chengdu City), and South China (Shangrao City and Hefei City). These 14 hospitals are classified as secondary and tertiary hospitals in China according to the Chinese hospital management regulations [48].

Hospitals in China can be roughly divided into three levels based on their size, number of professional staff members, and medical care resources that are available to patients [49]. First-level hospitals are grassroots hospitals that provide services for patients, focusing on disease prevention, rehabilitation, and healthcare services, which are regarded as basic medical care services in primary healthcare institutions. Secondary and tertiary hospitals play a significant role in providing medical care services for patients, in which patients are supposed to access most of the medical care resources [48]. After briefing the HR departments of the 14 hospitals on the value and significance of the study and ensuring the anonymity of the respondents, the departments facilitated the recruitment of participants via research assistants within their respective workgroups. For medical staff who expressed willingness to participate in the survey, the research assistant sent a WeChat link and asked them to respond online. Using the questionnaire link, the respondents independently completed the online questionnaire on their computers or mobile phones. After completing the questionnaire, the respondents received a remuneration of approximately US\$1. During the survey period, 600 questionnaire links were distributed, and 562 medical staff completed the questionnaire. Of these, 41 invalid questionnaires were excluded owing to inconsistencies, resulting in 521 valid questionnaires.

2.4. Participants. The respondents ranged in age from 25 to 60 years, with a mean age of 39.03 years (standard deviation [SD] = 7.65). There were 159 men (30.52%) and 362 women

(69.48%). A total of 415 respondents had a bachelor's degree or higher (79.65%). A total of 453 respondents (86.95%) were married, and the remaining 68 (13.05%) were unmarried or divorced. The average number of years of medical work practice for all respondents was 16.30 years ($SD=8.33$). In addition, 329 respondents (63.15%) had junior or senior professional titles, and 192 (36.85%) had primary titles. In addition to their routine work, 172 respondents (33.01%) had management responsibilities.

2.5. Ethical Considerations. This study was approved by the ethics committee of Anhui Normal University (approval number: AHNU-ET2023040), and it was conducted with the understanding and consent of the participants in accordance with the 1964 Declaration of Helsinki. Participants signed an informed consent form (or confirmed informed consent) after understanding the purpose of the study before completing the questionnaire.

2.6. Measures

2.6.1. SPA. This study used a modified, short version of the general policy alienation scale to measure SPA [32]. We modified six relevant policy items from the original scale for a medical care policy context, targeting the "powerlessness" and "meaninglessness" dimensions of the SPA of medical staff. However, we removed one item from the van Engen [32] scale because its correlation with the total score of medical care policy alienation was less than 0.3 [53]. Additionally, we included five relevant items from the policy alienation scale from Xu, Xia, and Ding [54] to measure the "implemented doubt" dimension and added one more item: "policy changes are too fast for implementers to adapt." The final SPA scale used in this study comprised 10 items, including powerlessness, meaninglessness, and implemented doubt. The responses were rated on a five-point Likert scale ranging from 1 = "strongly disagree" to 5 = "strongly agree." Our scale had good construct validity ($\chi^2/df=3.755$) and a comparative fit index (CFI) of 0.970, Tucker-Lewis index (TLI) of 0.958, standardized root mean square residual (SRMR) of 0.046, and root-mean-square error of approximation (RMSEA) of 0.073, which met the recommended standards [55]. In this study, the Cronbach's α of the SPA scale was 0.832. The mean score of all items was used as an indicator of SPA among medical staff; the higher the score, the higher the SPA level.

2.6.2. OC. The OC of medical staff was measured using the presence subscale of the Brief Calling Scale [56]. This subscale contains two items that were modified for this study to be more in line with the situation of medical staff [37], including (1) "I feel a calling to be a medical staff member and do my job" and (2) "I have a good understanding of my calling as it applies to my career." The responses were rated on a five-point Likert scale ranging from 1 = "not at all true for me" to 5 = "totally true for me." This subscale has good reliability and validity and is often used in OC-related

research [43]. In this study, the Cronbach's α of the scale was 0.842. The average score of all items was used as an indicator of the medical staff's OC; the higher the score, the stronger the OC.

2.6.3. Job Satisfaction. The General Job Satisfaction Scale was used to measure the overall job satisfaction of the medical staff in this study [57]. The scale contains three items, for example, "Generally speaking, I am very satisfied with my job." The responses were rated on a five-point Likert scale ranging from 1 = "strongly disagree" to 5 = "strongly agree". In this study, the Cronbach's α was 0.908. The mean value of all items was used as the index of job satisfaction; the higher the score, the higher the medical staff's job satisfaction.

2.6.4. Career Success. Six items from the financial success and work-life balance dimensions of the Career Success Scale compiled by Briscoe et al. [4] were used to measure career success in this study. These items are usually used by researchers to measure respondents' subjective career success [58]. The responses were rated on a five-point Likert scale ranging from 1 = "strongly disagree" to 5 = "strongly agree." The Cronbach's α was 0.906. The mean of all items was used as an index of career success; the higher the score, the higher the medical staff's career success level.

2.6.5. Work Overload. Referring to a previous study [59], respondents were asked, "In the past month, on average, how many hours did you work per week?" Respondents chose the period specified in the questionnaire. According to China's Labor Law [60], working overtime for employees means they work more than 8 hours per day and overtime hours are limited to no more than 3 hours per day and no more than 36 h per month. Thus, medical staff should have worked a maximum of 9 hours of overtime per week, plus a normal 5-day working week of 40 h per week; therefore, medical staff can work a maximum of 49 h per week. Medical staff who worked more than 49 h per week were defined as having work overload, and those who worked less than or equal to 49 h were not considered to have work overload.

2.6.6. Control Variables. Following the recommended method [61], this study controlled for participants' demographic information, including gender, age, education level (1 = undergraduate and above, 0 = other), and marital status (1 = married, 0 = other). Since working institutions, professional titles, and work positions also have an impact on career success [1], this study controlled for the level of the medical institution where the medical staff worked (1 = tertiary hospital, 0 = secondary hospital), their professional titles (1 = intermediate and senior professional titles; 0 = other), and whether they had management responsibilities (1 = yes, 0 = no). This study also controlled for the health condition of medical staff; whether they suffered from certain chronic diseases was used as a proxy indicator of health condition (1 = yes, 0 = no).

2.6.7. Summary of Measures. To summarize, the measurement tools used in this study have high reliability and validity. We used established measurement scales, including those for OC, job satisfaction, and career success. The data analysis in this study also confirmed their excellent Cronbach's α coefficients. Additionally, we combined scales from van Engen [32] and Xu, Xia, and Ding [54] to measure SPA; after assessing its structural validity via confirmatory factor analysis, the results demonstrated that the fit index was consistent with expert recommendations [55].

2.7. Data Analysis and Model Test. This study used SPSS 25.0 and M-plus 8.0 for data analysis. We first tested for the possible risk of common method bias. Second, we analyzed the means, SDs, and correlation coefficients of the main variables. Third, we established a moderated mediation model to test the hypotheses based on the bias-corrected nonparametric percentile bootstrap method recommended by statisticians [62–64]. Specifically, we examined the direct relationship between medical staff SPA and career success (Hypothesis 1), followed by the possible mediating impact of OC and job satisfaction on the relationship between SPA and career success (Hypotheses 2 and 3), and finally the chain mediating impact of SPA \rightarrow OC \rightarrow job satisfaction \rightarrow career success (Hypothesis 4). We also tested whether work overload moderated the relationship between SPA and OC (Hypothesis 5) and between SPA and job satisfaction (Hypothesis 6) [65]. Before constructing the analysis model, the continuous variables were mean-centered [66]. For the bootstrapping analysis of chain mediating and moderating effects, the number of repeated samplings was set to 10,000 [67]. Unless otherwise specified, control variables including demographic information, job title, and management responsibilities were included in the model.

3. Results

3.1. Common Method Bias. This study may be susceptible to common method bias due to its cross-sectional design and reliance on self-reported data [68]. To address this concern, Harman's single-factor test was used to analyze the data [69]. The results showed that seven factors could be extracted based on the items used in this study. The factor with the largest explanatory power accounted for only 29.551% of the total variance, which is below the recommended threshold of 40% [69], indicating the data were not significantly affected by common method bias.

3.2. Descriptive Statistics. Table 1 presents the relationships among the means, SDs, and correlation coefficients of the variables. We found that SPA was significantly negatively correlated with career success, OC, and job satisfaction. However, a significant positive correlation was found between OC, job satisfaction, and career success.

3.3. Direct Relationship Between SPA and Career Success. The results show that SPA was significantly negatively associated with medical staff's career success ($B = -0.771$, $p < 0.001$), and the 95% confidence interval (CI) calculated using 10,000 bootstrap samples was $[-0.865, -0.671]$, which did not contain 0. This means that medical staff who experienced higher SPA tended to have a lower possibility of achieving career success; therefore, Hypothesis 1 was supported.

3.4. Relationship Between SPA and Career Success Through OC and Job Satisfaction. The results of the mediation of OC and job satisfaction on the relationship between SPA and career success are summarized in Table 2. We found that SPA was significantly negatively related to OC, while OC was significantly positively related to career success. Furthermore, the relationship between SPA and career success mediated by OC was also significant, and the 95% CI did not include 0. OC was an intermediary variable between SPA and career success among medical staff. Therefore, Hypothesis 2 was supported (Table 2 and Figure 1). Furthermore, SPA was significantly negatively associated with job satisfaction and significantly positively associated with career success among medical staff. The relationship between SPA and career success through job satisfaction was significant (95% CI = $[-0.371, -0.204]$; the CI did not contain 0). These results suggest that SPA can affect medical staff's career success via job satisfaction; thus, Hypothesis 3 was supported (Table 2 and Figure 1). In addition, this study found that the relationship between SPA and career success via OC and job satisfaction was significant (95% CI = $[-0.168, -0.079]$), indicating a chain mediating impact and supporting Hypothesis 4 (Table 2 and Figure 1).

3.5. Moderating Role of Work Overload. In addition to the aforementioned mediating role, this study hypothesized that work overload played a moderating role in the relationship between SPA, OC, and job satisfaction. First, it tested whether the relationship between SPA and OC was moderated by work overload. The results showed that after including work overload as the moderating variable and incorporating the interaction term between SPA and work overload into the equation, SPA still had a significant negative relationship with OC; however, the interaction term between SPA and work overload had no significant association with OC ($p = 0.957$). The 95% CI of the interaction term = $[-0.205, 0.204]$ contained 0 (Table 3). Therefore, Hypothesis 5 was not supported.

Second, this study examined whether work overload moderated the relationship between SPA and job satisfaction; the results are shown in Table 3. According to the results, SPA still had a significant negative relationship with job satisfaction after adding work overload and the cross-product term between SPA and work overload. The interaction term between SPA and work overload was also significant (95% CI = $[-0.466, -0.096]$), and the CI did not contain 0. This suggests that work overload can modify the

TABLE 1: Means, SDs, and correlations of the study variables.

* $p < 0.05$.

** $p < 0.01$.

*** $p < 0.001$.

relationship between SPA and job satisfaction. To further clarify this moderating effect, a simple slope analysis was conducted, as shown in Figure 2. The analysis revealed that when medical staff were overloaded (WOL = 1), their SPA was significantly negatively associated with job satisfaction, $B = -0.703$, $p < 0.001$, 95% CI [-0.849, -0.558]; however, when they were not overloaded (WOL = 0), their SPA also had a significant negative association with job satisfaction, $B = -0.419$, $p < 0.001$, 95% CI [-0.548, -0.287]. We constructed an indicator to determine the difference in the relationship between SPA and job satisfaction according to overloaded and nonoverloaded medical staff. The 10,000 bootstrap calculations showed that the 95% CI of this indicator was [-0.466, -0.096], and 0 was not included, suggesting a significant difference in the SPA–job satisfaction relationship between overloaded and nonoverloaded medical staff. Compared to nonoverloaded staff, the SPA of overloaded staff had a greater negative association with job satisfaction. Hence, Hypothesis 6 was supported.

In addition, we further analyzed whether work overload moderated the relationship between SPA and career success through job satisfaction among medical staff. The results showed that the relationship between SPA and career success via job satisfaction was significant for overloaded, $B = -0.350$, $p < 0.001$, 95% CI [-0.462, -0.253], and nonoverloaded medical staff, $B = -0.209$, $p < 0.001$, 95% CI [-0.300, -0.134]. To determine the difference in job satisfaction's mediating effect between the two groups, we constructed an indicator representing overloaded and nonoverloaded staff. The 95% CI of this indicator, calculated using 10,000 bootstrap samples, was [-0.244, -0.052], which did not include 0. Thus, work overload moderated the relationship between SPA and career success through job satisfaction. Thus, compared to nonoverloaded medical staff, SPA's relationship with career success through job satisfaction was greater for overloaded medical staff. The final proposed model is presented in Figure 3.

3.6. Outcomes Without Control Variables. Following the recommended analysis method [61], this study examined whether the main results would change significantly with the

absence of control variables. In the model of the SPA–career success relationship, the association remained significant without control variables ($B = -0.786$, $p < 0.001$, 95% CI [-0.875, -0.692]). In the mediation model of the association between SPA and career success with OC and job satisfaction and mediators, the SPA–career success association through OC was still significant when control variables were excluded (95% CI = [-0.110, -0.022]). Similarly, this association was also significant with the mediating role of job satisfaction (95% CI = [-0.385, -0.219]); the chain mediating impact of SPA on career success through OC and job satisfaction also remained significant (95% CI = [-0.157, -0.073]). In the moderated mediation model, work overload did not moderate the relationship between SPA and OC without control variables, but it moderated that between SPA and job satisfaction. Specifically, compared to medical staff who were not overloaded, the association between SPA and job satisfaction was greater for overloaded staff, while that between SPA and career success via job satisfaction for overloaded staff was also greater. These results are consistent with those obtained when control variables were included, indicating the results are robust [70].

4. Discussion

4.1. Primary Relationship Identified. This study demonstrated that SPA was significantly negatively associated with medical staff's career success and that OC and job satisfaction acted as mediating factors in this relationship. This is consistent with the previous literature that has indicated career success has a significant impact on medical staff's occupational outcomes, work efficiency, and role in implementing medical care policies [1, 2]. Furthermore, our results suggest career success helps medical staff manage challenges in their professional lives. Notably, the chain mediating effect in the relationship between SPA and subjective career success through OC and job satisfaction was significant [2, 3]. Work overload moderated this relationship. Additionally, the study found that work overload moderated the relationship between SPA and job satisfaction, as well as the mediating role of SPA on career success through job satisfaction; the effects were more pronounced

FIGURE 2: Interaction between sense of medical care policy alienation (SPA) and workload on job satisfaction.

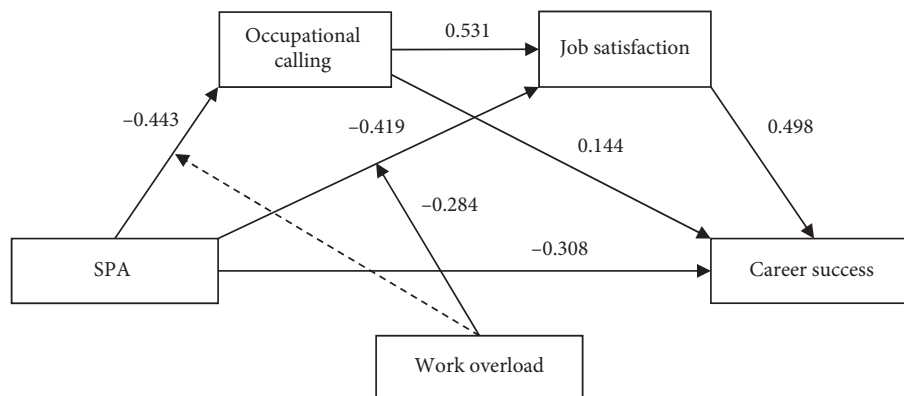

FIGURE 3: Proposed tested model. SPA: sense of medical care policy alienation.

among overloaded medical staff compared to nonoverloaded staff. This study's focus differs from that of previous studies, which have examined the impact of policy alienation on policy executors' willingness to implement social policies, job performance, work efficiency, and general well-being [37, 41, 71, 72]. We extend this research by comprehensively analyzing the conditions under which policy alienation impacts frontline policy executors, such as doctors. Our findings also differ from those of previous studies by highlighting a specific trend: medical staff's SPA is negatively associated with career success via a chain mediation mechanism involving OC and job satisfaction. While work overload did not moderate SPA's negative relationship with OC, it did moderate its relationship with job satisfaction.

4.2. Psychological Mechanisms Related to SPA and Career Success. This study identified two psychological mechanisms based on the association between SPA and career success. The first is OC: medical staff with high SPA had lower OC levels, making it difficult for them to achieve

career success [37, 41, 73]. The second mechanism is job satisfaction. Specifically, medical staff with high SPA may have lower job satisfaction, which could lead to poor career success [25, 71]. In addition, our findings support the idea that OC is associated with job satisfaction among medical staff [31, 72]. This suggests that SPA could affect career success through the chain mediating impact of OC and job satisfaction, with those with higher SPA experiencing less career success. SPA reduces medical staff's willingness to implement policies, hindering their ability to achieve career success. These findings deepen our understanding of the mechanisms underlying the impact of SPA.

In addition, this study identified conditions that may affect the degree of SPA. Specifically, we found that the relationship between SPA and job satisfaction for medical staff experiencing work overload (working over 49 h per week) was more negative than that for medical staff without work overload [18, 47, 73]. However, work overload did not affect the relationship between SPA and OC. A possible reason for this is that although work overload can lead to

physical and psychological fatigue in medical staff, it may also drive them to achieve career objectives [55, 74, 75]. These findings enhance our understanding of the conditions under which SPA interacts with high workloads among medical staff.

4.3. Burnout of Medical Staff. It is important to consider the negative impact of SPA on medical staff, particularly in relation to practical problems, such as work overload [76]. Many studies have shown that work overload among medical staff is a global issue [47, 47]. This overload often leads to burnout, which may even drive medical professionals to leave the field [77]. This study also found that work overload acts as a moderating factor, intensifying SPA's negative impact, which is consistent with existing literature highlighting that medical staff's work overload has a significant negative impact on medical staff's personal and professional well-being [45, 78]. In other words, under conditions of work overload, SPA has a stronger negative association with job satisfaction, and the mediating role of SPA on career success through job satisfaction is also strong. Given these findings, work overload among medical staff should be prioritized by governments and society as a whole [18]. We recommend medical institutions leverage information and intelligent technologies, such as artificial intelligence, to reduce workload by automating routines and repetitive tasks. This would free medical staff to focus more on patient relationships, improving their professional skills, and increasing their work efficiency [79, 80]. Medical professionals should be encouraged to devote more time and energy to communication skills, diagnosis, treatment, and rehabilitation processes rather than performing repetitive tasks [81, 82]. In addition, governments and medical institutions should minimize the management tasks of medical staff, thereby reducing their working hours, particularly over the long term [83, 84]. Establishing a mandatory resting system could also be beneficial. In cases of work overload, medical staff should be required to take rest periods before returning to work to increase their efficiency and avoid mistakes in medical services [45, 85].

5. Implications for Nursing Management

This study aimed to assess the current practices in medical care policy implementation and the impact of policy development [3]. It sheds light on medical staff management practices by understanding the nuances of medical care policy implementation [9, 86]. Promoting medical policy advocacy among medical staff is crucial. The study findings suggest that SPA among medical staff not only weakens their OC and increases their job dissatisfaction but also reduces their possibility of career success and effective work management. We recommend that the government solicit input from regular users and medical staff during the medical care policy-making process. This feedback should be incorporated into medical care policy reforms to reduce the sense of powerlessness medical professionals may experience during policy implementation process [6, 8]. Moreover, an

emerging challenge in medical care policy implementation is determining how to efficiently execute medical care policy [87, 88]. It is necessary for medical institutions to improve communication with medical staff when formulating implementation guidelines and publicizing medical care policies [78]. Enhanced communication could help medical staff better understand how to implement policies that might otherwise feel meaningless to them, thereby reducing their doubts regarding medical care implementation and lowering SPA. Finally, this study explores medical care policy implementation from various Chinese contexts, which contributes to the body of knowledge on international medical care policy management [89, 90].

5.1. Limitations. This study has some limitations that should be addressed in future research. First, as exploratory research, it utilized a cross-sectional design, limiting the ability to draw conclusions regarding the causal relationship between SPA and career success [91]. Future research should consider a longitudinal research design or experimental approach to gain a deeper understanding of this relationship and explore the potential mediating roles of OC and job satisfaction. Second, this study used short scales to measure OC and career success to increase the response rate and reduce the burden on busy medical staff. Although these short scales have high reliability and validity [92], future research should consider using complete scales to measure the constructs involved in this study. In addition, work overload was measured using self-reported working hours. Future research should explore additional workload indicators, such as the number of consultations [18]. Third, this study identified OC and job satisfaction as mediators between SPA and career success; however, the possibility of other mechanisms cannot be ruled out. Future research should continue to explore how SPA acts on career outcomes to deepen the academic understanding of its effects. Fourth, this study found that workload moderated the outcomes of SPA, with a stronger negative association with job satisfaction and career success among overloaded medical staff. Future studies should examine additional moderating variables, such as performance, to provide insight into the design of SPA interventions. Lastly, intervention research should be considered to develop appropriate programs that mitigate SPA or to lessen its impact on key outcome variables through appropriate environmental design.

6. Conclusions

If a chain mediating effect between SPA and subjective career success through OC and job satisfaction is established, it suggests that effective OC and job satisfaction can support career success even in cases wherein SPA negatively impacts career outcomes. Moreover, because work overload moderates the impact of SPA on medical staff to a certain extent, those with high work overload may be more satisfied with their jobs and have greater chances of achieving career success. Active discussion and motivation to address

medical care policy implementation issues, based on the experiences of medical staff, are essential for establishing an effective medical care policy implementation system that considers SPA among medical staff and assists them in improving job efficiency.

Background. As nursing interns enter challenging clinical settings, evaluating their preparation and readiness is vital for adaptation success. Sufficient real-world experience and patient care are crucial preparation components that enable effective practice and higher competencies. **Aim.** This study aimed to assess nurse interns' perception of clinical preparation and readiness for clinical internship experiences. **Methods.** A self-administered questionnaire was distributed, comprising three sections on demographics, clinical preparation requirements, and the Casey–Fink Readiness for Practice Survey. Descriptive statistics as the mean and standard deviation, numbers and percentages, linear regression model, and Pearson correlation coefficient were used for reporting normal distribution, categorical variables, and relationship between a scalar response and one or more explanatory variables and to calculate statistics between two continuous variables. **Results.** The participants were 130 nurse interns who were involved in an internship between 2016 and 2020, 50% of the nurse interns. They had a moderate level of clinical preparation, and 28.5% of them exhibited a low level. In addition, 53.8% were found to be moderately ready for practice, while 22.3% had a low level of readiness. **Conclusion.** The observed significant positive correlation between perceived preparation and readiness underscores the pivotal role of clinical preparation in influencing practice readiness. **Implications.** These findings emphasize the importance of targeted interventions aimed at enhancing clinical preparation to directly bolster overall readiness for professional practice among nurse interns.

1. Introduction

Adequate clinical preparation and readiness are vital for nursing interns entering challenging hospital environments. However, studies indicate inconsistencies in nursing students' perceived preparation, highlighting a crucial need to evaluate preparation programs [1]. As rising patient acuties increase demands on novice nurses, sufficient clinical skills and competencies determine adaptation success during role transitions from student to practicing nurse [2]. The intricacy of modern healthcare environments means nursing graduates must possess clinical reasoning, critical thinking, organizational skills, and communication capacities [3].

Given that essential skills are primarily developed through clinical placements, it is concerning that studies report discrepancies between students' perceived readiness and actual workplace readiness [4]. Determining alignment requires simultaneous investigation into multiple preparation elements including knowledge, nursing skills, critical thinking abilities, ethical comportment, and professional identity. Understanding where potential gaps exist allows educational initiatives targeting identified deficiencies. [5].

Adequate clinical preparation is vital for nursing students transitioning into demanding healthcare environments. However, research indicates inconsistencies in students' perceived readiness, highlighting a crucial need to

evaluate preparation programs [6]. Modern healthcare requires graduates have clinical reasoning, critical thinking, organizational skills, and communication capacities [5].

Clear clinical instruction assists nursing students through the transition period from student to registered, professional nurse [7]. To be competent, the nurse intern must have scientific/theoretical knowledge, particular technical psychomotor abilities, communication skills, professional values, and ethical behavior to provide care for patients in real situations [8].

Education plays a major role in the advancement of nursing discipline. Several programs, both undergraduate and postgraduate, have been developed to train nursing student. An educational program that can apply these characteristics is able to cover a large number of skills and traits that are essential in the professional environment [9].

The five-year Bachelor of Science in Nursing (BSN) program at most Saudi Arabia universities contains a mix of science and arts courses which advance nursing clinical practice and competency [10]. The program includes four years of theoretical education, and in the fifth year, a nursing internship year, which provides direct patient care experience in a healthcare setting [11].

An internship is designed to prepare the nurse intern for the different skills needed to be successful in the profession [12]. The one-year internships in Saudi Arabia rotate the nursing student through different clinical settings, including medical-surgical for pediatrics and adults, critical care in intensive care units, the emergency room, the operating room, triage area, dialysis units, labor and delivery units, and outpatient clinic [13].

Our study aimed to assess nurse interns' perceptions of their clinical preparation and readiness and examine relationships between perceived preparation and perceived practice readiness. The goal is to gain insight into the alignment between nurse interns' perceived capacities and workplace demands in order to guide educational approaches that optimize clinical preparation. Enhancing readiness aims to ease the role transition from nursing student to practicing nurse, facilitating better adaptation and competency as the next generation enters the healthcare workforce.

1.1. Research Questions

- (1) What is nurse interns' perception of clinical preparation and readiness for clinical internship experiences?
- (2) Are there significant correlations between nurse interns' perceived level of clinical preparation and their self-reported readiness for nursing practice during the internship?

2. Methods

A cross-sectional research design was utilized. This study was carried out at the College of Applied Medical Sciences, Hafr Al Batin University, Saudi Arabia.

2.1. Sampling. Participants for the study were recruited by homogeneous purposive sampling. The participants were 130 nurse interns. The study participants joined to this study according to the following inclusion criteria: the participants willing to participate in the study. The nurse interns enrolled in their internship year, which is the culmination of a graduate program consisting of a foundation year and a three-year baccalaureate program. The program also includes a mandatory 12-month internship, allowing nursing interns to gain practical experience in government hospitals.

There were 130 nurses involved in an internship between 2016 and 2020 (Table 1).

2.2. Data Collection. A self-administered questionnaire was utilized to collect data, covering aspects related to demographic characteristics, clinical preparation, and readiness for practice.

The questionnaire was translated into Arabic to ensure clarity and accessibility for participants.

Content validity was assured by a jury of 5 experts in the field of nursing management and nursing education and community health nursing.

For the first three groups (2016–2019), which represent nurse interns from the first three graduated years (2016–2019), data collection involved in-person interviews. The researcher conducted individual interviews with each nurse intern included in the study. During the interviews, participants responded to the questionnaire items, and the researcher recorded their responses to encourage interns and prevent hesitant to disclose information.

For the last year (2019–2020), researchers opted for an online data collection approach. The tools were distributed to nurse interns electronically through an online platform. The questionnaire was distributed via an official email specifically designated for nurse interns, ensuring confidentiality and targeted outreach. The response rate of 100% was calculated by dividing the number of valid responses by the total number of responses requested during interview and the number of emails replies compared to the number of emails sent.

2.3. Instruments

2.3.1. Part I: Characteristics of Nurse Interns. The characteristics of nurse interns were age, marital status, type of family, graduated year, last grade point average (GPA), what orientation program they attended, and whether it was effective.

Content validity was assured by a jury of 5 experts in the field of nursing management and nursing education and community health nursing.

2.3.2. Part II: Clinical Preparation Requirement Questionnaires. This tool was adapted from Hickey [14]. The tool comprises six components and a total of 45 items. These items are designed to evaluate the six critical components of necessary clinical preparation, namely, nursing process

TABLE 1: Characteristics of studied nurse interns ($n = 130$).

Items	N	%
Age (year)		
20–<25 years	35	26.9
25–30 years	95	73.1
Mean SD	26.09 ± 3.96	
Gender		
Female	130	100
Marital status		
Married	15	11.5
Unmarried	115	88.5
Last GPA		
<2	9	6.9
2–2.74	17	13.1
2.75–3.74	33	25.4
3.75–4.49	52	40
>4.49	19	14.6
Type of family		
Nuclear	50	38.5
Extended	80	61.5
Graduation year		
2016–2017	15	11.5
2017–2018	32	24.6
2018–2019	20	15.4
2019–2020	63	48.5
Attended orientation program		
Yes	130	100
Perception related effective of program of orientation		
Strongly agree	64	49.2
Agree	40	30.8
Disagree	20	15.4
Strongly disagree	6	4.6

steps, use of resources, psychomotor skills, teaching and information imparted, communication, and administrative aspects. Respondents rated each item on a scale ranging from (1) “not important” to (4) “essential.” The overall scale, with a possible range from 45 to 180, allowed for categorization based on importance; scores below 60 were considered of low importance, scores between 60 and 120 denoted moderate importance, and scores exceeding 120 indicated high importance.

Reliability testing was performed using Cronbach’s alpha, resulting in a value of 0.856.

Content validity was assured by a jury of 5 experts in the field of nursing management and nursing education and community health nursing.

2.3.3. Part III: Casey–Fink Readiness for Practice Survey. This scale was adapted from Casey et al. [15]. The selection of the tool is based on its utilization in previous research [16]. This tool was originally proposed by Kathy Casey and Regina Fink to measure newly licensed registered nurses’ comfort with skills over time. This part comprises 20 items distributed across four domains of readiness during an internship. The domains include clinical problem solving (7 items), learning techniques (2 items), professional identity (5 items), and trials and tribulations (6 items). Participants rated each item on a scale ranging from (1) “strongly disagree” to (4) “strongly agree.” The total scores for this scale

ranged from 20 to 80, with response categorization as follows: scores below 27 were considered of low importance, scores between 27 and 53 denoted moderate importance, and scores exceeding 53 indicated high importance.

Reliability testing was performed using Cronbach’s alpha, resulting in a value of 0.839.

Content validity was assured by a jury of 5 experts in the field of nursing management and nursing education and community health nursing.

2.4. Pilot Study. A pilot study was conducted with 13 nurse interns, representing 10% of the study cohort, to assess the construction and clarity of the tool. This pilot study also aimed to determine the time required for each participant to complete the questionnaire. The tools proved to be clear, and no modification was needed.

2.5. Statistical Analysis. Data were analyzed via the Statistical Package for Social Science (SPSS) software, version 23 (SPSS Inc. Chicago, IL, USA). Descriptive statistics as the mean and standard deviation were used for reporting normally distributed numerical variables. Numbers and percentages were used to describe categorical variables. A linear regression model was used to assess the relationship between a scalar response and one or more explanatory variables. The Pearson correlation coefficient was used to calculate statistics between two continuous variables.

2.6. Ethical Considerations. Institutional Review Board (IRB) approval was obtained from the local authoritative body. Written informed consent was obtained before data were collected during interwire or via an official email. Each nurse intern was knowledgeable about the aim of the study before participation. They were informed that their participation in the study was elective, and they had the decision to refuse participation at any time of the study without penalties. All patients’ data were confidential and used only for research purposes.

3. Results

Table 1 provides sociodemographic details of participating nurses. The mean age of the nurses was 26.09 (SD = 3.96) years, and all participants were female. The majority were unmarried, with two fifths (40%) holding a GPA of 3.75–4.49. In addition, all nurses attended orientation programs, with approximately half (49.2%) of them strongly agreeing on the effectiveness of their respective programs.

According to readiness for practice, Table 2 revealed that clinical problem-solving had the highest mean percentage at 70.5%, with a mean score of 19.745 ± 3.61 . In contrast, the lowest-scoring domain was trials and tribulations with a mean score of 4.23 ± 1.01 , with mean percentage 52.9%.

Regarding to the importance of clinical preparation, Table 3 detected that the mean score for the steps of the nursing process was 36.82 ± 9.76 , representing the lowest mean percentage at 41.8%. In addition, the mean score for the use of resources was 3.86 ± 0.98 , and for teaching and information giving, it was 19.56 ± 6.60 . On the other hand, communication skills had a mean score of 13.51 ± 4.49 , with the highest mean percentage of 84.4%. Administrative skills had a mean score of 10.11 ± 1.95 , accounting for 50.6%, as mentioned in Table 4.

Table 4 displays the results of the multiple linear regression model examining the perception related to clinical preparation requirements. The model shows a slight but significant fit, as indicated by the F-test value of 11.965 with a p value of 0.002. Approximately, 51% of the variation in clinical preparation requirements is explained by this model, as reflected by the R^2 value of 0.511.

Moreover, the analysis suggests that an increase in age by one unit is associated with a corresponding increase in perception related to preparation requirements by 0.169. Similarly, an increase in GPA by one unit is linked to a higher perception, showing an increment of 0.355. Notably, nurses who graduated in 2019 and 2020 demonstrated a higher perception compared to those who graduated in 2016-2017.

Table 5 illustrates that the multiple linear regression model for the Casey-Fink Readiness for Practice Survey indicates a statistically significant fit, as evidenced by the F-test value of 9.863 with a p value of 0.004. This model accounts for approximately 54% of the variation in the Casey-Fink Readiness for Practice Survey, as denoted by the R^2 value of 0.540.

The findings further reveal that an increase in GPA by one unit is associated with a corresponding increase in study subjects' readiness by 0.398. In addition, unmarried interns exhibit a higher level of readiness compared to married interns, with a difference of 0.171. Moreover, an increase in the perception of the orientation program by one unit is linked to an increased readiness by 0.189, see more in Table 6.

Table 6 shows that there was a highly significant correlation between the readiness for practice and clinical preparation requirements at p value <0.01 .

Figures 1 and 2 show that 50% of nurse interns had a moderate level of clinical preparation, and 28.5% of them exhibited a low level. In addition, 53.8% were found to be moderately ready for practice, and 23.90% had a highly ready for practices, while 22.3% had a low level of readiness.

4. Discussion

Navigating the shift from being a nursing student to a nurse intern is often difficult. Assessing how equipped students are for workplace demands can ease the transition process. Intern readiness to deliver secure, skilled care is an urgent issue because of rising workloads and elaborate healthcare frameworks. Ramifications of unsatisfactory preparation during this move can be examined both individually and organizationally. The effect of inadequate preparedness

TABLE 2: Readiness for practice among studied intern nurses ($n = 130$).

Items	Mean score	Mean percent
Clinical problem solving	19.745 ± 3.61	70.5
Professional identity	11.03 ± 2.50	55.2
Learning techniques	12.97 ± 4.02	54.04
Trials and tribulations	4.23 ± 1.01	52.9

TABLE 3: Clinical preparation requirements for intern nurses ($n = 130$).

Items	Mean SD	Mean percent
Communication skills	13.51 ± 4.49	84.4
Teaching and information giving	19.56 ± 6.60	69.9
Psychomotor skills	12.88 ± 4.07	64.4
Administrative skills	10.11 ± 1.95	50.6
Uses of resources	3.86 ± 0.98	48.2
Step of nursing process	36.82 ± 9.76	41.8

during transition can be viewed from the personal and from the system level.

Regarding readiness to practices, this study found that the highest mean percentage (70.5%) of new nurses felt most ready to practices regarding the domain of clinical problem solving. While, 52.9% of them they felt that the least read to practices regarding the domain of trials and tribulations.

These results are incongruent with [17], who reported that final-year undergraduate nursing students in a school in the Republic of Ireland are concerned about their readiness for practice. While Aswad et al. [18] revealed that only one quarter of study participants were highly ready.

Regarding specific clinical preparation skills, the current study revealed that communication skills were the strongest area reported with a mean percentage of 84.4%. However, applying the full nursing process and knowing how to utilize informational resources were relative reported weakness with a mean percentage of 41.8%. These results cohort with the study by Abdelkader et al. [19] who found that the highest scores for educational preparation requirements was in teaching and information giving, psychomotor skills, and communications skills (79.70%, 78.82%, and 76.92%, respectively). Furthermore, another study [20] reported that the majority of nurse interns (a mean percent of 50.6%) needed training in managerial skills. Nicholls [21] stated that both psychomotor and nursing process skills were extremely important requirements for clinical preparation assignments.

The study findings revealed that there was a highly significant correlation between the readiness level and perceived preparation requirements also underscores the importance of alignment. Nursing schools must adequately equip students for the real demands of clinical practice. Meanwhile, healthcare institutions must recognize the limitations of novice nurses and support their competent acclimation to the provider role. These results, similar to the study by Babaei et al. [22], found that there was a positive and significant correlation between nurses' attitudes and

TABLE 4: Best fitting multiple linear regression model for perception related to clinical preparation requirements.

	Unstandardized coefficient		Standardized coefficient	T test	p value
	B	Std. error			
Age	0.169	0.209	0.189	5.017	0.011
Last GPA	0.355	0.321	0.246	7.894	0.007
Graduated year	0.197	0.187	0.199	6.102	0.009

TABLE 5: Best fitting multiple linear regressions model for Casey–Fink Readiness for Practice Survey.

	Unstandardized coefficient		Standardized coefficient	T- test	p value
	B	Std. error			
Last GPA	0.398	0.257	0.157	4.135	0.010
Marital status	0.171	0.199	0.142	3.996	0.022
Perception related effective of orientation program	0.189	0.196	0.172	3.746	0.024

TABLE 6: Correlation between clinical preparation requirements and Casey–Fink Readiness for Practice Survey.

	Casey–Fink Readiness for Practice Survey
Clinical preparation requirements	<i>r</i> . 0.598 <i>p</i> 0.001

FIGURE 1: Distribution of nurse interns-related clinical preparation and readiness for practice (n = 130).

readiness. In addition, Ahmadi et al. [23] recommended that the clinical preparation of nursing students during the internship program enhances clinical readiness in internships.

The regression models provide further insight into factors impacting nurse interns’ preparation and readiness for practice. This study revealed a slight but significant fit relationship, as indicated by the F-test value of 11.965 with a *p* value of 0.002, which indicate that older nurse age and higher nursing GPA were associated with greater perceived preparation requirements and overall readiness levels. Similarly, an increase in GPA by one unit is linked to a higher perception, showing an increment of 0.355. These results go online with the study by [24] who detected that age ($\beta = 0.029$, $SE = 0.012$, and $p = 0.021$) and employment

FIGURE 2: Distribution of nurse interns-related readiness for practice (n = 130).

orientation duration ($\beta = -0.007$, $SE = 0.003$, and $p = 0.018$) were statistically significant factors influencing role transition experience among newly joined nurses. In addition, Alshammari et al. [25] mentioned that the GPA of nurse interns had a positive correlation on perception and adaptation during the training program, and Kaur [26] reported the importance of developing a positive interpersonal relationship with patients in nursing practice.

Furthermore, nurse interns more recently in 2019-2020 felt better prepared than those from 2016 to 2017. Notably, nurses who graduated in 2019 and 2020 demonstrated a higher perception compared to those who graduated in 2016-2017. Marital status and orientation program quality also appeared to influence readiness. Likewise, a study by Ahmed et al. [27] revealed that the marital status had no relation to nurse intern performance.

Also, Harrison et al. [28] found that an effective orientation program had a positive effect on increasing the standard of care.

On the other hand, Sharma et al. [29] stated that there was no association between nurse intern clinical competence and their satisfaction with an internship program.

With careful attention to rounding out nursing curricula, standardizing orientation programs, and bridging the transition into practice, new nurses' high levels of clinical knowledge can be translated into comprehensive readiness. This will empower them to deliver excellent care while building confidence in their evolving skills. At this context, Babamohamadi et al. [30] mentioned that the knowledge level of nurses' interns improves their readiness to the clinical situations. Also, Permana et al. [31] demonstrated a statistically significant correlation between students' caring conduct and clinical preparation.

4.1. Implication for Practice. Providing ongoing professional development opportunities for nurse interns can contribute to the continuous improvement of their skills and readiness. Encouraging collaboration between nursing education programs and healthcare institutions can foster a seamless transition from education to practice. Establishing mentorship programs can provide invaluable support for nurse interns.

4.2. Strength and Limitation. The strength of this study was the selection of topics related to perceived preparation and readiness of nurse internees. One of the limitations of this study was related purposive sampling technique. Further studies with more sample size using the randomized sampling technique needs to be conducted for large size of participants and different colleges in Saudia Arabia.

5. Conclusion

In conclusion, the study reveals that a substantial proportion of nurse interns, precisely half, displayed a moderate level of clinical preparation, while over one-quarter exhibited a low level. In addition, more than half of the interns were deemed moderately ready for practice, with over one-fifth categorized as having a low level of readiness. The observed significant positive correlation between perceived preparation and readiness underscores the pivotal role of clinical preparation in influencing practice readiness. These findings emphasize the importance of targeted interventions aimed at enhancing clinical preparation to directly bolster overall readiness for professional practice among nurse interns.

Data Availability

The data used to support the findings of this study are available from the corresponding author upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

The authors would like to thank the nurse interns for their willingness to contribute to this study. This work was supported by Princess Nourah Bint Abdulrahman

Objective. This study aimed to evaluate the current status and related factors of practice environments of nurse managers in China. **Background.** Insufficient nurse staffing and poor working environment directly increase the burnout and turnover of nurse leaders. Nurse managers play a pivotal role in healthcare organizations, and their performance has been inextricably linked to achieving optimal patient, staff, and healthcare organizational outcomes. However, there are few studies exploring the influencing factors of nurse manager practice environment. **Methods.** A cross-sectional study was undertaken to examine a sample of 405 nursing managers who were selected from 10 hospitals located across three provinces in China. The general characteristics questionnaire, the Nurse Manager Practice Environment Scale, the Perceived Stress Scale, and the Career Growth Scale were used. Data were analyzed by descriptive statistics, univariate analysis, and multiple stepwise linear regression. **Results.** The total scores of the nurse manager practice environments were 236.71 ± 27.635 (with 270 being the highest possible score), which was at a generally high level. The three lowest scores were adequate budgeted resources, fair and manageable workload, and nurse manager-physician relationships. Nurse manager practice environment was predicted by hospital geographic location, having (or not) training experience in higher ranked hospitals, levels of perceived stress, and career growth scores. **Conclusion.** Chinese nursing managers reported a relatively favorable nursing practice environment. Policymakers should pay more attention to the practice environment of nursing managers in small city hospitals, and they could regularly evaluate, monitor, and promote practice environment determinants that are sensitive to disparities between different hospitals. In addition, hospital managers can take action by implementing diversity training programs, developing stress-reduction initiatives, and creating robust career development programs for nurse managers to support nurse managers better. **Implications for nursing management:** a better understanding of the current practice environment of nursing managers is beneficial for improving nursing managers' work environment, which in turn will promote the quality of care delivered and nursing management work. For nurse managers, the characteristics of the management and work environment of the small city hospitals should be benchmarked and learned against the district capital hospitals. Also, hospital administrators were required to adopt strategies to foster psychological support of nurse managers and create pathways and opportunities for professional growth to create a supportive working environment.

1. Introduction

In the context global scarcity of nurses, recruiting and retaining nurse managers (NMs) have become a significant challenge [1]. The anticipated vacancy of NMs is alarming, as most NMs are about to retire or resign due to job burnout and dissatisfaction based on baby boomer retirement in the United States [2]. Recent studies have revealed that nurse managers (NMs) have

a central role in healthcare organizations, and their performance has been inextricably linked to achieving optimal patient and staff nurse outcomes [3, 4]. Compelling evidence in Saudi, Thailand, and China suggests that improving the quality of the nursing practice environment is considered an important strategy for dealing with the nursing shortage [5–8]. Thus, efforts to improve nurse retention rates must take into account the key role of nurse managers [4].

A good practice environment for NM can stimulate work enthusiasm and promote leadership, which will, in turn, create an environment conducive to supporting nursing staff [9]. Previous studies have been mainly conducted on the practice environments of staff nurses; however, the critical role of nurse managers is ignored [10, 11]. The nurse manager practice environment (NMPE) has been defined as the organizational environment that supports nurse manager practice and influences nurse, patient, and organizational outcomes [12]. Different from the nursing practice environment, NMPE mainly focuses on the role of NMs. Researchers found that the recognition of nurse managers' working environment differs from that of staff nurses [13]. Besides, NMs are indispensable in influencing the professional practice environment of frontline nurses. Thus, it is important to understand the current situation of NMPE. Ensuring a supportive work environment for NMs is the key to retaining these individuals in their roles [14]. Studies also showed that a positive practice environment is critical to job satisfaction, retention, and work performance for NMs [13]. Therefore, nurse managers' work environments warrant the attention of hospital administrators to achieve good workplaces where nurses can focus on patient care.

The established associations between the NMPE and nursing outcomes motivate research to understand the predictors of the NMPE. It is essential to consider a broader range of individual, psychological, and organizational factors, given that the work environment encompasses physical and psychosocial dimensions [12]. Regarding individual factors, there is controversy over the influence of some demographic factors, and more factors remain to be learned. It was reported that sociodemographic differences were considered necessary in evaluating the NMPE [15]. Overall, existing studies indicate the correlation between NMPE with some demographic variables, such as marital status, age, and education [13, 15–17]. Research indicates that hospital characteristics such as location were a significant variable in nurse staff's perception of the practice environment. However, there has been no research exploring the variable among nurse managers.

Few studies have analyzed the associations between nursing managers' perceptions of the practice environment from psychological perspectives. There is growing evidence that mental stress is associated with the practice environment in nurses [18, 19]. Occupational stress is considered a significant factor that negatively influences the practice environment [20]. Nurse managers work in a practice environment that reflects all-day responsibility and often unmanageable workloads, leading to high-stress levels [21]. Previous studies conducted with nursing staff showed that mental strain may affect their self-assessed working environment and the quality of care [18, 22]. Studies revealed that stress has a negative influence on NMPE [17, 23]. However, the abovementioned conclusions stem from a qualitative study and using universal measurement tools. Many findings focus on the staff nurse; the relationship between psychological stress and perceived work environment among NMs still needs further research.

Moreover, recent studies showed that the NMPE is more strongly impacted by organizational characteristics factors such as career development and promotion [4]. Considering the significance of nurses' professional development in assessing the caliber of the nursing practice environment, additional research is required to examine the influence of career development on the working environment of NMs. When organizational characteristics (ongoing development) support NMs' practice, they are more satisfied with their work environment [14, 21, 24]. Career growth is defined as the promotion and development of individual professional ability in the organization and contains career goal, career ability, and career opportunity [25]. It was reported that career development opportunities were the predictors of nurses' work environment [26]. However, there is a lack of evidence that describes career growth in relation to the NMPE.

The importance of nurse managers' practice environments in influencing nursing turnover, direct care, and patient outcomes has been thoroughly studied [17, 27, 28]. The current situation and influencing factors of the NMPE remain to be learned to make international comparisons. Prior studies have been mainly focused on the practice environments of clinical nurses; there is a lack of studies evaluating practice environments from the viewpoint of NMs [11, 28]. Besides, there have been no previous studies that have examined factors influencing NMPE from the perspective of psychological and organizational characteristics using quantitative research. Therefore, the present study aims to investigate the current status of the practice environment and its associated factors among nurse managers in China and to find the aspects that need to be improved the most.

2. Methods

2.1. Design and Sample. This was a multicenter cross-sectional study performed in August, 2023, in 10 hospitals in Hubei, Shanxi, and Jiangxi provinces in China. A multicenter cross-sectional study was conducted on nurse managers from 10 hospitals across three provinces (Hubei, Shanxi, and Jiangxi) in the central, northern, and southern areas of mainland China. Of the ten hospitals, four are tertiary hospitals located in the provincial capitals Wuhan, Taiyuan, and Nanchang. The remaining six secondary hospitals are located in smaller cities, namely, Suizhou, Shiyan, and Enshi. Cross-sectional designs help determine the current situation of the practice environment for nursing managers and analyze the impact of multiple factors simultaneously, as represented by a study sample. The target population of this study was inpatient and outpatient nurse managers with at least 12 months of experience in the nurse manager role. The study population includes hospitals from provincial capitals such as Taiyuan, Nanchang, and Wuhan, as well as prefecture-level cities such as Suizhou, Shiyan, and Enshi. The convenience sampling method was used in this study. A snowball methodology was used in a convenience sample identified by the director of the Nursing Department, the

chief nurse of internal medicine department, and the head nurses. The author confirmed and contacted the nursing department directors and head nurses of 10 hospitals, forwarded the online questionnaire to nursing managers of each hospital, and asked them to voluntarily fill it out. The inclusion criteria were (a) first-line registered nurse manager (head nurse or nursing supervisor) on duty; (b) having worked as nurse manager for more than one year; and (c) having volunteered to participate and provided informed consent. The exclusion criteria were (a) serving in an interim role and (b) nurse managers in administrative positions without managing any patient care areas. In terms of sample size estimation, G Power 3.1 software was used to calculate the sample size needed for this study. The linear multiple regression algorithm was selected. There were 24 variables in this study, including 11 sociodemographic characteristics and 13 scale-associated dimensions. With 95% confidence intervals and 0.8 power, the minimum sample size in our study was 169. Considering a possible 20% wastage rate, a total of 212 participants were needed.

2.2. Instrument

2.2.1. General Characteristics Questionnaire. The general characteristics that the questionnaire mainly investigated were the nurse managers' gender, age, marital status, highest education, hospital grade, hospital geographic location, professional title, working years, weekly working hours, teaching work experience, and whether they have training experience in higher ranked hospital.

2.2.2. The Nurse Manager Practice Environment Scale, NMPES. NMPES was designed to describe and assess nurse managers' practice environments by Dr Warshawsky and the Chinese version of NMPES had undergone cross-cultural debugging and validation [29, 30]. NMPES contains 45 items, with a total of 8 dimensions: (1) empowering administrative leaders to create a culture of patient safety (a blame-free environment with established lines of responsibility and accountability), (2) nurse manager-director relationship, (3) culture of generativity (the organization supports ongoing development of nursing leaders), (4) adequate budgeted resources, (5) culture of meaning (the organization's mission and vision are aligned with the organization's mission and vision), (6) NM-physician relationships, (7) NM-unit staff relationships, and (8) fair and controllable workload. Items are measured on a six-point Likert scale ranging from 1 = "completely disagree" to 6 = "completely agree". Scoring is based on the mean score for the overall scale and mean scores of the subscales. Mean scores close to 6 and 1 suggest that the practice environment is positive or negative (poor), respectively. The higher the score, the better the working environment of the nurse manager. The Chinese version of NMPES has a Cronbach's α of 0.917, retest reliability was 0.968, split-half reliability was 0.952, and Content validity was 0.96. The NMPES has a Cronbach's α of 0.917 in our study.

2.2.3. Perceived Stress Scale, PSS. PSS is a widely used psychological stress measurement tool. It was developed by DR Cohen and the Chinese version of PSS was translated and validated [31, 32]. It contains 14 items, 2 dimensions, i.e., perceived stress (7 items) and perceived coping ability (7 items), and uses a five-point Likert scale ranging from 0 = "never" to 4 = "always". The total score on the scale is 0–56 points, and the higher the score, the higher the occupational stress level. The Chinese version of PSS has a Cronbach's α of 0.78 and a validity coefficient of 0.73, indicating good reliability and validity.

2.2.4. Career Growth Scale, CGS. CGS was developed by Weng and Xi [33] and contains 15 items with 3 dimensions, namely, career goal, career capacity, and career opportunity. It uses a five-point Likert scale ranging from 1 = "no match at all" to 5 = "very high match"; a higher score indicates a higher level of professional growth status. The CGS has good internal consistency, with Cronbach's α of 0.926 for the total scale. Also, CGS was proven to be acceptable, valid, and reliable for the evaluation of nurse career growth in Chinese hospitals [25].

2.3. Data Collection and Ethical Considerations. A total of 5 participants were recruited to fill out the online survey questionnaire and provide feedback to ensure that the questionnaire can be understood without difficulty. The online questionnaire link was forwarded to the social media group by the nurse directors or head nurses of each hospital, as requested by the researcher. Participants received the link and were voluntary to fill out the questionnaires on the website platform. If the participants were interested in the study, they could visit the questionnaire and receive a study description at the beginning of the survey via the online link. Participants were required to read and sign an informed consent form before filling out the questionnaire. Only when the participants voluntarily click agree, can they continue to complete the questionnaire survey content. All participants in the survey were anonymous and voluntary, and they were allowed to withdraw from the study at any time. Questionnaires with a filling time of less than 120 seconds were considered invalid questionnaires and were excluded, according to the preliminary experimental results. Two researchers independently exported the results into Microsoft Excel format, checked them, and then imported them into the SPSS software. This study was approved by the Institutional Ethics Review Board of the Tongji Hospital, Tongji Medical Department, Huazhong University of Science and Technology (TJ-IRB20230845).

2.4. Statistics Methods. The data were analyzed by using SPSS 26.0. The measurement data all following a normal distribution were described by means and standard deviations. The counting data were described by frequency and percentage. This study used *t*-tests or one-way ANOVA to compare the differences in the practical environment of different groups of nurse managers. Pearson correlation

analysis was used to analyze the correlation between nurse manager's practice environments and perceived stress and career growth. Multiple linear regression analysis was used to analyze related factors. The statistical significance was defined as $P < 0.05$.

3. Results

3.1. Demographics of the Participants. A total of 446 participants were recruited, 405 (90.8%) were valid for analysis. Most of the participants were from the level III hospital (83.7%), located in the district capital (69.6%), female (95.7%), and 31–45 years old (70.6%). Over 60% of the participants had more than 15 years of job experience. Married nursing managers accounted for 93.8% of the participants. As for highest education, 84% of the nursing managers had bachelor's degrees, and only 3.7% of the study samples were in junior college or below. Participants with supervisor nurse and associate professor of nursing or above position titles accounted for 60% and 33.8% of the sample, respectively. In terms of weekly working hours, only 9.9% of participants had 40 hours or less per week; most of the participants had 41 to 59 hours per week. Over 50% of the participants had training experience (Table 1).

3.2. Scores of Nurse Manager Practice Environment. The total scores of the investigated nurse manager practice environments were 236.71 ± 27.635 , which was at a favorable level, and the specific scores of dimensions are presented in Table 2. NM-unit staff relationships, culture of meaning, and culture of generativity were marked highly, while comparatively lower scores were adequate resources, fair and controllable workload, and NM-physician relationships. In terms of the specific item, the highest-scored item was "maintaining a reputation for excellence is important to the hospital leaders (4.26 ± 1.387)", and the lowest-scored item was "the budget allocations for my patient care area(s) are adequate (5.77 ± 0.509)".

3.3. Factors Related to Nurse Manager Practice Environment. Independent sample *t*-tests and one-way ANOVA indicated that the total scores of nurse manager practice environment differed significantly among nurses of different hospital grade, hospital location, age, weekly working hours, and further education/training experience ($P < 0.05$) in Table 3.

Furthermore, the results in Table 4 show that the perceived stress score and career growth score had a significant correlation with nurse manager practice environments ($P < 0.05$). Also, the perceived stress and career growth of the nurse managers are at a moderate level. For perceived stress, the highest dimension score was the ability to cope with stressor (mean, 11.39 (SD, 5.28)). The lowest dimension was general stress (mean, 10.70 (SD, 4.29)). For career growth, the highest mean subscale score was career capability. The lowest mean subscale score was career opportunities (Table 4).

3.4. Multivariate Analyses of Nurse Manager Practice Environment Scores. A multiple linear regression model was used to avoid confounding factors, and variables that had a significant correlation with the nurse manager practice environment in the one-way ANOVA were taken as independent variables. Also, the stepwise introduction method was introduced into the corresponding regression equation. According to the results of the regression analyses, general stress, career growth, career opportunity, hospital location, and further education/training experience explained 58.6% of the total model variance (Table 5).

4. Discussion

This study was a multicenter cross-sectional study that examined the status and influencing factors of the nurse manager practice environment. The results showed that Chinese nursing managers reported a relatively favorable nursing practice environment, but the scores on subscales such as adequate budgeted resources, fair and manageable workload, and NM-physician relationships were still low. The results of the study showed that nurse managers working in hospitals located in small cities, with training experience in higher-ranked hospitals, higher levels of perceived stress, and poor career growth reported higher ratings of their practice environment.

The total score of the nurse manager practice environment was 236.71 (SD, 27.635) (where 270 was the highest possible score). The participants in this study reported a generally high level, which is marginally higher than the total score of NMPES reported in a previous study in China, i.e., 190.35 (SD = 14.66) and 216.13 (SD = 29.42) [30, 34]. These findings are consistent with research showing that NMPES scores were overall reported as moderate [27, 35]. Warshawsky's study reported a moderate to moderately high level among NMs with the same scale in the United States [36]. A survey in Finland showed that NMs experienced more negative perceptions of the practice environment [17]. The possible reason for these differences in results may be different investigation times and areas. We compare the results of the practice environment in pre-pandemic studies [30, 37], and the results showed some positive changes in the nurse manager practice environment. In the recovery and reconstruction process after the epidemic, a healthy working environment is an important component of our stable nursing team. Within the pandemic environment, managers may feel unsupported with their practice environment [35]. The results of the study indicate that the improvement of the nurse manager practice environments has been achieved. From a policy perspective, the Chinese government introduced a series of relevant policies to ensure the development of the nursing team from various aspects, providing a strong policy foundation for it. For instance, in the National Nursing Development Plan of the China (2021–2025), the importance was stressed to strengthen the construction and development of nursing teams, which optimizes the practical environment for nursing managers.

With regards to the subscales of NMPES, the findings showed that the adequate budgeted resources subscale had

TABLE 1: Sociodemographic data of the investigated nurse managers.

Variables		N = 405/means	Percentage/standard deviation
Hospital grade	Grade II hospital	66	16.3
	Grade III hospital	339	83.7
Hospital geographic location	District capital	282	69.6
	Small city	123	30.4
Gender	Male	17	4.2
	Female	388	95.8
Age (years)	≤30	13	3.2
	31–45	286	70.6
	>45	106	26.2
Working years	<5	6	1.5
	6–10	35	8.6
	11–15	103	25.4
	>15	261	64.4
Marital status	Married	380	93.8
	Unmarried	13	3.2
	Widowed/divorced	12	3.0
Highest education	Junior college or below	15	3.7
	Bachelor's degree	340	84.0
	Master's degree and above	50	12.3
Position title	Senior nurse	25	6.2
	Supervisor nurse	243	60
	Associate professor of nursing	130	32.1
	Professor of nursing	7	1.7
Weekly working hours(h)	≤40	40	9.9
	41–59	311	76.8
	≥60	54	13.3
Training experience in higher ranked hospitals	Yes	226	55.8
	No	179	44.2

TABLE 2: Scores of the NMPES.

Variables	Total score (mean ± SD)	Mean score (mean ± SD)	Rank
Nurse manager practice environment (45 items)	236.71 ± 27.635	5.26 ± 0.614	—
Adequate budgeted resources (4 items)	18.19 ± 4.227	4.54 ± 1.056	8
Fair and manageable workload (4 items)	19.84 ± 3.723	4.96 ± 0.931	7
NM-physician relationships (3 items)	15.95 ± 2.179	5.31 ± 0.726	6
Empowering organizational culture of patient safety (15 items)	79.88 ± 9.251	5.32 ± 0.616	5
NN-director relationship (6 items)	32.04 ± 4.475	5.34 ± 0.745	4
Culture of generativity (6 items)	21.92 ± 2.479	5.39 ± 0.659	3
Culture of meaning (4 items)	21.92 ± 2.479	5.47 ± 0.619	2
NM-unit staff relationships (3 items)	16.52 ± 1.803	5.50 ± 0.601	1

the lowest mean (SD) score (4.5 [1.1]), whereas NM-unit staff relationships were the subscale with the highest mean (SD) score (5.5 [0.6]). Overall, these findings are in accordance with findings reported by previous studies [13, 27, 35, 36]. They have demonstrated that the rational allocation and use of resources have become an important and common issue in the context of insufficient personnel and high workload and hospital leaders should align resources to support the creative work of nurse managers. Fair and manageable workload is also a prominent issue in the results of NMPES scores since the score is second only to the adequate budgeted resources. A qualitative study showed that none of the nurse managers reported satisfaction with their workload or work-life balance [38]. Similarly, it is

reported that nurse managers experienced significant work pressure, which increases their workload and working hours than other nurse staffs [39]. The results of this study show that a lack of resources and excessive workload were hindering factors that challenged nurse managers' practice environment. The item "the budget allocations for my patient care area(s) are adequate" resulted in the lowest score among all items, reminding us that in the context of poor staffing; managers still face the challenge of improving the level of nursing human resource allocation and achieving dynamic and reasonable allocation of human resources. Healthcare organizations and hospital senior administrators play an important role in promoting a healthy professional practice environment in NMs. Hospital managers should

TABLE 3: Scores for NM PE with different demographic characteristic.

Variables		Overall scores for nursing manager practice environment (mean \pm SD)	t/F value	P value

attach importance to the working environment of NMs, make efforts to support, authorize, and lead change to create a practice environment and ultimately further optimize nursing work.

The results of this study indicate that nurse managers from hospitals in the district capital had significantly higher nursing manager practice environment scores than in the small city. The findings are consistent with research showing that hospital geographic location is one of the influencing factors in the professional practice environment of nurse staffs [40]. One similar study conducted on nursing staff indicated that nurses from hospitals in district capitals rated practice environments significantly more highly than nurses from smaller city hospitals [40]. The findings match those observed in earlier studies using focus group interviews that the geographic location can influence how the nurse manager perceives their practice environment [41]. A possible explanation for this might be that nurse managers who worked in hospitals located in the district capital typically had a larger labor pool and more favorable physical environment than other hospitals, making it easier for them to fill vacancies. This finding is supported by another study that found that hospitals located in rural or suburban areas have fewer qualified registered nurses to fill the position of nurse manager and have decreased staffing, which may influence the nurse manager practice environment [42]. Therefore, the geographic location can influence how the nurse manager perceives the practice environment. It was reported that NMs who worked in private hospitals were more likely to evaluate the practice environments positively than those who worked in public or university hospitals [15, 43]. As for hospital grade, this study's results showed no differences in the NMPES at different levels of hospital. The results also provide evidence that the scores of NMPES of the small city as well as grade II hospital are in a relatively poor state and need to be improved urgently. For nurse managers, the managerial style and work environment of the small city hospitals should be benchmarked against the district capital hospitals. Therefore, it is recommended that hospital managers attach importance to the working environment of nursing managers in small cities by improving the hospital support and guarantee system and providing human resources support and equipment.

In this study, it is interesting to note that participants who had no training experience in higher-ranked hospitals scored highest overall on the nursing manager practice environment, which has not yet been reported before due to a lack of relevant research. The results of this study showed that NMs with training experience in higher ranked hospitals scored statistically significantly lower than those without training experience in terms of resources, workload, and other aspects by further analyzing the subscale score. In contrast, prior study revealed that nurses who have management training experience evaluate their practice environment more positively [15]. Unlike other studies, training experience in higher ranked hospitals referred to in this study does not include academic education but mainly includes training, internships, study visits, or overseas experience for NMs. Hospital rankings are routinely used by medical staffs as a guide in

further training in China. The "higher ranked" hospital usually refers to a comprehensive tertiary hospital, an affiliated teaching hospital of a well-known university, or foreign hospital in developed countries. This is probably a consequence of the equipment and system of the superior hospital being more perfect. It should be noted that the perceptions of nursing workplace were associated with having adequate staffing and resources [44]. We speculate that although the training experiences may offer a sense of fulfilment, the expectation of the gap between two different work environments may also decrease satisfaction for nurse managers in their current nursing unit. It was demonstrated in several studies that the different strategies and policies between hospitals will influence the work environment of nurses [45, 46]. This is supported by research that continuing training, usually at a higher-ranked hospital, provides opportunities for nurse managers to update their knowledge and technology, leading to high-level expectations of the practice environment [26]. Also, it seems that when the practice environment of the hospital where they trained is better, the expectations towards the current situation will be affected. However, more research is needed to analyze the differences between expectations and perceptions of the work environment since we did not measure the perceived and expected work environment by NMs. The unexpected findings have extended our knowledge of the perceptions of practice environment in NMs, which are affected by complex aspects. Thus, areas to improve the practice environment of nurse managers include considering the nurse manager's perspective on the current work environment and increasing their involvement in organizational decision-making. More support is provided to those with training experience, and NMs can transform and apply the management experience, organizational culture, and new technologies learned from higher ranked hospitals to help ultimately improve their work environment and nursing work.

The results also revealed that perceived stress had a significant correlation with NMPES. Both dimensions of perceived stress are negatively correlated with the working environment of nursing managers, and general stress is significantly correlated with NMPES. Better nursing manager practice environments are associated with less perceived stress. Previous studies have confirmed the relationship between a favorable environment for nursing practice and a lower occupational stress level [20, 47]. The work environment of nurse managers has been described as stressful and challenging [48]. It was reported that role overload was the primary predictor of work environment stress in nurse managers [17, 49]. A study in the United States also showed that approximately 62% of nursing managers plan to resign within the next 2–5 years due to occupational stress and burnout [50]. Burnout is a mainly negative consequence of stress, which may decrease satisfaction at work, thereby perpetuating unhealthy work environments of NMs [51]. Therefore, the influence of current psychological states on NMPES deserves attention, and more efforts are needed for nurse managers to keep stress in perspective, contributing to developing healthier work environments.

This study indicated that NMPES had a significant positive correlation with career goal, career capability, and career opportunity. Career growth measures the speed of the employee's career/professional development [33]. Career opportunity relates to the feedback and perception of their career development, promotion speed, and salary increase [25]. Several studies have confirmed the influence of career development is strongly positively correlated with nurses' perceptions of their work environment [52]. A quasiexperimental study in a Dutch hospital by Bloemhof indicated that developing multiple career paths for nurses can improve the nurse work environment [53]. Nurse managers need to conduct suitable career plans for every nurse manager and promote career development in organizational environments that support NM practice [36]. The results of Luse's study showed that managers' managerial strategies, such as career ladders can improve the overall working environment [54]. In a cross-sectional study of 1,010 nurses, career opportunities and job satisfaction were significant variables of the self-assessed work environment in Slovenian hospitals [26]. The majority of these variables also explained the NMPES in our study though the research population is different. This study is the first to report the effect of career growth on NMPES. Creating pathways for personal growth and development for nursing managers and enhancing management skills will improve their work environment.

4.1. Limitations. A few limitations were identified in our study. First, the method of convenience sampling and cross-sectional design used in this study may limit the generalization of the results. Although the research subjects involve different levels of hospitals and six regions, the representativeness of the sample will have a particular impact on the results. Second, regarding the data collection, only self-report online surveys were used, and this may result in reporter bias. The use of multiple data collection methods may enrich the findings. Finally, we only explored the influencing factors from the demographic, psychosocial, and organizational aspects. Other organizational and policy factors are also important variables of the nurse manager practice environment. It is recommended that more comprehensive influencing factors need to be explored to explain the nurse manager practice environment based on a mature theoretical framework. Similar studies in the future can conduct stratified random sampling research and carry out longitudinal studies in order to obtain more rigorous and accurate conclusions.

5. Conclusions

This study was conducted to investigate the status and influencing factors of the nurse manager practice environment in China. Our results indicated that the Chinese nursing manager practice environment has achieved some improvements with a relatively high score.

However, adequate budgeted resources, fair and manageable workload, and NM-physician relationships remain the main issues. Hospital geographic location, training experience in higher ranked hospitals, perceived stress, and career growth were associated factors of the nursing manager's practice environment. It is suggested that more actions need to be taken to improve nursing managers' practice environment by developing a reasonable human resource allocation plan and scientific workflow to increase nursing human resources and material support.

6. Implications for Nursing Management

The results of this study provide insight into nurse managers' perceptions of the practice environment and can be used to form recommendations related to strategies to improve the practice environment. Hospital managers should regularly evaluate the status of the nurse manager practice environment and make improvements in areas of weakness to improve the current status.

Moreover, healthcare leaders can promote a front-line nurse manager practice environment by enhancing the predictors of the practice environment. In terms of hospital characteristics (hospital locations), hospital managers need to learn from larger hospitals to improve human resources and the physical environment to equip the workplace in smaller city hospitals. The results of this study suggest that hospitals in small cities may face particular challenges and require more attention in the practice environment. Although geographical location is an unchangeable factor, hospitals can assess, monitor, and promote practice environment determinants that are sensitive to disparities between different hospital geographic locations. Hospital administrators should emphasize the importance of making constructive changes to the practice environment to attract and maintain nurse managers in these hospital settings. In terms of training experience in a higher-ranked hospital, it is possible to take advantage of the experience to improve the status quo of the current unit. Nursing managers' training experience may expand their horizons and can help to provide specific and personalized recommendations to improve the working environment. Training programs and further education opportunities directed at less experienced nurse managers, especially those working at hospitals in small cities, need to be emphasized. Regulations and policies should focus on addressing nurses' expectations and their satisfying factors to positively impact the practice environment and retention. In terms of psychosocial stress and career development, nursing leaders can take measures to reduce work pressure and provide stress management training programs for NMs, which may positively affect the practice environment. Healthcare leaders need to build a platform conducive to the career growth of NMs, provide career management programs, and consider framing these actions as strategies that potentially contribute to improving job satisfaction and nurse retention.

Data Availability

The cross-sectional study data used to support the findings of this study are available from the corresponding author upon reasonable request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

This study was funded by the Tongji Hospital Research Fund Project, Tongji Medical College, Huazhong University of Science and Technology, the project was a study on the construction of nurse manager career growth system based on career theory (2021D01).

Aims. (i) To evaluate the scope and quality of nurse-patient interactions recorded in the clinical notes of inpatient mental health units and (ii) to identify nursing interventions recorded in the context of the nurse-patient relationship in the clinical notes of inpatient mental health units. **Design.** A multimethod approach was used. **Methods.** Employing a quantitative cross-sectional design for the first aim, and a qualitative content analysis design of secondary data for the second aim. In total, 1,714 clinical notes were examined from 44 randomly selected patients who were hospitalized in five mental health units over the years 2022-2023. **Results.** The patient's experience of the interaction was present in 69.9% ($n = 1,198$) of the notes. However, only 12.0% ($n = 205$) of the notes reached a sufficient standard of quality in terms of describing the nurse-patient interactions. Specifically, more than half of the notes did not reflect any type of nursing intervention ($n = 723$; 60.4%). Thirty interventions compatible with the nursing intervention classification were identified, of which more than 70% corresponded to domains in the physiological area. **Conclusion.** This study shows that the quantity and scope of patients' clinical notes in mental health units do not sufficiently reflect the interventions performed by nurses, nor the quality or impact of these interventions in the context of the nurse-patient therapeutic relationship. **Implications for the Profession and/or Patient Care.** Improving the quality of clinical notes by integrating interventions and their impact can increase the quality of nursing care. **Impact.** The use of standardized nursing terminologies would contribute to the understanding of the extent and quality of nurse-patient interactions recorded in clinical notes. Thus, standardized documentation would also help to improve these interactions and their recording, which will facilitate decision-making. **Reporting Method.** Findings were reported using COREQ and STROBE guidelines. **Patient or Public Contributions.** There were no patient or public contributions.

1. Introduction

In the context of person-centered mental health care, proper recording of nursing documentation can be a key strategy for improving the quality and coordination of care and efficiency [1]. To this end, the patient's clinical documentation requires that nursing interventions and the quality of the nurse-patient relationship be properly recorded [2]. However, the literature points to significant deficiencies in documentation, particularly in acute mental health units, where the lack of detailed records affects the continuity and quality of care [3]. There is hardly any empirical evidence available on this issue at the international level, affecting clinical nursing practice in the field of mental health.

When patients are cared for in health services, especially within the hospital setting where they receive continuous care by different professionals, it is important that the care they receive is correctly recorded [4]. In nursing care, care interventions are recorded through nursing clinical notes, which collect a wide variety of information about the patient's care and progress [5]. Nursing clinical notes are defined as the record of nursing care that is planned and provided to patients by nurses or other caregivers with the nurse's supervision and approval [5]. Clinical notes are intended to show what happens in the nursing process and on what basis decisions are made during admission, together with interventions performed, nurse-patient rapport, progress assessments, and assessments by the patients themselves [6]. In addition, nursing clinical notes can be used for other purposes such as quality assurance, legal purposes, health planning, resource allocation, and nursing development and research. To achieve these purposes, nursing clinical notes should be structured [7], contain valid and reliable information, and comply with established standards [8]. Clear and concise nursing clinical notes help health care professionals to detect changes in patients' condition and improve the quality of care [9].

In particular, the recording of nursing interventions in clinical notes is an important part of nurses' work. The aim of these notes is to improve care by ensuring continuity of care [10, 11], enhancing patient safety, reducing miscommunication, and extending access to essential clinical information to all staff caring for a patient [12]. However, clinical notes are not always a description of what is actually done [13]. The quality of nursing clinical notes in some cases is inconsistent and often incomprehensible, poor, inaccurate, and inadequate regarding nursing care [14]. Sometimes, the effects of nursing interventions are neither visible nor verifiable [15]. The records tend to use terse language that is dominated by technical words, capture very limited aspects of nursing practice, and convey very little information to the lay reader [16].

In order to collect more accurate information from nursing notes, the literature recommends the use of standardized nursing terminologies (SNT) [13, 17, 18]. The use of SNTs can lead to improved decision-making, care effectiveness, and care plan evaluations [19], as well as creating links between nursing interventions and patient outcomes [7]. SNTs define nursing care, nursing interventions, and

patient outcomes. SNTs can guide nurses through phases of the nursing process and can enhance the accurate formulation of patient care needs, planning of specific interventions, and communication of care [17]. SNTs have the potential to reduce variability in how nurses define their practice and document its impact on patient care [4]. The American Nurses' Association has recognized the nursing intervention classification (NIC) as the most widely used and best validated SNT classification, with good sustainability compared to other classifications for recording nursing interventions [17, 18]. It describes nursing interventions and consists of seven domains (physiological: basic, complex, behavioral, safety, family, health system, and community), designed to represent care provided in all settings and specialties [18]. In mental health, the most frequently addressed domains are safety and behavioral [19].

In the context of care in mental health units, nurses are by far professionals who interact the most with patients throughout the day [20]. Nursing interventions are placed within the framework of interaction with the patient through the therapeutic relationship [21]. From a person-centered care perspective, active collaboration between nursing staff and patients is necessary to identify personalized recovery goals and develop strategies to achieve those [22]. This collaboration hinges on the principles of attunement and bond, recognized as essential components of the therapeutic relationship [23]. To establish a therapeutic bond, communication marked by empathy, care, and warmth is imperative [24]. In the interplay between bonding and empathy lies the concept of empathic attunement, where practitioners fully engage with the client's internal perspective, acknowledging and adapting to their evolving experience [23]. Therefore, empathy and attunement are fundamental in nursing mental health interventions [25]. Attuning to someone involves sincere efforts to grasp their inner world and convey understanding, a cornerstone of the empathetic therapeutic relationship, recognized as a vital nursing skill for fostering bonds in mental health inpatient care [24, 26].

In this context, it is especially important to use the clinical notes for nurses to record what happens in the nurse-patient relationship [27]. Although interventions delivered in the context of the therapeutic relationship are known to be more effective and have an impact on patients' health outcomes [28], many interventions are not recorded in the course of clinical care [27, 29, 30], rather the records focus more on the problems and symptoms presented by patients [16]. Although previous research has demonstrated that the quality of mental health nursing documentation needed to be improved to ensure continuity and quality of patient care [31], the lack of quality indicators poses a challenge for the search for high quality nursing documentation [17]. Along these lines, a study conducted by Myklebust and Bjørkly, 2019 in Norway, concluded that only 7.6% of the excerpts from the progress notes sufficiently described the interactions in terms of the rapport process in the nurse-patient relationship [27].

Despite the importance of the nurse-patient therapeutic relationship in mental health care, the literature highlights the inconsistency and lack of detail of nursing interventions

reflected in clinical notes. These deficiencies compromise the continuity and quality of care, affecting clinical decision-making and, ultimately, patient health outcomes [1, 3]. It seems necessary to fill the existing gap in empirical evidence on the quality and extent of nursing documentation in mental health by providing concrete data on the quality of records and the nature of interventions.

The present study was designed with a dual purpose: (i) to evaluate the scope and quality of nurse-patient interactions recorded in the clinical notes of inpatient mental health units and (ii) to identify nursing interventions recorded in the context of the nurse-patient relationship in the clinical notes of inpatient mental health units.

2. Materials and Methods

2.1. Study Design. A multimethod approach was used for the present study. A quantitative cross-sectional design was used to assess the extent and quality of the nurse-patient interactions recorded in the clinical notes. Also, a qualitative content analysis design of secondary data in clinical notes was used to identify the nursing interventions recorded in the context of the nurse-patient relationship.

2.2. Sample and Setting. The sample consisted of clinical notes from patients who were hospitalized in mental health units in Spain during the years 2022-2023. Five units were randomly selected for this study which was part of a multicenter project of 12 hospitals of the national health system in Spain called RTS_MHNursing. In this project, all the units were closed units for the care of adults with acute mental health problems. They represented the different geographic areas of the Spanish territory.

The patients included in the study were selected consecutively in each of the units chosen according to the same inclusion criteria as in the larger project. Therefore, adult patients, who consented to participate in the study on a voluntary basis, hospitalized in mental health inpatient units. Participants were excluded if at the time of recruitment they presented a language barrier, mechanical restraint, contraindication by the clinical referent, cognitive impairment, or intellectual disability. No other exclusions were made to maximize the external validity of the study. For the calculation of the sample size of clinical notes required, a study with the same objective, design, and evaluation instrument was used as a reference [25]; thus, the final sample consisted of a total of 1,714 nursing clinical notes from 44 patients who had been hospitalized in 5 mental health units in Spain during the years 2022-2023.

2.3. Data Collection. The researcher responsible for each unit was in charge of collecting the data from the patients' clinical documentation. She was responsible for anonymizing the names of the professionals and names of the patients in the nursing clinical notes of each of the patients included in the study. Records of professionals other than nurses were removed from the data before they were analyzed. The study data were collected and managed using

REDCap electronic data capture tools [32]. In accordance with the research objectives, clinical notes in which the nurse and patient did not have an opportunity to interact were excluded. If a clinical note contained more than one episode of interaction and different patient experiences were reported in relation to these episodes, the note was divided and counted as a separate note.

2.4. Measurement Instrument. To evaluate the extent and quality of nurse-patient interactions recorded, we used the Spanish version of the scale for the evaluation of staff-patient interactions in progress notes [6] and applied it to the selected clinical notes. The SESPI-SP scale assesses the quality of nurse-patient interactions recorded in the notes through patients' experience and the interventions made by the nurses and whether this intervention succeeds in meeting the emotional needs of the patients. This scale consists of four steps detailed as follows:

- (1) Step 1 aims to know if the patient's experience is described in the clinical note, "how is the patient when interacting with the nurse." This is answered dichotomously (Yes/No), and only an affirmative answer enables one to move to the next step.
- (2) Step 2 evaluates whether the patient's experience within the interaction with the nurse was positive or negative. Depending on the degree of satisfaction or dissatisfaction with the patient's response, a response of -II, -I, +I, or +II is given.
- (3) In step 3, one must identify and categorize the nurse's response to the interaction described in the clinical note. Four possible responses are found: (a) the nurse's response is not described in the clinical note; (b) the nurse's response is known, but not the patient's reaction; (c) the nurse's response and the patient's reaction is known, but not the patient's feelings; (d) the nurse's response, the patient's reaction, and the feelings produced by this intervention are recorded, and this feeling with the nurse is called attunement. Only this response enables one to move on to the next step.
- (4) In step 4, this attunement is evaluated positively or negatively depending on whether it has failed or succeeded. Again, the answer is -II, -I, +I, or +II.

3. Data Analysis

To analyze the quantitative data, descriptive statistics were calculated using the IBM SPSSv27 program. The results were presented in the form of frequency and percentages. The qualitative data analysis procedure was based on content analysis [33] and nurse interventions were identified from free-text nursing records in the acute mental health unit setting. First, the first author read the entire text to become familiar with the data. Because the text was not standardized, a data extraction matrix was designed to aid with a proper follow-up. Interventions were then inductively identified through a systematic mapping process. Descriptions of

nurses' actions were then categorized using a deductive approach that reflected the NIC definition of nursing interventions. These descriptions revealed the interventions that nurses performed for or with patients in the context of patient interactions. The first author repeated this analysis process after one month and compared their identifications of NIC interventions by revisiting the original texts and with the rest of the research team.

3.1. Ethical Considerations. This study was approved by the Ethical Committees of five hospitals, and research permission was granted. The data were analyzed anonymously to preserve the anonymity of patients and staff.

4. Results

4.1. Scope and Quality of Interactions in Clinical Notes. A total of 1,714 clinical notes were analyzed. Figure 1 provides an overview of the distribution of clinical notes according to four stages of classification as the quality of records increases. The most remarkable result was that only 12.0% ($n=205$) of notes described the interactions in a sufficient detail to be fully analyzed in terms of recording attunement.

4.2. Description of Patient Experiences in Clinical Notes. Although the description of the patient experience was present in 69.9% ($n=1,198$), almost one-third of the clinical notes did not include any patient-related experience. In most cases, nurses recorded positive and negative patient experiences in the middle range; only 8.3% of notes reflected an extreme positive or negative patient experience.

4.3. Description of Nurse-Patient Interactions in Clinical Notes. Of the notes in which the patient's experience of the interaction had been described, in more than half, no nurse intervention of any kind was recorded ($n=723$; 60.4%). In only 17.1% ($n=205$) of the cases, both nurse interventions and patient responses to that intervention were described. Only 205 of the 1,714 notes (12%) could be evaluated in relation to the quality of the interaction. In 7.8% of the cases, there was a connection in the failed interaction (-II), 0.5% were in the + II or successful connection category, and the majority of interactions were classified as partially failed (11.2%) and partially successful (80.5%).

4.4. Nursing Interventions Identified in Clinical Notes. Of the 1,714 notes analyzed, almost two thirds ($n=1250$; 72.9%) were found to contain an intervention compatible with the NIC taxonomy. From the data analysis, 30 NIC interventions were identified. Nearly 2/3 of the interventions recorded by nurses in the clinical notes were classified as "2304-medication administration: oral" (62.6%), followed by "5360-entertainment therapy" (10.4%). Other prevalent interventions were "4920-active listening" present in 6.1% of the occasions and "5270-emotional support," present in 4.3% of clinical notes (Table 1). It should be noted that more

than 70% of interventions recorded corresponded to domains in the physiological area. The total number of interventions identified and their distribution can be found in Supplementary File 1.

5. Discussion

The present study had a dual purpose; first, to assess the extent and quality of nurse-patient interactions recorded in clinical notes, and second, to identify nursing interventions recorded in the context of the nurse-patient relationship in clinical notes. Regarding the first purpose, the results show that only one out of 10 notes written by nurses sufficiently described interactions to enable a full analysis in terms of the quality of the recording of the nurse-patient interaction process. The most noteworthy result of the second purpose was that most of the nursing interventions recorded in the notes in the context of the nurse-patient relationship respond to interventions of the physiological domain, rather than interventions of a more relational nature, as could be expected in the context of nursing care in acute mental health units.

Nursing clinical notes should reflect how staff understand their patients, how they interact and what nursing care they receive [9]. Deacon and Fairhurst [34] described nursing care in psychiatric hospitalization as a set of activities that are hardly visible and difficult to conceptualize, characterized by individual attention, as well as by routine and continuous work.

Our study, a finding which is compatible with the study by Myklebust et al., showed that 1/3 of total nursing clinical notes studied contained no description of patient experiences [14]. However, the most notable finding was that only 12% ($n=205$) of extracts described nurse-patient interactions to an extent that enabled them to be analyzed in terms of quality. This means that up to 88% of extracts were impossible to evaluate according to attunement, which is a fundamental characteristic of the therapeutic relationship. Therefore, in most of the notes, the quality of the bond, an essential characteristic in the nurse-patient therapeutic relationship, could not be assessed [24]. These results are in line with previous research that has found that traditionally, nurses underestimate the value of their documentation and the extent to which their diagnostic accuracy leads to better patient outcomes [4].

In most cases, in clinical notes, nurses recorded descriptions of patients' experiences in terms of positive and negative attunement distributed in a medium range; thus, only 8.3% of notes reflected an extreme positive or negative experience of the patients. This result is in complete agreement with the findings by Myklebust and Bjørkly [25].

In over half of clinical notes, no intervention of any kind was recorded by the nurse towards the patient once there had been an interaction. Myklebust et al. [14] concluded that while writing clinical notes, nurses position themselves as observers, and although the relationship between staff and patients is essential, nurses do not consider the relevance of documenting these interactions. This may be one reason why

FIGURE 1: Distribution of the scope and quality of interactions in clinical notes.

TABLE 1: Distribution of identified nursing interventions' classification and related domains.

Nursing interventions' classification	n (%)	Domains
2304-medication administration: oral	783 (62.6)	Physiological: complex
5360-recreation therapy	130 (10.4)	Behavioral
4920-active listening	76 (6.1)	Behavioral
5270-emotional support	54 (4.3)	Behavioral
2313-medication administration: intramuscular (IM)	30 (2.4)	Physiological: complex
4380-limit setting	25 (2)	Behavioral
6580-physical restraint	18 (1.4)	Physiological: basic
1800-self-care assistance	16 (1.3)	Physiological: basic
3660-wound care	16 (1.3)	Physiological: complex
4360-behavior modification	16 (1.3)	Behavioral
5820-anxiety reduction	14 (1.1)	Behavioral
5020-conflict mediation	12 (1)	Behavioral
4640-anger control assistance	10 (0.8)	Behavioral
Others	50 (4)	

n = 1250.

the clinical notes included very little information about what the nurses had done to help the patient, other than observing and coordinating care.

Only one in five of clinical notes that did record the patient-related experience described both the nurses' interventions and the patients' responses. As in other studies, our findings indicate that nursing documentation does not accurately describe actual nursing care [27, 29, 30].

Inpatients positively value the ability of health care personnel to understand and comprehend their experiences and feelings [24]. This may explain why clinical notes

recording the interventions and the nurse-patient attunement in the interactions between them are mostly partially satisfactory (80.5%).

The second objective of our study was to identify and describe nursing interventions on nurse-patient interactions in clinical notes of acute mental health units using the NIC domains as a framework for assessing the outcomes of nursing clinical notes. In our study, almost two thirds of the nursing notes studied showed some intervention compatible with the NIC taxonomy. Frauenfelder et al. demonstrated that the NIC covers the essential nursing care interventions,

since 89.4% of all the intervention descriptions in their study fully coincided with the NIC [19]. However, our study is close to the one conducted by De Groot et al. [3] which concluded that only half of the respondents used SNT in their clinical notes. Ameel et al. [15] concluded that interventions such as presence or listening may not be recorded, as they are not perceived as interventions because they are an obvious part of nursing care.

In our study, the “active listening” intervention hardly appears; this finding may be because the nurses consider this intervention to be routine and for this reason, they do not consider it necessary in recording this intervention.

Another study conducted by Frauenfelder et al. [19] showed that the NIC intervention “surveillance” was essential as they concluded that the need for surveillance is one of the reasons for admitting patients to acute inpatient facilities for nurses to assess patients through interactions and observation of symptoms. However, in our study this intervention is not collected, only 30 NIC interventions were identified, a result far removed from the one performed by Ameel et al. [15]; who identified 71 different nursing interventions, 64 of which are described in the NIC. This lack of collection and recording of the interventions performed by the nurses in our study can be understood according to the findings by Ameel et al. [15] and Fore et al. [29] who explain that this occurs when nurses have integrated interventions as part of their work and do not record them.

In our study most of the interventions recorded corresponded to domains in the physiological area, represented by the administration of both oral and intramuscular medication and wound care. If we compare the results of our study with others conducted in a similar setting, hospital care. Ameel et al. [15] and Frauenfelder et al. [19] most prevalent interventions were in the safety and behavioral domains. The safety domain is not represented among the most prevalent NICs in our study, even though vigilance is one of the tasks most frequently performed in acute mental health units. This result can be explained by the delegation of competencies in the interdisciplinary team. However, the behavioral domain appears to be represented in several interventions such as (limit setting 4380; recreation therapy 5360; active listening 4920; emotional support 5270; behavior modification 4360; anxiety reduction 5820; conflict mediation 5020; anger control assistance 4640). Another study conducted by Thomé et al. [35] analyzed the documentation of patients in an outpatient center in Brazil, and their most prevalent interventions were assistance in self-care, socialization, and promotion of exercise. In this case, these interventions have not been collected in our study of clinical notes. This difference may be explained by the different health care context.

Nurses have a deep-rooted biomedical model of care [28], which influences the therapeutic relationship [14]. Therefore, these findings could in part explain the incomplete or inadequate nursing records in patients’ clinical notes, or records based more on the biomedical model than on nurse-patient interactions [30].

6. Strengths and Limitations

The nursing clinical notes from the selected facilities did not use SNT, which means that results are based on the analysis of free-text notes, which included very few direct descriptions of nursing interventions. With free-text note analysis, there is a possibility of using too much interpretation during the process of analyzing the notes.

Due to the large number of randomized extracts and the fact that around 100 people wrote in the selection period, the risk of author bias was low in the dataset.

One of the strengths of the present study was the considerable number of randomized evolution notes collected from five different acute mental health units. The five mental health units chosen for this research represented a wide range of patient illness stages, diagnoses, and degrees of coercive or voluntary treatment.

7. Implications for Nursing Management

To our knowledge, there are few international quantitative studies measuring the quantity and quality of staff-patient interactions in nursing documentation in mental health settings. Consequently, the present study appears to represent an important step in the effort to explore the extent and quality of documented staff-patient interactions and the quality of documented nurse-patient interactions.

Improving the quality of clinical notes by integrating interventions and their impact, also considering the degree of nurse-patient harmony, can contribute to an increase in the quality of nursing care. This could increase patient satisfaction with the admission and their experience. It would be interesting to try to raise awareness of the importance of a systematized record of nursing clinical courses that include SNT and patient experiences related to the interventions, which would reinforce the training curriculum of mental health nurses.

The SESPI-Sp can provide data to qualitatively assess nursing documentation in relation to nursing interventions performed in the context of interactions with patients in mental health units. In this manner, it contributes to the improvement of the quality of mental health nursing care.

The SNT could play an important role in the development of nursing documentation, thereby becoming a better source for the evaluation and development of staff-patient interactions in clinical practice.

A more standardized use would contribute to the understanding of the extent and quality of nurse-patient interactions recorded in clinical notes. In this manner, standardized documentation would also help to improve these interactions and their recording, which will facilitate decision-making and help to provide solutions to problems that may arise during patient care.

Reading the clinical notes log explored in this study suggests that nurses record very little of the time they spend interacting with patients in the context of the therapeutic relationship. These insights highlight the need for

interventions to establish and develop the nurse-patient relationship. Consequently, it could be of interest to managers when planning the structure and staffing needs in inpatient mental health care.

8. Conclusions

The results of this study provide insight into the quality and quantity of nursing clinical notes related to patient experiences and nurse-patient interactions. Of the total number of clinical notes studied, only 12% described the relationship and rapport between nurse and patient in their interactions with sufficient quality. This means that the patients' feelings and experiences revealed in the context of the nurse-patient relationship are not adequately recorded in the documentation.

The clinical notes studied identified the recorded nursing interventions, 30 of which are described in the NIC. However, interventions of a relational nature, which are considered highly relevant and important in mental health nursing care, were almost nonexistent in the clinical documentation.

Consequently, nursing clinical notes did not fully and adequately record the interventions that nurses perform, as well as the impact of the interventions.

Data Availability

The data that support the findings of this study are available from the corresponding author upon reasonable request.

Ethical Approval

This study was approved by the Ethical Committees of five hospitals, and research permission was granted.

Conflicts of Interest

The authors declare that there are no conflicts of interest.

Acknowledgments

The authors thank Dr. Kjellaug K. Myklebust and Dr. Stål Bjørkly for their expertise. The authors are grateful for the support from the Department of Research and Universities of the Generalitat of Catalonia in the framework of the call for SGR-Cat 2021 grants, group 2021 SGR 1083.

This qualitative study aimed at exploring nurses' experiences concerning patient safety incidents among hospitalized children in South Korea. From August 4 to 12, 2023, data were collected through in-depth individual interviews involving 14 clinical nurses. Employing thematic analysis, we identified 8 themes, which coalesced into three theme clusters: "challenges in pediatric patient safety nursing due to patient and caregiver characteristics," "emotional changes in nurses following patient safety incidents," and "sincere desire to prevent patient safety incidents in pediatric patients." The findings underscored that nurses experience significant burdens related to patient safety, emphasizing the necessity for robust support from caregivers, healthcare institutions, and national policies. Consequently, it is imperative to develop and implement programs and policies to foster a secure care environment for pediatric patients. Nurse managers and organizations must proactively design healthcare systems and related policies that prioritize safely protecting pediatric patients and nurses alike from patient safety incidents, considering the characteristics of pediatric patients and the experiences of the nurses caring for them.

1. Introduction

Ensuring patient safety in public healthcare remains a critical challenge globally, given its significant impact on mortality and disability rates [1]. In low- and middle-income countries, hospitals have witnessed approximately 134 million adverse events stemming from unsafe care [2]. Shockingly, these events contributed to 60% of all reported mortalities due to inadequate and substandard care [3]. Similarly, in high-income countries, on average, one in ten patients is reported to experience adverse events during hospitalization [4]. Patient safety encompasses a comprehensive approach, integrating cultures, processes, procedures, behaviors, and environments to mitigate risks and errors that could harm patients. It is currently a strategic priority for the healthcare field and is emphasized as a core aspect of national efforts towards universal health coverage [1].

Hospitalized children are especially vulnerable to severe, or even fatal, harm in the event of patient safety incidents. This vulnerability stems from their immature physical and physiological functions, as well as their limited ability to assess and manage risky situations [5]. Moreover, children are at a stage of rapid growth and development, and patient safety incidents at this stage can have severe, long-term effects on not only physical development but also psychological, cognitive, and social development [6]. Since nurses are the closest professional group providing direct care to hospitalized children, they are in an important position to improve patient safety [7]. While caring for patients, nurses experience many different patient safety incidents, including medication errors, falls, and bedsores [8]. Despite diligently performing their duties, these incidents can be unpredictable and persistently occur. It is imperative to delve deeper into nurses' firsthand experiences with patient safety incidents in clinical settings through comprehensive research to foster

safer hospital environments and systems tailored to pediatric patients.

In our examination of both domestic and international literature concerning patient safety incidents involving hospitalized children, we came across studies that focused on family perceptions or experiences related to these incidents [9–11]. Additionally, research has delved into the perspectives of physicians, nurses, and patient care technicians concerning collaborations with parents to ensure patient safety [12]. Moreover, investigations have explored the relationship between medication errors and job satisfaction among nurses in pediatric wards [13]. However, there is a notable gap in research specifically addressing the varied experiences of pediatric nurses who directly care for pediatric patients, as well as pinpointing areas of concern and improvement in pediatric patient safety.

In the case of South Korea, the total fertility rate in 2022 is 0.778, which is half of the OECD average of 1.59, the lowest among OECD countries [14]. In addition to the rapid decline in the number of newborns, the cost of pediatric treatment is very low. The lack of doctors and long waiting times cause a lot of rudeness, verbal abuse, and legal disputes from patients' parents against medical staff, making it the worst treatment environment for doctors and nurses [15]. As a result, doctors avoid treating children, and the pediatric care system in South Korea is collapsing [16]. Therefore, it is necessary to analyze the experiences of pediatric patient safety accidents that occurred in such a heavy workload and stressful working environment and establish policies to create an optimal working environment for pediatric nurses to improve pediatric patient safety.

In the present study, we applied qualitative research methods to delve deeply into the experiences of nurses regarding patient safety incidents involving pediatric patients. Our objective was to identify challenges, obstacles, and potential strategies to enhance the management of patient safety incidents as perceived by the nurses. We anticipate that our findings will help contribute to the formation of hospital environments adept at preventing and addressing patient safety incidents in pediatric care. Furthermore, we aspire to influence the development of healthcare policies that prioritize the safety and well-being of both patients and nurses.

2. Materials and Methods

2.1. Study Design. This was a qualitative study collecting and analyzing data from in-depth interviews, intending to comprehensively understand and explore nurses' experiences of patient safety incidents in hospitalized children.

2.2. Participant Selection and Investigator Preparation. The inclusion criteria for participants in this study were specific: We sought nurses currently employed at healthcare institutions with at least 6 months of nursing experience. Additionally, these nurses must have encountered patient safety incidents involving pediatric patients they cared for within the past three years. Importantly, the incidents should

have involved patients aged 15 years or younger at the time of hospitalization. The sole exclusion criterion was a refusal to have the interview recorded.

The researchers posted information about the study objectives and methods to an online community for nurses in Korea. People who wanted to participate could use a link or a QR barcode to access an online site for study participation. Visitors to the website could review the comprehensive study details and provide their contact details if they chose to participate voluntarily. Subsequently, the investigators reached out to these individuals to elucidate the study's purpose and arrange interview sessions. Interviews were conducted until reaching theoretical saturation, meaning no new significant insights emerged from participants' narratives. Ultimately, the study involved 14 participants.

Given that the main instruments for qualitative research are the researchers themselves, to ensure reliability and train their ability to analyze results, the researchers gave talks and lectures on qualitative research in graduate courses and at related academic conferences. The researchers also have direct experiences of conducting qualitative research several times. During our tenure at the hospital, the researchers worked at a quality and patient safety center that performs activities to analyze and improve patient safety incidents. During this time, they analyzed the causes of patient safety incidents, interviewed healthcare workers, patients, and caregivers to make improvements, and accumulated practical experience understanding the interview content. The corresponding author also has extensive experience in pediatric nursing for 5 years working as a nurse in a pediatric ICU. We made efforts to minimize the effects of researcher bias or opinions on the interviews and results analysis and to maximally reflect the experiences and opinions of the participants.

2.3. Ethical Consideration. Before conducting the study, we received approval from the institutional review board at Kyungpook National University (no. 2023-0365), where the participants were affiliated. Subsequently, we initiated the data collection process. Before conducting the interviews, the researchers thoroughly explained the study objectives, procedures, and methods to the participants. Importantly, participants were assured of their right to withdraw from the study at any time. The researchers explained that data collected from the participants would not be used for anything other than research purposes. Additionally, we clarified that all interviews would be recorded with strict confidentiality measures in place to safeguard participants' privacy. Furthermore, we assured participants that their involvement would incur no adverse consequences. Individuals willing to participate then submitted their online consent forms online before proceeding with the interview. The interview data were processed directly by the researchers to protect the participants' privacy; the data were coded and then stored in the laboratory. The participants were sent a mobile coupon as a token of appreciation.

2.4. Data Collection. The individual in-depth interviews with participants were conducted between August 4 and August 12, 2023. Given the prevailing COVID-19 circumstances, we opted for remote interviews facilitated through Zoom. To prevent missing or erroneous data, only audio recordings were made with explicit consent, ensuring no video recordings were captured to prevent the disclosure of personally identifiable details. Each participant was interviewed once, with each interview taking between 60 and 100 minutes. The questions in the interview guide were composed by two researchers who had been responsible for analyzing patient safety incidents at a healthcare institution and who had ample experience in interviewing healthcare workers. The questions were semistructured, and the interview guide was provided in Supplementary 1. The main question for the in-depth interviews was, "What experiences have you had relating to patient safety incidents affecting hospitalized children you were caring for?" Additional questions included the following: "If the cause of the incident was due to healthcare workers, caregivers, or the hospital, what was the cause?" "What do you find most difficult about patient safety nursing for pediatric patients?" and "What is needed to prevent and ameliorate patient safety incidents for pediatric patients?" Questions were asked sequentially, depending on the flow of the conversation, making efforts to extend the conversation without interrupting the participant. The participants' speech was transcribed word-for-word, and nonverbal expressions, such as silence and sighs, were also recorded during the interview.

2.5. Data Analysis. The recorded data in the analysis, including the transcriptions of the interview recordings and the researchers' notes taken during the interview, amounted to 176 pages of A4 paper. Postinterview, the recorded content was promptly transcribed within a day. Two researchers performed data analysis using a thematic analysis approach after all the interviews had been completed. The researchers reviewed and supplemented the analysis through discussions to produce the final analysis. The thematic analysis used in this study was performed in 6 stages, following the method of Braun and Clarke [17]. (1) The transcripts of the recordings were read repeatedly to achieve familiarity with the data; (2) the meaningful content in the transcripts was coded, and content corresponding to each code was combined; (3) potential themes were generated by grouping codes, and all data related to each theme were organized; (4) the relationships between the themes and coded data were reviewed, and similar themes were grouped repeatedly to define theme clusters; (5) each theme was given a distinctive name; and (6) examples were identified that could explain each theme, and the report was written.

2.6. Validity and Rigor. We aimed to ensure the rigor of this qualitative study based on the factors proposed by Sandelowski [18]: credibility, auditability, fittingness, and confirmability.

For credibility, at the participant selection stage, we recruited participants who had previous experiences of patient safety incidents affecting hospitalized children, and those who could describe their experiences. Through open questions and a comfortable atmosphere, we created an interview environment that would allow participants to express their opinions freely. Moreover, by transcribing interviews promptly within a day, we aimed to minimize omission and distortion of the interview content. During data analysis, we aimed to derive credible results through thorough discussions between the researchers.

Addressing auditability, we aimed to describe the study objectives and methods in detail and aid readers' understanding.

To satisfy the criteria for fittingness, we described the participants' general characteristics. In addition, we collected data until the saturation point, when participant's statements were repeating, and we could no longer derive any new content.

Finally, to ensure confirmability, we made efforts to minimize the researchers' bias, maintaining a neutral stance throughout the research process. This approach safeguarded against any undue influence of researchers' feelings or experiences on participants' responses.

3. Results

The general characteristics of the participants are presented in Table 1. The participants were all female, with a mean age of 31.6 ± 5.5 years. Specifically, seven participants (50.0%) fell within the 20- to 29-age bracket, while five participants (35.7%) were aged between 30 and 39 years. Regarding the type of healthcare institutions, 12 participants (85.7%) were affiliated with tertiary hospitals. In terms of departmental roles, 10 participants (71.4%) served in general wards, three (21.4%) worked in intensive care units, and one (7.2%) was stationed in the emergency room. The mean nursing experience was 8.0 ± 5.7 years, and three participants (21.4%) were parents themselves.

During the analysis of the interview content, 199 codes were generated in stages 1 and 2, and mutually related codes were classified to form 8 themes in stage 3. In stages 4 and 5, the themes were structured into three theme clusters with more comprehensive meanings: "challenges in pediatric patient safety nursing due to patient and caregiver characteristics," "emotional changes in nurses following patient safety incidents," and "sincere desire to prevent patient safety incidents in pediatric patients" (Table 2).

3.1. Challenges in Pediatric Patient Safety Nursing due to Patient and Caregiver Characteristics

3.1.1. Risk due to Difficulties Communicating with Pediatric Patients. The participants had experienced difficulties precisely identifying symptoms in pediatric patients because children have difficulty expressing themselves clearly or are afraid of healthcare workers, while infants are incapable of

TABLE 1: General characteristics of the participants.

ID	Sex	Age (yr)	Hospital	Department	Nursing career (yr)	Having children
1	F	28	General hospital	Ward	2.4	No
2	F	24	Tertiary hospital	Emergency room	1.5	No
3	F	40	Tertiary hospital	Ward	18.0	No
4	F	28	Tertiary hospital	Ward	2.5	No
5	F	34	Tertiary hospital	Ward	10.2	No
6	F	38	General hospital	Ward	16.5	No
7	F	30	Tertiary hospital	Ward	5.8	No
8	F	26	Tertiary hospital	Ward	4.3	No
9	F	35	Tertiary hospital	Intensive care unit	11.3	Yes
10	F	41	Tertiary hospital	Ward	15.0	Yes
11	F	29	Tertiary hospital	Ward	8.0	No
12	F	26	Tertiary hospital	Intensive care unit	0.8	No
13	F	34	Tertiary hospital	Ward	10.3	Yes
14	F	29	Tertiary hospital	Intensive care unit	5.0	No

communication. When a pediatric patient cries or complains of discomfort, it is difficult for nurses to tell whether it is due to pain, or if the child is simply whining. This can delay diagnosis, examinations, or treatment, amplifying the perceived urgency and potential risk of the situation. Given the inherent nature of childhood marked by curiosity, pediatric patients frequently engage in playful and sometimes reckless behaviors. This can include attempting to interact with medical equipment, removing dressings from injection sites, or even jumping on beds or climbing on IV poles despite being cautioned about the potential risks of falls. Such behaviors escalate the likelihood of patient safety incidents.

“Most children can not easily express themselves verbally, so you do not know if they are crying because it hurts. Often, even if I want to be proactive and help the patient quickly, I have to take a moment to think again. Those moments are difficult. It would be much better if they could tell us where they were hurting, but as the nurse, you have to test one thing at a time, and that takes a long time” (Participant 3).

“Children do not stay still just because you tell them to. They do not take the hospital seriously, and they run around all over the place playing however they like, pressing infusion pump buttons and turning IV regulators” (Participant 6).

3.1.2. Risk due to Excessive Workload. The participants highlighted that it was difficult to find the vein when placing an IV catheter in pediatric patients. Furthermore, the procedures took a long time due to a lack of cooperation, especially if patients were crying or moving, and they often required help from other people. Newly graduated nurses, lacking experience, frequently encounter difficulties in delivering treatments to pediatric patients, leading to errors that require intervention from more seasoned nurses. Additionally, tasks like changing hospital gowns or bedding for pediatric patients demand more time compared to adult care, intensifying the workload. Moreover, because children require smaller doses of medication, the dose needs to be calculated precisely, and when heavy workloads make it

difficult to practice safe nursing, there is a high risk of errors, which can lead to dangerous situations for the patient. This results in a greater sense of burden and danger for nurses.

“When children try to grab the IV, one person each needs to hold the arms and legs, so everyone has to stop what they are doing and help hold the IV. It is difficult to find the vein in children, and they cry and move around, and so you have to wrestle with them for twenty minutes. For all that time, nobody working on the ward can get anything else done” (Participant 6).

“When giving medication to adults, the prescription is 1 vial, so you can just give them the whole vial. For children, you have to calculate the dose accurately, and of course, you have to hand up the infusion pump, which takes more time and is something you have to worry about. In children, the consequences of me making even a small mistake can be very severe, and so it is a major burden for nurses. We should check one more time and be meticulous, but it is easy to miss something when we’re so busy” (Participant 13).

3.1.3. Stress due to Caregivers’ Sensitivity. Participants indicated that caregivers, despite recognizing the demanding nature of nursing duties and the critical needs of other patients, often prioritized their own child’s care. Consequently, some caregivers expressed anger, frustration, and impatience when they felt their child was not attended to promptly. In the ICU, caregivers would constantly call with inquiries even beyond designated visiting hours. Such interactions, coupled with caregivers occasionally eavesdropping on conversations, contributed to heightened stress levels among nurses. Due to these challenges, many nurses avoid working in pediatric wards, and new pediatric nurses also complain of high levels of stress.

“The sensitivity of caregivers is probably a difficulty that only pediatric nurses have to experience. Lately, people aren’t having many children, and when it is the parent’s only child, it is really precious. Even though I’ve told the caregiver that I have an urgent situation or I have to give

TABLE 2: Nurses' experience related to patient safety incidents of hospitalized children.

Theme clusters	Themes
Challenges in pediatric patient safety nursing due to patient and caregiver characteristics	Risk due to difficulties communicating with pediatric patients Risk due to excessive workload Stress due to caregivers' sensitivity
Emotional changes in nurses following patient safety incidents	Getting swept up in negative emotions Trying even harder to prevent accidents
Sincere desire to prevent patient safety incidents in pediatric patients	Improving safety awareness of caregivers Improving pediatric care-related infrastructure and policy support Improving support for patient safety activities and culture within the hospital

CPR to another patient, they shout at me, asking me to change the sheets. They can see for themselves that it is an emergency, but a lot of them get too sensitive about trivial things. The caregivers are far more sensitive than those in an adult ward” (Participant 7).

“A lot of nurses refuse to work in the pediatric department. That’s because there are so many complaints from caregivers. Everyone avoids working in the pediatric wards because the caregivers complain about everything, even down to the nurses” tone of speech. Experienced nurses may be able to somewhat control rude or sensitive caregivers, but new nurses are reduced to tears and say that controlling the caregivers is the hardest part (Participant 3).

3.2. Emotional Changes in Nurses following Patient Safety Incidents

3.2.1. Getting Swept Up in Negative Emotions. Following patient safety incidents, such as falls or medication errors, participants reported feeling surprised by the incident and also sorry that they could not care properly for the patient as their nurse. They were also worried or fearful of the patient’s condition worsening due to the safety incident and felt guilty about their error. Moreover, strained relationships with caregivers added to their sense of burden, making communication challenging. On the other hand, even though it was a patient safety incident caused by the mistake of a child or parents, nurses wrote the incident report, and some participants felt wronged by the fact that the nurse was held responsible for the cause of the accident blaming it on the nurse’s negligence and lack of explanation.

“I felt a sense of shame, thinking thoughts like, “I made a mistake to the child,” “What if something happens to the baby because of me?,” “Why did I make another mistake?” I felt like I had made an enormous mistake, and I felt like I was tiny” (Participant 12).

Writing a fall report is very stressful and difficult for nurses. It feels like it is placing too much of the responsibility on the nurse. I feel harshly treated because it makes it so that the fall is the fault of the primary nurse” (Participant 1).

3.2.2. Trying Even Harder to Prevent Accidents. Following a patient safety incident, the participants worked hard to follow patient safety principles, such as removing the IV site fixation dressing and checking for redness and swelling even if there is no complaint of pain, and repeated education on the risk of falls and the importance of prevention, even though they were busy. The participants performed their rounds more intensively to prevent new patient safety incidents and recurrence. They also continually provided education, explaining safety rules and their importance to improve caregivers’ perceptions of patient safety.

“Since it is all we can do to explain about safety, we try to keep reminding the caregivers. And we really did a lot of rounds. Not only the on-duty nurse, but also the nurse managers, and the nurse practitioners visited the patient multiple times” (Participant 8).

“Since the patient safety incident, I made efforts to follow the basic rules more precisely. I thought I should have checked the IV site, even if the child was sleeping. Since then, I explained a little more to the caregiver that, because it is an important and somewhat dangerous drug, they need to check the injection site, even if the child wakes up, and I also check more often” (Participant 13).

3.3. Sincere Desire to Prevent Patient Safety Incidents in Pediatric Patients

3.3.1. Improving Safety Awareness of Caregivers. Participants observed that caregivers frequently overlooked patient safety concerns. They expressed concerns about caregivers leaving infants unattended on beds while attending to other matters outside the ward. Additionally, caregivers often seemed distracted and engrossed in their phones or television screens, potentially compromising the child’s safety within the ward. Participants emphasized the need for caregivers to prevent children from engaging in hazardous behaviors and underscored the importance of imparting discipline. Recognizing that caregivers are ideally positioned to identify shifts in a patient’s condition, participants highlighted their pivotal role in effectively communicating the child’s status to healthcare professionals.

“Hospitals are unfamiliar environments for children, with a high risk of falls. Sometimes caregivers will lie down and play with their phones or watch TV or go in and out of the ward to take a phone call. It’s actually really dangerous to just leave a child alone. I think they feel like nothing could happen in a hospital” (Participant 6).

“Actually, the caregivers know better than me how the child is different from usual. It would be good if caregivers would tell the healthcare workers immediately if there was anything that seemed strange or there seemed to be a problem, and if they would ask us what had happened. Since there are many things we miss, these questions would provide us with an opportunity to check the patient again. It’s surprisingly uncommon for caregivers to ask questions like, “Why is this the case?” when visiting. Usually, they just say something like, “Please take good care of him/her” (Participant 14).

3.3.2. Improving Pediatric Care-Related Infrastructure and Policy Support. Participants highlighted that the diminishing number of pediatric residents in Korea over the last several years has resulted in an increased workload for nurses, as they assume tasks typically handled by pediatricians in tertiary hospitals. This shift has intensified work

pressures. Furthermore, the participants felt that patients' health was threatened by the gap in pediatric treatment due to the closure of pediatric hospitals and clinics. In addition, participants emphasized that caring for children entails more nursing responsibilities compared to adult patients. Patient safety incidents were attributed to the existing shortage of nursing staff. Specifically, new nurses have to care for the same number of patients despite lacking the required knowledge and skills, which further increases the risk of patient safety incidents. Participants expressed concern about the demanding workload of all nurses, such that newer ones found it challenging to seek or obtain assistance when needed. The participants reported the need for national policies to improve support for pediatric healthcare workers, including doctors and nurses, and to increase the fees for pediatric healthcare. In addition, given the characteristics of pediatric patients, they reported the need for support to further develop medical devices and materials to prevent patient safety incidents, urging their integration into healthcare institutions.

"We haven't had any new pediatric residents for 2 years, so the 3rd and 4th-year residents are continuing to be on duty on alternating days. As a result, the excessive workloads of pediatric doctors are getting worse. This means that doctors' work is being passed on to nurses. The lack of doctors is ultimately leading to excessive work for nurses. Blood collection was usually done by doctors, but now it is being done by nurses. Our time spent directly caring for patients has decreased, and I'm worried that this might lead to more patient safety incidents in pediatric wards in the future" (Participant 7).

"For medical materials as well, you can get by with just one or two sizes for adults, but you need to prepare all different sizes for children. It would be nice if we had all children's beds as well, because of falls, but nothing changes when we ask, because they are too expensive. Because children might try to press buttons on medical devices for fun, we need to bring in more secure devices, such as devices with locks" (Participant 3).

3.3.3. Improving Support for Patient Safety Activities and Culture within the Hospital. Participants proposed that creating educational videos within hospitals to instruct pediatric patients and their caregivers about falls and general patient safety could prove highly effective in both education and incident prevention. Additionally, they believed that distributing patient safety-related pamphlets or campaigns could enhance caregivers' awareness of patient safety. In addition, participants wanted parents to understand the poor and busy working environments of nurses, urging for mutual respect. They also hoped that a positive patient safety culture would be established that would move away from the negative culture that focuses on criticizing and punishing healthcare workers who cause patient safety accidents. Instead, it would focus on improving the work environment to prevent future patient safety incidents. The participants also reported the need to strengthen activities and support for

patient safety at the hospital level, such as asking the hospital to make a pediatric IV team to accurately and safely secure IVs in pediatric patients and to prevent vasculitis, which is a common complication among children.

"If we made short educational videos about patient safety and had the patient and caregiver watch these before admission, I think it would help with understanding when we explain. I think it would help if there were fall videos suited for children. Children can concentrate and watch videos on YouTube or other platforms. It would be easier for nurses to explain and also improve patients' awareness" (Participant 5).

"They blame everything on the nurses. Even if the doctor gave the wrong orders, they say it is the nurse's fault because they should have caught it. Nurses are busy and having a hard time because we have to see so many patients, but they do not think of that. When you are this busy, mistakes are inevitable, but they do not think about our circumstances and they only talk about the mistake. I wish [caregivers] would understand our situation and trust and listen to the healthcare workers" (Participant 14).

4. Discussion

In this study, we comprehensively explored nurses' experiences of patient safety incidents affecting hospitalized children. After analyzing the content of interviews with the nurses, we derived and discussed 3 theme clusters: "challenges in pediatric patient safety nursing due to patient and caregiver characteristics," "emotional changes in nurses following patient safety incidents," and "sincere desire to prevent patient safety incidents in pediatric patients."

In the first theme cluster, participants expressed the sense of burden felt by pediatric nurses who always have to be extremely careful to try to prevent patient safety incidents while caring for pediatric patients. In addition, when caring for infant patients, clear communication is impossible, and cooperation during treatment is difficult, often resulting in prolonged treatment durations and heightened nurse workload. Furthermore, there is a considerable burden associated with the need to precisely calculate medication doses relative to body weight for children; however, sensitive reactions from caregivers who often prioritize their child's needs exclusively further exacerbate the stress of nurses. This aligns with findings from a prior study on pediatric nurses [19], where family caregivers sometimes exhibited behaviors, such as prioritizing their own child's needs to the exclusion of respecting nurses or even resorting to derogatory language. Such interactions elicited negative emotions from nurses and introduced ethical dilemmas when these sentiments impacted patient care. Given that children are inherently more vulnerable and susceptible to anxiety and fear than adults, it underscores the imperative for pediatric nurses to exhibit heightened patience, expertise, and an unwavering commitment to patient safety [20]. In China, the combination of a demanding workload and challenging

interactions with discerning parents has been pinpointed as contributing factors to heightened work stress, burnout, and turnover rates among pediatric nurses, with a notable 40% of pediatric nurses expressing job dissatisfaction [21]. Family-centered care is a core aspect of pediatric nursing care, with nurses respecting the dignity of the child and their family and providing care based on partnerships [22]. However, for patients to receive the highest level of safe nursing, it is essential for the patient's parents also to try to understand and respect the difficulties of nurses and make efforts to form positive partnerships with the nurses. Moreover, there is a need to provide opportunities and compensation to improve pediatric nurses' workload, reduce work stress, and encourage continual career development [21].

In the second theme cluster, nurses reported being consumed by negative emotions, including not only surprise but also sorrow towards the patient, concern and fear about the patient's condition, and guilt about their own mistakes. However, they also worked even harder to follow patient safety principles after an incident, went on rounds more often to prevent recurrence, and continued education to explain the importance of patient safety to caregivers.

Since a hazardous accident can lead to severe injury or even death, the primary victims of such accidents are the patient and their family. Nevertheless, healthcare workers affected can also experience psychological shock and emotional distress and thus are recognized as second victims of these accidents [23]. The second victims of patient safety incidents show emotional responses, including guilt, anger, despair, psychological stress, and fear, and have even been reported to show physical symptoms, such as fatigue and insomnia, as well as divergent behaviors [24]. Some nurses have even experienced difficulties sleeping or eating [25]. These responses by second victims can lead to harmful outcomes in the personal and professional lives of healthcare workers, including posttraumatic stress disorder, turnover, and suicide [26]. Nurses experience more negative emotions compared to physicians [27], and this can lead to a worsening cycle by inducing burnout and depression, making nurses further unable to provide appropriate care [28]. Specifically, when nurses continue working without properly addressing the emotional stress stemming from a patient safety incident, it can escalate the risk of subsequent accidents. Moreover, improper healthcare provision can have additional effects on patients, other healthcare workers, and the overall reputation of the healthcare institution [29]. The negative emotions experienced by nurses after a patient safety incident can gradually improve. However, the lingering impact of such incidents can remain deeply distressing for an extended period [7], underscoring the urgency for timely resolution. As such, healthcare institutions need to ascertain the current state of second victims, explore related factors, and prepare individualized interventions for second victims depending on their symptoms [7]. Understanding the unique requirements of healthcare professionals is crucial when crafting targeted support programs for nurses affected by patient safety incidents [30]. Notably, distress experienced by these second victims can significantly influence work-related outcomes,

including intentions to leave their positions and increased absenteeism; organizational support has also been reported to show a full mediation effect [26]. Therefore, to reduce turnover and absenteeism among nurses who have experienced patient safety incidents, it will be necessary to proactively develop support measures at the organizational level.

The third theme cluster centered on the "sincere desire to prevent patient safety incidents in pediatric patients." Nurses often perceived the risk of patient safety incidence while observing caregivers who were not paying sufficient attention to the patient. Following patient safety incidents, there is a prevalent tendency among caregivers to place blame on the nurses, with organizations also primarily holding the staff accountable. Nurses articulated a strong desire for acknowledgment and respect from caregivers, coupled with the establishment of a robust patient safety culture within their institutions. Many nurses conveyed a sense of disappointment with the existing conditions. The majority emphasized the urgency of bolstering nurse staffing levels to enhance patient safety. They also underscored the necessity for national policies aimed at augmenting pediatric healthcare fees and fortifying support systems for healthcare professionals, encompassing both physicians and nurses. Additionally, there is a pressing call for organizational and political backing to facilitate the creation and effective deployment of medical devices and materials tailored to the unique needs of children. Within healthcare institutions, nurses advocated for a range of initiatives, including comprehensive patient safety education to heighten caregivers' awareness and the establishment of specialized pediatric IV teams.

As part of its program for patient safety, the World Health Organization (WHO), recognizing the roles and values of patient participation, has demanded cooperation and partnership between patients, family, healthcare providers, and policymakers in constructing safer healthcare systems and has encouraged patients to be at the center of healthcare services [31]. The Joint Commission has also suggested patient and family participation as one of 7 types of evidence for safe, high-quality care [32], and patient participation is known to be a means of preventing healthcare errors [33]. Patient participation involves fostering an environment that encourages the active participation of patients, families, and caregivers in their care to improve the safety, quality, and patient-centricity of healthcare services [34]. Healthcare institutions have the potential to promote this active patient involvement as a strategic measure to safeguard patients' health and well-being [35]. According to previous studies, patient participation in nursing is essential to guarantee high-quality care [36]. This active involvement provides important information for diagnosis and treatment and can potentially help to improve healthcare systems [37]. Because treatment-related decisions for pediatric patients are made by their caregivers, in this respect, promoting caregiver participation will help to prevent patient safety incidents, improve caregivers' safety awareness, and help to achieve safe nursing.

In a study investigating healthcare workers' perspectives on pediatric patient safety culture [5], findings revealed that aspects like organizational continuous-learning improvement and feedback and communication on errors were notably strong among healthcare professionals, including nurses. However, areas such as management support for patient safety and adopting a nonpunitive approach to errors were perceived weakly. This suggests that while there are robust communication and feedback mechanisms in place following patient safety incidents, there is a distinct need for enhanced support and fostering a nonpunitive culture for healthcare workers. This is consistent with our findings, with the participants in our study reporting that, in the event of a patient safety incident, both caregivers and the organizations only blamed individual nurses for the accident, and the participants were disappointed at the lack of respect from caregivers and the failure to establish a patient safety culture within organizations.

Most of the nurses who participated in the study complained of the need to increase nurse staffing for patient safety and emphasized the need for national policies to raise pediatric healthcare fees and improve support for pediatric healthcare workers. In 2021, among public healthcare workers in South Korea, the number of clinical physicians was 2.6 physicians per 1,000 population, which was very low compared to the OECD average of 3.7 physicians per 1,000 population, and the number of clinical nurses, at 8.8 nurses per 1,000 population, was also lower than the OECD average of 9.8 nurses per 1,000 population [38]. The so-called pediatric department "open-run," where patients are waiting outside the doors at opening times for pediatric clinics, has become an everyday reality for parents [39]. Amidst the current climate of low birth rates in South Korea, healthcare fees for pediatrics are very low, and there is a high risk of legal disputes due to healthcare accidents, causing future residents to avoid applying to pediatric departments, thus threatening a collapse of the pediatric emergency care system [16]. Healthcare staff shortages are exacerbating workloads, which increases the risk of safety incidents; therefore, there is an urgent need for basic corrective measures.

Alongside national policies, nurses also reported the need for organizational support, such as the development and provision of medical devices and materials suited for pediatric patients. Nurses demanded specific activities and support for patient safety, such as improving patient safety education as a means of enhancing safety awareness among caregivers and forming specialized pediatric IV teams. It is critical to develop and implement safety-related education to prevent patient safety incidents from occurring at hospitals [7]. Since fall prevention education was effective at improving fall-related knowledge and preventive behaviors in caregivers of hospitalized children [40], we expect that the development and application of caregiver-targeted educational programs will help improve caregivers' awareness of patient safety. The preparation and implementation of these specific interventions could promote caregiver cooperation and accelerate the establishment of a patient safety culture in healthcare institutions.

5. Conclusions

In this study, we explored the experiences of nurses regarding patient safety incidents affecting hospitalized children, uncovering their sincere desire to prevent such incidents. It is imperative to devise organizational and policy initiatives that prioritize safeguarding both hospitalized children and nurses from patient safety incidents, incorporating the insights gleaned from this study. Within healthcare organizations, fostering a culture rooted in mutual understanding and respect is paramount. Fundamental steps include increasing nurse staffing, enhancing pediatric medical infrastructure, and formulating supportive policies. In this regard, nursing administrators and healthcare institutions must collaborate to strategize and advocate for pertinent policies at the organizational level.

6. Implications for Nursing Management

Considering the characteristics of patient safety incidents in children, caregivers' trust and respect for nurses, as well as their cooperation and participation in the patient care process, are crucial. Therefore, specific strategies are required to strengthen patient safety activities within hospitals. These strategies include educational programs aimed at improving caregivers' awareness and understanding of patient safety. Additionally, developing and implementing psychological support and counseling services, as well as peer support programs, can assist nurses in mitigating and overcoming the negative emotions associated with patient safety incidents.

Providing continuous education programs to enhance nurses' work efficiency and job satisfaction and establishing clear career paths for the professional development of pediatric nurses are critical considerations for organizational managers. Given the current characteristics of Korean society, such as having the world's lowest birth rate and the increased workload burden consequent on the decrease in pediatric specialists and infrastructure, it is imperative to devise long-term strategies to reduce the workload of pediatric nurses and safeguard them from patient safety incidents. This includes policy support for expanding the number of nurses and enhancing the infrastructure of pediatric hospitals.

A comprehensive set of policies should be developed to address the specific challenges facing pediatric nurses in the context of Korea's extremely low birth rate. These policies should support pediatric nurses by mandating rest periods, ensuring safe staffing ratios, and providing professional development opportunities. By integrating these innovative actions with context-specific insights, it will be possible to formulate comprehensive measures that effectively support pediatric nurses. Although Korea's low birth rate presents unique challenges, the strategies developed could offer valuable lessons for other countries facing similar issues in pediatric care.

To this end, active intervention and cooperation from nursing managers and policymakers are essential. Their involvement is crucial in the development and

implementation of these policies and strategies, ensuring that pediatric nurses receive the needed support to deliver safe and effective care to their patients.

Background. Catastrophes are challenging events for nations and health systems that require healthcare providers, especially nurses, to be prepared to respond effectively. Although nurses play a critical role in managing catastrophes and postcatastrophic situations, their preparedness is often inadequate and affected by their organizational commitment. Therefore, this study assessed nurses' preparedness for catastrophe management and its relationship with their organizational commitment. **Methods.** A cross-sectional correlational, descriptive design involving 286 conveniently sampled nurses was conducted in four public hospitals in Hail city. Data were collected using a questionnaire that compiled two tools: the Disaster Preparedness Evaluation Tool to assess nurses' preparedness for catastrophe management and the Organizational Commitment Scale to assess their attachment to their hospitals. Correlations between mean scores of nurses' knowledge, skills, and preparedness for postcatastrophe management and organizational commitment were tested using Spearman's correlation, with a significance level of <0.05 . **Results.** Most nurses had low levels of knowledge (79.7%), skills (78.7%), and preparedness for postcatastrophe management (78.7% each). Meanwhile, 57.3% of nurses had low levels of affective commitment to their hospitals, compared to 78.7% for continuance and normative commitments. Statistically significant positive, moderate correlations were found between nurses' knowledge and skills in managing catastrophes ($r=0.512$; $p<0.01$) and knowledge and preparedness for postcatastrophe management ($r=0.492$; $p<0.01$), as well as nurses' skills and preparedness for postcatastrophe management ($r=0.533$; $p<0.01$). However, the nurses' level of organizational commitment was not significantly correlated with their knowledge, skills, or preparedness for postcatastrophe management. **Conclusion.** Nurses in Hail city are not adequately prepared to respond to and manage catastrophes and postcatastrophic situations, and they have low organizational commitments to their hospitals. Therefore, nursing education should integrate catastrophe management into the curricula, and hospital administrators should prioritize a supportive work environment that strengthens organizational commitment and provides ongoing education and regular training to improve nurses' preparedness for catastrophe management.

1. Introduction

Throughout history, catastrophic events have threatened entire nations and civilizations and resulted in lasting impacts on people's lives at various economic, social, and political levels. These impacts include death, disability, financial loss, and deterioration in living standards [1]. As catastrophes occur more frequently now than ever before, nurses must be well-prepared to respond and mitigate the negative effects they have on the affected population [2]. Despite efforts to prepare nurses for catastrophic events, they are still not adequately prepared to manage such situations. However, nurses' substantial contributions to global catastrophe relief efforts have been documented [3]. In 2015, natural catastrophes occurred in 99 countries, resulting in the displacement of millions of people, over 22,000 deaths, and an estimated economic loss of 70.3 billion USD [4].

A catastrophe is defined as any event that results in a dangerous and unstable situation that impacts a person, a group, or the entire society [5]. Unfavorable changes in human or environmental circumstances are called crises, especially when they occur unexpectedly and without warning. In a broader sense, a catastrophe is a difficult situation or an emergency. In other words, it is a "complex system" for the family, economy, and society that is disorganized [6].

Catastrophe nursing involves the systematic application of nursing knowledge and skills to address the challenges caused by catastrophes. It involves developing and implementing evidence-based practices to minimize the adverse health impacts of catastrophes and mitigate their life-threatening hazards [1]. A recent study showed that inadequate preparedness, inadequate formal training, limited empirical research, ethical and legal considerations, and concerns about personal safety and well-being during a catastrophe response are the most common challenges nurses face when responding to catastrophic events [7]. The lack of specificity in the extensive research in this area makes it necessary to identify the competencies required for the intended audiences and for different catastrophe situations and environments [8, 9].

Nurses' awareness of catastrophic events has increased in recent decades, but there remains a compelling need for further enhancement [10]. Many nurses lack the necessary psychological and educational preparedness to respond effectively to catastrophes [11–13]. Furthermore, much larger catastrophes are expected in the future, highlighting the need for greater awareness and preparedness. As a result, nurses should receive regular training in this area to keep their skills up-to-date [14, 15]. Since nurses play a vital role and are engaged in all phases of catastrophe response and management, it is important to provide them with the necessary knowledge, skills, and competencies and enhance their organizational commitment to effectively manage catastrophic events [16–18].

Organizational commitment refers to the psychological attachment that an employee feels toward a certain organization, which is characterized by alignment with its goals and values, as well as a strong desire to continue working

there [19]. Nurses' organizational commitment is a critical factor in the success and effectiveness of healthcare facilities [20]. This commitment critically depends on the attitudes and behaviors of nurses, particularly when there are unmet expectations or limited resources [21]. Nurses who are highly committed to their organizations are more productive due to their dedication, loyalty, and sense of responsibility [6, 22].

Assessment of organizational commitment is important to understand staff nurses' commitment to the organization's mission and promote consistent work conduct [23], which can positively impact their performance, motivation, and attachment to the organization [24]. A recent study in Saudi Arabia by Al Harthi et al. [25] revealed certain strategies that could improve nursing management during disasters, such as providing personal protective equipment to nurses to reduce the risk of infection, developing assessment tools, and recognizing nurses for their efforts to reduce stress during a disaster [25]. More recently, Al Dulijand et al. [26] found lower rates of knowledge about incident command systems (49.9%) and mass casualty plans (56.1%) among healthcare workers in Saudi Arabia. The authors emphasized the need for targeted initiatives to improve their knowledge and training in these areas of disaster preparedness [26].

Several studies have focused on the social and environmental impacts of catastrophes [27, 28], but research on the relationship between nurses' organizational commitment and their readiness to manage catastrophes is limited. Although nurses are among the frontline responders during catastrophic events, their organizational commitment plays an important role in their ability to provide effective care to patients affected by these catastrophes [29]. In this regard, a positive relationship has been found between organizational commitment and nurses' ability to manage emergencies [22]. Therefore, this study aimed to assess nurses' preparedness for catastrophe management (knowledge, skills, and preparedness for post-catastrophe management) and its correlation with their level of organizational commitment.

1.1. Research Questions

- (1) What was the level of nurses' preparedness for catastrophe management?
- (2) What was the level of nurses' organizational commitment?
- (3) Was there a relationship between nurses' preparedness for catastrophe management and their organizational commitment?

2. Methods

2.1. Design. A cross-sectional correlational design was used. This study fulfilled the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) guideline [30].

2.2. Setting. This study was conducted in four main public hospitals in Hail city, Saudi Arabia: King Salman Hospital (500 beds), Hail General Hospital (136 beds), King Khaled Hospital (285 beds), and Maternity and Children's Hospital (200 beds).

2.3. Sampling Technique. A convenience sampling technique was used in this study. Considering a total of 1120 nurses in the four study hospitals, a minimum sample size of 286 was determined using the Raosoft® sample size calculator (https://www.raosoft.com/sample_size.html), based on a 50% response distribution, a 95% confidence level, and a 5% accepted margin of error. The final sample consisted of 55 nurses from King Salman Hospital, 46 from Hail General Hospital, 85 from King Khaled Hospital, and 100 from Maternity and Children's Hospital.

The study included nurses who had a diploma or higher degree in nursing with at least one year of work experience, had worked as registered nurses in the selected hospitals, and agreed to voluntarily participate in the study. Assistant nurses, those with less than one year of work experience, and those who refused to give informed consent were excluded from the study.

2.4. Study Instruments. Data were collected using a questionnaire that compiled two tools: the Disaster Preparedness Evaluation Tool (DPET) and the Organizational Commitment Scale (OCS). Furthermore, the questionnaire included questions about the characteristics of nurses, including age, gender, nationality, qualification, work experience, number of hours worked per week, hospital affiliation, and involvement in real catastrophe management.

The Arabic version of the DPET, which was translated and validated by Al Khalailah et al. [31], was used to assess nurses' perceptions of their preparedness for catastrophe management in three dimensions: knowledge, skills, and preparedness for postcatastrophe response and management [31]. It comprised the following 45 items: knowledge (13 items), skills (11 items), and postdisaster management (21 items). Nurses' responses to each item were rated on a 6-point Likert scale, ranging from 1 (strongly disagree) to 6 (strongly agree). Accordingly, the total scores for each participant ranged from 13 to 78 for knowledge, 11 to 66 for skills, and 21 to 126 for preparedness for postcatastrophe management, with higher scores indicating higher levels of preparedness. To calculate the mean total score for each dimension, the individual scores of participants for that dimension were summed and divided by the maximum possible score. The mean total scores were then converted into percentages by multiplying by 100. Based on the mean total percentage, the level of preparedness in each dimension was classified as low (<60%), moderate (60–75%), and high (>75%) [32–34].

The OCS was originally developed by Meyer and Allen in 1990 [35] and later updated in 1993 [36]. This scale comprised 18 items, divided evenly into three subscales: affective commitment, continuance commitment, and normative commitment. Nurses' responses to each item were rated on

a 5-point Likert scale, ranging from 1 (strongly disagree) to 5 (strongly agree). To ensure consistent interpretation of responses, negatively worded items (3, 4, 5, and 13) were reverse scored. The mean organizational commitment score was calculated by summing the individual scores and dividing by the maximum possible score. The mean overall percentage of organizational commitment was then calculated by multiplying the mean total score by 100. Based on the mean overall percentage, nurses' organizational commitment was classified as low (<60%), moderate (60–75%), and high (>75%) [32–34].

2.5. Instrument Validity and Reliability. A panel of five nursing administration academics from five nursing faculties at the universities of Benha, Ain Shams, Menoufia, Tanta, and Zagazig in Egypt evaluated the study instruments for their face and content validity. They evaluated the instrument items for conciseness, accuracy, completeness, and relevance. They approved the instrument tools after minor adjustments. Prior to actual data collection, a pilot study was conducted on 29 nurses, who were not included in the final statistical analysis of the study, to assess the feasibility, applicability, and clarity of the tools. According to this study, the estimated time to complete the questionnaire was 20–25 minutes.

The reliability of the study instrument was high, as revealed by Cronbach's alpha, with coefficients of 0.983, 0.986, and 0.996 for the knowledge, skills, and post-catastrophe management dimensions of the DPET, respectively, and 0.997, 0.991, and 0.995 for the affective, continuance, and normative commitment subscales of the OCS, respectively.

2.6. Fieldwork. Data were collected between July and the end of August 2023. The researchers provided nurses with a clear explanation of the study objectives and the process for completing the questionnaire. The head nurse of each unit scheduled the nurses' working hours based on their workload, and the researchers distributed the questionnaires and consent forms to the nurses at the scheduled times. The completed questionnaires were collected daily during the morning and afternoon shifts.

2.7. Ethical Considerations. This study received ethical approval from the Hail Research Ethics Committee (REC) (REC no. H-2023-316). The purpose of the study was clearly explained to eligible nurses before informed consent was obtained from those willing to voluntarily participate in the study. Nurses were informed that they had the right to withdraw from the study without consequences and that their data would only be used for research and analysis purposes. Nurses' privacy and the confidentiality of their data were strictly guaranteed.

2.8. Data Analysis. Data were coded and entered into Microsoft Excel spreadsheets for verification. They were then exported to IBM SPSS Statistics for Windows, version 25

(IBM Corp., Armonk, NY, USA) for subsequent analysis. Quantitative data were presented as mean and standard deviation (SD) for normally distributed data, or as median and interquartile range for nonnormally distributed data. Categorical data were presented as frequencies and percentages. The Mann–Whitney *U* test or Kruskal–Wallis *H* test was used to compare the median scores of nonnormally distributed data according to nurses' characteristics. In addition, Spearman's correlation was used to test the relationship between the mean total scores for knowledge, skills, and preparedness for postcatastrophe management and organizational commitment. Statistical significance was set at a *p* value of <0.05.

3. Results

3.1. Characteristics of the Respondent Nurses. The mean age of respondent nurses in this study was 32.1 ± 7.6 years, with most nurses aged 21–30 years (45.4%), followed by those aged 31–40 years (40.5%). The majority of nurses were females (81.1%), non-Saudi nationals (73.8%), and married (94.8%). Of the married and divorced nurses, 95.1% had children. Regarding qualifications, most nurses held a bachelor's degree in nursing or higher (72%), while the remainder had a diploma degree. The mean length of nurses' work experience was 9.7 ± 7.6 years (range: 1–28), with more than half having 1–9 years of experience. Most nurses were affiliated with the Maternity and Children's Hospital and King Khaled Hospital (35.0% and 29.7%, respectively) and reported no prior experience in catastrophe management (78.3%). On average, nurses cared for 6.0 ± 2.0 patients per shift and worked 8.7 ± 1.5 hours per day (Table 1).

3.2. Nurses' Preparedness for Catastrophe Management. The mean total scores for nurses' knowledge, skills, and preparedness for postcatastrophe management were 2.34 ± 1.26 , 2.96 ± 1.18 , and 2.88 ± 1.22 , respectively, corresponding to a tendency toward disagreement (Table 2).

Regarding the level of preparedness, Figure 1 shows that most nurses had low levels of knowledge about catastrophe management (79.7%), compared with 7% and 13.3% for moderate and high levels of knowledge, respectively. Similarly, most nurses had low levels of catastrophe management skills (78.7%), compared with 6.6% and 14.7% for moderate and high levels of skills, respectively. In addition, low levels of preparedness for postcatastrophe management were observed in 78.7% of nurses, compared with 5.6% and 15.7% for moderate and high levels of postcatastrophe management, respectively.

3.3. Nurses' Organizational Commitment. The mean total scores for nurses' affective, continuance, and normative organizational commitments to their hospitals were 2.54 ± 1.25 , 2.07 ± 1.36 , and 2.39 ± 1.22 , respectively, corresponding to a tendency toward disagreement. Furthermore, the level of organizational commitment was low, with a mean total score of 2.33 ± 1.22 (Table 3).

SD, standard deviation.

Regarding the levels of organizational commitment, Figure 2 shows that 57.3% of nurses had low levels of affective commitment to their hospitals, compared with 78.7% for continuance and normative commitments. In contrast, 21.3% of nurses demonstrated high levels of commitment to their hospitals on all three subscales of organizational commitment. However, moderate levels of affective commitment to hospitals were observed for 21.3% of the nurses, with no nurses demonstrating moderate levels of continuance or normative commitment.

3.4. Relationship between Nurses' Preparedness for Catastrophe Management and Their Organizational Commitment. Statistically significant positive, moderate correlations were found between nurses' knowledge and skills in managing catastrophes ($r = 0.512$; $p < 0.01$), knowledge and preparedness for postcatastrophe management ($r = 0.492$; $p < 0.01$), as well as nurses' skills and preparedness for

FIGURE 2: Levels of organizational commitment among nurses.

postcatastrophe management ($r = 0.533$; $p < 0.01$). However, the nurses' level of organizational commitment was not significantly correlated with their knowledge, skills, or preparedness for postcatastrophe management (Table 4).

3.5. Differences in Nurses' Preparedness for Catastrophe Management and Organizational Commitment according to Their Characteristics. The median score for organizational commitment was significantly higher among single/divorced nurses ($P = 0.001$), nurses without children ($P = 0.001$), and those previously involved in real catastrophe management ($P = 0.001$) than among their counterparts. The median score of catastrophe management skills was significantly higher among nurses aged 21–30 years ($P = 0.001$) and nurses with 1–9 years of experience ($P = 0.008$) than among their counterparts, while the median score of postcatastrophe management was significantly higher among nurses aged 21–30 years and 31–40 years than those aged 40 years or older. However, no statistically significant differences were observed in the median knowledge scores according to nurses' characteristics (Table 5).

4. Discussion

By leveraging available resources and tools to prepare for catastrophes, catastrophe management provides a framework for managing the prevention and mitigation of negative consequences [37]. In this context, nurses must have the necessary knowledge and skills and be well-prepared to respond to and manage catastrophes effectively. Therefore, it is important to assess nurses' preparedness for catastrophe management and understand its relationship with their organizational commitment. To the best of our knowledge, this is the first study to assess the preparedness of nurses in public hospitals in Hail city in the northern region of Saudi Arabia for catastrophe management and its relationship with their organizational commitment.

The preparedness of nurses in the present study for catastrophe management was inadequate, as evidenced by their low levels of knowledge, skills, and preparedness for postcatastrophe management. This finding emphasizes the need for bolstering education and training in catastrophe management to improve their preparedness for responding to and managing potentially emerging catastrophes. As the likelihood of catastrophes in the future is on the rise, nurses should regularly undergo training in catastrophe management to ensure their skills remain up-to-date. The low preparedness of nurses could be due to the hospitals included in this study not prioritizing nursing training in risk management, considering that these hospitals are equipped with advanced technology aimed at protecting both patients and caregivers from potential risks. In accordance with the present study, it was found that most nursing students in Turkey lack the psychological and educational foundation required for responsible crisis response [14]. Similarly, Hasan et al. [37] found that nurses in Dhaka city, Bangladesh, had average levels of knowledge, skills, and catastrophe preparedness, suggesting that further training is needed to

effectively manage catastrophes. In addition, nurses in Jordan and the Asia-Pacific region have been found to have low-to-moderate levels of preparedness for catastrophic events [31, 38].

This study also found nurses' low commitment to their hospitals, which may be attributed in part to their perception of being disconnected from these hospitals due to their inability to engage in decision-making and fewer opportunities to interact directly with supervisors. In addition, hospitals may lack clear communication channels in this regard. Many nurses may also have little experience and lack emotional attachment to their hospitals. This finding contradicts the finding of Elzohairy et al. [39], who found that professional nurses in Damanhur, Egypt, had moderate organizational commitment. Moreover, Callado et al. reported that primary healthcare nurses were highly committed to their organizations [40].

The significant positive moderate correlation between nurses' knowledge and their skills in managing catastrophes in the present study suggests a logical direct relationship between these two factors. In this regard, more knowledgeable nurses tend to be more skilled at dealing with catastrophic situations, reflecting the importance of nursing education in catastrophe management to improve nurses' ability to respond to and manage catastrophes effectively. This finding is consistent with the findings of Hasan et al. [37], who revealed such a relationship among nurses in Dhaka city. Furthermore, the significant positive moderate correlation between nurses' knowledge and preparedness for catastrophe management in the present study could be attributed to the willingness of knowledgeable nurses to learn, practice, and acquire the skills required to deal with catastrophic situations. This finding also agrees with that reported among nurses in Dhaka city [37]. On the other hand, the nurses' level of skills in the present was significantly and positively correlated with their preparedness for post-catastrophe management, suggesting that better skills are linked to higher preparedness. This finding agrees with that reported among nurses in Dhaka city [37].

Despite not finding a significant correlation between nurses' preparedness for catastrophe management and their organizational commitment, it is possible that this commitment still indirectly affects their preparedness. Various factors, including emotional attachment to their hospitals, involvement in decision-making, direct interaction with supervisors, and clear communication channels within the hospital, influence nurses' organizational commitment. Nurses who are committed to their organizations may be more likely to pursue professional development that can improve their catastrophe management knowledge and skills. In contrast to the present finding, a positive correlation was found between Indonesian nurses' organizational commitment and their preparedness for dealing with patients during natural catastrophes [22].

The present study found that organizational commitment increased significantly among single or divorced nurses, those who had no children, and nurses with prior involvement in real catastrophe management. It is plausible that the fewer family-related obligations or distractions of

these nurses may allow them to dedicate more time to their organizational goals, enhancing their organizational commitment. On the other hand, the struggle to balance work and family obligations can often dilute nurses' commitment to their organizations. Personal circumstances, such as marriage and childcare responsibilities and preoccupation with family matters can negatively influence nurses' commitment to their organizations. In contrast, a previous study in Saudi Arabia found that married nurses had significantly higher levels of organizational commitment [41].

Nurses' level of skills in the present study increased significantly by their age and experience. Similarly, nurses with less than three years of experience in Saudi Arabia were found to need more catastrophe management training [7]. On the other hand, the increase in nurses' organizational commitment because of their experience in catastrophe management could be attributed to the fact that the acquired nurses' experience enhances their loyalty to the organization by deepening their understanding of institutional policies, regulations, and procedures. Consequently, greater

experience is associated with greater organizational commitment. In contrast to the present study, Alammam et al. [42] found no significant difference in Omani nurses' organizational commitment according to their years of experience. However, the present study found a decrease in nurses' preparedness for catastrophe management with their age increase, which is contrary to the common belief that learning and cognitive skills for education increase with age. This finding is consistent with previous studies among nurses in Japan and Iran [43, 44].

This study provides valuable information about the preparedness of nursing staff in Hail city for catastrophe management. However, there are several limitations that may affect the interpretation of the results. The cross-sectional correlational design of this study makes it difficult to establish a causal relationship between nurses' preparedness for catastrophe management and their organizational commitment, as well as other potential influencing factors. In addition, restricting the study to public hospitals and relying on convenience sampling also contribute to the limited generalizability of the results to the broader nursing population in the city. It is worth mentioning that nurses in the private sector may face different situations, working conditions, and organizational structures that may lead to different scenarios regarding the topic under study. Therefore, large-scale studies with more representative samples, along with longitudinal designs, are recommended to assess the relationship between nurses' preparedness for catastrophe management and their organizational commitment.

4.1. Implications for Practice, Research, and Education. Greater commitment of nurses to their hospitals increases the likelihood of adequate preparedness to deal with catastrophic events effectively. Therefore, hospitals should prioritize improving the organizational commitment of their nursing staff by fostering a supportive work environment. In addition, it is crucial to implement strategies that strengthen nurses' attachment to their hospitals, such as offering opportunities for professional development and recognizing the positive contributions made by nurses. This study emphasizes the importance of integrating catastrophe management into nursing curricula and programs to improve nurses' knowledge and skills in preparing for and responding to catastrophes and post-catastrophic situations. Hospital administrators should also provide nurses with continuous education and regular training programs to keep them up-to-date and improve their capability to handle catastrophic events. The findings of this study warrant further studies to identify and predict potential factors affecting nurses' preparedness for catastrophe management, as well as the development of effective strategies that ensure a more efficient response and management of catastrophic events.

5. Conclusion

Nurses in Hail city are not adequately prepared to respond to and manage catastrophes and postcatastrophic situations, and they have low organizational commitments to their

hospitals. Therefore, nursing education should integrate catastrophe management into the curricula, and hospital administrators should prioritize a supportive work environment that strengthens organizational commitment and provides ongoing education and regular training to improve nurses' preparedness for catastrophe management.

Data Availability

The data used to support the findings of this study are available from the corresponding author upon request.

Ethical Approval

Loyalty to entirely applicable ethical standards and legal requirements, involving the Helsinki Declaration, was precisely upheld through the research process. Ethical clearance was obtained from the Research Ethics Committee (REC) of Hail University (REC No. H-2023-316) on May 6, 2023.

Consent

The researchers obtained informed consent from nurses after an explanation of the objectives of the study. Moreover, nurses were given the right to refuse or withdraw from the study without any explanation. In addition, they gave assurances that the data would be kept private and anonymous and would only be utilized for scientific study.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

All researchers in this study were involved in designing the study, conducting the survey and data collection, analyzing the data, and interpreting the results. Aziza Z. Ali, Sameer A. Alkubati, Wessam A. Elsayed, and Laila A. Hamed wrote the first draft of the paper and contributed to the revision of the whole paper. All authors have read and agreed to the published version of the manuscript.

Acknowledgments

The authors appreciated all the nurses who took part in this study.

Aim. The purpose of our review was to assess the role of nurses' workplace social capital in meeting the Sustainable Development Goals (SDGs) of the United Nations (UN). **Background.** In 2015, the 2030 Agenda for Sustainable Development with 17 universal goals was adopted by members of the UN. Although nurses have been acknowledged as important contributors to sustainable development, they still have difficulties in connecting their work to the SDGs. Nurses' workplace social capital is an important concept in nursing management due to its constructive consequences. However, the potential association between nurses' workplace social capital and the SDGs has not been evaluated. **Evaluation.** We conducted an integrative review, following the methodology of Whittemore and Knafl. Seven databases, Medline, CINAHL, Web of Science, Cochrane Library, Embase, PsycINFO, and Scopus with no restriction on publication year, were searched in May 2023 to identify statistically significant empirical evidence. Only peer-reviewed research papers published in English language journals were considered. We applied the Mixed Methods Appraisal Tool to evaluate the quality of the selected articles. We categorized outcomes of nurses' workplace social capital into themes and connected them to the SDGs through repeated comparisons and discussions. **Key Issues.** Twenty-nine of 2,188 retrieved articles were included in the final data analysis. Twenty-three outcomes of nurses' workplace social capital were identified, and three themes were abstracted. Nurses' workplace social capital is positively associated with SDG 3 (good health and well-being), SDG 8 (decent work and economic growth), and SDG 17 (partnerships for the goals). **Conclusion.** Findings of our integrative review shed light on the importance of nurses' workplace social capital and the role of nurses in achieving the global movement for sustainable development. **Implication for Nursing Management.** Investment in nursing workforce and nurses' workplace social capital can further strengthen the position of nurses to support and deliver the SDGs.

1. Introduction

The concept of sustainability was introduced to the field of management in the 1950s because of the negative environmental impacts of human actions [1]. In September 2015, the 2030 Agenda for Sustainable Development by the UN endorsed 17 universal and transformative SDGs [2]. These 17 goals address economic, social, and environmental aspects of sustainable development. People, Planet, Peace, Prosperity, and Partnership (5Ps) form the pillars of the SDGs, with a shared vision to build a peaceful and healthy

world [2, 3]. In 2020, the UN launched the Decade of Action plan, calling for the direct involvement of people, individually and collectively, to ascertain meeting the SDGs by 2030 [4].

Nurses carry a pivotal role in the sustainability movement of the healthcare industry. The statement by McMillan "the profession of nursing claims no geographical boundaries, working in diverse areas of health care. These range from outpost and global nursing to areas in policy development. Such diverse job profiles position nursing at the heart of the sustainability movement in health care" [[5], p.757]

underlines the importance of nurses' roles and responsibilities in achieving sustainability. Additionally, the International Council of Nurses (ICN) has cited practical case examples from different countries to endorse the importance of nurses' contributions to the 17 SDGs [6]. Nurses, on a daily basis, contribute to some, if not most, of the 17 SDGs even though they might not be cognizant of their contributions. Their routine professional responsibilities are part and parcel of the activities that can achieve the goals of sustainable development [6, 7].

The concept of social capital can be traced back to the early 20th century [8]. Workplace social capital, a concept under the umbrella term of social capital, explains the interactive relational networks in a workplace; it is the tenet of a healthy work environment that can protect employees' mental and psychological well-being and ensure their efficiency and effectiveness in delivering their professional responsibilities [9–11]. Workplace social capital has become more prominent in the healthcare industry because of the complexities of the delivery of healthcare services and therefore the interdependencies of healthcare professionals [12–14].

The concept of nurses' workplace social capital has been defined as *"a relational network configured by respectful interactions among nursing professionals and between the other healthcare professionals. These interactions are characterized by the norms of trust, reciprocity, shared understanding, and social cohesion"* [[14], p. 252]. Nurses' workplace social capital is a useful professional resource because it is a segue to a spectrum of positive outcomes for the healthcare industry, people, and the environment [13–15]. For example, nurses' workplace social capital has been attributed to safety and quality in the delivery of healthcare services, e.g., reduction of unnecessary duplication of services and/or medication errors or other interventions [16].

Does nurses' workplace social capital contribute to the SDGs of the UN? Despite the implicit evidence in practical cases [6], no research has been conducted to evaluate the association between these two pivotal concepts. Whitemore and Knafl [17] suggest that the approach of an integrative review allows bridging and connecting knowledge in providing a comprehensive and collective picture of a specific scientific phenomenon. In this integrative review, we attempt to demonstrate the association between nurses' workplace social capital and different domains of the SDGs based on empirical evidence. The results of our work should set the foundation for understanding the connection between nurses' workplace social capital and the SDGs; more importantly, our findings should shed further light on the critical roles of nurses in meeting the 2020 Decade of Action plan by the UN through their daily work responsibilities.

2. Methods

2.1. Study Design. We applied the integrative review approach of Whitemore and Knafl [17] to conduct our study. Five stages such as *Problem Identification, Literature Search, Data Evaluation, Data Analysis, and Presentation of the Findings* were implemented [17, 18].

2.2. Problem Identification. We reviewed the literature on social capital and sustainability to identify gaps in addressing the association between nurses' workplace social capital and the SDGs.

2.3. Literature Search Stage. Seven databases, Medline, CINAHL, Web of Science, Cochrane Library, Embase, PsycINFO, and Scopus, with no restriction on publication year, were searched to identify potential resources. In the initial stage of our search, we used the terms "social capital," "sustainable development," "sustainability," "nurses," and "nursing" with proper combination by the Boolean operators. Due to the limited number of identified publications, it became necessary to broaden the scope of our search; therefore, we used the terms "social capital," "nurses," "nurse," and "nursing" to identify the potential resources. The details of our search can be found in Supplementary Table 1. The final systematic search was completed on May 31st, 2023. Additionally, we reviewed references of the selected papers to identify additional resources.

2.3.1. Inclusion and Exclusion Criteria. We set three inclusion criteria: (1) empirical research papers that had assessed the direct or indirect association between nurses' workplace social capital and the SDGs; (2) English language publications; and (3) published in peer-reviewed journals. We did not discriminate on the method of empirical research, qualitative, quantitative, and mixed methods. We excluded empirical studies addressing patients' social capital, nursing students' social capital, and social capital among the other professionals. Furthermore, we eliminated studies that addressed social capital in circumstances other than the workplace; finally, we excluded studies of nurses' workplace social capital in which outcomes were not explicitly discussed.

2.3.2. Search Outcomes. An adapted PRISMA flow diagram was used to present the process and outcome of article selection [19] (Figure 1). Initially, a total of 2,188 potentially eligible records were identified from the selected seven databases. After removing duplicates using the EndNote software package, a total of 1,141 articles remained. The titles and abstracts of the remaining articles were then screened and a total of 176 articles remained for the full-text review. Of these, 150 articles were excluded for different reasons (Figure 1). Additionally, we reviewed references of the selected articles and retrieved three full-text papers. A total of 29 articles were included for the next stage, data evaluation. Two of the authors (QCG and YXL) conducted the literature search, while the screening process for meeting the inclusion criteria was performed by a third author (JMX). The result was confirmed by the team.

2.4. Data Evaluation Stage. We used the Mixed Methods Appraisal Tool (MMAT) to evaluate quality of the selected studies [20]. We justified the application of this tool because it is a comprehensive and a critical appraisal tool that can be

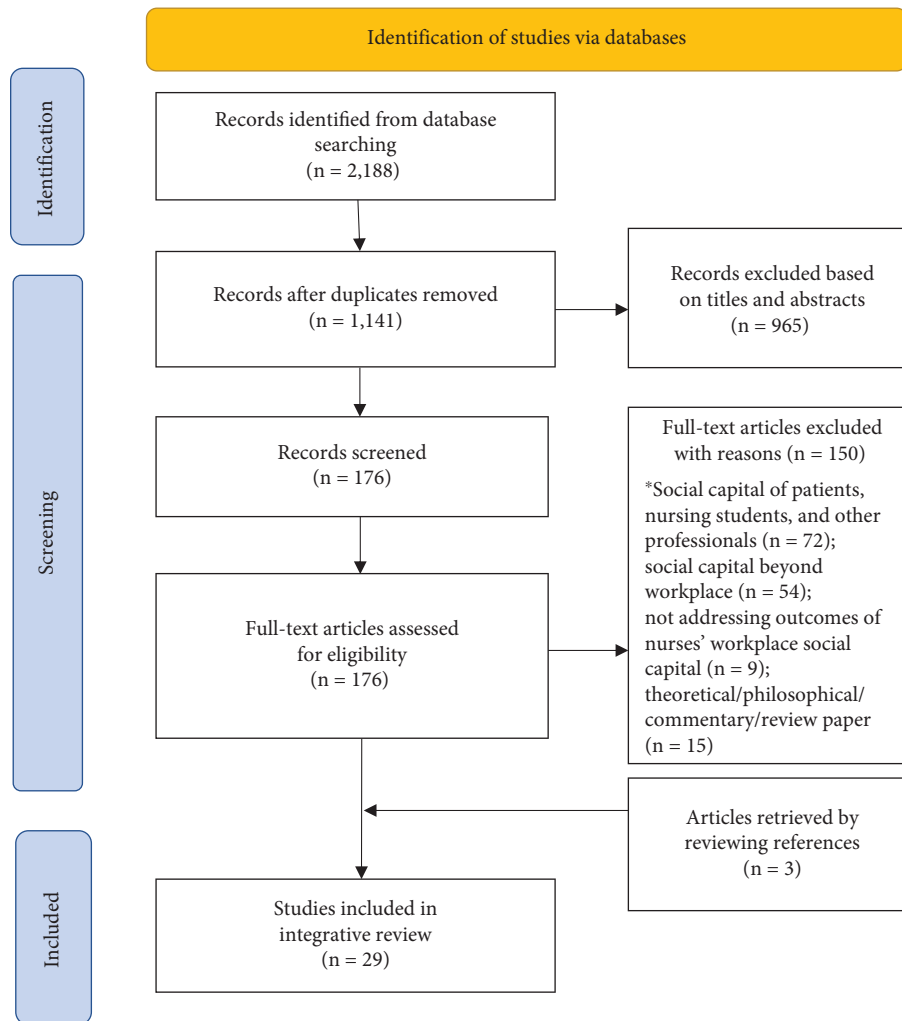

FIGURE 1: PRISMA flowchart for article selection.

used for different types of research including qualitative, quantitative, and mixed-methods studies (including instrument development and test) [20]. Initially, two of the authors (JMX and MGC) worked independently to critically evaluate the quality of the selected papers; disagreements were addressed by team discussions and by achieving a unanimous agreement among the authors. The details of the data appraisal are presented in Supplementary Table 2. No study was excluded in this process because the main purpose of our review was to integrate all empirical evidence of the contributions of nurses' workplace social capital to sustainable development. All the 29 identified articles were included in the next stage, data analysis.

2.5. Data Analysis Stage. The goal of data analysis in an integrative review is to summarize the data systematically and unbiasedly. The objective is to develop an innovative approach to synthesize data for the next stage which is the comprehensive presentation. The method of data analysis that we applied included data reduction, data display, data comparison, and drawing the conclusion and verification [17]. We developed a template to extract and display the

characteristics of the selected studies; the variables that we included in categorizing the data were reference, study design, sample size, main findings, and instruments (Table 1). First, we coded the data and then grouped them under the appropriate variables. Under the variable of "main findings," we classified the statistically significant outcomes of nurses' workplace social capital into themes (Figure 2). For example, the two reported outcomes "quality of care" and "patient safety" were clustered under the theme of "healthcare services management." Finally, we applied the technique of repeated comparisons and discussions to link outcomes under each theme to the 17 SDGs (Table 2). Two of the authors (JMX and MGC) prepared the initial data extraction and data categorization which were then confirmed and improved by all team members.

3. Results

3.1. Study Characteristics. The characteristics of the 29 selected studies are presented chronologically by the year of publication (Table 1). A broad spectrum of sample size, ranging from 8 to 1,201, was identified among these studies.

TABLE 1: Study characteristics.

Reference	Design	Sample size	Main findings (statistically significant outcomes of nurses' workplace social capital)	Instruments for the main findings
Kida et al. (2023) [21] (Japan)	Cross-sectional survey	659	Workplace social capital had direct effects on affective organizational commitment ($\beta = 0.302$, $p < 0.001$) and normative organizational commitment ($\beta = 0.231$, $p < 0.001$) Social capital (networks and networking) was a factor for positive retention intentions	Bonding Workplace Social Capital Scale; Organizational Commitment Scale in the Human Resource Management checklist
Fisher et al. (2022) [22] (UK)	Qualitative description	8	Workplace social capital was positively correlated with moral courage ($r = 0.29$, $p < 0.01$) and happiness ($r = 0.32$, $p < 0.01$) during the COVID-19 pandemic; social capital was a positive predictor of moral courage and happiness ($p < 0.001$) Social capital had a direct relationship with second victim severity ($\beta = -0.801$, $p < 0.001$) and psychological capital ($\beta = 0.778$, $p < 0.001$)	N/A
Pirdelkhosh et al. (2022) [23] (Iran)	Cross-sectional survey	169	Workplace social capital positively predicted professional identity during the COVID-19 outbreak ($\beta = 1.26$, $p < 0.001$) Increased social capital led to increased perception of quality of care ($\beta = 0.324$, $p < 0.05$) and personal accomplishment ($\beta = 0.269$, $p < 0.05$), and decreased emotional exhaustion ($\beta = -0.303$, $p < 0.05$) and depersonalization ($\beta = -0.186$, $p < 0.05$)	Onyx and Bullen Social Capital Questionnaire; Moral Courage Questionnaire; Oxford Happiness Inventory
Terri Hinkley (2022) [24] (USA)	Cross-sectional survey	999	As the social capital score increased, the job satisfaction score increased ($r = 0.313$, $p = 0.002$) Social capital in the form of social support is a major preventative strategy for workplace occupational injuries and accidents	Social Capital of Nursing (SCON); Second Victim Experience and Support Tool (SVEST); Psychological Capital Questionnaire (PCQ)
Zhang et al. (2021) [25] (mainland China)	Cross-sectional survey	308	Workplace social capital was positively related to work engagement ($r = 0.36$, $p = 0.01$) and negatively associated with turnover intention ($r = -0.40$, $p = 0.01$)	Chinese Workplace Social Capital Scale (eight-item measure); Chinese Nurse's Professional Identity Scale
Gensimore et al. (2020) [26] (USA)	Cross-sectional survey	507		A modified Social Capital Scale; the item measuring perception of unit quality (quality of care); Maslach Burnout Inventory
Gholami Motlagh et al. (2020) [27] (Iran)	Cross-sectional survey	99		Nahapiet and Ghoshal Social Capital Questionnaire; Minnesota Satisfaction Questionnaire (MSQ)
Hafeez et al. (2020) [28] (Pakistan)	Qualitative description	20		N/A
Norikoshi et al. (2020) [29] (Japan)	Mixed methods (instrument development and test)	Interviewed 32 nurses for item generation; 414 in the quantitative test stage		Relational Workplace Social Capital Scale for Japanese Nurses (RWSCS-JN); Japanese Short Version of the Utrecht Work Engagement Scale; Turnover Intention Scale

TABLE 1: Continued.

Reference	Design	Sample size	Main findings (statistically significant outcomes of nurses' workplace social capital)	Instruments for the main findings
Chang et al. (2019) [30] (Taiwan)	Cross-sectional survey	524	Social capital was positively related to normative professional commitment ($\beta = 0.34$, $p = 0.001$)	Modified Contextual Barriers and Supports Measure (Social Capital Subscale); items from Occupational Commitment Scale
Chang et al. (2019) [31] (Taiwan)	Cross-sectional survey	502	Social capital was positively related to intention to improve professional capabilities (path coefficient = 0.21, $p < 0.05$)	Modified Contextual Barriers and Supports Measure (Social Capital Subscale); Choice Goal Subscale)
Pham et al. (2019) [32] (Taiwan)	Cross-sectional survey	166	Mentor-mentee rapport (social capital relationships) was positively related to mentors' willingness to mentor ($\beta = 0.85$, $p < 0.001$) and mentees' willingness to be mentored ($\beta = 0.75$, $p < 0.001$)	Adapted items measuring rapport and willingness to mentor/be mentored
Jafari et al. (2018) [33] (Iran)	Cross-sectional survey	215	Social capital was positively related to clinical risk management ($r = 0.142$, $p = 0.040$)	Self-developed Social Capital Questionnaire; Risk Management Questionnaire
Middleton et al. (2018) [34] (Cyprus)	Cross-sectional survey	362	Increased odds of mental distress ($OR = 2.16$; 95% CI = 1.05, 4.42) and decreased self-rated health (mean difference = 8.4; 95% CI = 2.8, 14.0) were observed among nurses with the lowest level of workplace social capital	Eight-item Measure of Workplace Social Capital; General Health Questionnaire (GHQ-12); 0–100 Visual Analogue Scale (VAS) on self-rated health
Vagharseyyedin et al. (2018) [35] (Iran)	Cross-sectional survey	250	Workplace social capital could predict affective organizational commitment ($B = 0.2$, $p < 0.05$)	Eight-item Measure of Workplace Social Capital; Allen and Meyer's Affective Commitment Scale (ACS)
Shin and Lee (2017) [36] (South Korea)	Cross-sectional survey	432	Social capital was a predictor of evidence-based practice (EBP) adoption ($F = 4.393$ – 55.003 ; $p = 0.001$ or < 0.001 for different dimensions)	Social Capital of Nursing (SCON); Developing Evidence-Based Practice Questionnaire (DEBPQ)
Van Bogaert et al. (2017) [37] (Belgium)	Mixed methods (explanatory sequential)	751 in the quantitative survey part; 19 in the qualitative stage	Social capital inversely impacted feelings of emotional exhaustion (path coefficient = -0.18 , $p < 0.05$) and positively impacted feelings of vigor (path coefficient = 0.23 , $p < 0.05$); associations were supported by qualitative findings	Social Capital in Organizations; Maslach Burnout Inventory; Utrecht Work Engagement Scale
Shin and Lee (2016) [38] (South Korea)	Cross-sectional survey	432	Social capital was a positive predictor of job satisfaction ($R^2 = 0.501$, $p < 0.001$) and quality of care ($R^2 = 0.244$, $p < 0.001$)	Social Capital of Nursing (SCON); three questions developed by Sheingold and Sheingold on job satisfaction; Service Quality (SERVQUAL)

TABLE 1: Continued.

Reference	Design	Sample size	Main findings (statistically significant outcomes of nurses' workplace social capital)	Instruments for the main findings
Farahbod et al. (2015) [39] (Iran)	Cross-sectional survey	214	There was an inverse association between social capital and burnout ($r = -0.451$, $p < 0.0001$); social capital could predict burnout ($\beta = -0.34$)	Social Capital Questionnaire devised by Boyas and colleagues; Maslach Burnout Inventory
Read and Laschinger (2015) [40] (Canada)	Longitudinal survey	191	Relational social capital had a negative direct effect on mental health symptoms ($\beta = -0.21$, $p < 0.05$) and a positive direct effect on job satisfaction ($\beta = 0.50$, $p < 0.05$)	Community Subscale of Areas of Worklife Scale (AWS); Mental Health Inventory (MHI-5); items from Shaver and Lacey's scale on job satisfaction
Laschinger et al. (2014) [41] (Canada)	Cross-sectional survey	525	Social capital had direct effects on unit effectiveness ($\beta = 0.29$, $p < 0.05$) and quality of care ($\beta = 0.21$, $p < 0.05$)	Items from Shortell Organizational Culture Scale (social capital and unit effectiveness); a single item developed in the Magnet hospital studies (quality of care)
Van Bogaert et al. (2014) [16] (Belgium)	Cross-sectional survey	1,108	Social capital was related to job satisfaction (OR = 2.19; 95% CI = 1.39, 3.45), (no) intention to leave (OR = 2.07, 95% CI = 1.36, 3.16), quality of care (OR = 1.3, 1.8, 95% CI = 7.85, 22.92), and medication errors (OR = 0.61, 95% CI = 0.43, 0.86)	Social Capital in Organizations; self-developed measures on job outcome (job satisfaction and intention to leave), quality of care, and adverse patient events (medication errors)
Van Bogaert et al. (2014) [42] (Belgium)	Cross-sectional survey	1,201	Social capital had a statistically significant effect on vigor in the improved structural equation model (path coefficient = 0.24)	Social Capital in Organizations; Utrecht Work Engagement Scale
Sheingold and Sheingold (2013) [43] (USA)	Mixed methods (instrument development and test)	Focus groups with 80 nurses for item generation; 325 in the quantitative test stage	Social capital had positive impacts on job satisfaction ($R^2 = 0.557$, $p = 0.000$) and intention to stay ($R^2 = 0.345$, $p = 0.000$) A direct path was accepted between social capital and emotional exhaustion in the improved structural equation model (path coefficient = -0.16 , $p < 0.05$)	Social Capital of Nursing (SCON); self-developed measures on job satisfaction and intention to stay
Van Bogaert et al. (2013) [44] (Belgium)	Cross-sectional survey	1,201	Trust ($\beta = 0.220$, $p < 0.01$) and shared vision ($\beta = 0.184$, $p < 0.05$) of social capital directly affected knowledge sharing; shared vision had a significant effect on patient safety ($\beta = 0.195$, $p < 0.05$)	Social Capital in Organizations; Maslach Burnout Inventory
Chang et al. (2012) [45] (Taiwan)	Cross-sectional survey	797	Social capital (social interaction ($\beta = 0.13$, $p < 0.05$), trust ($\beta = 0.27$, $p < 0.01$), and shared vision ($\beta = 0.34$, $p < 0.001$)) positively impacted organizational commitment	Items from three valid scales (social capital); items adapted from van den Hooff and van Weenen on knowledge sharing; indicators proposed by JCAHO on patient safety
Hsu et al. (2011) [46] (Taiwan)	Cross-sectional survey	797		Measures adapted from several valid instruments

TABLE 1: Continued.

Reference	Design	Sample size	Main findings (statistically significant outcomes of nurses' workplace social capital)	Instruments for the main findings
Kowalski et al. (2010) [47] (Germany)	Cross-sectional survey	959	Social capital was negatively associated with emotional exhaustion (OR = 0.549, 95% CI = 0.403, 0.746)	Social Capital in Organizations; Maslach Burnout Inventory
Ernstmann et al. (2009) [48] (Germany)	Cross-sectional survey	959	Higher social capital was associated with better clinical risk management behavior in the hospital (intercorrelation coefficient = 0.472, $p = 0.01$)	Social Capital in Organizations; Risk Management Questionnaire

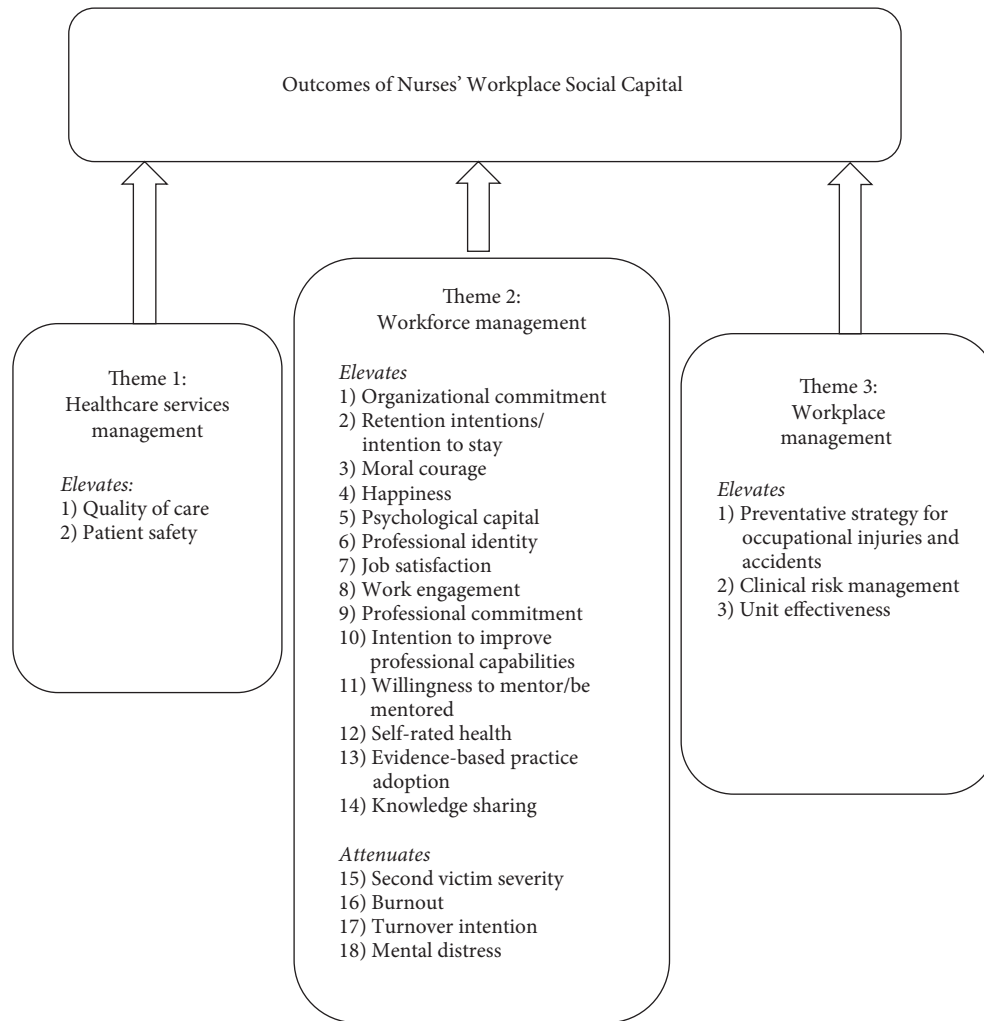

FIGURE 2: Emergence of three themes: healthcare services management, workforce management, and workplace management. Twenty-three statistically significant outcomes of nurses' workplace social capital reported by the 29 studies were grouped into three themes according to their characteristics and contributions.

Ernstmann and colleagues were the first to empirically assess the association between nurses' workplace social capital and clinical risk management in hospitals [48]. Subsequently, a total of 28 other studies were implemented in different settings to assess the empirical association between nurses' workplace social capital and various positive outcomes in healthcare settings [16, 21–47].

Of the 29 selected studies, 24 were quantitative, two were qualitative, and the designs of the remaining three were mixed methods. The majority of the quantitative studies ($n = 23$) had a cross-sectional survey design. Only one study was designed as a longitudinal survey in which the investigators followed up newly employed nurses for one year to assess the impact of social capital on their job satisfaction and their mental health [40].

One of the two qualitative studies aimed to assess the value of nurses' workplace social capital in preventing occupational injuries and accidents in hospital settings [28]; while the second study was conducted among nurses who participated in management initiative training by the English National Health Service Trust [22]. Findings from the

study asserted the positive influence of social capital networks and networking on nurses' retention intentions [22]. Finally, the result of our literature search yielded three mixed-methods studies. One was conducted among nurses in two university hospitals; the investigators explored the associations among several work-related variables and reported that emotional exhaustion, one dimension of burnout, was considerably reduced because of the workplace social capital; meanwhile, vigor, one dimension of work engagement, was increased [37]. The other two studies were implemented with the objective of developing and testing instruments to assess nurses' workplace social capital in different work environments with different workplace cultural norms and values [29, 43].

3.2. Outcomes of Nurses' Workplace Social Capital. We identified a total of 23 outcomes of nurses' workplace social capital. These outcomes were compared and inductively synthesized into three themes (Figure 2): healthcare services management (Theme 1), workforce management (Theme 2),

TABLE 2: Influence of nurses' workplace social capital on the sustainable development goals (SDGs).

Outcomes of nurses' workplace social capital	Number of outcomes	Themes	Main influence on the SDGs
Quality of care [16, 26, 38, 41] Patient safety [16, 45] Happiness [23] Self-rated health [34]	2	Theme 1	SDG 3: good health and well-being
Mental distress* [34, 40] Second victim severity* [24] Burnout* [26, 37, 39, 44, 47]	5	Theme 2	
Preventative strategy for occupational injuries and accidents [28] Clinical risk management [33, 48] Unit effectiveness [41]	3	Theme 3	
Organizational commitment [21, 35, 46] Professional commitment [30] Retention intentions/intention to stay [16, 22, 43] Turnover intention* [29] Moral courage [23] Psychological capital [24] Professional identity [25]	11	Theme 2	SDG 8: decent work and economic growth
Job satisfaction [16, 27, 38, 40, 43] Work engagement [29, 37, 42] Intention to improve professional capabilities [31] Evidence-based practice adoption [36] Willingness to mentor/be mentored [32]	2	Theme 2	SDG17: partnerships for the goals
Knowledge sharing [45] Total	23		

Note: Theme 1: healthcare services management; Theme 2: workforce management; Theme 3: workplace management. *Nurses' workplace social capital attenuates the level of mental distress, second victim severity, burnout, and turnover intention.

and workplace management (Theme 3). Of the 23 identified outcomes, 18 were grouped under the theme of workforce management. We grouped quality of care and patient safety under the theme of healthcare services management. Finally, the theme of workplace management was summarized based on the three following outcomes: a preventative strategy for occupational injuries and accidents, clinical risk management, and unit effectiveness. It is notable that all the 23 outcomes were positive as reported in the selected empirical studies.

3.3. Nurses' Workplace Social Capital and the SDGs. Of all the 29 studies that were reviewed by the authors, none had directly assessed and described the association between nurses' workplace social capital and the SDGs. However, the implicit influence of nurses' workplace social capital on the SDGs was reported and discussed in these 29 studies. The implicit influence of nurses' workplace social capital was mostly reverberated on SDGs 3, 8, and 17 based on connections between its outcomes and SDGs (Table 2).

3.3.1. Influence on Good Health and Well-Being (SDG 3). Nurses are the critical contributors to attainment of SDG 3 [49, 50]. Quality of care and patient safety, which are the outcomes of nurses' workplace social capital (Theme 1) [16, 26, 38, 41, 45], are tightly linked to patients' good health and well-being. For instance, Van Bogaert et al. [16] reported that nurses' workplace social capital improves patients' safety through reduction in medication errors and improves the overall quality of care delivered to patients.

The five outcomes that are clustered under workforce management (Theme 2) demonstrate the influence of workplace social capital on health status of nurses, who are the backbone of provision of healthcare services. According to the findings by Middleton et al. [34], nurses with perception of low level of workplace social capital are at a higher risk for mental distress and compromised health status. The direct protective effect of workplace social capital on nurses' mental health was also reported by Read and Laschinger [40].

Burnout is a complex syndrome with multiple signs and symptoms. Improvement of nurses' workplace social capital is associated with feelings of increased personal accomplishment and decreased emotional exhaustion and depersonalization [26, 37, 39, 44, 47]. Diminished personal accomplishment, emotional exhaustion, and depersonalization have been cited as the core elements of burnout and the main cause of psychological and physical distress among nurses [26, 37, 39, 44, 47].

Self-perception of happiness is an important element for an individual's health and well-being. Pirdelkhosh et al. [23] reported that workplace social capital can be a positive facilitator of nurses' happiness in hospital settings during the stressful period such as COVID-19. The importance of strengthening nurses' workplace social capital in mitigating the possibilities of experiencing the second victimization, in case of an unanticipated adverse patient event, also has been documented [24].

Finally, the three outcomes of nurses' workplace social capital, a preventative strategy for occupational injuries and

accidents at work, clinical risk management, and unit effectiveness, are classified under the theme of workplace management (Theme 3). These three outcomes are also in a close association with SDG 3 (good health and well-being). Social capital, in the form of social support, is instrumental in prevention of occupational injuries and accidents among nurses [28]. Nurses who possess a higher workplace social capital, in general, are more effective and perform more efficiently in managing clinical risk behaviors [33, 48]. Furthermore, unit work effectiveness in hospitals as perceived by nurses is also tightly linked to the positive effects of workplace social capital [41]. These outcomes of nurses' workplace social capital contribute to developing, implementing, and sustaining policies and procedures for a safe and constructive healthcare environment for patients and professionals. A constructive healthcare environment improves the overall health and permits good health and well-being for all (SDG 3).

3.3.2. Influence on Decent Work and Economic Growth (SDG 8). A total of 11 outcomes of nurses' workplace social capital under the theme of workforce management (Theme 2) are closely related to SDG 8 (Table 2). Investments in healthcare employment and the healthcare industry can improve economic productivity and economic growth [51]. Nurses are the backbone of delivery of healthcare services and the largest workforce in the healthcare industry. Unfortunately, in recent years the nursing profession has been grappling with the exodus of nurses from the field [52]. We identified a range of outcomes of nurses' workplace social capital (Theme 2) as the contributing factors in reducing, if not preventing, exodus and/or high turnover of nurses. Sheingold and Sheingold [43] and Van Bogaert et al. [16] reported that workplace social capital could increase nurses' intention to stay (no intention to leave). Fisher et al. [22] reported that social capital networks and networking at the workplace are positive factors that can influence nurses' retention intentions. Also, Norikoshi et al. [29] reported the protective effect of nurses' workplace social capital in ameliorating turnover intention. Job satisfaction is an important variable that can influence turnover and possibly could prevent the exodus of nurses from the field. Nurses' workplace social capital has been reported as a positive influencer of job satisfaction in several studies [16, 27, 38, 40, 43].

Other factors such as personal values and beliefs of the workforce can also influence the perception of work dignity and decent work. For example, personal commitment to the profession and organization of nursing, psychological capital, work engagement, willingness to adopt evidence-based nursing practice, and intention to improve self-professional capabilities (Theme 2) are important influencers of perception about work dignity and decent work at personal level [21, 24, 29–31, 35–37, 42, 46]. The value of workplace social capital is particularly noticed during crises such as the COVID-19 pandemic. Nurses who had a positive perception about their workplace social capital were able to demonstrate stronger moral courage and professional identity [23, 25].

3.3.3. Influence on Partnerships for the Goals (SDG 17). This goal emphasizes developing innovative strategies for collaboration and cooperation at every level of work settings. Partnership is one of the core pillars of sustainable development and should be initiated at the base of this pillar which is the workplace. We identified two outcomes of nurses' workplace social capital (Theme 2) that are closely related to SDG 17. Trust is the fulcrum for an effective partnership and the tenet of nurses' workplace social capital. Chang et al. [45] documented that nurses who have stronger trust in their workplace are more likely to share their knowledge and tangible and intangible resources with each other. Nurses' workplace social capital also influences effectiveness in dissemination of information and cooperative learning. Pham et al. [32] reported that willingness to mentor and to be mentored increases with constructive workplace social capital network. Nurses' workplace social capital can be perceived as a factor influencing partnerships for the goals (SDG 17).

4. Discussion

Nurses by virtue of their professional responsibilities have positive influence in achieving the SDGs of the UN. The precursors to the SDGs can be traced back to Florence Nightingale's remarkable contributions to global health more than a century ago [53]. Nevertheless, nurses may either underestimate and/or misconstrue the strength of their professional power in contributing to the SDGs [7, 49]. Professionally tailored discussions and education are essential in awakening and empowering nurses to assume responsibilities either at the individual level or collectively in the global movement for sustainable development [49, 54, 55].

We conducted this integrative review based on empirical research evidence to address the association between nurses' workplace social capital and the SDGs. We identified 23 outcomes of nurses' workplace social capital which we classified under three themes and have demonstrated their connections and contributions to the goals 3, 8, and 17 of sustainable development (Figure 2 and Table 2).

The core objective of the nursing profession is to promote health for all people, including nurses themselves, at every age and in any setting [6]. Workplace social capital promotes constructive and respectful relational networks between nurses and the other healthcare professionals [11, 15, 56]. These positive interactions reduce the risks of errors in the delivery of healthcare services, improve the practice of shared decision-making in diagnostic and treatment process, and improve the overall quality of care. Furthermore, respectful and trustworthy interactions among nurses and with the other healthcare professionals improve efficiency and effectiveness of the delivery of healthcare services and facilitate constructive clinical management. Ultimately, patients and healthcare providers can benefit from a safer healthcare environment, healthy lives, and overall well-being which are the main objectives of SDG 3 [4].

The high rate of nursing turnover and nursing shortage is a global issue that can have severe economic consequences [57]. For example, the annual economic loss of one percentage increase in nursing turnover rate has been estimated at an average of additional \$380,600 per annum for a hospital [58]. In a recent publication, Gilbert discussed the importance of nursing workplace social capital in closing the gap of nursing shortage [12]. Nurses' workplace social capital promotes a supportive and trustworthy work environment which promotes dignity and stability of the workforce and therefore contributes to SDG 8 (decent work and economic growth).

Since the time of Florence Nightingale, nurses have been acting as catalysts in diplomatic, political, and combat arenas, although mostly in marginal positions, to strengthen constructive international partnerships and to reduce human suffering [59]. Establishment of partnerships and cooperation at all levels, SDG 17, is based on mutual trust and leadership. Strengthening nurses' confidence in assuming leadership positions at the national and international levels requires involvement in policy decision-making processes [6, 49]. We argue that nurses' workplace social capital can assist with strengthening of nurses' confidence in seeking leadership positions and diplomatic decision-making processes. However, findings from our present study lack adequate data to support our statement. Future research should shed light on the potential positive effects of nurses' workplace social capital on nurses' confidence in assuming leadership spots and international diplomatic relationship positions.

Finally, we believe nurses' workplace social capital contributes to gender equality (SDG 5). Despite our extensive search, we were not able to identify empirical evidence to support the association between nurses' workplace social capital and gender equality. Nurses despite their long history and contributions to patient care and clinical services, in general, are perceived and treated as "second-class citizens" in the healthcare industry [60, 61]. Women make up 70% of the healthcare professionals across the globe. Yet, they occupy only 25% of all leadership positions. Furthermore, they are paid less than their male counterparts holding similar positions [62]. Meanwhile, gender equality extends beyond women's suffrage and equal pay at work. Nursing historically has been a female-dominant profession; however, since the turn of 21st century more men have been opting to enter this field, despite the implicit cultural stigma [63]. We set forth that the attribute of social cohesion of the nurses' workplace social capital can be a conduit for gender equality. Social cohesion is defined as a resource for generating group unity in nourishing a sense of community among people with diverse backgrounds [14]. We voice that the concept of diverse backgrounds does not preclude gender identity. To our knowledge, presently no research has been published to address the association between nurses' workplace social capital and gender diversity in the nursing profession.

4.1. Limitations. Some limitations exist in our integrative review. First, we focused on empirical evidence published in peer-reviewed journals that might not be able to fully demonstrate the contribution of nurses' workplace social capital to the SDGs. Theoretical evidence and other potential resources (e.g., book chapters and grey literature) should be considered in future work. Second, most of the quantitative studies in the literature were conducted with a cross-sectional design. Studies with more robust designs, e.g., longitudinal or interventional, would be beneficial to strengthen our findings. Qualitative studies exploring the benefits of nurses' workplace social capital should be encouraged as we were able to identify only two qualitative studies. Moreover, studies directly addressing the relationships between nurses' workplace social capital and sustainability are suggested. Finally, we only searched articles published in the English language. Evidence published in other languages potentially was missed. Despite these limitations, our integrative review is the first to address the contributions of nurses' workplace social capital to the 17 SDGs of the UN in response to calls for contextualizing and promoting sustainable development. Findings of our integrative review innovatively raise a picture of and clarify dedications of the nurses to a sustainable, peaceful, and healthy world.

5. Conclusion

We have conducted an integrative review following the methodology by Whitemore and Knafel [17]. A range of outcomes of nurses' workplace social capital were identified from the empirical evidence and three themes were abstracted. Findings of our review shed light on the significant role of nurses' workplace social capital in attaining three of the SDGs, good health and well-being (SDG 3), decent work and economic growth (SDG 8), and partnerships for the goals (SDG 17). Empirical evidence on the other SDGs, e.g., gender equality (SDG 5), should be explored in future studies. Nurses' depth of knowledge and appreciation of their contributions to the SDGs should be encouraged and facilitated. Our work is the first step in connecting and integrating nurses' workplace social capital to the SDGs in academic context and curriculum. This effort helps nurses to understand their roles and responsibilities in sustainable development in their daily work and is beneficial to the development of nurses' workplace social capital.

6. Implication for Nursing Management

Nurses' workplace social capital has become an important concept in the academic domain of nursing management due to its favorable outcomes related to healthcare provisions, workforce, and healthcare organizations. We have made efforts to connect these outcomes to the SDGs. The campaign of sustainable development has offered nurses opportunities to raise their voice at the policy tables; nurses

are considered the backbone of healthcare services which is connected to every and all the 17 SDGs. Concrete plans and methodologies that tailor these broad goals to nursing daily work and nursing management are paramount of importance in elevating the role and responsibilities of the nursing professionals. Our work promotes and accelerates this crucial process from a management perspective of nurses' workplace social capital. Education is crucial for integrating nurses into active engagement with the SDGs [49, 50]. The relatively high prevalence of disconnection between the role and responsibilities of nurses and the SDGs among nurses calls for constructive educational interventions. Our findings can be used as educational and management resources in clinical and curricula formulation in academic nursing. Importantly, investments and research on nurses' workplace social capital can be greatly strengthened by connecting and revealing its contributions to the UN universal goals of sustainable development.

Data Availability

Aim. The objective of this study is to provide a comprehensive analysis and synthesis of pertinent research on the subject of nursing professionalism. **Background.** The number of studies documenting nursing professionalism has been consistently increasing over the years; however, a comprehensive synthesis and analysis of the evidence presented in these reports is currently lacking. **Evaluation.** The scope reviews were conducted using electronic databases including PubMed, Web of Science, Cochrane Library, Embase, Chinese National Knowledge Infrastructure (CNKI), Chinese Science and Technology Periodical Database (VIP), and Wanfang database. **Key Issues.** This review included 15 studies and identified 4 significant pertinent issues: (1) the need for further investigation into the implementation level of nursing professionalism; (2) the development of culturally sensitive instruments to assess nursing professionalism; (3) an in-depth exploration of the associated factors influencing nursing professionalism; and (4) the critical implementation of diverse intervention strategies to enhance nursing professionalism. **Conclusions.** This review presents a comprehensive overview of the implementation level, assessment tools, influential factors, and intervention strategies in nursing professionalism research. In addition, it emphasizes the future research direction in this field. **Implications for Nursing Management.** Nursing administrators need to understand the significance of improving the professional education and training of nurses, fostering a conducive work environment, and providing support for their active development of professional skills and nursing professionalism. These factors collectively contribute to the long-term professional development of nurses and enhance the quality of patient care.

1. Introduction

Nursing professionalism serves as a guiding principle for nurses, ensuring patient safety and the delivery of high-quality nursing care. It underscores the significance of societal service, deeply rooted in the essence of humanity, thereby conferring a distinct meaning to nursing professionalism. Jiang et al. [1] believed that nursing professionalism encompasses the integration of fundamental practical concepts, value orientation, professional personality, professional standards, and professional style exhibited

by nurses in their interactions with patients, which is a reflection of the nurses' attitudes and behaviors toward nursing work. Hafferty [2] concluded that professional competence, self-regulation, honor and integrity, altruism, respect, teamwork, responsibility, and continuous learning constitute the fundamental components of nursing professionalism. Miller [3] employed the prevalent professional perspectives of sociologists and nursing managers to develop the model of the wheel of professionalism in nursing based on ethical principles articulated in the American Nurses Association's (ANA) Code of Ethics for nurses policy

statement. In the context of education in a university setting and scientific background in nursing, the model defines the professional spirit from the behavioral perspective, which includes (1) continuing education and competency; (2) adherence to the code for nurses; (3) professional organization participation; (4) publication and communication; (5) self-regulation and autonomy; (6) community service orientation; (7) theory: development, use, and evaluation; and (8) research: development, use, and evaluation. The term *nursing professionalism* refers to the fundamental professional ideas, attitudes, and values that nurses demonstrate in their nursing practice [4, 5], which includes the service concept of “*patient-centered*,” the professional attitude of “*patient interests above all*,” and the values of “*promoting the physical and mental health of patients*.”

Nursing professionalism plays an important guiding role in the nursing profession. It highlights ethical principles, beliefs, and life perspectives and also represents the moral development, civilization, and spiritual attitude of nurses [6]. Nursing professionalism exerts a positive impact on elevating nursing standards, enhancing job satisfaction, promoting the sustained choice of the nursing profession, and mitigating the turnover rate among the nursing staff [7–11]. The cultivation and perpetuation of nursing professionalism are imperative for the development of exceptional nurses. The establishment of a truly exemplary nursing profession necessitates comprehensive legislation, a compassionate social environment, and most importantly, collaborative efforts from healthcare practitioners, educators, and administrators [12].

Studies on the implementation level of the nursing professionalism in clinical practice have been extensively conducted in various countries and regions. However, there is currently a dearth of empirical evidence exploring the nursing professionalism instruments in various cultural contexts, the associated influential factors, and the diversified intervention strategies. In this review, the assessment tools, influential factors, and intervention strategies of nursing professionalism were systematically evaluated based on the reporting framework for scope review proposed by Arksey and O’Malley in 2005 [13]. This comprehensive assessment aims to provide a reference for future studies.

2. Methods

2.1. Refining the Research Inquiry. To ensure the smoothness of this scoping review, the research questions were developed as follows:

- (1) What is the implementation level of nursing professionalism in clinical practice?
- (2) What assessment tools are available for the evaluation of nursing professionalism?
- (3) What are the key factors that influence nursing professionalism?
- (4) What effective interventions can be implemented to enhance nursing professionalism?

2.2. Identifying Pertinent Studies. The literature for this review was obtained by conducting comprehensive searches in seven electronic databases, including PubMed, Web of Science, Cochrane Library, Embase, CNKI, VIP, and Wanfang. These databases were searched from their inception until 13 July 2023. A combination of subject terms and free words was used to ascertain the topic of all relevant research, and the Boolean operators *OR* and *AND* were utilized to amalgamate the outcomes. The search theme was as follows: (a) *Professional spirit, Professionalism medical professionalism, Professionalism education, Occupational spirit, and Vocational spirit* and (b) *Nurses, nursing, Nursing students, Nursing personnel, Registered nurses, and Pupil nurses*. The specific strategies for retrieving data from the database can be found in Supplemental File 1.

2.3. Selecting Relevant Studies. The studies included in this review met the following criteria: (a) they were written in English or Chinese; (b) the subjects of the study were nurses or nursing students; and (c) they included the implementation level of nursing professionalism, instruments for measuring nursing professionalism, associated influential factors, or intervention strategies. Studies were excluded if (a) full text was not accessible; (b) their results had been duplicated in another article; and (c) they belonged to categories such as reviews, general comments, editorials, or case reports.

A total of 4,387 studies (Figure 1) were identified and imported into the NoteExpress software. After removing duplicates, 3,184 studies remained. These studies were further evaluated based on their titles and abstracts to determine their compliance with the inclusion and exclusion criteria. Subsequently, 3,015 studies that did not meet the inclusion criteria were excluded, and the remaining 169 full-text studies were retrieved and independently assessed by two co-first authors. Following a meticulous examination of the inclusion and exclusion criteria, 15 studies were finally included in this review.

2.4. Data Extraction. Two researchers independently extracted data using a designated data extraction form, under the close supervision of another researcher. The extracted information encompassed details such as authorship, publication year, country of origin, subjects, study design, implementation level of nursing professionalism, assessment tools, influential factors, intervention strategies, and intervention duration.

3. Results

3.1. Description of Studies. A total of 15 papers were published between 2014 and 2023. The majority of studies originated from China ($n = 8$), and the remaining papers were contributed by Japan ($n = 3$), Korea ($n = 2$), India, and Czechoslovakia ($n = 1$ each). The content of the study included the implementation level ($n = 8$), assessment tools ($n = 14$), the influential factors ($n = 12$), and the intervention strategies ($n = 3$). The study design encompassed a range of methodologies, including cross-sectional studies ($n = 9$), quasi-experimental

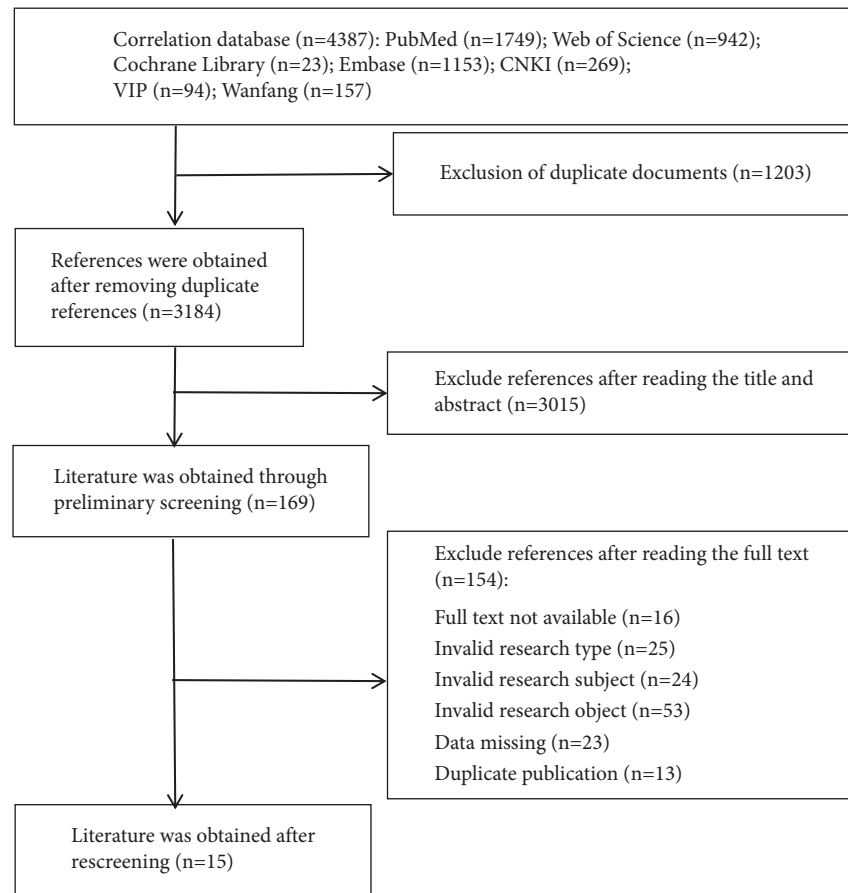

FIGURE 1: Flowchart of literature screening.

studies ($n = 1$), randomized controlled trials ($n = 2$), qualitative studies ($n = 1$), and mixed studies ($n = 2$). The subjects consisted of both nurses ($n = 10$) and nursing students ($n = 5$). Table 1 shows the details of the included studies.

3.2. Implementation Level of Nursing Professionalism Level. Among the 15 studies included, 8 papers discussed the implementation level of nursing professionalism in clinical practice in different regions. The existing research conducted in China indicates that undergraduate nursing students possess a moderate level of nursing professionalism [5, 22]. A separate study by Ma et al. [17] reveals a prevalent decline in the perception of nursing professionalism among low-income nurses. The nursing professionalism among the surveyed nurses from seven Chinese third-class A general hospital nurses was marginally lower than that of Korean-American nurses and similar to the average level in the United States [18]. Kuručová [20] conducted a survey on Czechoslovakian nurses with a moderate level of nursing professionalism, while Tanaka et al. [25] found a poor level of nursing professionalism among Japanese nurses.

3.3. Assessment Tools of Nursing Professionalism. Among the 15 publications, a total of 7 assessment tools were examined. Table 2 shows detailed information of the assessment tools of nursing professionalism. Currently, the commonly used

assessment tools have a number of limitations. The Chinese version of Hall's Professionalism Inventory (HPI) [22] exhibits robust reliability, effectiveness, and cultural sensitivity. However, stratified random sampling of various populations is still required to further corroborate the results of the confirmatory factor analysis and further refine the sampling technique used in the exploratory factor analysis of the scale. Based on a theoretical model, the Behavioral Inventory for Professionalism in Nursing (BIPN) (Miller, 1985) exhibits good reliability and validity. Nevertheless, its general applicability needs to be confirmed considering cultural variations. The Nurses' Professionalism Inventory (NPI) [24] is a reliable tool with a high degree of fit for each of its factors, while it lacks validity testing and does not adhere to any specific theoretical model during its development process, and the Korean-Nursing Profession Value (KNPV) [27] has the same problem. The self-designed questionnaire [17] has gathered concentrated expert consultation opinions on indicators at all levels. These experts possess high motivation and authority, ensuring the questionnaire's scientific rigor. However, it is imperative to further consider the completeness of index construction due to insufficient letters consulted with experts. The Nurse Professionalism Scale (NPS) (Gyung, 2022) demonstrates reliability and a rigorous design, but it suffers from a limited sample size and lacks a large multicenter survey. Despite demonstrating excellent internal consistency and stability,

TABLE 1: Characteristics of the included studies ($n = 15$).

Author (year)	Country	Subjects	Study design	Implementation level (score)	Evaluation instruments	Influencing factors	Intervention strategies (intervention duration)
Zhang et al. [5]	China	Nursing students	Cross-sectional	Medium (69.83 ± 9.01)	Hall's professionalism inventory (Chinese version)	Gender; reasons for applying; willingness and recognition of nursing; role model	— (—)
Xue et al. [14]	China	Nursing students	Randomized controlled trials	—	Hall's professionalism inventory (Chinese version)	—	Control group: diary writing; Experimental group: narrative medicine and narrative writing theory courses (12 months)
Sun et al. [15]	China	Nursing students	Randomized controlled trials	—	Hall's professionalism inventory (Chinese version)	—	Control group: conventional nursing education, including courses in nursing humanities, nursing psychology, nurse skills training and basic nurses Courses; Experimental group: an additional health communication education course on the basis of conventional care education (3 months)
Dong and Shao [16]	China	Nurses	Quasi-experimental	—	Hall's professionalism inventory (Chinese version)	—	Control group: newly enrolled nurses receive one-on-one class-based training once a week, which includes intensive instruction on hospital systems, theoretical knowledge of the operating room, and operational skills; Experimental group: standardized training in penguin culture (including a professional tutor responsible for imparting knowledge to newly enrolled nurses, a mentor responsible for cultivating the desired attitude among these nurses, a training partner responsible for skills training, and a supervisor responsible for the supervision of the curriculum development and teaching methodologies) (12 months)

TABLE 1: Continued.

Author (year)	Country	Subjects	Study design	Implementation level (score)	Evaluation instruments	Influencing factors	Intervention strategies (intervention duration)
Ma et al. [17]	China	Nurses	Cross-sectional	Low (—)	Self-designed questionnaire	Personal factors; hospital factors; social factors	— (—)
Yu et al. [18]	China	Nurses	Cross-sectional	Low (83.41 ± 8.75)	Hall's professionalism inventory (Chinese version)	Gender; whether the first choice of college entrance examination is nursing major; first education; employment form; receipt of nursing-related rewards for the last 3 years	— (—)
Gyung [19]	Korea	Nursing students	Cross-sectional	—	Nursing professionalism scale	Critical thinking; leadership	— (—)
Kurucová et al. [20]	Czechoslovakia	Nurses	Cross-sectional	Medium (136.74 ± 32.66)	Nurses' professionalism inventory	Professional ranks and titles; education background	— (—)
Pareek and Batra [21]	India	Nurses	Qualitative	—	Focus interview group	Personal factors; organizational factors; environmental factors	— (—)
Wu et al. [22]	China	Nursing students	Cross-sectional	Medium (67.76 ± 6.40)	Hall's professionalism inventory (Chinese version)	Humanitarian care Capacity; social support	— (—)
Zhao et al. [23]	China	Nurses	Mixed	—	Nurse professionalism questionnaire	Gender; professional ranks and titles; education background; work years	— (—)
Ichikaw et al. [24]	Japan	Nurses	Mixed	—	Nurses' professionalism inventory	Beliefs and attitudes on the basis of professional behavior in nurses	— (—)
Tanaka et al. [25]	Japan	Nurses	Cross-sectional	Low (6.74 ± 3.89)	Behavioral inventory for professionalism in nursing	Education background; work years; whether the current nursing manager	— (—)
Tanaka et al. [26]	Japan	Nurses	Cross-sectional	Low (9.19 ± 3.89)	Behavioral inventory for professionalism in nursing	Nursing experience; education preparation; the current position as a nurse administrator	— (—)
Kim and Park [27]	Korea	Nurses	Cross-sectional	Medium (96.64 ± 13.48)	Korean-nursing professional value	Self-efficacy; job embeddedness	— (—)

Note. — means "none."

TABLE 2: Assessment tools of nursing professionalism ($n = 7$).

Evaluation instruments	Country	Author (year)	Scoring system	Dimension number/dimension name	Number of items	Reliability and validity
Hall's professionalism inventory (Chinese version)	China	Wu [28]	Likert 5	6/participation in group organization; public service concept; professional autonomy; self-discipline; sense of professional mission; work satisfaction	25	Cronbach's α 0.750; test-retest reliability 0.840;
Behavioral inventory for professionalism in nursing	American	Miler [3]	—	9/educational preparation; autonomy; theory; code of ethics; community service; competence; publication; research; professional organizations	48	Cronbach's α 0.760;
Nurses' professionalism inventory	Japan	Ichikawa [24]	Likert 6	5/accountability; self-improvement; professional attitudes; nursing professional development; professional members	28	Cronbach's α 0.950; test-retest reliability 0.940;
Self-designed questionnaire	China	Ma [6]	—	4/professional ethics; professional awareness; professional skills; personality characteristics	40	Cronbach's α 0.778;
Nurse professionalism scale	Korea	Gyung [19]	Likert 5	5/professional self-concept; social awareness; nursing professionalism; nursing role and nursing originality	18	Cronbach's α 0.870;
Nurse professionalism questionnaire	China	Zhao [23]	Likert 5	5/unity and cooperation spirit; professional identity; professional development of independent consciousness; spirit of self-determination; dedication	19	Cronbach's α 0.737; content validity 0.859
Korean-nursing professional value	Korea	Yeun et al. [29]	Likert 5	5/professional self-concept; social recognition; nursing expertise; nursing competence; nursing autonomy	29	Cronbach's α 0.920

Note. — means not provided.

the nurse professionalism questionnaire [23] is limited in its research scope and requires careful consideration of its authority.

3.4. Influential Factors of Nursing Professionalism. Among the 15 publications, 10 articles were related to the influential factors of nursing professionalism, mainly including individual and organizational factors. Individual factors include gender, personal abilities, volunteer application, education level, and job position. In the existing studies, researchers have confirmed the effect of these influential factors on nursing professionalism. Specifically, male nurses tend to demonstrate comparatively lower levels of professionalism in comparison to their female counterparts [5, 18, 23]; the level of nursing professionalism is positively associated with critical thinking abilities, self-leadership skills, humanistic care capabilities, and self-efficacy [17, 21, 22, 27]; the level of nursing professionalism of nursing students is significantly elevated when they autonomously select the field [5, 18]; the higher level of education raises the standard for the level of nursing professionalism [5, 18, 23, 26]; in addition, nurses in higher job positions exhibit the higher level of nursing professionalism [20, 26]. Organizational factors such as rules and regulations, decision-making authority, and organizational culture also significantly affect nurses' professionalism [21].

3.5. Intervention Methods for Nursing Professionalism. Intervention studies on nursing professionalism were conducted in 3 out of the 13 articles [14–16]. Intervention methods mainly include narrative medicine education [14], health communication courses [15], and penguin style training [16]. Xue et al. [14] cultivated students' narrative ability through storytelling, careful reading, reflective writing, sharing, and discussions, and confirmed that narrative medicine can enhance students' nursing professionalism after a 12-month intervention study. In addition, the study reaffirmed the significance of empathy and humanistic care. Social media play a pivotal role in health communication courses, and Sun et al. [15] instructed nursing students on the effective utilization of social media platforms while monitoring their progress in developing social media competencies. After a 3-month intervention study, the social media capabilities of nursing students were significantly improved after receiving health communication education, and the utilization of social media platforms exerted a positive impact on the professionalism of nursing students. Dong and Shao [16] proposed the penguin style cultivation method for nursing professionalism. Specifically, a penguin style cultivation teaching group was first established, including nursing professional tutors, mental mentors, supervision tutors, and training partners, and then the penguin style training method was employed. The knowledge training of nurses was entrusted to professional tutors, while the attitude training was overseen by mental tutors. Skill training of nurses was facilitated by training partners, and supervision tutors were assigned the responsibility of overseeing teaching plans and methods,

ultimately leading to a significant enhancement in nurses' professionalism.

4. Discussion

The importance of nursing professionalism lies in its promotion of patient health, maintenance of medical quality and safety, attention to holistic patient needs, the transmission of professional responsibility and values, and enhancement of nurses' career satisfaction. These attributes represent the fundamental qualities and attitudes that nurses must possess [30]. The concept of nursing professionalism should not be limited to a mere professional ethic, but rather as an ethics framework for nursing and even the broader healthcare industry. Therefore, it is essential to provide an overview of current research on nursing professionalism for nursing administrators and to maintain the stability of the nursing team.

In recent years, there has been a growing global interest in nursing professionalism, as evidenced by the findings of this study. Notably, Asian countries have shown particular attention to this aspect, which may be related to the high turnover rate of nurses in these regions [31, 32]. Consequently, research on nursing professionalism is seen as a means to enhance professional identity within the nursing profession.

The future trajectory of nursing professionalism warrants further investigation. Currently, disparities exist in research findings regarding the level of nursing professionalism across different countries and regions. For example, the level of professionalism among nurses in Czechoslovakia is considered moderate [20], whereas the professionalism level among nurses in Japan is comparatively low [25]. This disparity may be attributed to the absence of a unified connotation of nursing professionalism. Connotations are context-specific, and cultural and institutional contexts can influence the definition of connotations [33]. The connotation of nursing professionalism in China primarily focuses on the individual level, encompassing practice concepts, professional attitudes, value pursuits, professional ethics, and professional abilities. In other countries, the connotation of nursing professional spirit is directly implemented at the personal, interpersonal, and public levels [21]. The in-depth analysis of connotations and the clarification of variable indicators can guide further related research, and logical analysis methods should be applied to delineate specific issues [34]. Currently, inadequate breadth and depth of research along with ambiguous definitions of connotations have led to some studies deviating from objective facts. In the future, it is necessary to elucidate the connotations, structural components, and key points, clarify the ambiguous connotation, unify the relevant connotation, and further explore the level of professionalism of nursing. This review serves as a valuable reference for future research, the development of assessment scales, and the formulation of relevant intervention measures and policies in the field of nursing professionalism.

We urgently need to develop a culturally specific assessment tool for nursing professionalism that can be

applied to diverse cultural backgrounds. Accurate measurement of nursing professionalism can assist nursing staff in forming more standardized and unified nursing behaviors [35]. The levels of nursing professionalism vary across different countries and regions, leading to different requirements for measurement instruments and challenges in the coordination of measurement standards and indicators. The limitations and imbalances of measurement instruments also restrict the comprehensiveness of assessment results, leading to one-sided and misleading evaluations [36]. Currently, the nursing professionalism assessment tool developed by Hall and Miler is grounded in a theoretical framework and extensively studies professionalism as a comprehensive concept, with broad applications [37–40]. Moreover, certain researchers focus on specific attributes of nursing professionalism and use corresponding scales as assessment tools [24]. At present, the development process of some research instruments lacks a specific theoretical model; some research instruments have not undergone reliability and validity testing, leading to limited research scope and a lack of multicenter and large-sample investigations. In summary, current assessment tools for nursing professionalism are still imperfect, as they lack clear evaluation effects, robust validity, and specificity. In the future, researchers should develop assessment tools with local characteristics based on the distinctive features of nursing professionalism in diverse regional cultural backgrounds. Furthermore, these tools should prioritize scientific rigor, reliability, and practicality while undergoing rigorous validation and refinement through relevant research studies.

The factors influencing nursing professionalism necessitate further exploration. The results of our scope review indicate that nursing professionalism is influenced by many complex factors. In terms of individual factors, studies mainly focus on gender, personal abilities, and career choice. Previous studies have demonstrated that male nurses tend to exhibit lower overall professionalism scores compared to their female counterparts [5, 18]. In addition, the level of nursing professionalism is positively associated with critical thinking abilities, self-leadership skills, and humanistic care capabilities. In China, due to the disproportionate number of candidates in college entrance examinations, colleges and universities are compelled to reassign unsuccessful candidates from their initial voluntary majors to undersubscribed majors. This process is commonly referred to as transfer. Nursing students who are transferred to the nursing profession have deep-seated psychological resistance to the nursing profession and experience strong emotional discrepancies due to the transfer results, which in turn affect their professionalism [17, 18]. In terms of organizational factors, the sense of responsibility and professionalism of nurse educators can be enhanced through adherence to rules and regulations, delegation of decision-making power to nurses by leaders, and fostering a positive organizational atmosphere [21]. These interventions will facilitate nurses in recognizing their intrinsic value, thereby fostering the cultivation of appropriate professional values. Nursing professionalism is an integral part of professional culture, necessitating comprehensive consideration of social and

psychological factors and cultural traditions in future research. However, nursing professionalism is embedded within the professional culture, and future research should fully consider the influence of organizational managers, social psychological factors, and cultural traditional factors. The current research predominantly relies on cross-sectional surveys, while cross-sectional surveys are limited in their ability to elucidate intricate phenomena, establish causal relationships, and make future predictions. There are few reports on the interaction and causal mechanisms among various influential factors. Therefore, multicenter, large-sample, specific population, and longitudinal studies based on different cultural backgrounds are required to fully explore the factors affecting nursing professionalism.

Diversified interventions play a crucial role in enhancing nursing professionalism. The intervention study on nursing professionalism is still in its developmental stage, and its positive impact has been preliminarily validated, but there is still significant potential for further development and improvement. Currently, interventions aimed at enhancing nursing professionalism mainly include narrative medicine education [14], health communication courses [15], and penguin style training [16]. Specifically, narrative medicine education can be used to facilitate nurses' self-reflection, foster their empathetic abilities [41], and understand patients' real feelings from different perspectives, thus shaping the correct professional values. However, this study adopted voluntary participation and self-report surveys, and the results may be influenced by subjective factors. Furthermore, the absence of long-term evaluation regarding the impact of narrative medicine programs limits the understanding of their potential influence on the development of longitudinal intervention strategies [14]. The role of social media in health communication is increasingly significant, and nursing students demonstrate a high level of engagement with social media platforms [14]. Therefore, the research on health communication courses exhibits good innovation and feasibility. Sun et al. carried out randomized controlled experiments to conduct an intervention using health communication courses, while the blinding experimental design was not used, leading to the reduced reliability of the research results. The concept of penguin style training is derived from the cooperative breeding behavior of emperor penguins in harsh and densely populated environments, serving as a team-oriented pedagogical approach [16]. This training method is particularly applicable to departments and groups characterized by close-knit teamwork, such as operating rooms [16]. In the study conducted by Dong et al., although the efficacy of the penguin style breeding method in improving nursing professionalism has been verified, the limited sample size may have slightly compromised the statistical significance. In addition, quasi-experimental research was employed in their study. The research design of the quasi-experimental study is not rigorous, and there are different degrees of deviations from the allocation of research objects, the implementation of intervention measures, and the measurement of outcome indicators, which reduce the accuracy of the research results. Previous studies have shown that randomized controlled trials are the highest

level of evidence for evaluating the effectiveness of interventions [42]. Therefore, future interventional studies should prioritize standard randomized controlled trials in order to enhance the professionalism of nursing. However, it is worth noting that certain intervention plans lack comprehensive design principles, reference models, or theoretical foundations. Due to the complexity of the concept and the diversity of influential factors, the development of the plans should involve multidisciplinary teams and formulate multilevel, scientifically effective intervention plans [43]. In view of this, the formulation of intervention plans should be based on mature and comprehensive models as theoretical guidance, aiming to develop scientifically rigorous multidisciplinary intervention plans. In the future, mixed research methods should also be used to improve the investigation of influential factors that promote or inhibit nursing professionalism and their underlying mechanisms.

5. Conclusion

Currently, the connotation of nursing professionalism needs to be enriched, which will facilitate further exploration of the level of nursing professionalism in the future. Although there are various assessment tools for nursing professionalism, their reliability and validity still need to be verified, and specific assessment tools applicable to different cultural backgrounds are urgently required. The research methods of influential factors related to nursing professionalism should be diversified, while further enhancements are needed for interventional research designs. The following research should prioritize the exploration and construction of nursing professionalism's connotation, by drawing upon well-established theoretical models from various countries for the development of assessment tools. In addition, employing mixed research methods can facilitate the investigation of influential factors associated with nursing professionalism, and diverse intervention measures can be implemented to enhance professionalism levels and indirectly improve the quality of nursing services.

6. Implications for Nursing Management

The study of nursing professionalism provides an in-depth understanding of nursing work and offers guidance for nursing managers to support the development of nursing staff and improve their job satisfaction. Nursing professionalism constitutes a fundamental aspect of nursing practice, contributing to the improvement of the quality of nursing care, enhancement of cooperation between medical teams, and growth of reputation of medical institutions [30]. To ensure the safe and efficient working of nurses, nursing managers should provide a conducive working environment with necessary facilities and equipment, enhance their professional education and training, as well as strengthen their professional awareness and sense of responsibility. In addition, incentive mechanisms should be established to reward and commend outstanding nurses, thereby fostering their motivation to actively showcase their professional abilities and uphold professionalism. Only through

continuous enhancement of their competence can nurses deliver high-quality nursing services to patients and achieve the sustainable development of the nursing profession.

Background. By utilizing the nursing care process, healthcare professionals can implement nursing knowledge effectively and efficiently, ultimately leading to a significant improvement in the quality of care provided. **Objective.** This study aimed to assess writing nursing care plan competence among Ardabil nursing students in northwestern Iran. **Methods.** The study involved 248 nursing students from the second to eighth semesters in three nursing and midwifery schools located in the Ardabil province of northern Iran. The data were collected using a simple random sampling method and included a demographic questionnaire along with a survey questionnaire on nursing care plan writing skills. This was conducted between May and June 2023. Descriptive statistics, Pearson correlation, *t*-test, ANOVA, and multiple linear regression analyses were conducted for data analysis. **Results.** The mean score (SD) for writing a nursing care plan in a student survey was 3.35 (0.57) on a scale of 1 to 5. The survey's weighted mean score for each dimension is as follows: data gathering (*D*) = 3.40 (0.73), identification of client's problems (*P*) = 3.40 (0.73), sustainable goals (*G*) = 3.31 (0.77), appropriateness of intervention (*I*) = 3.30 (0.67), and recognizing outcomes (*O*) = 3.37 (0.69). This indicates that the students performed well overall. However, the lowest score was in the appropriateness of interventions dimension. Multiple linear regression analysis revealed that four variables, mean score of grade point average (GPA), age, academic term, and time spent studying (hours per day), were significant predictors of the student survey's scores on writing nursing care plans. These variables could predict 61% of the total variance. **Implication for Nursing Management.** Nursing school administrators can establish programs to improve education and practice in nursing care plan development based on this study. They can use these findings to enhance nursing education and practice for students, which will ultimately lead to better nursing care plans. Administrators should ensure that students have the necessary skills for writing efficient care plans and provide training courses to improve their writing and critical thinking skills. Policies can be implemented to encourage students to increase their study hours and maintain quality care programs. **Conclusion.** Nursing students are skilled in creating well-written nursing care plans that follow the nursing process. The quality of these plans improves with higher GPAs and longer study hours. To enhance nursing care plans, nursing education should focus on developing skills and allocating sufficient time for studying and practicing. Collaborating with faculty and administrators, as well as using reliable resources, can also help improve the quality of care plans.

1. Introduction

Nursing care is a critical aspect of nursing practice that involves efficiently managing care for patients [1]. The nursing process is a scientific approach that is widely

accepted and involves five stages: assessment, nursing diagnosis, planning, implementation, and evaluation [2, 3]. The nursing process is a problem-solving method that uses scientific reasoning, critical thinking, and problem-solving skills to guide nurses in providing individualized patient care

according to their unique needs [1, 2]. The primary objective of nursing care is to provide high-quality care that enhances patient outcomes [4, 5]. The nursing process is a fundamental policy and principle for nursing care and it promotes analytical reasoning and standardizes performance among nurses [3]. Its effective implementation in patient care enhances nursing efficiency, facilitates care documentation, and provides a unified language for the nursing profession [6]. Nursing is a globally accepted approach in clinical practice to deliver quality, individualized patient care [2]. Nursing students are expected to demonstrate high competency levels in clinical settings [7].

Healthcare providers must possess practical knowledge, skills, and attitudes to carry out care tasks effectively [8]. Maintaining high standards of nursing performance is a challenge for the healthcare sector of any country [9]. Weak nursing competencies can result in low-quality healthcare and increased mortality rates [2]. According to a study by Seçer and Karaca, 93.4% of nurses believed the nursing process should be used for care [1]. Another survey by Zeleke et al. reported that 74.7% of nurses followed the process [3]. Assessing the skills of nursing students can provide accurate information for better planning and management at educational and practical levels [10]. Precise educational strategies are necessary to improve future nursing competencies [11].

Nursing education management is crucial for bridging the gap between theory and practice in the nursing process. Assessing the skills and effectiveness of nursing students is essential for their development and improvement in the nursing process [10]. Evaluating the quality of nursing process development by students helps enhance their competencies in patient care management [5]. Nursing instructors need a clear understanding of critical competencies in nursing to effectively support their students and seize opportunities to assist them [11]. Nursing students must be well prepared and qualified to plan care and emphasize accurate documentation for patient safety. Mastering the art and science of writing a nursing process is crucial for every student [5]. At the undergraduate level, nursing students require varying support, supervision, and regulatory guidance to learn skills such as physical examination and nursing processes while gaining practical experience [12].

Implementing the nursing process in hospitals is challenging due to factors such as lack of time, inadequate training, insufficient managerial support, low motivation, shortage of specialized individuals, unclear job descriptions, and low salaries [2, 6]. One solution is to involve nursing mentors who can provide courses and active learning strategies to improve nursing students' competency. National policy frameworks and interventions are necessary to enhance education and the implementation of the nursing process in clinical settings [2, 3, 6]. Adequate staffing levels and reduced workloads for individual nurses are crucial for effectively using the nursing process and improving patient care quality [6]. Standardizing nursing process documents across all hospitals can streamline the process and enhance problem-solving skills [3]. Positive attitudes and nursing

students' ability to develop and implement the nursing process can improve the quality of patient care [2, 13–15].

Optimizing the nursing process is essential for providing quality patient care, reducing expenses, and minimizing medical errors. Focusing on research in this area can lead to better patient outcomes, lower healthcare costs, and improved community health. Nursing students have a unique opportunity to develop their nursing process development skills, contribute to enhancing healthcare outcomes, and improve the quality of patient care. This study aims to evaluate the competency of Ardabil nursing students in writing nursing care plans in Northwestern Iran.

2. Materials and Methods

2.1. Setting, Sample, and Data Collection. A cross-sectional, descriptive study was conducted to investigate the competencies of nursing students in writing nursing care plans. The study included nursing students from the second to eighth semesters, studying at nursing schools in Ardabil province, located in northern Iran. The Ardabil province has three nursing and midwifery schools: Ardabil, Meshgin, and Germe. Nursing students in Iran learn the nursing process in theoretical courses such as principles and skills of nursing and nursing concepts in the first semester, which they use during their internships. First-semester students were excluded from the study as they had yet to pass the nursing process unit. The total number of nursing students in these schools was 667. Using Epi Info StatCalc version 7 software, a sample size of 244 was estimated at a 95% confidence level and a 0.05 margin of error. Considering a nonresponse rate of 10%, the final sample size was determined to be 268 individuals. The sample attrition rate in this study was 8%, with 22 incomplete questionnaires removed due to missing data. The required number of samples from each center was distributed among second-, third- and fourth-year students based on their population size. Therefore, students from each year were randomly selected for the study (152 from Ardabil nursing and midwifery school, 51 from Germe nursing school, and 45 from Meshgin nursing school). Data from 248 samples were analyzed and collected face-to-face based on the student's educational program from May to June 2023.

2.2. Measures. Data were collected through a two-part questionnaire: (1) sociodemographic variables and (2) student survey on writing a nursing care plan.

2.2.1. Sociodemographic Variables. The data collection tools comprised a demographic information questionnaire and a student survey on writing a nursing care plan. The demographic information questionnaire included questions related to demographic characteristics such as age, gender, marital status, academic term status, grade point average (GPA)—which is graded on a scale of 0 to 20, interest in nursing commitment, nursing school or city of study, participation in a nursing process course (yes or no), interest in the nursing field (yes or no), and time spent studying (in hours per day).

2.2.2. The Student Survey on Writing Nursing Care Plan Questionnaire. In 2020, Salvador et al. developed a questionnaire to evaluate the competency of nursing students in developing nursing care plans. The student survey on writing a nursing care plan consists of 25 items categorized into five domains: (1) data gathering (*D*); (2) identification of client's problems (*P*); (3) sustainable goals (*G*); (4) appropriateness of intervention (*I*); and (5) Recognizing outcomes (*O*). Participants respond to questions using a 5-point Likert scale (poor = 1, fair = 2, good = 3, very good = 4, excellent = 5), and the overall mean score is interpreted from poor to excellent [5]. This questionnaire was translated and cross-culturally adapted in Iran by Ramezanzadeh et al. [10] in 2023. Permission to use the original questionnaire [5] and the translated version in Iran was obtained. Internal consistency was assessed using Cronbach's alpha coefficient, which was 0.93 in Salvador's study and 0.95 in Ramezanzadeh et al.'s study [10]. Our analysis yielded a Cronbach's alpha coefficient of 0.91, indicating high internal consistency among the measured variables.

2.3. Ethical Considerations. The Ethics Committee of Ardabil University of Medical Sciences approved the present study with a corresponding ethics code (code number = IR.ARUMS.REC.1402.034). Eligible individuals interested in participating were informed about the study's objectives and encouraged to participate voluntarily. Only those who provided written informed consent and willingly agreed to participate were given the questionnaire. The confidentiality of their responses was ensured, and there would be no adverse consequences resulting from their refusal to participate. All researchers involved in the study were responsible for distributing and collecting the questionnaires, and they took full responsibility for ensuring that the participant's privacy and confidentiality were maintained. The questionnaire was self-reported, and it took 5 to 15 minutes to complete. The first page of the questionnaire included details of the study objectives, confidentiality, anonymity, and privacy of the respondents. The participants' responses were kept confidential, and the researchers involved were responsible for distributing and collecting the questionnaires.

2.4. Data Analysis. To describe the demographic characteristics and research variables, descriptive statistics such as percentages, frequencies, mean, and standard deviation were used. The questionnaire items were analyzed using mean, standard deviation, and a 95% confidence interval. *T* test, ANOVA, and Pearson correlation were used to examine the difference and relationship between the main study variable and demographic factors of nursing students. To evaluate the predictors of student surveys on writing nursing care plans, multiple linear regression analysis was employed, using demographic factors as independent variables. A significance level of 0.05 was set for this study.

3. Results

A total of 248 nursing students participated in this study, comprising 134 females (54%) and 114 males (46%). They had a mean GPA of 16.37 (1.29) on a scale of 0–20. Out of the total participants, 231 (85.9%) were single. The study included 152 students (61.3%) from the midwifery nursing department in Ardabil. Among them, 207 (83.5%) had not completed the nursing process in their education, while 199 (80.2%) showed a keen interest in nursing. In addition, 96 students (38.7%) studied for one to two hours daily. You can check Table 1 for more information on the demographic characteristics of the participants.

The scores of Table 2 from the survey questionnaire for student survey on writing nursing care plans were organized into domains. In the data gathering subgroup, the item that received the highest rank mean score 3.45 (standard deviation (SD) = 0.98) was "I utilize a systematic way in collecting my objective data like Gordon's Assessment or any other pertinent assessment tool," while the lowest level among nursing students 3.33 (0.83) was for the item "I utilize therapeutic communication throughout patient assessment." In the identifying clients' problem subgroup, the highest-ranked phrase 3.43 (0.95) was "I am aware of the various ways on how to formulate good nursing diagnoses," while the lowest-ranked item 3.34 (1.02) was "I use and refer to NANDA resources every time I formulate my client's nursing diagnosis." In addition, in the formulating sustainable goals subgroup, the item that obtained the highest rank 3.34 (1.07) was "I specify in my planning the recipient and reason for formulating the nursing care plan," while the lowest-ranked item 3.28 (0.99) was "I put a time frame whenever I formulate my nursing care plan for evaluation." In the providing appropriate interventions subgroup, the item that received the highest score 3.35 (1.01) was "I base my independent interventions on the identified needs of my patient," while the lowest score 3.20 (0.96) was received by the item "I incorporate interdependent collaborations with various healthcare departments whenever I plan care for my client." Finally, in the recognizing Client's outcomes subgroup, the item that received the highest score 3.45 (0.95) was "I seek back to my planning's goals and objectives if I have achieved my SMART plan." while the lowest score 3.29 (1.09) was received by the item "I review my nursing care plan and decide whether to terminate, continue and change it after a series of evaluation." The overall mean score of the student survey on writing nursing care plans was 3.35 (0.57) on a scale of 1 to 5.

Table 2 presents the weighted mean score and interpretation for each dimension. The scores we obtained are as follows: (a) data gathering (*D*) = 3.40 (0.73), which is considered good; (b) identification of client's problems (*P*) = 3.40 (0.73), which is also good; (c) sustainable goals (*G*) = 3.31 (0.77), again, good; (d) appropriateness of intervention (*I*) = 3.30 (0.67), good; and (e) recognizing outcomes (*O*) = 3.37 (0.69), which is, again, good. The overall weighted mean score is 3.35 (0.57), indicating that the students' nursing care plan (NCP) writing skills are of good quality. The dimension with the lowest score was the appropriateness of intervention.

TABLE 1: Sociodemographic characteristics of the study sample ($N=248$).

Characteristics	Categories	Mean (n)	SD (%)
Grade point average (grading is based on a 0 to 20 score)		16.37	1.296
Age	18–22	122	49.2
	23–27	126	50.8
Gender	Female	134	54.0
	Male	114	46.0
Marital status	Single	213	85.9
	Married	35	14.1
Semester	2	23	9.3
	3	47	19.0
	4	23	9.3
	5	56	22.6
	6	26	10.5
	7	55	22.2
Interest for nursing commitment	8	18	7.3
	Yes	54	21.8
	No	194	78.2
Nursing school	Ardabil	152	61.3
	Meshgin	45	18.1
	Germi	51	20.6
Nursing process course	Yes	41	16.5
	No	207	83.5
Interest in the nursing field	Yes	199	80.2
	No	49	19.8
Time spent studying (hours per day)	Less than 1 hour	71	28.6
	Between 1 and 2 hours	96	38.7
	Between 2 and 3 hours	72	29.0
	More than 3 hours	9	3.6

Table 3 summarizes the relationship between the student survey on writing a nursing care plan and the demographic factors of nursing students. It shows the study's overall mean scores and range based on the participants' demographic characteristics. The results indicate a significant positive correlation between the overall mean score of the student survey on writing a nursing care plan and the mean score of grade point average (GPA), academic term, interest in nursing commitment, interest in the nursing field, and time spent studying. On the other hand, there is a significant inverse correlation between the overall mean score of the student survey on writing a nursing care plan and age.

The results of multiple regression analysis, indicating the predictors of the student survey on writing a nursing care plan, are shown in Table 4. A considerable variable regression analysis was conducted using the student survey on writing a nursing care plan as the dependent variable and demographic characteristics as the independent variable. Of these ten variables, 4 were significant predictors of the student survey on writing a nursing care plan. The regression model's coefficient of determination (R^2) indicates that 61% of the total score of the student survey on writing a nursing care plan can be explained by the input variables in the model. Among the input variables in the model using the ENTER method, as reported in the table, there was a statistically significant relationship between mean GPA, age, academic term, and time spent studying (hours per day).

4. Discussion

Nursing students play a crucial role in providing continuous care and improving the healthcare system in the future. The nursing process serves as a framework for nursing care, an essential tool for implementing nursing knowledge that enhances the quality of care. Writing nursing care plans is a skill and competency identified in the nursing profession. This study was conducted to investigate nursing students' competence in writing nursing care plans.

Although students showed a good score in writing NCP, previous studies have indicated that nursing students require appropriate training to improve their implementation of the nursing process [6, 16]. There are several barriers to implementing the nursing process, such as high patient-to-nurse ratios, inadequate and improper training, lack of continuous supervision and control, insufficient time allocated for training, and lack of retraining opportunities [17]. Nursing students must be familiar with real-life conditions and appropriate tools to effectively implement the process. Addressing these obstacles can lead to better outcomes. Improper implementation of the nursing process is often due to insufficient education, inadequate attitudes, and a lack of training in nursing schools [18]. Nurses who are more familiar with the nursing process and use it in their care have a more positive attitude towards it [3]. The nursing process enhances the quality of nursing care by ensuring individualized and high-quality care [6, 19]. To ensure

TABLE 2: The status of Iranian nursing student survey on writing nursing care plan (N = 248).

Items	Mean	SD
<i>Data gathering (D)</i>	3.40 good	0.734
(1) I utilize therapeutic communication all throughout the duration of patient assessment	3.33	0.831
(2) I maximize my time during the entire course of patient-nurse interaction	3.40	0.985
(3) I find it easy to recognize irregularities from normal to abnormal changes based on my assessment	3.38	0.915
(4) I utilize systematic way in collecting my objective data like Gordon's Assessment or any other pertinent assessment tool	3.45	0.980
(5) I make sure that the client's given data are coherent	3.42	0.923
<i>Identification of client's problems (P)</i>	3.40 good	0.738
(6) I determine my client's needs based from my assessment based from Maslow's hierarchy of needs	3.42	0.999
(7) I categorize my client's needs based from the various types of nursing diagnoses like actual, risk, wellness, syndrome, and possible	3.42	0.991
(8) I am aware of the various ways on how to formulate good nursing diagnoses	3.43	0.958
(9) I understand the different terminologies used in formulating nursing diagnosis	3.35	1.039
(10) I use and refer to NANDA resources every time I formulate my client's nursing diagnosis	3.34	1.034
<i>Sustainable goals (G)</i>	3.31 good	0.777
(11) I specify in my planning the recipient and reason for formulating the nursing care plan	3.34	1.078
(12) I look on the measurable quantifiers that will be used as parameters for my planning	3.33	1.052
(13) I make sure that the goals and objectives I set for my nursing care plan are attainable	3.30	1.038
(14) I see to it that my nursing care plan is realistic and does not only base from imagination	3.31	1.062
(15) I put time frame whenever I formulate my nursing care plan for evaluation	3.28	0.998
<i>Appropriateness of intervention (I)</i>	3.30 good	0.679
(16) I assessed my patient before I start my interventions to come up with baseline data and use it as my parameters for ongoing evaluation	3.32	0.978
(17) I based my independent interventions based from the identified needs of my patient	3.35	1.012
(18) I put stand-alone rationales in all the nursing interventions I plan to implement for my patient	3.28	0.965
(19) I resort getting doctor's orders when I am planning for my nursing interventions especially with pharmacological, medical and surgical treatments and modalities	3.32	0.990
(20) I incorporate interdependent collaborations with various healthcare departments whenever I plan care for my client	3.20	0.966
<i>Recognizing outcomes (O)</i>	3.37 good	0.690
(21) I re-assess my patient after all the nursing interventions done	3.38	1.007
(22) I go back to my nursing diagnosis if my nursing care plan answered the client's health needs	3.40	0.989
(23) I seek back to my planning's goals and objectives if I have achieved my SMART plan	3.45	0.955
(24) I evaluate all the nursing interventions done to my client to check and validate its appropriateness and effectiveness	3.35	1.062
(25) I review my nursing care plan and decide whether to terminate, continue and change it after series of evaluation	3.29	1.093
<i>Total</i>	3.35 good	0.576

Note. Interpretation: excellent = 4.21–5.0; very good = 3.41–4.20; good = 2.61–3.40; fair = 1.81–2.60; poor = 1.00–1.80.

mastery and translation into practice, nursing educators should use active teaching strategies [6]. Patient care skills and the nursing process should be assessed and monitored through evaluation courses [17].

The results showed nursing students have good writing skills for creating nursing care plans (NCPs). They are

proficient in data collection during the evaluation phase, with an average score of 3.40. In a study by Salvador et al., nursing students performed excellently [5]. Assessing patients is the first step in nursing and guiding interventions [20]. Nurses' initial patient assessment translates theory into practice and demonstrates the value of knowledge, skills, and attitudes in

TABLE 3: Relationship between nurses' sociodemographic characteristics and student survey on writing nursing care plan ($N = 248$).

Characteristics	Categories	Mean	SD	Statistical	p value

$R^2 = 0.61$, adjusted $R^2 = 0.59$, $F (37.43)$, and $p < 0.001$.

providing individualized care to complex healthcare needs. It is crucial for nursing diagnosis and the nursing process [3]. In Namibia, nursing students may miss out on physical examination aspects due to not completing all stages of nursing. This can lead to incorrect diagnoses as each stage of nursing is interrelated and a failure in one stage can affect other stages [21]. The difference in mean data collection between the two communities is due to cultural differences [5].

Among the data collection items, the lowest score was related to "I use therapeutic communications throughout the patient assessment." Good communication and

collaboration are important competencies in patient-centered care and nursing practice. Students' perception highlights that nursing is influenced by various aspects of patient care, including patient preferences and effective communication. Language barriers and patients' preferences for professional nurses may hinder nursing students' ability to apply the nursing process [11, 21].

Based on our results, in the second component of the survey, students had a good quality level in writing NCP, meaning that nursing students have good foundations during problem identification or nursing diagnoses

($P = 3.31$). As per Salvador et al., the lowest score was related to “I use NANDA nursing diagnosis resources every time I formulate a nursing diagnosis.” Nursing diagnosis should be based on assessment results and used as a reference for interventions [22]. Nurses and nursing students should apply the nursing process to enhance patient care quality and safety [23]. Nursing students learn education topics and use the nursing process to understand patient health problems and study evidence [24]. A nursing diagnosis reflects the student’s ability to identify patient problems during the initial assessment. A correct diagnosis leads to proper intervention and evaluation, while an incorrect diagnosis can have the opposite effect. Identifying patient problems is critical for quality care [25].

The study results indicated that in the third dimension, nursing students also had good quality in developing nursing processes, meaning they had reasonable primary goals (G) or planning for patient nursing diagnoses. In Salvador et al. study, most nursing students felt the management course provided enough knowledge to set patient goals. Nursing mentors should teach SMART goal-setting principles [5]. A review in Iran found that the nursing process is not commonly used in low-income countries like Iran, Ethiopia, Kenya, and Taiwan. Reasons include a lack of awareness among nursing faculty about the process, inadequate hospital infrastructure, and insufficient support from nursing organizations [26]. It is imperative to adopt and implement appropriate policies that ensure nursing students can confidently execute the nursing process in the clinical environments of low-income countries on a widespread and continuous basis.

The lowest score among the items was related to “I set a time frame when scheduling my nursing care plan for evaluation.” The nursing process is challenging, time-consuming, and difficult to perform. Taking care of multiple patients simultaneously can disrupt decision-making. Software can help manage time and streamline the process [26]. Nurses cite workload and staff shortages as obstacles to using the nursing process effectively in patient care, as per Bassah et al. and colleagues [6]. It is essential that managers take prompt action to overcome any obstacles hindering nurses from implementing the nursing process effectively. By doing so, nurses will have adequate time to provide individualized care to patients, leading to better health outcomes.

According to the study results, nursing students had good-quality writing NCP in the fourth dimension. Nursing students could use appropriate interventions (I) based on sound planning. In the Salvador et al.’s study, students achieved a perfect score. In the Sendir et al.’s study, nursing students faced difficulty determining nursing interventions [27]. The appropriate diagnosis of intervention depends on the nurse’s knowledge and awareness of the disease and the patient’s status. According to Zeleke et al., nurse awareness is the most predictive factor for the nursing process [3]. Students had the lowest score in the fourth-dimension item, “Whenever I intend to take care of my patient, I consider the collaborative efforts with various healthcare departments.” One of the issues surrounding nursing profession

development includes physician dominance in healthcare systems. When nurses demonstrate sufficient ability to improve the quality of care they provide, other health teams can identify the nursing profession [11].

The study results indicated students exhibited high-quality nursing writing skills in the fifth dimension. This finding meant that nursing students had good foundations in evaluating outcomes (O) or evaluating interventions performed. However, in the Salvador et al.’s study, students had achieved excellent grades. Nursing students must master the art of writing a care plan using all available resources to ensure optimal patient health [5]. Among the items related to the fifth dimension, the lowest score was related to the item “I review my nursing process and decide whether to terminate it after a series of evaluations, continue it, or make changes.” Through the nursing process, nursing students and nurses play a significant role in evaluating nursing care results [9]. The evaluation stage assesses nursing care programs for efficiency, completeness, and adequacy while identifying deficiencies in previous programs [28]. Nursing education is crucial in preparing students with the knowledge and skills needed for effective nursing practice [10]. Nursing instructors shape the future of nursing. They must equip students with the skills to deliver quality care. The nursing process and final evaluation are critical components of patient care. Prioritizing them empowers nurses to deliver the best care and improve patient health outcomes. Let us support the full implementation of the nursing process and final evaluation.

The findings suggest that as students’ GPAs increase, their scores in writing nursing care plans rise, which is consistent with prior research [29]. According to a study by Vasli et al., GPA is a significant predictor of clinical competency scores among nursing students [29]. It is possible that academic skills have an impact on clinical skills, which could explain the results. Students who excel in their academic studies and have high GPAs may have a better understanding of nursing concepts, which can have a positive impact on their clinical skills. On the other hand, students with lower GPAs may need to have a deeper understanding and application of the nursing process. Therefore, it is crucial for students who did not receive satisfactory GPAs during their academic years to enhance their competence in writing nursing process formulations through more practice and study. However, further research is required to comprehend and confirm this relationship fully.

According to the results of the present study, as students’ progress through their academic terms, their competency scores in nursing process formulation increase, which is consistent with the findings of Huang et al. According to Huang et al. study, first- and second-year nursing students had lower nursing competency scores than third- and fourth-year students [11]. The use of the nursing process depends on many factors, including knowledge and skills that ideally should be developed in nursing students throughout their education [21]. In addition, as students’ age, their competency scores in nursing process formulation also increase. This finding contradicts the results of Bassah et al.’s study [6]. These findings may be due to improved

clinical experience and practice in formulating the nursing process with age and longer academic terms.

The findings of this study suggest that an increase in nursing students' time spent studying (hours per day) can lead to an improvement in their ability to develop nursing processes. This may be due to the higher level of knowledge that nursing students possess due to increased studying and staying up-to-date with the latest information. Therefore, nursing instructors and managers should promote programs that enhance students' academic motivation [30]. Nursing is a dynamic and demanding profession requiring high knowledge and experience [31]. As such, nursing students should continuously study to become familiar with the latest advancements in the field and provide the best possible care to patients. In addition, increased studying helps students perform better in nursing and cope with this profession's complex and risky conditions.

4.1. Limitations. The study's small sample size of nursing students presents a significant limitation, which may compromise the generalizability of the results. To ensure more accurate and reliable outcomes, it is imperative for future studies to consider evaluating nursing care programs with larger sample sizes. It is important to note that this study solely focused on undergraduate nursing students at Ardebil University of Medical Sciences; thus, caution should be exercised when applying these findings to the entire population of Iran. In order to enhance the generalizability of the findings, it is highly recommended to conduct multicenter studies involving students from various universities in Iran as well as different regions of the world. Lastly, it is crucial to address the limitations of this study by conducting further research in the future, which will contribute to a more comprehensive understanding of the topic.

4.2. Implications for Nursing Management. Nursing schools must prioritize the development of practical care plan writing skills among their students. Teachers should use effective teaching methods and implement comprehensive training programs to facilitate learning [32]. Students should also be encouraged to aim for greater efficiency and create high-quality care programs. These initiatives will help to advance research methodologies and improve nursing studies. Investing in these efforts will ensure that nursing education meets the needs of society and empower students to promote community health.

5. Conclusions

According to the study, nursing students can create high-quality writing nursing care plans. Nurses are essential as caregivers, coordinators, educators, and information sources [33]. The study found that nursing students with higher GPAs and more time studying produced better nursing care plans. Therefore, it is recommended that students focus on improving their skills in various courses during their training period. They should strive to have a deep and accurate understanding of nursing concepts and principles and

devote sufficient time to studying and practicing nursing care plans. Using reliable and up-to-date resources in nursing care planning and collaborating with faculty members and school administrators can also help improve the quality of nursing care programs. Based on these findings, school nursing administrators can develop programs to enhance the quality of education and training in nursing care planning for students. However, further studies are needed to conduct additional qualitative research to analyze the ability of nursing students to write care plans.

Data Availability

The data supporting the results of this study are available on request from the corresponding author. The data are not publicly available due to privacy or ethical restrictions.

Ethical Approval

This study was performed in line with the principles of the Declaration of Helsinki. The project was approved by the Ethics Committee of the Ardabil University of Medical Sciences (IR.ARUMS.REC.1402.034).

Consent

All subjects were informed about the purpose and content of the study, and all provided written informed consent.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

All the authors were involved in designing the study. Mohammad Javad Jafari, Pouya Mostafazadeh, Mohammad Reza Mojebi, and Ali Jabraeelzadeh Kamblash carried out the data collection and data entry. Alireza Mirzaei and Reza Nemati-Vakilabad performed the statistical analyses and interpretations. Alireza Mirzaei, Ali Jabraeelzadeh Kamblash, Reza Nemati-Vakilabad, Mohammad Javad Jafari, Pouya Mostafazadeh, and Mohammad Reza Mojebi wrote the final report and manuscript. All the authors have read and approved the final manuscript.

Acknowledgments

The authors would like to thank all participating students, the student Research Committee of Ardabil University of Medical Sciences, the Vice-Chancellor for Research of Ardabil University of Medical Sciences, and all those who helped them in this study.

Background. Despite the importance of studying factors contributing to nursing students' attitudes toward artificial intelligence, yet according to our knowledge, no study has addressed the relationship between personality traits and the attitude of nursing students toward artificial intelligence. **Aim.** This study aimed to unveil whether nursing students' personality traits are related to their attitude toward AI. **Methods.** This multicenter cross-sectional study included 218 nursing students from three governmental universities across various regions of the Kingdom of Saudi Arabia. Data were gathered online, utilizing the Big Five Inventory, the General Attitudes toward Artificial Intelligence Scale, and a demographic questionnaire. Descriptive statistics, Pearson's correlation, and regression analysis were employed. The research complied with the STROBE checklist. **Results.** Findings indicated that nursing students with a high score in the openness trait displayed positive attitudes toward artificial intelligence. Conversely, those who scored high in neuroticism and agreeableness exhibited fewer positive attitudes toward artificial intelligence and more negative attitudes toward artificial intelligence. Additionally, nursing students who ranked high in conscientiousness showed a negative attitude toward artificial intelligence. **Conclusion.** Except for extraversion, personality traits appear to predict attitudes toward artificial intelligence. **Implications for Nursing Management.** The current study provides a foundation for understanding how generative AI can be integrated into nursing education and practice in a manner that is both effective and considerate of the diverse psychological profiles of students.

1. Introduction

Artificial intelligence (AI) is progressively shaping the scene of healthcare, with its integration becoming more pervasive across various domains such as patient care, diagnostics, and administrative tasks [1]. In recent years, the healthcare sector has perceived a surge in the adoption of AI technologies, ranging

from machine learning algorithms aiding in disease prediction to robotic assistance in surgical procedures [2]. The potential of AI to enhance efficiency, accuracy, and patient outcomes is widely acknowledged, necessitating a workforce that is adept and comfortable working alongside these technologies [3].

The integration of AI in healthcare settings is challenging due to trust, ethics, and job security concerns [4].

Addressing these issues proactively and fostering a positive outlook toward AI among nursing students can pave the way for smoother integration and optimal utilization of AI in healthcare [5]. Understanding nursing students' attitudes toward AI is crucial as it influences their future interactions with AI technologies and integration into healthcare practices [6]. Attitudes can vary, with younger, tech-savvy students often embracing AI, while older or less tech-savvy individuals may be skeptical [7, 8]. As future healthcare professionals, nursing students' attitudes will shape the broader workforce's readiness for AI [9, 10]. Studying these attitudes provides insights into the educational needs and interventions required to prepare future nurses for the AI-driven healthcare landscape. There is a pressing need to incorporate AI-related content into nursing curricula and training programs to equip students with the necessary knowledge and skills [11, 12]. By exploring the factors influencing these attitudes, educators and policymakers can devise targeted strategies to foster positive attitudes and readiness for AI integration [9].

The relationship between personality traits and attitudes toward technology or innovation has been the subject of extensive research, with several studies highlighting the significance of individual personality characteristics in shaping one's perception and acceptance of technology [13]. Drawing upon the technology acceptance model, which postulates that perceived affluence of usage and perceived helpfulness are key determinants of technology acceptance, it can be inferred that personality traits play a critical role in shaping these perceptions [14]. Moreover, the Big Five personality traits model provides a comprehensive framework to understand how different personality dimensions may influence attitudes toward AI [15, 16].

The Big Five personality traits framework categorizes personality into five dimensions: openness, conscientiousness, extraversion, agreeableness, and neuroticism (OCEAN). Openness involves receptiveness to new experiences; conscientiousness denotes diligence and responsibility; extraversion encompasses sociability; agreeableness signifies compassion and cooperation; and neuroticism involves emotional instability and anxiety [17]. Individuals with high openness are likely to have positive attitudes toward AI due to their receptiveness to change [18]. In contrast, those high in neuroticism may have negative attitudes toward AI, perceiving it as threatening. Highly agreeable individuals might also be more skeptical of AI's impact on interpersonal aspects of patient care [19].

In the context of AI in healthcare, it is plausible to expect that these personality traits would play a significant part in shaping nursing students' attitudes toward AI. For instance, students high in conscientiousness may exhibit meticulousness in their interactions with AI, ensuring that all protocols are followed, but they may also be more critical of AI's potential limitations. Extraversion may influence how nursing students communicate and collaborate with AI technologies, with more extroverted students potentially being more open to engaging with AI in team-based settings. Thus, understanding how each of these personality traits correlates with attitudes toward AI is crucial for developing targeted educational and training interventions [11, 12].

Despite the increasing interest in the impact of AI on healthcare and the importance of fostering positive attitudes toward AI among healthcare professionals, there is a noticeable gap in the literature concerning the specific relationship between nursing students' personality traits and their attitudes toward AI [9]. Most existing studies have focused on healthcare professionals' attitudes toward AI in general, without delving into the nuanced ways in which individual personality traits may influence these attitudes [20–23].

Recent studies have begun to explore the intersection of AI, healthcare, and personality traits in various cultural settings. For example, research in South America has examined the role of personality in the acceptance of AI among healthcare workers, revealing distinct patterns influenced by cultural values and healthcare systems [18]. Similarly, studies from Africa have shed light on the unique challenges and opportunities presented by AI in healthcare, emphasizing the need for culturally sensitive approaches to AI integration [24]. In Asia, the rapid adoption of AI in healthcare has prompted investigations into the influence of personality traits on AI acceptance among nursing students and professionals, highlighting differences in attitudes compared to Western counterparts [9, 25, 26].

Furthermore, the few studies that have explored the relationship between personality traits and attitudes toward technology in healthcare have largely been conducted in Western and Eastern contexts, leaving a gap in our understanding of how these dynamics play out in the Middle East, especially the Kingdom of Saudi Arabia. Addressing this gap is imperative, as the cultural and educational context of the Kingdom of Saudi Arabia presents unique challenges and opportunities in the integration of AI in healthcare. The country has been making significant strides in incorporating AI into various sectors, including healthcare, as part of its Vision 2030 Strategic Plan [27–29]. However, to fully realize the potential of AI in enhancing healthcare delivery, it is crucial to understand how nursing students, who represent the future of the healthcare workforce in the region, perceive and interact with AI.

Aim of the Study. This study aimed to investigate the relationship between nursing students' personality traits and their attitudes toward AI.

1.1. Objectives

- (1) To investigate the relationship between nursing students' personality traits and their attitudes toward artificial intelligence (AI)
- (2) To identify the distinct personality traits of nursing students who have positive attitudes toward AI compared to those with negative attitudes
- (3) To determine which specific personality traits (e.g., openness, conscientiousness, extraversion, agreeableness, and neuroticism) predict nursing students' attitudes toward AI

1.2. Hypotheses

- (1) H1: nursing students' personality traits are significantly associated with their attitudes toward AI
- (2) H2: nursing students with a positive attitude toward AI exhibit distinct personality traits compared to those with a negative attitude toward AI
- (3) H3: specific personality traits (e.g., openness, conscientiousness, extraversion, agreeableness, and neuroticism) predict nursing students' attitudes toward AI

2. Methods

2.1. Design. A multicenter cross-sectional online survey was performed.

2.2. Participants and Setting. We recruited nursing students using convenience sampling from three governmental universities across three regions of the Kingdom of Saudi Arabia: Prince Sattam Bin Abdulaziz University, Bisha University, and Najran University. Eligible participants were undergraduate nursing students, from any year of their bachelor's program, at one of the three specified governmental universities in the Kingdom of Saudi Arabia, and willing to engage in the survey. Exclusion criteria include postgraduate students, students with mental health challenges or undergoing mental health therapy, or those enrolled in self-improvement or professional development courses.

Calculations for determining the sample size were conducted using G*Power software (version 3.1.9.4), leveraging a linear model calculation method [30]. The parameters employed consisted of a power level of 0.95, an alpha level of 0.01, an effect size of $d=0.15$ [31], and 9 predictors (five related to personality traits and four to demographics). These parameters pointed to a need for a minimum of 214 participants. A total of 218 nursing students completed the online survey.

2.3. Measures. The Big Five Inventory (BFI) and the General Attitudes toward Artificial Intelligence Scale (GAAIS), advanced in English, and a demographic questionnaire were used in the current study. Together, the English scales were translated into Arabic using the translation-back-translation technique [32]. Initially, the English scale was translated into Arabic by the primary researcher, and a skilled translator subsequently performed a back translation from Arabic to English. The back-translated version was then cross-checked with the original English scale, resulting in certain corrections to ensure a close alignment with the original content. A team of five nursing professors, who are experts in the field, revised the translated form in comparison with the genuine one to confirm that the terms used were equivalent and that the language was clear and easy to understand. After translation, the scales were initially tested with 31 nursing students to confirm the validity of the final version. Both

scales used a 5-point Likert scale for responses, with the scoring system ranging from 1 (strongly disagree) to 5 (strongly agree).

2.3.1. BFI. This scale was established by Benet-Martinez and John [33] to assess the five major personality traits using 44 items. These traits are "extraversion (8 items), agreeableness (9 items), conscientiousness (9 items), neuroticism (8 items), and openness (10 items)." Among nursing students, the trait with the highest score reflects their most dominant personality characteristic. In its original form, Cronbach's alpha for the scale varied from 0.65 to 0.84. In the current study, a confirmatory factor analysis (CFA) was conducted, contrasting two models. The initial model grouped all items of scale under one factor, whereas the later model examined a suggested structure of five distinct factors. The data suggested that the five-factor model was more fitting than the single-factor model, as evidenced by the following metrics: $\chi^2 = 1453.043$, $df = 892$, $\chi^2/df = 1.629$, CFI = 0.90, IFI = 0.89, and RMSEA = 0.054, in contrast to $\chi^2 = 4964.743$, $df = 911$, $\chi^2/df = 5.450$, CFI = 0.21, TLI = 0.21, and RMSEA = 0.143 for the single-factor model.

2.3.2. GAAIS. This scale was established by Schepman and Rodway [34] to gauge people's general attitudes toward AI. This scale encompasses 20 items with two dimensions: positive attitude toward AI (12 items) and negative attitude toward AI (8 items). Each dimension yields a separate score, with higher scores reflecting more intense attitudes, be they positive or negative, toward AI. In the original study, Cronbach's alpha for the positive dimension was 0.88 and 0.83 for the negative dimension. In this study, the CFA indicated that the two-factor model exhibited a more satisfactory structure compared to a one-factor model ($\chi^2 = 281.195$, $df = 169$, $\chi^2/df = 1.664$, IFI = 0.96, CFI = 0.96, and RMSEA = 0.055 vs. $\chi^2 = 619.023$, $df = 170$, $\chi^2/df = 3.641$, TLI = 0.82, CFI = 0.82, and RMSEA = 0.110).

2.3.3. The Demographic Questionnaire. The demographic questionnaire involved data about age, gender, marital status, and educational level.

2.4. Data Collection and Ethical Consideration. Data were collected through an online survey created using Google Forms, which is a readily available web-based survey platform. The survey link, attended by invitation, was disseminated to students via email and through private student Telegram groups affiliated with each university. The invitation letter outlined the study's purpose and specified the target participants. Participation was entirely voluntary, and confidentiality was guaranteed. An online informed consent method was provided, and participants were required to acknowledge their agreement by clicking on an "I agree" button before proceeding to the survey. To ensure data quality, all survey questions were mandatory, preventing the submission of incomplete responses. Additionally, measures were in place to prevent participants from submitting

multiple responses using a similar account or device. Once the number of submissions surpassed the predetermined sample size, data collection was halted. The data collection period spanned from mid-March to mid-June 2023. The Standing Committee of Bioethics Research (SCBR), Prince Sattam Bin Abdulaziz University, approved the study (Approval No. SCBR-181/2023).

2.5. Statistical Analysis. Statistical analyses were performed using SPSS version 27.0, with validity analysis performed in Amos version 23.0. Descriptive statistics, including counts, percentages, means, and standard deviations, were performed to depict participants' demographic features and study variables. Measures were taken to ensure the validity and reliability of the study variables. Differences in study outcomes based on demographic characteristics were examined using independent-samples *t*-tests and one-way analyses of variance (ANOVA). The Pearson *r* correlation coefficient was applied to ascertain the relationships between personality traits and attitudes toward AI. Stepwise multiple regression analyses were carried out for both positive and negative attitudes toward AI, focusing on variables that showed significance in the prior difference and correlation tests. To ensure model stability and the absence of multicollinearity, both tolerance and variance inflation factor metrics were examined and confirmed to be within acceptable limits.

2.6. Common Method Bias (CMB). The data for the current research were obtained solely from a lone source via self-reported methods, thereby heightening the risk of CMB. To mitigate current potentiality, both statistical and procedural strategies were implemented. Procedurally, participants received a thorough orientation regarding the study's aims, and assurances of voluntary participation, unwavering anonymity, and strict confidentiality were provided. Furthermore, the items within the study's scales were randomized and subjected to preliminary testing to augment clarity [35]. On the statistical front, Harman's single-factor test was adopted [36]. The results indicated that only 18.47% of the variance was due to a single factor, which is well below the 50% threshold [37], suggesting that CMV was not a predominant concern. Furthermore, the CFA of the scales addressing personality traits and attitudes toward AI demonstrated a satisfactory fit with a multifactor model than with a singular-factor model, pointing to an absence of widespread CMV.

3. Results

3.1. Preliminary Analysis. The study participants were predominantly female (81.7%), unmarried (88.1%), and were in their fourth year of education. The majority of the participants were aged 20 years or older, constituting 55.5%. There was no statistically significant difference in attitudes, positive or negative, toward AI based on the demographics of the nursing students. However, there were specific differences observed across the educational levels of students, and the

mean positive attitude score was highest among second-year students ($M = 3.62$), while the mean negative attitude score was highest among third-year students ($M = 2.61$). Interns had the lowest mean positive attitude score ($M = 3.22$), and first-year students had the lowest mean negative attitude score ($M = 2.21$) (Table 1).

3.2. Reliability and Validity. A CFA was conducted to validate the study scales. Initially, the Kaiser–Meyer–Olkin (KMO) measure and the Bartlett test of sphericity assessed the suitability of the sample. A KMO measure should ideally exceed 0.60, while the Bartlett test of sphericity ought to be statistically significant at $P < 0.05$. The findings showcased KMO values of 0.861 ($P < 0.001$) for the scale assessing personality traits and 0.953 ($P < 0.001$) for the scale measuring attitudes toward AI. Factor loadings for all scale items surpassed the benchmark of 0.5 [38], corroborating the scales' construct validity. In addition, all average variance extracted (AVE) exceeded the 0.50 benchmark for the study variables, signifying adherence to convergent validity. The AVE values were observed to be greater than the maximum shared variance (MSV), thus reinforcing the discriminant validity of the research model [39] (Table 2).

Reliability was further scrutinized using Cronbach's alphas and composite reliability (CR). Study results revealed Cronbach's alpha values spanning from 0.89 to 0.92 for all scale factors, exceeding the 0.7 threshold [40], implying robust internal consistency. Additionally, CR values ranged between 0.89 and 0.93 for all study scale factors, all surpassing the 0.70 threshold [41], underscoring the scales' elevated reliability (Table 2).

3.3. Descriptive Statistics. As presented in Table 2, the personality traits of the nursing students who contributed in this study ranked as follows: "conscientiousness" ($M = 3.18$, $SD = 0.75$), "openness" ($M = 3.10$, $SD = 0.75$), "agreeableness" ($M = 2.90$, $SD = 0.77$), "extraversion" ($M = 2.67$, $SD = 0.81$), and "neuroticism" ($M = 2.18$, $SD = 0.68$). The participating nursing students exhibited a more positive attitude toward AI ($M = 3.37$, $SD = 0.81$) compared to a negative attitude toward AI ($M = 2.39$, $SD = 0.79$).

3.4. Correlations. Table 3 presents the results of the Pearson correlation analysis. It indicates that the positive attitude toward AI significantly and positively correlates with the openness personality trait ($r = 0.499$, $P < 0.001$) and negatively correlates with both the agreeableness ($r = -0.153$, $P = 0.024$) and neuroticism ($r = -0.142$, $P = 0.036$) personality traits. Additionally, the results revealed a significant positive correlation between negative attitude toward AI and agreeableness ($r = 0.488$, $P < 0.001$), conscientiousness ($r = 0.316$, $P < 0.001$), and neuroticism ($r = 0.319$, $P < 0.001$) personality traits.

3.5. Stepwise Multiple Regression Analysis of Attitude toward AI. A stepwise multiple regression investigation was done to explore how nursing students' attitudes toward AI, either

TABLE 1: Students' demographics and differences in attitude toward AI ($N=218$).

Characteristics	Category	No.	%	Positive		Negative	
				M (SD)	t/F (P)	M (SD)	t/F (P)

	p	0.036
Openness	r	0.499
	p	<0.001

AI: artificial intelligence; r : Pearson's correlation; p : level of significance.

positive or negative, as the dependent variable, correlated with personality traits that showed statistical significance in Pearson's correlation analysis as independent variables. Sociodemographic factors were not included in the regression model since they did not show any significant impact on the attitudes toward AI (as detailed in Table 1).

The analysis found no multicollinearity issues; for positive attitudes, the tolerance values were between 0.86 and 0.97 (above 0.1), and the variance inflation factors (VIFs) were between 1.04 and 1.17 (below 3). Similarly, for negative attitudes, tolerance values ranged from 0.78 to 0.89 (above 0.1), and VIF values ranged from 1.12 to 1.28 (below 3).

In the regression analysis predicting positive attitudes toward AI, the results indicated that high openness ($\beta = 0.499$, $P < 0.001$), low neuroticism ($\beta = -0.178$, $P = 0.005$), and low agreeableness traits ($\beta = -0.175$, $P = 0.019$) were significant predictors of positive attitudes toward AI. The model accounted for 27.2% of the variance in nursing students' attitudes toward AI (Table 4).

In the regression analysis predicting negative attitudes toward AI, the results displayed that agreeableness ($\beta = 0.372$, $P < 0.001$), conscientiousness ($\beta = 0.172$, $P = 0.005$), and neuroticism ($\beta = 0.160$, $P = 0.011$) were significant predictors of negative attitudes toward AI. The model accounted for 28.7% of the variance in nursing students' negative attitudes toward AI (Table 5).

4. Discussion

This study examined the relationship between nursing students' personality traits and their attitudes toward artificial intelligence (AI), focusing specifically on a Saudi Arabian context. While there have been studies examining healthcare professionals' attitudes toward AI, limited research has focused on nursing students in Saudi Arabia. This study aimed to fill that gap by exploring how personality traits, as categorized by the Big Five framework, influence attitudes toward AI.

The study findings indicated no statistically significant difference in the students' attitudes toward AI, either positive or negative, while taking into account the demographic characteristics of the students. Previous studies have suggested that cultural factors can influence attitudes toward technology, supporting the idea that a similar cultural background may lead to consistent attitudes [11, 18, 20]. This lack of difference could be attributed to the homogeneous cultural background of the participants. Saudi Arabian nursing students may share similar cultural values and educational experiences, which could result in comparable attitudes toward AI. However, there is limited direct evidence linking similar cultures as predictors of attitudes toward AI. Other possible explanatory factors include varying levels of exposure to AI technologies and differences in educational curricula, which can significantly impact attitudes. Further research in diverse cultural settings is needed to fully understand the cross-cultural differences in attitudes toward AI.

4.1. Personality Traits and Attitudes toward AI. Overall, the findings conclude that the Big Five personality traits—openness to new experiences, agreeableness, neuroticism, and conscientiousness—all tend to predict attitudes toward artificial intelligence, whether they are positive or negative, with the exception of extraversion: nursing students who scored highly on the openness trait had positive attitude toward AI; in contrast, those with high neuroticism and agreeableness scores showed more negative than positive attitudes toward AI; moreover, conscientiousness-scoring nursing students had negative attitudes toward artificial

intelligence. Thus, the findings of the study align with recent studies that found personality traits, to typically have a substantial effect on people's attitudes toward AI [8, 15, 18, 19, 42].

4.1.1. Openness. The findings are in line with other authors who contend that people who score highly on openness to experience are more likely to be flexible, curious, respectful of innovation, and open to new technologies—all of which are indicators of positive attitudes toward artificial intelligence. This supports existing knowledge that openness is associated with positive perceptions of technology [13, 19].

4.1.2. Agreeableness. However, the results of our study are consistent with suggestions that agreeableness was a significant predictor of people's negative attitudes toward AI [13, 43, 44]. Likewise, recent studies discovered no significant relationship between agreeableness and positive attitudes toward AI [19, 44]. In an explanation of such results, studies argued that people with higher agreeableness scores—such as etiquette, social skills, and willingness to compromise nature—might be more able to withstand the negative effects of AI [13, 43–45].

4.1.3. Conscientiousness. In the current study, nursing students who ranked high in conscientiousness showed a negative attitude toward artificial intelligence. However, a research study stated that conscientiousness did not significantly predict positive or negative attitudes toward AI; nevertheless, it showed a weak but significant positive correlation with negative attitudes [13, 46, 47]. However, those who are highly conscientious may have a more positive opinion of AI since they place great importance on organization, efficiency, and observing regulations. These individuals may also see AI as a tool to boost efficiency and production as they understand the importance of aptitude, efficacy, and organization [19]. This highlights a mixed understanding of how conscientiousness influences AI attitudes, suggesting further investigation is needed.

4.1.4. Neuroticism. The findings of our study showed that those who scored high in neuroticism exhibited more negative than positive attitudes toward artificial intelligence. Similarly, another study indicated that those who score highly on the neuroticism trait are more likely to be skeptical, fearful, and anxious, about the potential risks and implications of AI and consequently have negative attitudes toward artificial intelligence [19]. They may see AI as a threat rather than a helpful tool. The idea of machines mimicking human capabilities and potentially taking over tasks that were traditionally performed by humans may trigger feelings of insecurity and unease for these individuals. Their fear of AI replacing human jobs and potentially causing unemployment can further contribute to their negative attitudes [42, 48].

TABLE 4: Results of a multiple stepwise linear regression analysis predicting positive attitude toward AI of the studied nursing students ($N = 218$).

Predictors	B	SE (B)	β	T	P value	95% CI
Constant	2.623	0.260	—	10.075	<0.001	2.11–3.14
Openness	0.538	0.064	0.499	8.408	<0.001	0.412–0.664
Agreeableness	-0.186	0.066	-0.178	-2.822	0.005	-0.317–0.056

Neuroticism	0.185	0.072	0.160	2.581	0.011	0.044–0.326

B : unstandardized regression coefficient; SE: standard error; β : standardized regression coefficient; T : T -statistic; P : level of significance; 95% CI: 95% confidence interval; R (multiple correlation coefficient): 0.536; R^2 (coefficient of determination): 0.287; ΔR^2 (change in R^2): 0.277; F (F -statistic): 28.719; $P < 0.001$.

4.1.5. Extraversion. Although extraversion is a personality characteristic that may predict attitudes toward AI generally [44], our study indicates that extraversion is not a significant predictor of favorable or negative attitudes toward AI for Saudi Arabian nursing students involved in our sample. These results seem to be in line with studies that showed extroversion not to be a significant predictor of attitudes toward artificial intelligence, either positive or negative [13, 19, 46]. One possible explanation is that students come from a cultural background where solidarity and social harmony are valued more highly than individuality. This might lead to less extraversion and a more cautious approach toward artificial intelligence [49]. This may suggest that extraversion may not be a strong predictor of attitudes toward artificial intelligence in this specific population. Conversely, Schepman [44] showed a negative correlation between extroversion and attitudes toward AI, suggesting that introversion traits increase positive attitudes toward AI [44].

One possible explanation of the results of our study could be the cultural context in Saudi Arabia. In cultures where collectivism and conformity are emphasized, individual personality traits such as extraversion may have a diminished influence on attitudes toward technology. However, because artificial intelligence is still an evolving and complex area, nursing students may have varying degrees of exposure to and awareness of its potential benefits and implications for their field of work.

4.2. Implications of the Study. Given the paucity of research on the personality traits and attitudes of Saudi Arabian nursing students toward artificial intelligence, the current study is crucial for examining the attitudes of these students

and their preparedness to adopt AI in the field of nursing. Understanding the viewpoints and experiences of nursing students is imperative to address the scarcity of nurses, advance nursing, and improve patient outcomes.

Focusing on Saudi Arabia provides valuable insights into how cultural and educational contexts influence the acceptance of AI among future nurses. This information can help tailor AI healthcare systems to better align with the preferences and mindsets of their users, leading to more effective and efficient integration of AI in nursing practices. By doing so, we can enhance the efficiency of nursing workflows, reduce the burden on nurses, and potentially attract more individuals to the profession.

Moreover, improving the readiness of nursing students to adopt AI can lead to better patient outcomes by ensuring that future nurses are well equipped to utilize AI technologies in patient care. AI can assist in tasks such as patient monitoring, diagnostics, and personalized care plans, which can improve the quality of care provided. By understanding and addressing the specific attitudes and personality traits of Saudi Arabian nursing students, we can develop targeted educational strategies and interventions that foster a positive attitude toward AI, ultimately benefiting both nurses and patients.

To guide future strategies for promoting and applying AI in nursing, our findings suggest the need for targeted educational interventions that consider the diverse personality traits of nursing students. Training programs should emphasize the benefits and practical applications of AI in nursing to alleviate fears and resistance, particularly among those with high neuroticism and conscientiousness. Additionally, integrating AI-related content into nursing curricula can help build familiarity and competence, paving the

way for smoother adoption and utilization of AI technologies in healthcare settings. These strategies can contribute to a more prepared and adaptable nursing workforce, capable of leveraging AI to improve patient outcomes and address the ongoing challenges in the healthcare sector.

4.3. Limitations. There are some limitations to the research. The initial multicenter, cross-sectional research methodology of this study made it harder to build a causal relationship between the identified factors and nurses' knowledge and attitudes toward artificial intelligence. A long-term study on the personality traits of nursing students is recommended in order to have a more comprehensive understanding of the students' traits throughout various points in time of their lives and in relation to various clinical and professional concerns. Second, there is a greater chance of source/response bias because self-reported measures were employed to collect the data simultaneously and using the same method: online. Future studies should consider using a variety of data sources, such as focused groups and individual interviews, in order to preserve objectivity.

Third, depending on their personality traits, some students showed a more positive attitude toward AI than others, while others showed a more tendency toward negative ones. The negative attitudes might be a result of a variety of complex aspects such as worries that artificial intelligence (AI) could outsmart humans, create moral/ethical dilemmas, or lead to loss of jobs. Therefore, it is crucial to take into account the social and cultural elements that can affect Saudi Arabians' attitudes toward artificial intelligence. Fourth, although the study was multicentered, it was limited to a specific sample of Saudi Arabian nursing students, which may have limited the findings' generalizability and application to other populations of nursing students or healthcare settings. It would be helpful to replicate this study with greater and more varied samples to confirm rigor and generalizability.

Another limitation is that while the study assessed nursing students' attitudes toward AI integration, it did not evaluate the possible actual incorporation of AI technology in their educational practices. Upcoming research could discover the real operation of AI tools by nursing students and evaluate its influence on their learning consequences and clinical training. Overall, these limitations highlight areas where improvements can be made in future studies to enhance our understanding of personality traits and attitudes toward AI among Saudi Arabian nursing students.

5. Conclusion

Artificial intelligence is developing swiftly and is already showing up in a number of health-related fields, including nursing. To properly integrate this technology into the nursing profession, it is therefore imperative to comprehend the elements that influence attitudes toward it. Overall, it appears that personality traits can influence individuals' attitudes toward AI, with certain traits being more closely related to positive or negative attitudes. Given the dearth of

research on Saudi Arabian nursing students, the study's findings provide important insights into the personality traits and attitudes of Saudi Arabian nursing students toward artificial intelligence. The findings show that personality traits, except for extraversion, are often predictive of attitudes toward artificial intelligence whether positive or negative. The findings indicated that nursing students' positive attitudes toward artificial intelligence were strongly correlated with their openness to new experiences. Conversely, those whose personality traits scored highly on agreeableness and neuroticism were more likely to have negative than positive attitudes toward AI. Furthermore, conscientious nursing students have a negative attitude toward artificial intelligence.

Data Availability

The data used to support the findings of this study are available from the corresponding author upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

GS and MAZ planned the study and made substantial contributions to the conception and design, or acquisition of data, or analysis and interpretation of data. HEE, GS, MAZ, and AM were major contributors in writing and drafting the manuscript. GS and HEE were major contributors in writing the Discussion section. TA collected the manuscript and made the final revision. All authors have given final approval of the version to be published and agreed to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved.

Acknowledgments

The authors would like to thank all of the responding students for their cooperation. This study was supported via funding from Prince Sattam Bin Abdulaziz University (project number PSAU/2023/R/1445).

Aims. This study aimed to explore workload whether Nursing Activities Scores on one shift could predict workload for the next shift. **Method.** This was a retrospective observational exploratory study of cross-sectional design carried out in a postoperative and intensive care unit at a local, nonprofit hospital in Norway. Data were collected from the hospital's internal database from January 1st to June 30th, 2016. **Results.** A total of 2,695 patients and 5,916 Nursing Activities Scores were included. The model could predict a 55.1% to 66.9% variation in Nursing Activities Scores for the next shift. When the number of patients was added, the model explained up to 80% of the variation. **Conclusions.** The Nursing Activities Score can be used to predict nursing workload from one shift to another and as an instrument for managers to adjust their staffing requirements. **Implications for Nursing Management.** Nursing Activities Score assessing nursing workload for all patients in a unit can support the resource planning with accuracy for nurse staffing.

1. Background

The mix and size of nursing teams have implications for patient safety, quality of work, nurses' well-being, and the cost of patient care. There is increasing pressure on health expenditure, and several international studies have described resource planning in medical and surgical intensive care units (ICUs) [1–3]. There have also been studies on workload on postoperative and medium care units [4–6]. A review of 26 studies from ICUs found an association between the patient-per-nurse ratio and adverse events such as infections, postoperative complications, unplanned extubations, and burnout syndrome in nurses [7]. A study from 15 Dutch ICUs found that ICU mortality was associated with the nursing workload [8]. Other studies have

found that nursing workload is influenced by patient and nurse characteristics [9, 10], and that nursing workload and perceived workload are related [11].

In many postoperative units/ICUs, patient-per-nurse ratios are fixed per shift. However, the association between patient-per-nurse ratios and workload per patient has been found to be weak [8]. Therefore, using workload in one shift to predict workload in the next shift could be a better way for leaders to prioritize resources. Decock et al. [12] investigated whether nurse-level intensity within an intensity group of patients could predict nurse-level intensity on the next shift and on the same shift the next day [12]. The study divided patients into three categories (i.e., levels of lower, median, and high intensity) and could predict 69.7%–74.0% of workload within the categories.

A reliable and validated instrument can help managers prioritize resources to guide resource planning in the short and long term. The Nursing Activities Score (NAS) is a classification instrument used worldwide in medical and surgical ICUs [13]. The instrument was designed to monitor nursing workload per patient per day and shift in order to plan short- and long-term staffing [1, 12, 14]. The NAS consists of 23 different activities that measure direct and indirect ICU patient care, and the instrument has been validated to calculate 81% of actual nursing time. The items were defined by work sampling, and the score represents the calculated percentage of time one nurse spends on each item. A total score of 100% was defined as equal full-time work for one nurse per shift. However, studies have found that one nurse can manage 61–90% of NAS [15] and that certified intensive care nurses manage a higher workload than registered nurses [9]. Several electronic applications are used to find the operational characteristics of the NAS both in the short and long term [16]. Our study can support the idea of an application using NAS as an active tool in planning resources on a shift-to-shift-basis.

Nursing workload can be used as a factor in nurse staffing, and we suggest considering all short stays in a unit in calculating the workload. Monitoring, hygiene procedures, support and care of patients, and administrative and discharge duties are all part of nursing activities for all patients regardless length of stay, and nurse encounters are time consuming in postoperative units/ICUs. The aims of our study were to explore whether the NAS of one shift could predict the NAS of the next shift and to investigate whether the scores were influenced by patient sex, age, ward, type of admission, and the number of patients.

2. Methods

2.1. Design and Setting. This retrospective, observational, exploratory study was conducted at the postoperative and ICU at a local hospital in the eastern part of Norway. The hospital provides general services within fields such as internal medicine, surgery, and mental health for 145,000 people. The facility is also responsible for treating older people with hip fractures from a larger area. The postoperative unit/ICU is a 19-bed unit that provides invasive and noninvasive respiratory care, invasive hemodynamic monitoring with an arterial catheter, pulse-induced continuous cardiac output, administration of vasoactive and inotropic medications, and continuous dialysis replacement. The unit admits patients from the emergency room, medical and surgical wards, and the operation theater. The postoperative unit/ICU support the outpatient ward when they have 100% bed occupancy and after closing at night. Medical outpatients who receive electrical cardioversion are treated in the postoperative unit/ICU. The nursing staff consists of 50% registered nurses (RNs) with a bachelor's degree and 50% specialized nurses, some with a master's degree. Specialized nurses have a 1.5-year full-time postgraduate education in critical care nursing, nurse anesthetist, or 1-year full-time postgraduate education in cardiac nursing. Anesthesiologists and medical doctors are responsible for

medical treatment. During the daytime, a secretary takes care of administrative paperwork and calls, and a technical assistant is responsible for equipment maintenance, storage, and cleaning. The nurse-per-patient ratio varies from 1 : 3 for postoperative patients to 1 : 1 for ICU patients and 2 : 1 for demanding patients. The unit has more nurses during day shifts on weekdays than on other shifts and weekends. Staffing is flexible, and the manager can adjust for the next shift whenever there is a need for more or fewer nurses.

2.2. Sample. Data were collected from an internal database in the hospital's administrative system, anonymized, and transferred to a separate file for statistical analysis. The study period was from January 1 to June 30, 2016, and included 2,695 patients and 5,916 scores of NAS over 182 days. The study included all patients admitted to the unit during this period.

2.3. Variables. Study variables included patient age, sex, ward (medical or surgical), type of admission (elective or emergency), type of surgery (gastro surgical, orthopedic, or nonsurgical patients), length of stay in the postoperative unit/ICU, patients per day, and shift (Table 1). The median NAS scored per patient for each shift is presented in Table 2.

2.4. Procedure Description. The validity and reliability of NAS has been tested in several Norwegian postoperative units and ICUs [5, 15, 17, 18]. From 2014, nurses at our postoperative/ICU scored the Nursing Activities Score on all patients admitted to the hospital. Before its introduction in 2014, nurses had been educated in using the instrument and subsequently undertook an updated course every year. Nurses responsible for the patient care collected the NAS on paper, and the secretary plotted all the data into an internal database. Data were checked for quality by the first author.

The scores of NAS were measured in three 8 hour (h) shifts per 24 h. Night shift began from midnight until 08:00, day shift from 08:00 to 16:00, and evening shift from 16:00 to midnight. For patients with a short length of stay of <8 h, the database was designed to calculate the shift and 24 h scores according to the time the patient stayed in the unit. For example, if a patient had a 50% NAS and stayed only 3 h, then the shift score would be 18.75% NAS, and the 24 h score would be 6.25% NAS for that patient. This aligns with the results of another study [5]. By including length of stay in NAS, a patient with a high workload and short length of stay could get a low NAS score, and a patient with a low workload and a long length of stay get a relatively high NAS.

2.5. Statistical Analysis. The data were analyzed using IBM SPSS Statistics version 25.0. Categorical variables were reported as absolute and relative frequencies and analyzed using the Chi-square or Kruskal–Wallis tests as appropriate. Continuous variables were reported as mean and standard deviation (SD) or median as appropriate. Differences between groups were analyzed with Student's *t*-test or

Mann–Whitney *U* test. Furthermore, univariable and multivariable linear regression models were used to investigate whether there was an association between the NAS and individual data.

To explore whether the NAS on one shift could predict the NAS on the next shift, the data were aggregated by day. Patient characteristics were also aggregated and included to investigate whether there was an association between the characteristics and the aggregated NAS. In the aggregated material, the NAS and number of patients were summed, and the average ages were determined. The gender, ward, and type of admission were calculated as an average between 0 and 1, indicating the percentages. To explore the extent to which NAS-night shift could predict NAS-day shift, NAS-day shift was set as the dependent variable and NAS-night shift as the independent variable in the regression analysis. To investigate whether NAS-day shift was associated with patient characteristics, the characteristics of day shifts were included in the model. The same method was used to investigate whether the NAS-day shift could predict the NAS-evening shift and to what extent patient characteristics on the evening shift were associated with NAS. In all analyses, a *p* value <0.05 indicate statistical significance.

2.6. Ethical Approval. Ethical standards and regulations were followed. In each case, observations were measured and entered in an electronic system, which recorded and displayed results. The need to require informed consent from patients was waived, and data were anonymized prior to transfer to the research team. The study was approved by the local data protection officer of the hospital on the 4th of July 2018 with case number 18/11020. The decision ruled out bioethics committee.

3. Results

3.1. Patient Characteristics. Demographic and clinical characteristics of participants are presented in Table 1. Most patients were admitted to the emergency department (61.2%) and surgically treated (77.3%). The length of stay varied from 10 min to 23 days, and 62.7% of the surgical and 40.6% of the medical patients stayed in the unit for less than 4 h (not shown). The NAS per shift is described by sex, ward, type of admission, and type of surgery in Table 2. The patients on night shift had the highest NAS with a median of 55.7%. Patients on evening shift had 21.6%, and patients on day shift a median of 19.6% NAS.

3.2. Association between NAS Shift Scores and Individual Patient Data. Ward ($\beta = -0.33$, $p < 0.001$) and type of admission ($\beta = 0.33$, $p < 0.001$) had the strongest association with NAS-day shift as the dependent variable in the univariable linear regression on individual data in Table 3. The multivariate model explained 17.4% of the variation in the NAS-day shift. This was also observed with the NAS-evening shift as the dependent variables (ward $\beta = -0.40$, $p < 0.001$ and type of admission $\beta = 0.25$, $p < 0.001$), and the multivariate model could explain 19.3% of the variation in NAS-evening shift.

3.3. Association between NAS Shift Scores and Aggregated Data. Table 4 shows that NAS-nightshift ($\beta = 0.74$, $p < 0.001$) and the proportion of emergency patients during the day shift ($\beta = -0.39$, $p < 0.001$) had the strongest association with NAS-day shift as dependent variables on aggregated data in univariable linear regression. The model could explain 73.1% of the variation in NAS-day shift in multivariate linear

regression. NAS-night shift and NAS-day shift had a correlation coefficient of 0.74 (not shown), and NAS-night shift could explain 55.1% of the variation in NAS-day shift, Figure 1.

The NAS-day shift had the strongest association with the NAS-evening shift ($\beta = 0.82$, $p < 0.001$) and the proportion of emergency patients in the evening shift ($\beta = -0.32$, $p < 0.001$). In multivariate linear regression, the model explained 66.3% of the variation in the NAS-day shift. The NAS-day and evening shifts had a correlation coefficient of 0.82 (not shown), and the NAS-day shift could explain 66.9% of the variation in the NAS-evening shift, Figure 1.

We postulated that NAS shift scores were associated with the number of patients undergoing the shift. With the NAS-day shift as the dependent variable and the NAS-night shift and the number of patients during the day shift as independent variables, multivariate linear regression explained 80.7% of the variation in the NAS-day shift (not shown). If NAS increased by 1% on the night shift, the NAS-day shift increased by 0.8%. For every admitted patient during the day shift, NAS increased by 16.4%. The correlation coefficient between the NAS-day shift and the number of patients on the day shift was 0.70. The same was done with the NAS-evening shift as the dependent variable and the NAS-day shift and number of patients on the evening shift as independent variables. Multivariate linear regression explained 70.4% of the variation in the NAS-evening shift. If NAS increased by 1% on the day shift, the NAS-evening shift would increase by 0.7%. For every patient admitted during the evening shift, the NAS increased by 10.8%. The correlation coefficient between the NAS-evening shift and the number of patients on evening shift was 0.70 (not shown).

4. Discussion

This study found a strong association between the NAS in one shift and the NAS in the next shift. When the number of patients in the next shift was added to the model, the NAS-night shift could explain up to 80% of the variation of NAS-day shift, and the NAS-day shift could explain 70% of the variation of NAS-evening shift. This was valid for the unit however not for individual patients. In our study, we analyzed the number of patients in the next shift retrospective. That number would be an unknown factor prospectively, but mean number of patients expected for the shift could be included in the calculation. In this study, patient characteristics had no practical impact on the NAS unlike results found in other studies [2, 10]. Results above 70% show that NAS on one shift has a large effect on NAS on the next shift [19] and that the patient classification system, NAS, can support nurses and managers with the allocation of resources from one shift to the next. The NAS is a dynamic bottom-up instrument that can guide resource planning for a postoperative unit/ICU. Studies have found that bottom-up approach could be a more accurate instrument to guide costing approach [18, 20, 21].

To our knowledge, this is the first study to explore whether total NAS in one shift could predict total NAS in the next shift. To get the full overview of workload in a unit, we ask that all

patients regardless of the length of stay should be included since everybody receives nursing care. The study by Decock et al. [12] determined care intensity by NAS cut-offs and found a predictivity of 69.7%–74.0% from one shift to the next. The study included all patients (3,295) admitted on weekdays, unlike our study, which also included patients admitted on weekends. The main difference between the studies was the length of stay, with a short median time of 3.4 h, versus Decock et al.'s 2.8 days. The study by Decock et al. does not describe whether patients with a short length of stay were included or whether patients were adults and/or children, surgical, and/or medical [12]. The study confirmed the findings in our study that NAS can substantially contribute to predicting workload on the next shift.

The staff in charge use their professional judgement to estimate if available resources and expected use of resources agree. Electronic systems are already used to operational NAS trends and characteristics [16]. A mobile NAS application set up to calculate and predict the workload for the next shift could confirm the professional judgement in allocation of resources for the next shift.

The length of stay in our study is in line with a study from a postoperative unit that included all patients with a length of stay of more than 1 h [6]. Other studies have excluded patients with length of stay < 4 –24 h [8, 15, 22, 23]. We argue that all patients receiving care from a nurse should be included regardless of the length of stay. Not to include all admitted patients could unintentionally exclude a significant amount of workload. Several studies have found an association between the NAS and length of stay [1, 6, 10, 23]. Our study could not analyze this association because the length of stay was included and calculated within the NAS.

In our study, older patients and men were associated with higher scores of NAS when individual data were analyzed. This association was small (not significant), which is in line with other studies [1, 6, 10, 23, 24]. Furthermore, surgical patients had lower scores than medical patients which is in line with the findings of a study by Moghadam et al. [10]. Type of surgery could explain the lower scores for surgical patients as the hospital does not perform heart-, lung-, neuro-, or trauma surgery. There are no gynecological or children service at the hospital. Lima and Rabelo found an association between NAS, length of stay, and magnitude of surgery [6]. Whether the magnitude of surgery or length of stay had the strongest association with NAS was not explored in our study and requires further research.

We found that the NAS from patients on the night shift had the highest median score (55.6%) versus the patients on the day shift (19.6%). On the other hand, the total scores from all patients (aggregated data) were lowest on night shifts and highest on day shifts. Other studies have found low scores on night shifts and the highest scores during the day shifts [1, 10, 22]. In our study, fewer patients at night could explain the low aggregated scores on the night shifts. This means that the unit needed fewer nurses at night, but patients who stayed in the unit at night received more nursing activities.

FIGURE 1: Association between NAS-night shift vs NAS-day shift and NAS-day shift vs NAS-evening shift on aggregated data. NAS, Nursing Activities Score.

In our study, the NAS was scored by nurses responsible for patient care. A study by Stuedahl found poor agreement between scores performed by bedside nurses versus managers and physicians [17] and confirmed the initiation by Miranda et al. that the bedside nurse should perform the NAS on every shift [14].

4.1. Limitations. This study had some limitations. Only one unit was included, and the retrospective design could only assess associations, not causalities. Including only patients who stayed over to the next shift could change the results and requires further investigation. The study population was a case mix of medical, surgical, elective, and emergency patients, and further research should be performed on the generalizability of our findings. The NAS does not consider the competence level of nurses, and further research should investigate the associations and factors between competence level, workload, patient safety, and quality of care. The NAS does not include emergency preparedness in the scoring, which are important factors for allocating nurses to the next shift. Our unit included length of stay in the NAS, which makes the scores difficult to compare with earlier studies. The COVID-19 pandemic, with an extraordinary workload worldwide, caused a delay in processing results and writing articles.

The strengths of this study include having a complete dataset for all days and shifts during the study period, and that bedside nurse scored NAS on all patients.

4.2. Implications and Recommendations for Practice. This study found that the NAS together with number of patients on the next shift could explain up to 80% of the variation of workload on the next shift. Implications for practice could be that the NAS tool can confirm professional judgement to allocate resources for the upcoming shift. We recommend the development of a mobile NAS application that merge the NAS for one shift, the number of patients expected on the next shift, available nurse staff, and emergency preparedness. This objective application together with professional judgement can empower managers prioritize scarce resources on a shift-to-shift-basis.

5. Conclusions

This study found that the NAS can be used to predict nursing workload from one shift to the next and be a beneficial instrument for managers to adjust their staffing requirements. However, patient safety and the best quality of care are also influenced by other factors, such as nurses' qualifications, cooperation among healthcare professionals, and external variables. However, these were not included in the aim of this study and require further research.

Data Availability

Data were collected from an internal database in the hospital's administrative system.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

AMH designed and conducted the study, supervised data collection, administered the project, and performed data analysis, interpretation, and writing of the original manuscript. ØK designed the study, performed data analysis and interpretation, and contributed to the writing of the manuscript. SKS contributed to the interpretation of data and writing of the manuscript. AMH, SKS, and ØK conceptualized the study. AMH curated the data. AMH, SKS, and ØK performed the formal analysis. AMH and ØK designed the methodology. SKS and ØK supervised the study. AMH, SKS, and ØK validated the study. AMH, SKS, and ØK contributed to the visualization. AMH, SKS, and ØK reviewed and edited the manuscript. All authors have read and approved the final manuscript.

Background. In the rapidly evolving healthcare management landscape, technology integration and artificial intelligence utilization play pivotal roles in shaping employee productivity. This research investigates these dynamics within Riyadh Province, Kingdom of Saudi Arabia, focusing on the relationships between technology integration, the use of artificial intelligence in nursing profession, nursing workforce competencies, technological leadership, and employee productivity. **Methods.** A quantitative approach was employed, involving 329 nurses from five hospitals in Riyadh Province. Partial Least Squares Structural Equation Modeling facilitated comprehensive analysis of direct and indirect relationships among variables. **Results.** Findings reveal that technology integration significantly enhances nursing productivity, while the use of artificial intelligence initially presents disruptions before yielding productivity gains. Nursing workforce competencies mediate these relationships, emphasizing the critical role of workforce readiness in harnessing technology's benefits. Surprisingly, technological leadership did not significantly moderate these effects. **Conclusions.** This research offers vital insights for healthcare organizations, advocating strategic technology integration and workforce development. It underscores the significance of nursing competencies in navigating technological transformations and affirms the enduring importance of leadership in guiding these changes. As healthcare evolves, these findings provide guidance for optimizing technology and artificial intelligence to enhance employee productivity and patient care.

1. Introduction

The continuous evolution of technology and its integration into healthcare systems have ushered in a transformative era in the field of healthcare management [1]. In the contemporary healthcare landscape, where innovation plays a pivotal role, understanding the intricate dynamics between technology, workforce competencies, leadership, and employee productivity is paramount [2, 3]. As healthcare organizations adopt technology and artificial intelligence (AI) to enhance patient care and streamline operations, understanding the implications of these advancements on

employee productivity becomes crucial [1]. Technology integration, encompassing the assimilation of various technologies into healthcare processes, and the use of AI in nursing roles, representing the incorporation of AI tools into nursing roles, hold immense significance within this context [3]. Furthermore, the role of nursing workforce competencies in navigating these technological shifts and the influence of technological leadership in guiding these changes are of paramount importance [4].

Prior research has consistently emphasized the positive impact of technology integration on healthcare organizations [3, 4]. Effective technology integration can lead to

improved operational efficiency and enhanced patient care outcomes [5]. Additionally, healthcare organizations that successfully integrate technology experience higher levels of employee productivity [6]. Recent studies have explored the integration of AI into nursing roles and its implications [4]. The study by Chicoine observed that while AI can optimize healthcare processes, its introduction may initially disrupt established workflows, potentially affecting productivity [4]. The AI integration requires workforce adjustments and training to mitigate any negative impact on productivity [3].

Moreover, the role of workforce competencies in healthcare settings has been extensively investigated [7]. Research has emphasized the importance of nursing competencies in effectively utilizing technology to enhance patient care [6]. Workforce competencies are critical in realizing the potential benefits of technological advancements in healthcare [8]. Additionally, the role of leadership in guiding technology adoption has been a subject of inquiry. A study by Khan highlighted the significance of transformational leadership in fostering an innovative culture within healthcare organizations [9]. Also, leadership plays a crucial role in ensuring that technology adoption aligns with organizational objective [10].

Despite the substantial body of research on each of these variables individually, there exists a notable gap in comprehensively understanding how they interact within the specific context of healthcare organizations [4]. Previous studies have often focused on isolated aspects, neglecting the holistic interplay between technology integration, the use of AI in nursing roles, nursing workforce competencies, technological leadership, and their combined impact on employee productivity [4, 6, 9].

Additionally, the specific contextual factors in Riyadh Province and the broader Kingdom of Saudi Arabia may introduce unique dynamics that warrant dedicated investigation [11, 12]. Riyadh, the capital and largest city of Saudi Arabia, boasts a diverse population and a wide array of healthcare institutions, encompassing primary care facilities and advanced hospitals. Notably, approximately 82% of private health institutions are located in Riyadh city, with the remaining 18% distributed across peripheral provinces [13]. The Kingdom of Saudi Arabia is now experiencing fast modernization and development, with a special focus on the healthcare sector. These efforts are being pushed by the Vision 2030 projects, which aim to diversify the economy and enhance healthcare services [14].

This research seeks to address these gaps by providing a comprehensive examination of these variables and their relationships, offering valuable insights for healthcare organizations navigating the evolving landscape of healthcare management. This research endeavors to shed light on these critical relationships within the context of healthcare organizations. By examining the impact of technology integration, the use of AI in nursing roles, nursing workforce competencies, and technological leadership on employee productivity, this study aims to contribute valuable insights to the healthcare management literature and offer practical implications for healthcare organizations navigating this dynamic terrain.

This study is driven by several interconnected objectives. Firstly, it aims to investigate the impact of technology integration on productivity within healthcare organizations. Secondly, it seeks to explore how the use of AI in nursing influences employee productivity in this context. Thirdly, the research aims to understand the mediating role of nursing workforce competencies in the relationships between technology integration and employee productivity, as well as the use of AI in nursing and employee productivity. Lastly, it endeavors to examine whether technological leadership moderates the relationships between technology integration and employee productivity and the use of AI in nursing and employee productivity.

Based on the identified gap in the literature and the overall objective of the study, this research aims to address the following research questions:

- (1) How does technology integration impact productivity within healthcare organizations?
- (2) What is the influence of the use of AI in nursing on employee productivity in the healthcare context?
- (3) What is the mediating role of nursing workforce competencies in the relationships between technology integration and employee productivity, as well as the use of AI in nursing and employee productivity?
- (4) Does technological leadership moderate the relationships between technology integration and employee productivity and the use of AI in nursing and employee productivity?

2. Literature Review and Hypothesis Development

The healthcare sector in Saudi Arabia has experienced significant growth and advancement in recent decades [11]. This shift has been marked by extensive funding for healthcare facilities, technologies, and employee training in an effort to improve healthcare delivery across the country [5]. The healthcare system in the Kingdom has undergone a transition from predominantly government-funded and government-provided to encompassing private sector involvement, fostering heightened competition and innovation [12]. Riyadh, as the capital and largest metropolis of the Kingdom, is at the forefront of advancements in medical treatment [15]. The urban area has several medical facilities, encompassing both publicly and privately funded institutions, all of which demonstrate a steadfast dedication to delivering exemplary healthcare services [15]. It is crucial for healthcare organizations to prioritize addressing issues related to nurses' productivity, as it directly impacts the quality of care delivered to patients. Recognizing the importance of improving employee productivity, healthcare organizations aim to enhance patient outcomes and ensure the highest level of care within the healthcare sector [6].

The implementation of advanced technologies has played a significant role in healthcare reform initiatives in Saudi Arabia [11]. Hospitals in Riyadh and across the

Kingdom have deployed advanced information technology systems to improve patient record management, streamline administrative processes, and enhance diagnostic and therapeutic capabilities [12]. Technological integration is expected to considerably impact the delivery of healthcare services, which may have a consequential effect on healthcare workers' efficiency [16]. Furthermore, Riyadh hospitals and the healthcare industry in Saudi Arabia as a whole have given significant attention to AI in nursing. AI-driven applications such as medical diagnosis algorithms and robotic surgical aids have the potential to improve healthcare delivery [17].

The introduction of AI into nursing positions is anticipated to result in significant shifts in the nature of nursing work and its impact on overall workforce productivity [16]. The successful implementation of technology and AI in Riyadh hospitals relies heavily on the competencies of the nursing profession, another focal point of this research [15]. Healthcare personnel, including nurses, in Saudi Arabia have benefited from extensive government-funded training and development initiatives to prepare them for the impact of technological changes [18]. However, the role that these skills play in mediating the connection between tech adoption, AI utilization, and worker output is still a subject of debate [4]. Technological leadership also plays a crucial role in the current healthcare system [19, 20]. Leaders in Riyadh's hospitals, both at the managerial and clinical levels, play a critical role in advancing technological projects, fostering a spirit of innovation, and maximizing the benefits of technology and AI while minimizing their drawbacks [3, 15]. Effective leadership is essential for guiding the healthcare industry through the technological transition taking place in Riyadh, Saudi Arabia, as evidenced by the moderating influence of technological leadership on the relationship between technology integration, AI utilization, and employee productivity [17, 18].

2.1. Technology Integration and Employees' Productivity. Technology integration refers to the extent to which an organization incorporates advanced technologies, digital tools, and information systems into its daily operations and workflows [21]. This encompasses not only the adoption of technology but also its effective utilization to streamline processes and enhance overall organizational performance [22]. Empirical evidence from diverse sectors underscores the pivotal role of technology integration in enhancing employee productivity [23]. Employee productivity, a multifaceted concept encompassing the measurement of an employee's work output, including factors such as task completion, work quality, and efficiency, has garnered significant attention in organizational research [24]. At its core, it reflects the organization's ability to effectively utilize its human resources to achieve its goals and objectives. One prominent factor influencing employee productivity is the level of technology integration within the organization [25].

Theoretical support for the relationship between technology integration and employees' productivity can be found in the Resource-Based View (RBV) of the firm, which

posits that organizations can gain sustained competitive advantages by possessing and effectively leveraging valuable and rare resources [26]. In the context of technology integration, advanced technological infrastructure becomes a valuable resource that contributes to increased productivity. By integrating technology effectively into their operations, organizations can optimize their processes, improve task efficiency, and ultimately bolster employee productivity [27]. Numerous empirical studies have corroborated the positive relationship between technology integration and employee productivity across various industries [28]. For example, firms that have successfully integrated technology into their operations have reported higher levels of employee productivity compared to those that lag in technological adoption [3]. In the healthcare sector, the adoption of health information technologies has been linked to improvements in both employee productivity and patient care outcomes [8], further emphasizing the broad applicability of this relationship.

From a theoretical standpoint, the RBV framework provides insights into how technology integration influences employee productivity by viewing technology as a valuable resource that contributes to organizational success [29]. This perspective aligns with the notion that technology, when effectively integrated, serves as a catalyst for efficiency improvement and productivity enhancement [30]. Thus, organizations that strategically leverage technology as a resource are better positioned to achieve sustainable competitive advantages and foster a culture of productivity and innovation. Therefore, we developed the following hypothesis.

Hypothesis 1. Technology integration significantly affects employees' productivity.

2.2. Utilization of AI and Employee Productivity. The utilization of AI in nursing occupations refers to the extent to which AI technologies, including AI-assisted diagnostics and decision support systems, are embedded within the responsibilities of nurses in healthcare settings [31]. In the context of healthcare, where precision and timeliness are paramount, the integration of AI technologies into nursing roles emerges as a significant independent variable that shapes the landscape of employee productivity [32]. Empirical investigation demonstrated that AI integration holds promise for enhancing the efficiency and productivity of healthcare personnel, particularly nurses [30].

Employee productivity, a multifaceted construct encompassing job completion, work quality, and efficiency, is a critical measure of organizational performance and effectiveness [33].

The concept of augmentation suggests that AI technologies serve to complement rather than replace human capabilities, aligning seamlessly with the notion that AI integration in nursing roles enhances employee efficiency [34]. The concept of augmentation also provides a theoretical framework for the relationship between the utilization of AI and employee productivity. Empirical evidence underscores

the significant impact of AI applications on employee productivity within the healthcare sector [35]. AI-driven solutions, such as clinical decision support systems and AI-assisted diagnostics, have demonstrated potential in expediting and refining patient care processes, thereby bolstering the productivity of healthcare staff, including nurses [36]. Notably, in fields like radiology, AI algorithms have markedly improved the efficiency of radiologists' work, highlighting the positive influence of AI on productivity [37]. The theoretical underpinning of the augmentation concept further validates this hypothesis, emphasizing that the goal of AI technology is to complement human labor rather than supplant it [38]. When integrated into nursing roles, AI technologies can support healthcare professionals in tasks such as data analysis, decision making, and patient monitoring, enabling them to fulfill their responsibilities more effectively [39]. Thus, the theoretical expectation is that the utilization of AI in nursing roles will enhance their productivity by augmenting their capabilities, aligning closely with the proposed hypothesis.

Hypothesis 2. Use of AI significantly affects nurses' productivity.

2.3. Nursing Workforce Competencies as Mediator. Nurses' competencies encompass all aspects of nursing and include knowledge, attitude, and skills [40]. Nursing workforce competencies are pivotal in facilitating the effective utilization of technology and thereby contributing to organizational productivity [31]. Extensive empirical research has consistently highlighted the positive correlation between technology integration and employee productivity across diverse industries, underlining the significance of technological advancements in enhancing organizational performance [41]. Similarly, studies have underscored the profound impact of a highly competent nursing workforce on organizational productivity, emphasizing the critical role of competencies in driving efficiency and effectiveness [27]. However, while existing research has independently explored the relationships between technology integration, employee productivity, and the influence of competencies on productivity, there remains a dearth of empirical studies directly investigating the mediating role of nursing workforce competencies in the context of technology integration within healthcare settings [42]. Nonetheless, given the crucial role of nursing competencies in leveraging the potential of technology, it is theoretically plausible to posit that nursing workforce competencies serve as a mediating mechanism in the relationship between technology integration and employee productivity [28]. The theoretical support for this hypothesis based on the Job Demands-Resources (JD-R) model suggests that job demands and job resources influence employee outcomes, including productivity [43]. In the context of technology integration in nursing, competencies can be seen as job resources. By possessing the necessary competencies, nurses are better equipped to manage the demands of using technology in their work. These competencies act as mediators between technology integration and employee productivity, as they

enable nurses to effectively navigate and utilize technology, leading to improved productivity outcomes [44].

Grounded in this theoretical framework, it is proposed that the competencies possessed by nursing professionals act as a conduit between the integration of technology and its subsequent impact on employee productivity [45]. As nurses acquire greater proficiency and knowledge in effectively utilizing technology, they are better equipped to optimize their productivity levels, thereby supporting the proposition of the mediating role of nursing workforce competencies in the context of technology integration [46]. This hypothesis underscores the intricate interplay between technology integration, nursing workforce competencies, and employee productivity, emphasizing the need for further empirical investigation to unravel the underlying mechanisms and implications for healthcare organizations.

Hypothesis 3. Nursing workforce competencies significantly mediate the relationship between technology integration and employees' productivity.

Empirical research has emerged as a strong advocate for the integration of AI within healthcare, particularly in nursing roles, as a means to bolster efficiency and productivity [39]. This body of evidence underscores the transformative potential of AI technologies in streamlining processes, optimizing decision making, and improving patient outcomes. Concurrently, a wealth of studies has consistently highlighted the positive correlation between a highly competent nursing workforce and organizational productivity [38].

The competencies possessed by nursing professionals, including clinical expertise, critical thinking skills, and technological proficiency, are acknowledged as key drivers of operational effectiveness and quality of care delivery [37]. However, despite the abundance of research in both domains, there remains a notable gap in the literature concerning the direct exploration of the mediating role of nursing workforce competencies in the context of AI utilization within nursing roles [36]. This gap presents an opportunity for theoretical exploration and empirical investigation to shed light on the intricate interplay between these variables [34].

The theoretical framework supporting the hypothesis of nursing workforce competencies as a mediator between AI utilization and employee productivity is rooted in the concept of mediation, a fundamental tenet of causal inference in social science research [30]. According to this framework, nursing workforce competencies serve as an intermediary mechanism through which the utilization of AI technologies influences employee productivity. The rationale behind this proposition lies in the premise that more competent nurses are inherently better equipped to leverage AI tools effectively within their roles [21].

Competencies related to AI, such as data interpretation, algorithm understanding, and system integration, empower nurses to harness the full potential of AI technologies to enhance their workflow efficiency, clinical decision making, and overall productivity [25]. As nursing professionals acquire and apply these competencies in their daily practice, they are theoretically poised to optimize their productivity

levels, thereby bridging the gap between AI utilization and enhanced employee productivity [24]. This theoretical perspective not only provides a conceptual framework for understanding the dynamics at play but also offers practical insights for healthcare organizations seeking to leverage AI technologies to their fullest potential [22].

In summary, the hypothesis of nursing workforce competencies as a mediator between AI utilization and employee productivity represents a novel avenue for research inquiry in the field of healthcare management and nursing practice [23]. By elucidating the underlying mechanisms and pathways through which AI technologies impact productivity outcomes, this line of research has the potential to inform evidence-based strategies for workforce development, technology implementation, and organizational performance improvement within healthcare settings.

Hypothesis 4. Nursing workforce competencies significantly mediate the relationship between the use of AI and nurses' productivity.

2.4. Technological Leadership as Moderator. Technological leadership in healthcare refers to utilizing advanced technology as AI applications to enhance the quality of care and assist patients, healthcare professionals, and organizations in diagnosis, treatment, safety, and resource allocation [19]. Technological leadership in healthcare requires proactive and visionary leaders that actively promote digital innovation, set a good example, and adapt to changing circumstances to ensure the effective adoption of health information technology in the healthcare field [47].

Technological leadership serves as a crucial determinant of an organization's ability to effectively adopt and implement technology, thereby fostering innovation and maximizing its utilization [3]. Empirical research consistently underscores the positive relationship between technology integration and employee productivity, highlighting the importance of integrating advanced technologies into organizational workflows [26]. Additionally, studies have emphasized the pivotal role of effective leadership in shaping the outcomes of technology adoption and implementation across various industries. However, despite the recognized significance of leadership in technology-related decisions and organizational culture, limited empirical research directly examines the moderating effect of technological leadership on the relationship between technology integration and employee productivity within healthcare settings [33]. Nevertheless, it is theoretically plausible to posit that technological leadership acts as a moderator in this relationship, potentially enhancing or attenuating its strength depending on the effectiveness of leadership practices [32]. The theoretical basis for this hypothesis draws upon the concept of moderation, which suggests that technological leadership can exert an influence on the strength and direction of the relationship between technology integration and employee productivity [31].

Effective leadership practices may facilitate the successful integration and utilization of technology, thereby amplifying its positive impact on employee productivity. Conversely, ineffective leadership may impede technology integration efforts, resulting in a weaker relationship between technology adoption and productivity [41]. The theoretical underpinning of this hypothesis underscores the importance of leadership in shaping organizational processes and outcomes, particularly in the context of technology adoption and utilization [27]. By recognizing the moderating role of technological leadership, healthcare organizations can better understand and leverage leadership practices to optimize the impact of technology on employee productivity [28]. Further empirical research is warranted to empirically validate this theoretical proposition and elucidate its implications for healthcare management and leadership practices.

Hypothesis 5. Technological leadership significantly moderates the relationship between technology integration and nurses' productivity.

Empirical research has unequivocally demonstrated the potential of AI to enhance employee productivity within healthcare, particularly in nursing professions [48]. Simultaneously, studies have underscored the critical role of leadership in shaping the outcomes of technology adoption and deployment across various industries [44]. However, despite the growing body of evidence supporting the individual impacts of AI utilization and technological leadership, there exists a gap in empirical research regarding the moderating effect of technological leadership on the relationship between AI utilization in nursing roles and employee productivity within healthcare settings [45]. Nevertheless, from a theoretical standpoint, it is plausible to suggest that technological leadership acts as a moderator in this relationship, exerting influence on the strength and direction of the impact of AI utilization on employee productivity based on leadership effectiveness [46].

The theoretical foundation for this hypothesis is grounded in the concept of moderation, which posits that technological leadership can shape the relationship between the use of AI in nursing roles and employee productivity [39]. Effective leadership practices may facilitate the successful integration and utilization of AI technologies within nursing workflows, thereby enhancing employee productivity [38]. Conversely, ineffective leadership may impede AI adoption efforts, resulting in a weaker relationship between AI utilization and productivity [37]. Thus, the theoretical support for this hypothesis stems from the notion that technological leadership can moderate the relationship between AI utilization in nursing roles and employee productivity within healthcare organizations [36]. In essence, understanding the moderating role of technological leadership can provide valuable insights for healthcare organizations seeking to optimize the impact of AI technologies on employee productivity [34]. Further empirical research is needed to validate this theoretical proposition and explore

its implications for leadership practices and technology implementation strategies in healthcare settings.

Hypothesis 6. Technological leadership significantly moderates the relationship between the use of AI in nursing roles and employee productivity.

Based on the aforementioned review of literature and hypothesis development, the conceptual and theoretical model of the study was developed as shown in Figure 1.

2.5. Methodology. This study adopted a quantitative research design to investigate the intricate relationships among key variables in healthcare organizations located in Riyadh Province, Kingdom of Saudi Arabia. A purposive sampling method was employed to select a sample of 329 nurses, drawn from five different hospitals within Riyadh Province, ensuring representation from diverse healthcare facilities. The participants met specific inclusion criteria, namely, active involvement in clinical nursing practice within the selected hospitals.

To assess the research variables, validated measurement scales and items from previous research were adapted and customized to align with the unique context of this study. The key variables under scrutiny included technology integration, the use of AI, nursing workforce competencies, technological leadership, and productivity among nursing workforce.

The study variables were measured using adapted items from the scales of previous studies as follows: Technology integration was measured with three items [49]. The use of AI in nursing jobs was measured with eight items [50]. A three-item scale was employed for assessing nursing workforce competencies [51]. Technological leadership was measured with seven items [52]. Nursing productivity was measured on a six-item scale [53]. The participants rated their responses on a five-point Likert scale.

Data analysis was conducted using Partial Least Squares Structural Equation Modeling (PLS-SEM), a robust statistical technique suitable for analyzing complex models, particularly in scenarios with smaller sample sizes and a focus on prediction and understanding intricate relationships. PLS-SEM allows for the examination of both direct and indirect effects among variables, making it an ideal choice for this research.

The analytical process consisted of several steps, including data preprocessing, measurement model assessment, structural model estimation, and mediation and moderation analysis. Data were cleaned, checked for outliers, and assessed for normality to ensure data validity. Missing data were managed using appropriate imputation techniques.

The measurement model was evaluated to confirm the reliability and validity of measurement scales. This involved assessments of composite reliability (CR), average variance extracted (AVE), and discriminant validity. The structural model was then estimated to explore relationships among variables, and mediation and moderation effects were analyzed to understand the roles of nursing workforce competencies and technological leadership in mediating and moderating relationships.

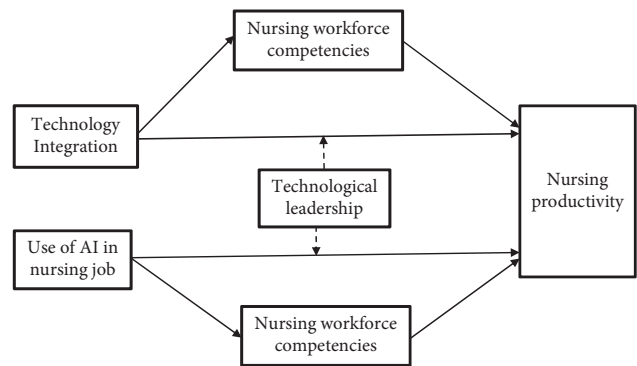

FIGURE 1: Conceptual and theoretical model of the study.

To ensure research validity and reliability, rigorous strategies were employed, including robust questionnaire design, adaptation of validated scales, and meticulous data analysis techniques. The quality and accuracy of the measurement model were validated through assessments CR, AVE, and discriminant validity.

Data collection was conducted through a meticulously designed structured questionnaire, tailored specifically for this study. To maximize convenience and efficiency, participants were administered the questionnaire electronically via e-mail and online survey platforms. Clear instructions were provided, emphasizing the research's purpose and the importance of providing accurate responses. Data collection was conducted over a defined period to ensure consistency and minimize potential external influences.

Ethical approval for this study was obtained from the Research Ethics Committee at the University of Hail in Saudi Arabia (Reference number: H-2023-298; dated: August 2, 2023). The study was conducted in accordance with the principles of the Declaration of Helsinki. Participants were informed of the study's aim, voluntary participation, and right to withdraw without penalty. Each individual gave informed consent before completing the questionnaire. All responses were kept strictly confidential for research purposes only, and the results did not personally identify respondents. The data collection period was carefully planned to maintain consistency and minimize potential temporal variations that could affect research outcomes. Data handling and storage adhered to data protection regulations to uphold participant confidentiality and privacy.

3. Results

Table 1 and Figure 2 show that the item loadings of utilization of AI in nursing jobs construct vary from 0.791 to 0.858, suggesting a robust association between the items and the construct. The CR rating of 0.938 above the required threshold of 0.7 suggests excellent internal consistency. The AVE score of 0.684 indicates that 68.4% of the variability in the construct is explained by the items. Cronbach's alpha coefficient of 0.923 provides additional evidence supporting the dependability of the concept.

Furthermore, the item loadings of employee productivity construct vary from 0.544 to 0.847, suggesting a reasonable

TABLE 1: Reliability and validity statistics of the study variables.

Construct	Items	Item loading	CR	AVE	Cronbach's alpha
Use of AI in nursing jobs	AI1	0.810	0.938	0.684	0.923
	AI2	0.855			
	AI3	0.796			
	AI4	0.830			
	AI5	0.848			
	AI6	0.791			
	AI7	0.858			
Employee productivity	EP3	0.544	0.835	0.566	0.741
	EP4	0.752			
	EP5	0.847			
	EP6	0.827			
Nursing workforce competencies	NWC1	0.723	0.754	0.508	0.729
	NWC2	0.625			
	NWC3	0.781			
Technology integration	TI1	0.828	0.798	0.569	0.724
	TI2	0.692			
	TI3	0.738			
Technological leadership	TL1	0.510	0.858	0.565	0.806
	TL2	0.926			
	TL3	0.485			
	TL4	0.931			
	TL5	0.778			

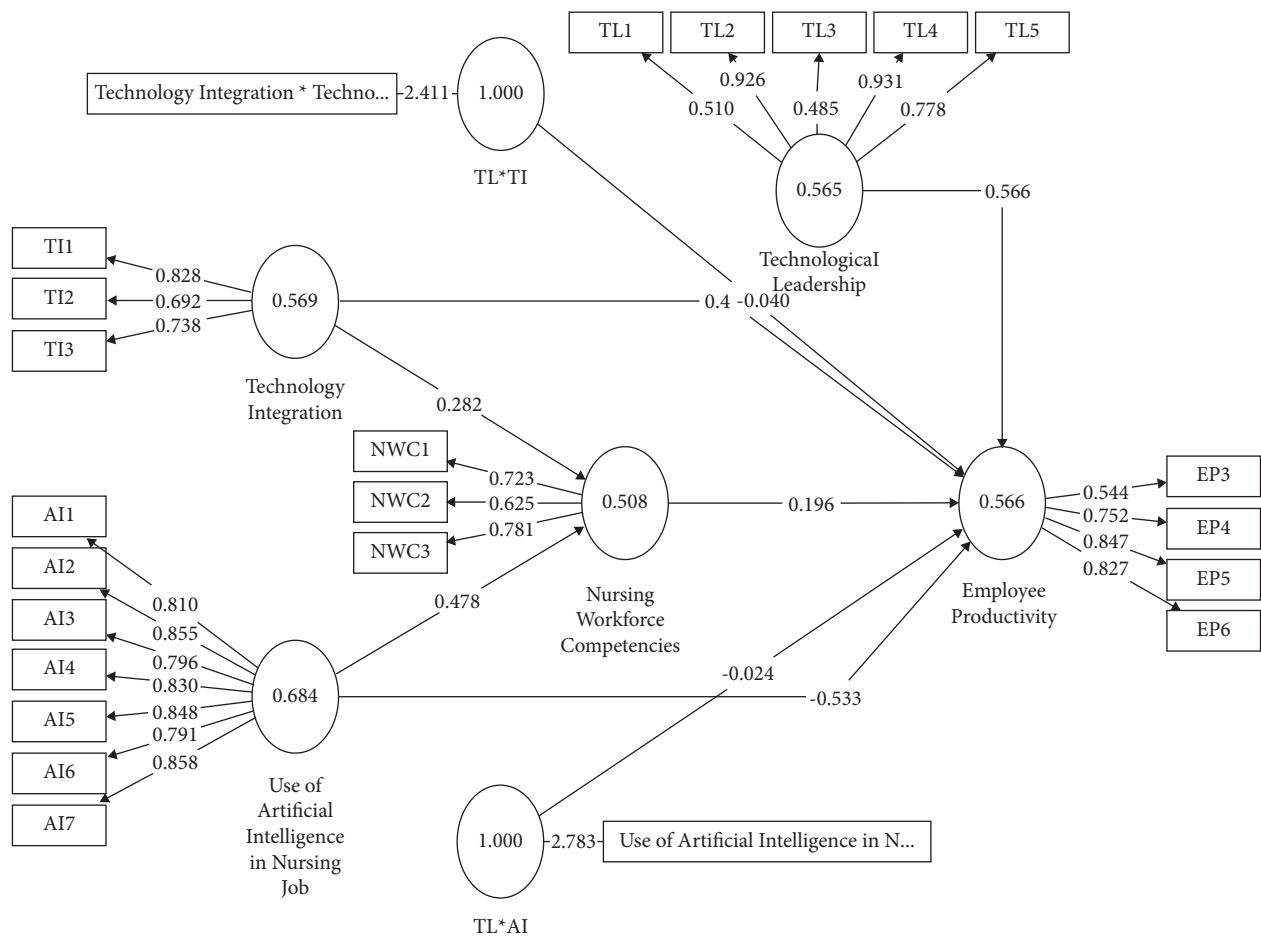

FIGURE 2: Measurement model.

correlation between the items and the construct. The CR value was 0.835 above the predetermined threshold, indicating a high level of internal consistency. The AVE of 0.566 indicates that 56.6% of the variation in the construct is explained by the components. Cronbach's alpha coefficient of 0.741 provides additional evidence for the dependability of the concept.

The item loadings of nursing workforce competencies construct vary from 0.625 to 0.781, suggesting a satisfactory correlation between the items and the construct. The CR value of 0.754 satisfies the required level, suggesting satisfactory internal consistency. The AVE score of 0.508 indicates that 50.8% of the variability in the construct can be accounted for by the components. Cronbach's alpha coefficient of 0.729 provides additional evidence of the construct's dependability. The item loadings of technology integration construct vary from 0.692 to 0.828, suggesting a reasonable correlation between the items and the construct. The CR value of 0.798 above the threshold indicates excellent internal consistency. The AVE score of 0.569 indicates that 56.9% of the variability in the construct can be explained by the items. Cronbach's alpha coefficient of 0.724 provides additional evidence for the dependability of the concept.

The item loadings of technological leadership vary from 0.510 to 0.931, suggesting a satisfactory correlation between the items and the construct. The CR value of 0.858 above the threshold indicates excellent internal consistency. The AVE score of 0.565 indicates that 56.5% of the variability in the construct is accounted for by the components. Cronbach's alpha coefficient of 0.806 provides additional evidence supporting the dependability of the concept.

Table 2 presents the Fornell–Larcker model, which assesses the discriminant validity of the study's constructs. This model examines whether each construct is more strongly correlated with its own latent variable than with other latent variables, thereby confirming their distinctiveness. The diagonal elements of the table display the square roots of the AVE values for each construct. For employee productivity, the diagonal value is 0.752, indicating that the AVE of this construct is greater than its correlations with other constructs, confirming its discriminant validity. Similarly, for nursing workforce competencies, the diagonal value is 0.712, exceeding its correlations with other constructs, supporting its distinctiveness. Technological leadership also demonstrates distinctiveness, as its diagonal value of 0.751 is higher than its correlations with other constructs. Technology integration exhibits distinctiveness with a diagonal value of 0.755, surpassing its correlations with other constructs. Finally, the use of AI in nursing job construct displays strong discriminant validity, as its diagonal value of 0.827 is greater than its correlations with other constructs. These results from the Fornell–Larcker model confirm that each construct in the study is distinct from the others, substantiating their discriminant validity and supporting the robustness of the measurement model.

Table 3 presents the results based on the Heterotrait-Monotrait (HTMT) criterion, which evaluates the discriminant validity of the study's constructs. The HTMT

TABLE 2: Fornell–Larcker model.

	1	2	3	4	5
Employee productivity	0.752				
Nursing workforce competencies	0.481	0.712			
Technological leadership	0.646	0.520	0.751		
Technology integration	0.560	0.565	0.411	0.755	
Use of AI in nursing job	0.291	0.645	0.584	0.593	0.827

TABLE 3: HTMT criterion.

	1	2	3	4	5
Employee productivity					
Nursing workforce competencies	0.741				
Technological leadership	0.693	0.749			
Technology integration	0.810	0.711	0.670		
Use of AI in nursing job	0.335	0.603	0.874	0.757	

values indicate the extent to which constructs are more correlated with their own latent variables compared to others. For employee productivity, the table is empty, indicating that this construct does not correlate with other constructs beyond its latent variable. For nursing workforce competencies, the HTMT value is 0.741, suggesting that it has a stronger correlation with its own latent variable than with others, supporting its discriminant validity. Technological leadership exhibits a HTMT value of 0.749, indicating that it is more strongly correlated with its own latent variable than with other constructs, thus confirming its distinctiveness. Technology integration demonstrates HTMT values of 0.810, 0.711, and 0.670 with other constructs, all below the threshold of 0.85, which is indicative of discriminant validity. The use of AI in nursing job exhibits HTMT values of 0.335, 0.603, 0.874, and 0.757, all below the 0.85 threshold, indicating that this construct is distinct from others and possesses discriminant validity. These results based on the HTMT criterion affirm the discriminant validity of each construct in the study, providing confidence in the measurement model's robustness.

Table 4 displays the model fit statistics, which assess the predictive quality of the research model. The $Q^2_{predict}$ value, equal to 0.612, represents the model's predictive accuracy. This value suggests that the research model has a good predictive capability, indicating that it can effectively estimate and explain the relationships among the studied variables. A root mean square error (RMSE) of 0.073 was found. The root mean square error (RMSE) is a measure of how well a model fits the data, and a smaller RMSE suggests that the model's predictions are close to the observed values. The mean absolute error (MAE) value is also provided (0.084). The mean absolute error (MAE) quantifies how off estimates are, on average. Higher predictive accuracy is indicated by a smaller MAE, which indicates that the model's predictions are, on average, quite close to the actual data. Taken together, these model fit statistics indicate that the research model is a good fit for the data and may be used to make informed inferences about the relationships between the variables of interest.

TABLE 4: Model fit.

Q ² predict	RMSE	MAE
0.612	0.073	0.084

TABLE 5: R-square.

Variable	R-square
Employee productivity	0.636
Nursing workforce competencies	0.467

Table 5 presents the R-square values for the study's variables, which indicate the proportion of variance in the dependent variable explained by the independent variables. For employee productivity, the R-square value is 0.636. This indicates that approximately 63.6% of the variance in employee productivity can be explained by the independent variables in the model, suggesting a strong explanatory power. For nursing workforce competencies, the R-square value is 0.467. This suggests that the model's explanatory power is moderate, as the independent variables account for about 46.7% of the variance in nursing workforce competencies. These R-square values assist in evaluating the overall explanatory power of the model by showing how well the independent variables in the study explain the variability in the relevant dependent variables.

Table 6 provides valuable insights into the F-square values, which illuminate the proportion of variance in the dependent variable explained by the independent variables within the study. In the context of employee productivity, these F-square values demonstrate the contributions of each independent variable: technological leadership emerges as a significant factor, explaining approximately 35.1% of the variance in employee productivity. Technology integration also plays a substantial role, contributing around 26.4% to the explanation of employee productivity. Additionally, the use of AI in nursing profession exhibits notable influence, contributing approximately 26.5% to the explanation of employee productivity. Nursing workforce competencies contribute about 5.3% to the explanation of the variance in employee productivity. For nursing workforce competencies, it is noteworthy that technological leadership contributes about 9.7% to the explanation of the variance in nursing workforce competencies. Technology integration contributes around 2.64% to the explanation of nursing workforce competencies, and it also contributes about 5.3% to its own variance. These F-square values collectively shed light on the explanatory power of the independent variables in relation to the dependent variables.

Table 7 presents the results of the path analysis, which elucidate the relationships between the variables in the research model. First, the path from technology integration to employee productivity demonstrates a positive relationship with a path coefficient of 0.437. This finding indicates that an increase in technology integration is associated with higher employee productivity (see Figure 3). The T-statistic of 6.093 is statistically significant ($p < 0.001$), underlining the robustness of this relationship. Similarly, the path from the use

of AI in nursing jobs to employee productivity shows a negative relationship with a path coefficient of -0.533 . This implies that a greater use of AI in nursing jobs is linked to lower employee productivity. This relationship is statistically significant with a T-statistic of 6.861 ($p < 0.001$).

Moreover, the indirect path from technology integration to nursing workforce competencies and subsequently to employee productivity reveals a positive relationship with a path coefficient of 0.055. This indicates that as technology integration increases, it positively affects nursing workforce competencies, which, in turn, enhances employee productivity. This path is statistically significant, with a T-statistic of 2.354 ($p = 0.009$). Similarly, the indirect path from the use of AI in nursing jobs to nursing workforce competencies and then to employee productivity shows a positive relationship with a path coefficient of 0.094. This suggests that an increased use of AI in nursing jobs positively influences nursing workforce competencies, subsequently leading to higher employee productivity. This path is also statistically significant, with a T-statistic of 3.214 ($p = 0.001$). Regarding moderation effects, the interaction terms (TLAI and TLTI) did not yield statistically significant relationships with employee productivity. The path coefficients for TLAJ and TLTI are -0.024 and -0.040 , respectively, with T-statistics of 0.678 ($p = 0.249$) and 0.981 ($p = 0.164$), suggesting that technological leadership does not significantly moderate the relationship between the use of AI in nursing duties or technology integration and employee productivity. These path analysis results provide a comprehensive understanding of how the variables in the study are interrelated and their respective impacts on employee productivity within the context of the research model (see Table 7).

4. Discussion

The purpose of the research was to examine the correlations between technological leadership, employee productivity, nursing workforce competencies, AI usage in the nursing jobs, and technological integration among nursing staff in the healthcare organizations at Riyadh Province, Saudi Arabia. A positive and statistically significant association between technology integration and employee productivity was indicated by the data, which verified Hypothesis 1. This finding aligns with previous research suggesting that effective integration of technology can enhance employee productivity [17]. Hypothesis 2 was also supported by the results, revealing a negative and statistically significant relationship between the use of AI in nursing job and employee productivity. This is consistent with prior studies, which suggest that the introduction of AI in healthcare settings may necessitate workforce adjustments and potentially lead to initial decreases in productivity [3]. The mediation effect proposed in Hypothesis 3 was substantiated by the data. It was found that nursing workforce competencies significantly mediate the relationship between technology integration and employee productivity. This result emphasizes the crucial role of nursing competencies in harnessing the benefits of technology, aligning with existing literature [24]. Hypothesis 4 was also supported, with

TABLE 6: *F*-square.

The study variables	Employee productivity	Nursing workforce competencies
Nursing workforce competencies	0.053	
Technological leadership	0.351	
Technology integration	0.264	0.097
Use of AI in nursing profession	0.265	0.278

nursing workforce competencies mediating the relationship between the use of AI in nursing duties and employee productivity. This underscores the importance of competence development among nurses to maximize the positive impact of AI technologies, in line with prior studies [3].

Hypothesis 5 did not receive empirical support, as technological leadership was not found to significantly moderate the relationship between technology integration and employee productivity. This finding contrasts with some existing research [48] and suggests that within the healthcare context studied, leadership may not play a significant moderating role in this specific relationship. Similarly, Hypothesis 6 was not supported by the data. Technological leadership was not found to significantly moderate the relationship between the use of AI in nursing tasks and employee productivity. This outcome may indicate that, within the healthcare context studied, leadership did not exert a notable moderating influence on this specific relationship.

The findings of this research provide valuable insights into the intricate dynamics between technology, workforce competencies, leadership, and productivity in healthcare organizations in Riyadh Province, Kingdom of Saudi Arabia. They underscore the need for healthcare institutions to carefully manage the integration of technology and the introduction of AI into nursing roles to optimize employee productivity. The positive relationship between technology integration and employee productivity highlights the potential benefits of effectively adopting and integrating advanced technologies in healthcare settings. This finding supports the idea that technology can enhance operational efficiencies and ultimately lead to improved productivity, which is consistent with previous literature [24]. Conversely, the negative relationship between the use of AI in nursing duties and employee productivity suggests that while AI technologies offer significant advantages in healthcare, their implementation can initially disrupt established workflows and processes. This finding resonates with research indicating that the introduction of AI may require adjustments and training to mitigate any negative impact on productivity [48].

The mediating role of nursing workforce competencies in both relationships emphasizes the importance of equipping healthcare professionals, particularly nurses, with the necessary skills and knowledge to effectively use technology and AI tools. This finding aligns with existing literature emphasizing the role of workforce competencies in realizing the potential benefits of technological advancements in healthcare [54]. Surprisingly, the study did not find significant moderation effects of technological leadership in either relationship. This result suggests that, in the specific healthcare context studied, leadership may not exert

a substantial influence on the relationship between technology adoption and employee productivity. However, it is important to note that leadership remains a critical component of successful technology implementation in healthcare organizations [54].

4.1. Limitations and Future Research Directions. While this research contributes valuable insights to the field of healthcare management and technology adoption, it is important to acknowledge its limitations. Firstly, the study was conducted in the specific context of healthcare organizations in Riyadh Province, Kingdom of Saudi Arabia. The findings may not be directly transferable to diverse cultural, organizational, or regional settings. Future research should explore the generalizability of these findings across diverse healthcare contexts. Secondly, the research primarily relied on quantitative data, and the results are based on self-reported measures. While this approach provides valuable quantitative insights, it may not capture the full spectrum of qualitative nuances and contextual factors that influence technology adoption and employee productivity in healthcare settings. Future studies could incorporate qualitative methods to provide a richer understanding of these dynamics. Thirdly, this research focused on a selected set of variables, primarily technology integration, the use of AI, nursing workforce competencies, and technological leadership. While these variables are critical within the healthcare context, there may be additional factors, such as organizational culture, resource availability, and patient demographics, that influence the relationships explored in this study. Future research should consider a broader range of variables to provide a more comprehensive analysis.

Building on the insights gained from this research, several avenues for future investigation emerge. Firstly, further exploration of the role of leadership in technology adoption and its impact on employee productivity is warranted. The qualitative studies can delve into the leadership styles and practices that effectively facilitate technology integration in healthcare organizations. Secondly, as technology and AI continue to evolve rapidly, ongoing research is needed to assess their long-term effects on employee productivity and patient outcomes. Longitudinal studies can provide valuable insights into the sustainability of productivity gains and potential adjustments required over time. Thirdly, cross-cultural research can shed light on how cultural factors influence the relationships examined in this study. Comparative analyses across different healthcare systems and regions can enhance our understanding of the generalizability of these findings and the role of cultural

TABLE 7: Path analysis.

	Original sample	Standard deviation	T statistics	P values
Technology integration \geq employee productivity	0.437	0.072	6.093	≤ 0.001
Use of AI in nursing \geq employee productivity	-0.533	0.078	6.861	≤ 0.001
Technology integration \geq nursing workforce competencies \geq employee productivity	0.055	0.023	2.354	0.009
Use of AI in nursing \geq nursing workforce competencies \geq employee productivity	0.094	0.029	3.214	0.001
Technological leadership * use of AI in nursing \geq employee productivity	-0.024	0.036	0.678	0.249
Technological leadership * technology integration \geq employee productivity	-0.040	0.041	0.981	0.164

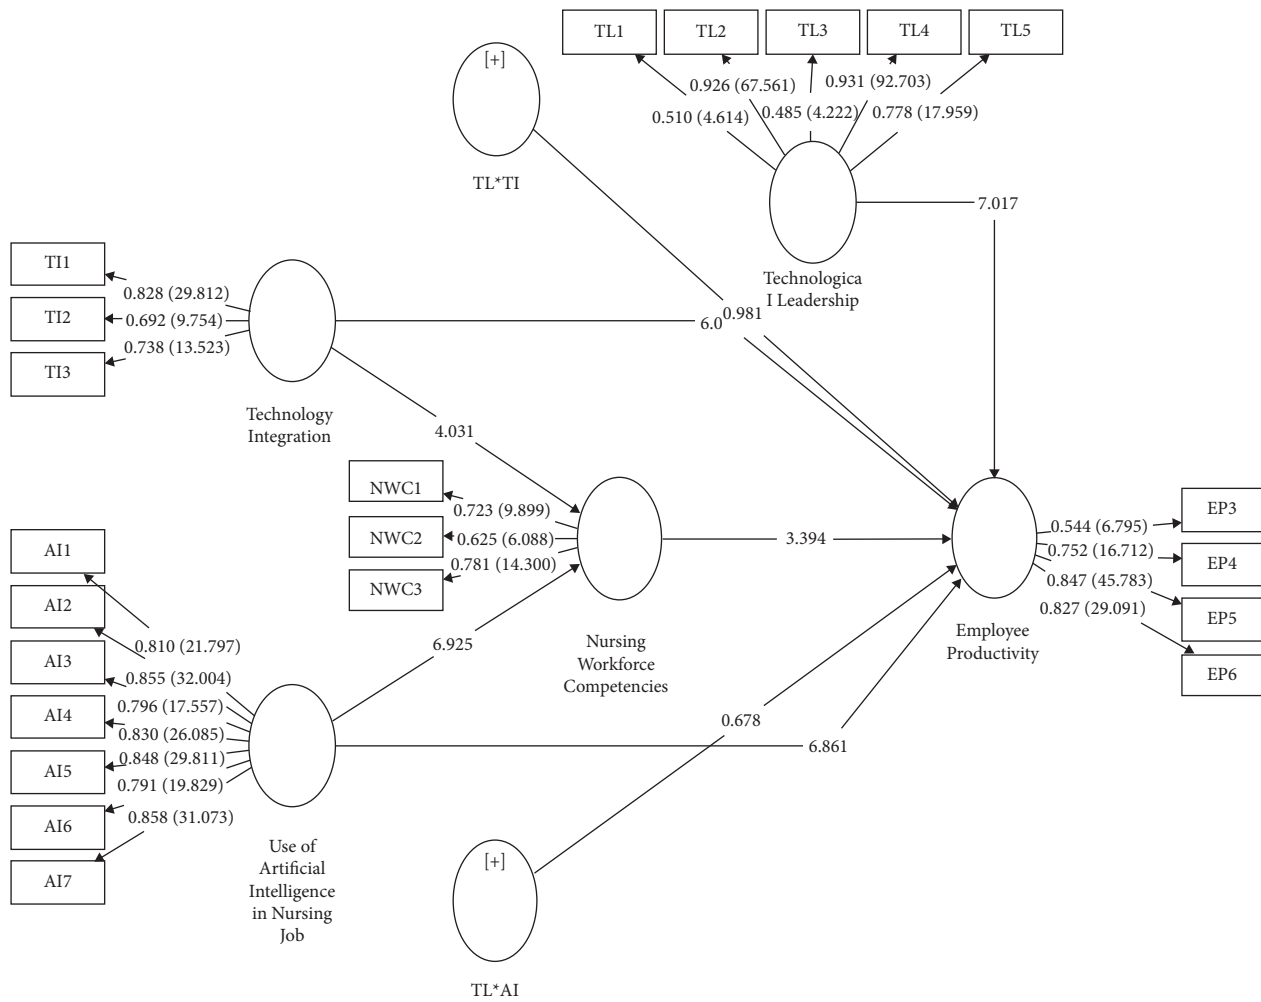

FIGURE 3: Structural model results.

contexts. Lastly, investigations into the impact of specific AI applications and technologies on nursing roles and patient care outcomes could offer specialized insights. Research could focus on the effectiveness of AI tools in tasks such as diagnostics, treatment planning, and patient monitoring, providing a more granular understanding of their effects.

In summary, this research lays the foundation for future studies to explore, refine, and expand upon the relationships between technology adoption, workforce competencies, leadership, and employee productivity in healthcare settings. Addressing these limitations and pursuing these research directions will contribute to a more nuanced and comprehensive understanding of technology-driven transformations in healthcare management.

4.2. Implications of the Study

4.2.1. Theoretical Implications. This research has several theoretical implications that contribute to the existing body of knowledge in healthcare management and technology adoption. Firstly, it reinforces the importance of considering the mediating role of nursing workforce

competencies when examining the impact of technology integration and the use of AI on employee productivity. This mediation framework provides a more comprehensive understanding of the complex relationships within healthcare organizations. Secondly, the findings challenge the assumption that technological leadership invariably moderates the relationship between technology adoption and employee productivity. This suggests that the influence of leadership may vary depending on contextual factors and organizational dynamics. It prompts further exploration of the nuanced role of leadership in technology-driven healthcare environments.

4.2.2. Practical Implications. Based on the study's findings, healthcare organizations should develop comprehensive training programs to enhance nurses' competencies in technology utilization. This can include specific training on various technologies, such as Electronic Health Record (EHR) systems, telemedicine platforms, and remote monitoring devices. By equipping nurses with the necessary skills and knowledge, they will be better prepared to effectively leverage technology in their daily practice.

While the study did not find significant moderation effects of technological leadership, it is still an essential component of successful technology implementation. Therefore, healthcare leaders should prioritize the development of a culture that encourages innovation and embraces technological advancements. Creating platforms for nurses to share insights and ideas on utilizing technology to improve processes can foster collaboration between nurses and technology specialists. Additionally, establishing innovation committees or task forces can help drive the adoption of innovative solutions.

Continuous monitoring and evaluation of technology integration's impact on nurse productivity and job satisfaction is crucial. Regular assessments, surveys, or feedback mechanisms can be utilized for this purpose. By collecting and analyzing data on the effectiveness of technology implementation, healthcare organizations can identify areas for improvement and make necessary adjustments to optimize outcomes.

To facilitate a smooth transition to technology integration, healthcare organizations should provide the necessary resources and support systems. This includes offering technical support, providing access to training materials and resources, and ensuring that nurses have sufficient time and support to adapt to new technologies. Establishing regular communication and feedback channels will address any concerns or challenges that may arise during the implementation process.

Healthcare organizations should also develop workforce adjustment strategies. This can involve reevaluating job roles and responsibilities, considering workload redistribution, or providing additional training and support to help nurses adapt to AI technologies. Proactive measures to address potential challenges can mitigate the negative impact on productivity and promote job satisfaction. By implementing these practical recommendations, healthcare organizations can enhance nurse productivity while increasing job satisfaction. This, in turn, can lead to improved patient outcomes and overall organizational performance.

5. Conclusions

In conclusion, this research has provided valuable insights into the complex dynamics between technology integration, the use of AI in nursing jobs, nursing workforce competencies, technological leadership, and employee productivity within healthcare organizations in Riyadh Province, Kingdom of Saudi Arabia. The study confirmed that effective technology integration positively influences employee productivity, while the use of AI, while beneficial in the long term, may initially pose productivity challenges. Furthermore, the mediating role of nursing workforce competencies emphasizes the critical need for ongoing training and skill development to harness the full potential of technology and AI in healthcare settings. Although this study did not find significant moderating effects of technological leadership, it is essential to recognize the enduring importance of leadership in guiding technological advancements and change management in healthcare organizations. Leaders must play

a pivotal role in fostering a culture of innovation and ensuring that technology adoption aligns with organizational goals. The findings underscore the significance of a well-prepared and adaptable healthcare workforce, capable of embracing and effectively utilizing technological advancements to enhance patient care and overall organizational performance. Healthcare organizations should prioritize workforce development programs and training initiatives to bridge competency gaps and facilitate the successful integration of technology. In summary, this research contributes to the understanding of how technology, AI, competencies, and leadership intersect in the healthcare sector. It provides healthcare administrators and policymakers in Riyadh Province, Kingdom of Saudi Arabia, with valuable insights to inform strategic decisions and investments in technology, workforce development, and leadership practices. As the healthcare landscape continues to evolve, these insights will be instrumental in ensuring that organizations can maximize the benefits of technological advancements while maintaining and improving employee productivity and patient care.

Data Availability

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

AA and MHA were responsible for study design, data collection, and study supervision. AA, MHA, and IAI were responsible for data analysis and interpretation and manuscript writing. IAI was responsible for statistical advice, rewriting, review, editing, and critical revisions for important intellectual content. All authors are in agreement with the content of the manuscript. Additionally, each author had provided final approval of the version to be published.

Acknowledgments

The authors would like to thank the Deanship of Scientific Research at Shaqra University for supporting this work.

Background. The link between organizational culture, organizational trust, job satisfaction, and team-based practice among nurse practitioners (NPs) has not been examined simultaneously. **Aim.** To identify the effects of organizational culture, organizational trust, and other factors on NPs such as job satisfaction and team-based practice. **Methods.** We used a cross-sectional design with a national sample. Data were collected using an online survey of 1,100 NPs working in acute care settings. The survey included demographic and working characteristics, the Organizational Culture Scale, the Organizational Trust Scale, the Misener Nurse Practitioner Job Satisfaction Scale (MNPJSS), and the NP-physician relations (NP-PR) subscale of the Nurse Practitioner Primary Care Organizational Climate (NP-PCOCQ). Multiple regression analysis with a stepwise selection method explored potential factors that influence job satisfaction and team-based practice. **Results.** A learning environment, psychological safety, senior leadership support, commitment to the organization, and the organizational culture and trust were positively associated with higher job satisfaction, which accounted for 49.2% of the variance in NPs' job satisfaction. Organizational trust, commitment to the organization, and learning environment promoted better team-based practice significantly. Also, NPs working a fixed shift pattern showed higher levels of team-based practice. These factors accounted for 23.66% of variances in team-based practice. **Conclusion.** Organizational culture and organizational trust affect the job satisfaction and team-based practice of NPs in acute care practices. **Implications for Nursing Management.** Acute care hospitals are encouraged to develop policies to enhance a learning environment, a supportive organizational culture, and trust in NPs' practice.

1. Introduction

Within 3 years, Taiwan is entering a superaged society (20% of the population above 65 years old in 2026) [1]. This will impose an even higher demand and burden on the healthcare system. Since 2006, in response to the growing demands of healthcare in the aging population, nurse practitioners (NPs) hold a key position as healthcare providers in acute care hospitals.

The scope of Nurse Practitioners' (NPs) practice was influenced by state laws and regulations in the USA, leading to three primary practice classifications: full practice, reduced practice, and restricted practice (American Association of Nurse Practitioners) [2]. Notably, NPs' practice scope in Taiwan aligns closely with the US model of restricted practice, involving supervision by physicians during clinical patient care [3].

Currently, more than 10,000 NPs provide healthcare in more than 350 acute care hospitals in Taiwan (Taiwan Association of Nurse Practitioners [4]). A recent study documented that NPs not only provide high-quality healthcare but also alleviate the burden on the healthcare system [5]. Hence, developing and retaining the NP workforce is a critical strategy for enhancing the quality and outcomes of acute care organizations. Specifically, the job satisfaction of NPs within acute care practices contributes to the care outcomes and retention of NPs [6].

NPs in Taiwan mainly work closely with physicians using a team-based practice model. A higher team climate or collaboration reported better care outcomes and higher job satisfaction [7]. NP studies further suggested that the various organizational supports enhance the job satisfaction of NPs [8–10]. For instance, findings from Ho et al. [8] indicated that NPs who perceived higher levels of organizational support experienced greater job satisfaction. Similarly, Luo et al. [9] concluded that healthcare administrators could enhance NPs' job satisfaction by improving organizational support in practice. In addition, studies on physicians similarly documented that organizational culture affects physicians' trust in the organization, which impacts job satisfaction and patients' trust [11, 12], especially when physicians perceive their organizational cultures to have an emphasis on quality, communication, and information, cohesiveness among clinicians, and values alignment between physicians and leaders [12]. However, those studies were conducted in the medical professions. Whether those results can be applied to NPs warrant further study to verify the results. Furthermore, the relationship between organizational culture, trust, team-based practice, and job satisfaction of NPs in acute care practices requires to be examined simultaneously. The results of the study can provide vital pieces of information to administrators for creating policies that could enhance team-based practice and job satisfaction of NPs.

Organizational culture is defined as the mutual perspective, assumptions, and standards of an organization's membership, and strong organizational cultures can support staff members to accomplish goals, complete tasks assigned to them, and perceive fulfillment in their job [13]. An enhanced organizational culture could also enable healthcare professionals to cope with complex and changing environments [14]. Several studies have shown that organizational culture is an important factor in job satisfaction [13, 15–17]. Zhang and Li [17] found a relationship between organizational culture and employee satisfaction. Kim et al. [18] reported that organizational culture significantly predicted job satisfaction among registered nurses. Similarly, Tsai [19] stated that organizational culture significantly increased job satisfaction in Taiwan. To summarize, the supportive organizational culture was beneficial for healthcare professionals to practice effectively, and hence they demonstrated better job satisfaction. Although a positive correlation between organizational culture and job satisfaction has been reported among healthcare professionals or nurses, the results of previous studies were limited by sample size,

generalizability, and non-NP samples. The link between organizational culture and job satisfaction among NPs has yet to be explored.

Interdisciplinary teamwork is an essential model for delivering healthcare to patients in acute care settings. Teamwork or team-based practice is defined as activities or processes through which team members achieve common goals by collaborating as a team [20]. Healthcare practice required well communication and cooperation between diverse clinical professionals. The relationship between NPs and physicians is important in team-based practice, which promotes better health outcomes [21]. Moreover, a strong culture engaged healthcare professionals to develop stronger teams with competitive advantages [22]. Several studies have shown the effects of organizational culture on team-based practice. Clarke [23] indicated that organizational culture develops mutual learning that facilitated discussions and negotiations among team members to meet patients' needs and achieve interdisciplinary team working. Abu-Jarad et al. [24] noted that organizational culture is a key dimension in studies that investigate organizational performance, and they found that organizational culture was positively correlated with organizational performance. Körner et al. [25], in a multicenter study, also found a direct influence of organizational culture on teamwork. As this literature has shown, a supportive organizational culture was the benefit of establishing effective teamwork. However, these results were based upon data from a small sample, and the specific influence of different dimensions of organizational culture on team-based practice among NPs is still unclear.

Although the influence of organizational culture on job satisfaction or teamwork has been studied extensively, studies within acute care settings among NPs are still scarce. Moreover, a significant body of previous studies measured culture as a single dimension. Measuring only one dimension of culture may cause a narrow view of the concept that ignores various sources of heterogeneity such as the environment or management support. Yet, organizational culture is a multidimensional construct, so the influence of organizational culture on professional outcomes can be viewed from a broader perspective [26]. Therefore, it is necessary to explore the influence of multiple dimensions of culture on NP practice outcomes such as job satisfaction and team-based practice among NPs.

In addition, organizational trust was a critical factor for job satisfaction. Organizational trust could be viewed as the faith of employees that the organization will make an all-out effort to achieve the commitment of employees [27]. Moreover, organizational trust may enhance the cooperation between employees and organizations, lead to effective communication, and compensate for any inadequate abilities of employees [28, 29]. Evidence from management and nursing studies suggested that organizational trust was essential for well-function organizations [30–32]. However, only a few studies have investigated the correlation between organizational trust and job satisfaction with nurses or healthcare professionals. For example, a positive correlation between organizational trust and job satisfaction was supported for nurses [31] and physicians

[30]. Furthermore, clinicians with improved or stable high trust reported higher satisfaction than those whose trust declined [11]. Nevertheless, the role and context of practice differed between NPs and other employees. At present, there are few studies focusing on the effects of organizational trust on job satisfaction among NPs.

Likewise, the correlation between organizational trust and teamwork was also examined by previous literature. Nonetheless, research on the influence of organizational trust on teamwork in the clinical field is scarce. Isik et al. [33] found that there is a positive relationship between teamwork and organizational trust among workers in call centers. Tekingündüz et al. [34] revealed that employees who worked at hospitals with higher levels of trust could feel valuable and important; hence, they were more willing to perform better. In addition, recent studies identified that organizational trust was positively related to team performance [35, 36]. However, these results were focused on a nonclinical sample, and the generalizability of previously published research on this issue was problematic. To the best of our knowledge, the lack of exploration of the link between organizational trust and job satisfaction among NPs remains a gap in the literature.

In considering the results of previous literature, we applied Herzberg's motivation-hygiene theory to explore potential factors affecting job satisfaction and team-based practice among NPs. Herzberg [37] classified factors influencing job satisfaction into motivators and hygiene factors in the workplace. The motivators are sometimes referred to as satisfiers, which are intrinsic conditions of the job itself, such as personal growth, opportunities for advancement, and a sense of importance to an organization. The hygiene factors are sometimes referred to as dissatisfiers, which are extrinsic to the work itself, such as working conditions, relationships with colleagues or supervisors, and organizational policies. If these hygiene factors were absent, staff would demonstrate more dissatisfaction with their job. In the current study, we classified NPs' demographic characteristics, organizational culture, and organizational trust as motivators or hygiene factors. We aimed and hypothesized that various organizational cultures and organizational trust affect NPs' job satisfaction and team-based practice.

2. Methods

2.1. Design. This study had a cross-sectional design, and it involved a national online survey to explore potential factors influencing job satisfaction and team-based practice.

2.2. Participants. We recruited participants from the Taiwan Association of Nurse Practitioners (TANP). NPs who had national certified licenses and had been working as NPs in acute care settings for at least 1 year were eligible for inclusion.

2.3. Ethical Considerations. The study was approved by the Institutional Review Board (IRB) of the China Medical University Hospital (CMUH111-REC3-059). Before eligible

NPs filled out the questionnaire, they were asked to read the detailed information about the contents of the study and complete a written informed consent via a unique link to the online survey. The study was also conducted in compliance with the ethical standards of the Helsinki Declaration.

2.4. Data Collection. There were 9,536 active members of TANP, and 6,808 eligible NPs were invited to participate from March to May 2022. Detailed information about the study's aims, procedures, written informed consent, and a unique link to the online survey were provided in each e-mail. In total, 1,113 NPs agreed to participate and completed the survey. The response rate was 16.35%. Thirteen participants were excluded from the analysis due to incomplete data (e.g., missing values in demographic data). As result, 1,100 participants were retained for further analysis. There was no significant difference between incomplete data and analyzed data in job satisfaction ($t = 0.07$, 95% CI (-2.60, 2.80), $p = 0.94$) and teamwork ($t < 0.001$, 95% CI (-0.25, 0.25), $p = 1.00$). The setting of a power analysis was conducted with $G * Power$ 3.1.9.7 for multiple regression analysis [38, 39]. According to the previous finding, the effect size (Cohen's f^2) ranged from 0.19 to 0.53 [15, 25]. We used a medium effect size value of 0.15 to conservatively calculate the sample size. With the effect size (Cohen's f^2) of 0.15, a statistical power of 0.90, a significant level of 0.05, and 10 potential predictors, the estimated sample size was 147. In addition, we assumed that the attrition rate of the online survey was about 10% [40]. Hence, the effective sample size for multiple regression analysis should be more than 162. The final number of the current study ($n = 1,100$) was sufficient to conduct the analysis.

2.5. Measurement

2.5.1. Demographic and Working Characteristics. The demographic characteristics of NPs, including age, gender, marital status, educational degree, working status, hospital level of practice, working hours per day, years of NP experience, NP advancement level, patient load, and annual salary, were surveyed by a series of questions.

2.5.2. Job Satisfaction. NPs' job satisfaction was assessed using the Misener Nurse Practitioner Job Satisfaction Scale (MNPJSS) developed by Misener and Cox [41]. This scale comprised 44 self-administered items with six dimensions, namely intrapractice partnership/collegiality; challenge/autonomy; professional, social, and community interaction; professional growth; time; and benefits. Each item was rated on a 6-point scale (ranging from very dissatisfied to very satisfied). Higher scores indicated a higher level of job satisfaction perceived by individuals in practice. MNPJSS has demonstrated proper reliability and validity in previous research relating to job satisfaction, and Cronbach's alpha was 0.94–0.96 [41, 42]. Cronbach's alpha value for this study was 0.95.

2.5.3. Team-Based Care. NPs' team-based care was evaluated using the NP-physician relations (NP-PR) subscale of the Nurse Practitioner Primary Care Organizational

Climate (NP-PCOCQ) developed by Poghosyan et al. [43]. This scale was developed specifically for the NP practice environment. This scale comprised 29 self-administered items with four subscales: NP-PR, professional visibility (PV), NP-administration relations (NP-AR), and independent practice and support (IPS). Each item was rated on a 4-point scale (ranging from strongly disagree to strongly agree). The NP-PR subscale measured the teamwork, communication, and relationships between NPs and physicians in practice. Higher scores obtained from the NP-PR subscale indicated better teamwork in practice. Previous research also showed adequate reliability and validity. The Cronbach alpha of this subscale ranged from 0.87 to 0.95 in previous studies [43, 44]. Cronbach's alpha value for the NP-PR subscale for this study was 0.90.

2.5.4. Organizational Culture. NPs' organizational culture was measured with the Organizational Culture Scale designed by Bradley et al. [45]. This scale could identify substantial diversity in culture related to patient care. It consisted of 31 items rated on a 5-point scale with options from 1 (disagree strongly) to 5 (agree strongly). This scale detected organizational culture in five domains: (a) learning environment, (b) psychological safety, (c) commitment to the organization, (d) senior leadership support, and (e) time for improvement efforts. The learning environment indicated that hospitals provided the latest information or knowledge about patient care for NPs. Psychological safety revealed that hospitals valued NPs' challenging assumptions, new ideas, or unique skills, and that it is quite easy to seek help in practice. Commitment to the organization indicated the emotional attachment between NPs and hospitals. Senior leadership support occurred when opinion leaders focused on improvement, encouraged changes in the quality of patient care, and offered the necessary resources (e.g., personnel or equipment) for NPs in practice. Time for improvement efforts refers to the time invested in enhancing the quality of patients' care. Higher scores indicated that NPs perceived a higher level of organizational culture in the hospital. This Cronbach's alpha was 0.94 for the entire scale and ranged from 0.77 to 0.88 for the subscales, which showed substantial reliability and validity in previous studies [45, 46]. The Cronbach alpha was 0.91 for the whole scale, and it ranged from 0.61 to 0.93 for the subscales (learning = 0.93; psychological safety = 0.78; commitment = 0.69; support = 0.87; time for improvement = 0.61).

2.5.5. Organizational Trust. Organizational trust was assessed using the scale developed by Gabarro and Athos [47]. This scale is a 5-item self-reported scale rated on a 4-point Likert-type scale from 1 (strongly disagree) to 4 (strongly agree). Higher scores indicate a stronger level of employee trust in the organization. Previous research also demonstrated satisfactory reliability and validity for this scale and Cronbach's alpha was 0.94 [47, 48]. Cronbach's alpha in the current study was 0.82.

2.6. Statistical Analysis. The distributions of NPs' characteristics and study variables were used for univariate descriptive analyses including percentage, mean, and standard deviation (SD). An independent *t*-test was used to compare the means of two independent groups. Pearson product-moment correlation coefficients (γ) were calculated to examine the correlations between two continuous variables. Potential factors influencing job satisfaction and team-based practice were explored by multiple regression analysis with a stepwise selection method. The stepwise selection aims to identify a subset of variables that are most relevant for predicting job satisfaction. The significant variables from the univariate analysis were included in the regression analysis. The unstandardized coefficient (*B*), 95% confidence interval (95% CI), standardized coefficient (β), standard error (SE), ΔR^2 , and adjusted R^2 were also estimated by the multiple regression model. The multicollinearity of regression was examined with the variance inflation factor (VIF) [49]. The VIF should be less than 5 [50]. All data were analyzed with SPSS Statistics Version 22.0 (IBM, Armonk, NY, USA) software. The value of significance was 0.05.

3. Results

3.1. Descriptive Statistics for NPs' Characteristics. A total of 1,100 NPs with completed data were included in statistical analyses. The average age of our sample was 43.49 (SD = 5.84). Most NPs were females ($n = 1,052$; 95.60%), married ($n = 729$, 66.30%), and had completed a university ($n = 896$; 81.50%) or Master's/Ph.D. degree ($n = 204$, 18.5%). The average years of experience as NPs were 9.12 years (SD = 4.10), and most worked in regional hospitals ($n = 776$; 70.50%). More than half of NPs worked fixed shifts ($n = 619$; 56.30%), the average daily working hours were 9.16 (SD = 1.40), and they cared for 13.3 (SD = 8.39) patients per day shift. The NPs' professional career ladder level was mainly NP1 ($n = 271$, 24.6%) or NP2 ($n = 411$, 37.4%) (Table 1).

3.2. Correlations between NPs' Background, Job Satisfaction, and Team-Based Practice. The correlations between NPs demographic characteristics, job satisfaction, and team-based practice are summarised in Table 2. NPs who were married ($t = -2.36$, 95% CI (-0.81, -8.88), $p = 0.02$), higher on the professional career ladder level ($r = 0.12$, $p < 0.001$), and had higher annual salaries ($r = 0.15$, $p < 0.001$) reported higher job satisfaction. Daily working hours were negatively related to job satisfaction ($r = -0.09$, $p < 0.01$). Age ($r = 0.08$, $p = 0.01$), years of NP experience ($r = 0.11$, $p < 0.001$), professional career ladder level ($r = 0.09$, $p < 0.01$), and annual salary ($r = 0.12$, $p < 0.001$) were positively correlated with team-based practice. However, working in a rotating shift rather than on a fixed shift showed a lower level of team-based practice ($t = -2.89$, 95% CI (-0.17, -0.87), $p < 0.01$).

There was a significant positive association between job satisfaction and organizational trust ($r = 0.55$, $p < 0.001$) (Table 3). Job satisfaction was positively

TABLE 1: NPs' characteristics and study variables (N = 1,100).

Variable	n (mean)	% (SD)
Age (years)	43.49	5.84
<i>Gender</i>

Note. * $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$.

TABLE 3: Correlations among organizational culture, organizational trust, job satisfaction, and team-based practice ($N = 1,100$).

Variable	Job satisfaction	Team-based practice
Organizational trust	0.55***	0.45***
<i>Organizational culture</i>		
Learning environment	0.62***	0.39***
Psychological safety	0.59***	0.34***
Commitment to organization	0.51***	0.37***
Senior management support	0.56***	0.31***
Time for improvement efforts	0.02	-0.01
Total	0.69***	0.42***

Note. *** $p < 0.001$.

associated with all dimensions of organizational culture (r ranged from 0.56 to 0.62, $p < 0.001$) except for time for improvement. Furthermore, team-based practice was positively associated with organizational trust ($r = 0.45$, $p < 0.001$). Except for the time for improvement, all subscales of organizational culture were positively associated with team-based practice (r ranged from 0.31 to 0.39, $p < 0.001$).

3.3. Factors Influencing Job Satisfaction and Team-Based Practice. The results of the stepwise multiple regression on NPs' job satisfaction are in Table 4. Some 49.2% of the variances in NPs' job satisfaction were explained by organizational culture (learning environment, commitment to the organization, psychological safety, and senior leadership support), and organizational trust. Of these, the primary two variables that accounted for 37.8% of the variances were the learning environment dimension of organizational culture and psychological safety (7.2%). The higher learning environment ($B = 1.18$, 95% CI (0.77, 1.59), $p < 0.001$), psychological safety ($B = 1.77$, 95% CI (1.34, 2.21), $p < 0.001$), senior leadership support ($B = 1.54$, 95% CI (0.85, 2.23), $p < 0.001$), commitment to the organization ($B = 0.81$, 95% CI (0.33, 1.30), $p < 0.01$), and organizational trust ($B = 2.59$, 95% CI (1.75, 3.42), $p < 0.001$) were positively associated with higher job satisfaction.

Organizational trust, organizational culture (commitment to the organization and learning environment), and working status accounted for 23.66% of the variance in NPs' team-based practice. Organizational trust was the strongest independent predictor accounting for 20% of the variance in terms of team-based practice. Higher organizational trust ($B = 0.37$, 95% CI (0.27, 0.46), $p < 0.001$), commitment to the organization ($B = 0.13$, 95% CI (0.08, 0.18), $p < 0.001$), and learning environment ($B = 0.07$, 95% CI (0.13, 0.11), $p = 0.001$) were positively associated with higher team-based practice. Moreover, NPs who worked fixed shifts rather than rotating shifts had higher levels of team-based practice ($B = 0.38$, 95% CI (0.07, 0.69), $p < 0.001$) (Table 4).

The VIFs of each significant predictor for job satisfaction (which ranged from 1.82 to 2.74) and team-based practice (which ranged from 1.00 to 1.92) were less than 5, which indicated that there was no multicollinearity in the multiple regression model [50].

4. Discussion

Our findings were consistent with Herzberg's motivation-hygiene theory. We found that motivators such as organizational trust could promote both job satisfaction and team-based practice in practice. For the hygiene factors, only working status reduced NPs' performance in team-based practice. These results highlight the importance of the organizations' role in significantly improving the positive organizational culture in healthcare organizations and trust levels within the practice. Moreover, managers or supervisors could modify the working shift patterns of NPs to ensure better team-based practice.

4.1. Variables Affecting Job Satisfaction. Our study identified specific dimensions of organizational culture that influenced NPs' job satisfaction, which was consistent with Herzberg's motivation-hygiene theory (Figure 1(a)). To begin with, better learning environments improve job satisfaction. This might be because the learning environment may inspire NPs to put forth the remarkable effort and enhance their professional competency and professional growth. Along similar lines, hospitals with better learning environments could help NPs to gain new knowledge and advanced skills in the process of providing care. The internally motivated work behavior could improve the psychological states of employees (e.g., job satisfaction in the current study) [51]. One recent study also indicated that the utilization of NPs' education or on-the-job training was significantly correlated with job satisfaction [52]. The learning environment might increase practice variety and enhance NPs' motivation while producing better effectiveness in practice. Laschinger et al. [53] indicated that the enhancement of professional knowledge and expertise is critical for being effective in practice. Similarly, NPs viewed learning environments such as by continuing education as a vital element for professional growth, which could be recognized for their organizational efforts and enhance job satisfaction [54]. Subsequently, the learning environment increases NPs' identification and effectiveness of practice, which promote job satisfaction. To improve job satisfaction, the healthcare organizations should develop a supportive learning environment at the organizational level such as implementing advanced education programs, enhancing interdisciplinary communication, and improving the process of care by utilizing the latest information or clinical equipment.

TABLE 4: Potential factors associated with job satisfaction and teamwork among acute care NPs (N= 1,100).

FIGURE 1: Effect of variables on job satisfaction and teamwork.

Furthermore, our study also found that senior management support can increase NPs' job satisfaction, which is supported by previous studies [8, 10]. Senior managers could gain greater insight and provide the necessary support or resources for NPs to deliver care, thereby increasing NPs' job satisfaction. Poghosyan et al. [10] noted that the importance of organizational support, especially higher organizational-level support, was

associated with higher job satisfaction. Eskandari et al. [55] also indicated that nursing leaders or managers were key in creating supportive working environments, which increases job satisfaction. Thus, support from senior managers is essential for the job satisfaction of NPs. On the other hand, senior managers could also implement policies to empower NPs' practice. Senior managers could coordinate with other supervisors or middle managers

and even convince administrators that sufficient empowerment is critical for acute care and that it can improve job satisfaction. Consequently, NPs could practice more efficiently and report better job satisfaction. This finding suggests that it is necessary to encourage NPs to communicate with senior managers and that senior managers should be proactive in empowering NPs at the organizational level of practice by implementing policies to improve job satisfaction.

Moreover, we found that feelings of psychological safety could increase job satisfaction. Psychological safety could be defined as “an individual’s perceptions of the consequences of taking interpersonal risks in a workplace” [56], P. 23). The positive effect of psychological safety on job satisfaction might likely contribute to sufficient support from organizations. The NP system was implemented for over fifteen years in Taiwan, and hospital administrators aware of the scope of practice of NPs and have given them the necessary support for practice [5]. In consequence, NPs perceived greater psychological safety and improved job satisfaction. Therefore, healthcare organizations should continue to support NPs’ practice at the organizational level.

Lastly, our result showed that the greater organization’s commitment, the better job satisfaction was demonstrated. This finding was supported by previous studies documenting that commitment was a significant predictor of job satisfaction [6, 30]. This would be explained that job satisfaction would increase by the greater organizations’ commitment through satisfactory empowerment. According to Meyer and Allen [57], organizational commitment refers to psychological attachment or affective commitment initiated in relation to an individual’s identification and involvement within the organization. NPs with supportive working environments might fully practice their professional role which promotes organizational commitment. Moreover, recent studies had showed that organizational support is a vital factor in enhancing work commitment [58, 59]. Therefore, healthcare organizations are suggested to modify policies to balance the practice rights of NPs and physicians in the collaborative practice model, which might strengthen the organizational commitment and improve job satisfaction of NPs.

Except for organizational culture, the results of our study have revealed the positive effect of organizational trust on job satisfaction. This might be explained by different authorizations of hospitals to allow NP practice [9, 60]. This lack of uniform guidelines of practice may cause conflicts between NPs’ professional roles and hospitals’ regulations, which could lead to limits on NPs’ practice rights. Thus, NPs might not trust hospitals and might therefore have poor job satisfaction [61]. On the contrary, a sufficient organizational trust might enable NPs to perceive their own professional value and enhance job satisfaction [34]. The health department of the government should formulate uniform guidelines of practice to promote the trust relationship between NPs and organizations; hence, NPs would show better job satisfaction.

4.2. Variables Affecting Team-Based Practice. The current study showed that team-based practice was influenced by organizational trust, organizational culture, and the fixed shifts (Figure 1(b)). Above all, organizational trust is essential to improve team-based practice, which was in accordance with previous studies [33, 35, 36]. This might be because organizational trust could improve communication between team members [28, 29]. In Taiwan, NPs mainly work with physicians to deliver team-based care to meet the complex needs of patients [44]; hence, effective communication is vital for team-based care. Ozluk and Baykal [62] noted that healthcare professionals provide care for patients, which requires high concentration in the collaboration process, so even the smallest neglect might lead to patient safety issues. Employees are likely to reciprocate organizational trust through better performance as organizations provide employees with sufficient trust from managers (vertical trust) or coworkers [35]. Consequently, NPs would perceive more organizational trust, which may lead to better team-based practice.

Furthermore, our findings demonstrated that team-based practice was positively influenced by the learning environment. The practice of NPs is complex and improvements in the learning environment such as new skills or sharing information, along with better cooperation with other professional staff are critical for healthcare. A previous review study also noted that there would be beneficial effects for health professionals to experience good learning environments such as teamwork education programs in acute care settings [63]. If organizations focused on building the culture including continuous improvement in the practice, it would encourage NPs to deliver superior performance [64]. Similarly, Engle et al. [65] found that better organizational cultures had links with high performance, and they indicated that some medical centers fostered multidisciplinary approaches, which could facilitate the delivery of both evidence-based practice and patient care. Therefore, they suggested that organizations should enhance the opportunities for interdisciplinary collaboration and the implementation of digital data management to increase the performance of team-based practice in acute care settings.

In addition, our findings also indicated that organizational commitment could increase the effectiveness of team-based practice. We found that organizational culture had direct effects on team-based practice, which were comparable with previous studies [22, 23, 25]. This might be explained by the fact that NPs’ roles were ambiguous in the collaborative care model as they might not be adequately supported. Even though NPs worked with physicians to deliver team-based care and basically followed practice guidelines. Therefore, organizations need to empower NPs with policies to ensure their clinical practice is valued within team-based care and each team member is aligned with his or her responsibility in patient care, which promotes efficient team-based practice.

Lastly, we found that NPs were more likely to demonstrate high efficiency in team-based practice, as they worked on a fixed schedule, which was consistent with previous studies [66, 67]. This result might contribute to the distress

or burnout shift workers experience. Compared to workers with fixed schedules, they reported more frequent burnout, which also leads to circadian rhythm disruption [68]. The rotating shift workers had insufficient rest time, which led to burnout or fatigue [69]. As a result, teamwork care may be compromised. Furthermore, NPs with rotating shift schedules may have to collaborate with many healthcare teams in practice, and this can reduce job satisfaction [70]. Hence, on a fixed working schedule, it is easier to develop positive relationships between team members and better team-based practice. Healthcare organizations are encouraged to schedule NPs on fixed shifts to alleviate the impact of shift work on team-based care.

4.3. Limitations. This study has some limitations. First, as this study had a cross-sectional design, it was not possible to make causal inferences between organizational culture and organizational trust with job satisfaction and teamwork in practice. Nevertheless, our results may be viewed as exploratory, and other researchers might identify distinct motivators or hygiene factors in organizational contexts affecting job satisfaction or teamwork over time. Furthermore, the participants in this study were only recruited from Taiwan, and organizational culture could vary in different countries. Hence, the generalizability of our findings could be limited. The culture difference might also lead to a lower Cronbach's alpha for time for improvement (Cronbach's alpha = 0.61) in the current study. The contents of this subscale might modify for better reliability in future studies. In addition, we used the subscale of NP-PCOCQ to measure teamwork, and it was not designed to be a standalone tool to measure teamwork. However, patients' healthcare mainly relied on the collaboration between NPs and physicians in Taiwan, such collaboration would reflect the performance of teamwork. Future studies would conduct a unique tool for measuring teamwork in studies. Finally, there might be a response bias due to the self-completed questionnaire design. Despite these limitations, this study has uncovered the influence of organizational context on both job satisfaction and team-based practice using a national-based survey in Taiwan.

5. Conclusion

Organizational culture and trust were key for improvements in job satisfaction and team-based practice. The learning environment and organizational trust were the two most influential factors in job satisfaction and team-based practice, respectively. Hospitals could establish a supportive atmosphere of practice using an appropriate organizational culture and providing sufficient trust to promote both NPs' job satisfaction and team-based practice. Also, because the effects of organizational culture and trust on job satisfaction and team-based practice have not been studied previously in a national sample, our results provide a foundation to fill the knowledge gap in this field and to develop future studies.

6. Implication for Nursing Management

Continuing to improve the organizational culture and trust of NPs is critical to enhancing NPs' job satisfaction and teamwork in acute care practices. In the process, hospital administrators are encouraged to develop and implement policies to enrich supportive organizational cultures, such as enhancing the learning environment and building up an interdisciplinary collaboration that could improve job satisfaction and team-based care. Moreover, empowering NPs in practice at the organizational level and encouraging communication with senior managers are beneficial for increasing NPs' psychological safety and gaining the support of senior managers.

It is also suggested that acute care hospitals need to implement policies to ensure the rights of NPs in the collaborative practice model, which therefore might improve job satisfaction and efficiency of the team-based practice. In particular, authorized practice guidelines might strengthen organizational trust in acute care settings, which promotes better job satisfaction and proficient team-based practice.

Data Availability

The data used to support the findings of this study are available on request from the author.

Ethical Approval

The study was approved by the Institutional Review Board (IRB) of the China Medical University Hospital (CMUH111-REC3-059).

Disclosure

We shared a small part of the information with a poster presentation at the research conference of the International Council of Nurses in July, 2023.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

The authors wish to acknowledge the assistance from all participants who completed this study. This research project was supported by a grant from the Taiwan Association of Nurse Practitioners (TANP).

Aim. This study aims to investigate the level of organizational learning within urban Chinese Community Health Centres and reveal its potential association with primary care nurses' work performance and well-being. **Background.** Globally, there is a push to establish learning healthcare systems for complex health reform challenges. Existing studies on organizational learning mainly focus on North American and European hospital settings, offering limited insights into primary care environments, particularly in developing countries. **Design.** Cross-sectional study. **Methods.** We recruited 175 nurses from 38 community health centres in four Chinese cities (Shanghai, Shenzhen, Tianjin, and Jinan) using convenience sampling. Trained research assistants conducted face-to-face surveys, measuring organizational learning with the Learning Orientation Scale. Nurse-level outcomes included self-directed learning, quality of care, organizational commitment, and work stress. Data analysis employed multilevel linear modelling. **Results.** The 38 community health centres displayed a relatively high level of organizational learning, and there was a positive and significant association between organizational learning within community health centres and nurses' self-directed learning as well as the quality of care. However, there was no significant association between organizational learning and nurses' organizational commitment or work stress. **Conclusion.** This study demonstrates a high-level organizational learning capacity in urban community health centres in China. It provides a new perspective on the potential relationship between CHCs' organizational learning and primary care nurses' well-being and work performance. Further research is needed to clarify unexpected findings and identify factors promoting organizational learning in primary care settings. **Implications for Nursing Management.** In China's evolving primary care system, nurses play a vital role amidst physician shortages. Policy should prioritize internal management reform alongside structural changes. This study highlights the importance of fostering organizational learning in primary care settings. Strategic interventions should promote a learning culture in CHCs, which may enhance nurses' self-directed learning and improve the quality of care.

1. Introduction

Today's healthcare systems operate in an uncertain, turbulent, and interconnected environment, facing constant pressure from policymakers, healthcare

analysts, and funders to provide quality healthcare while also maintaining operational efficiency and cost-effectiveness [1]. Internationally, there are reform initiatives aimed at establishing high-performing primary care delivery models, such as the Patient-Centred

Medical Homes (PCMHs) and Accountable Care Organizations (ACOs) in the United States [2], Family Health Teams and Family Medicine Groups in Canada [3], and Family Doctor Teams in China [4].

The ever-shifting demographics, evolving political priorities, and ongoing financial concerns continually introduce new challenges into the healthcare landscape, meaning that these current reform initiatives have a finite lifespan. One healthcare constant is the system's ability to adapt and respond effectively to these changing conditions and evolving patient needs [5]. This adaptation requires ongoing experimentation and a commitment to change, reliant on the internal capacity for organizational learning and development [6]. For example, a recent study in the UK examined how a large healthcare organization responded to complex and disruptive changes, notably during the recent pandemic. The study revealed that the organization transformed into a learning organization, which is a critical factor for effectively addressing disruptive changes and facilitating postpandemic organizational recovery [7].

Scholars hold diverse perspectives on organizational learning. Some argue that organizational learning takes place when members of an organization act as learning agents, responding to changes in the organization's internal and external environments by detecting and correcting errors in the organization's theory in use [8]. The concept of organizational learning also can be traced back to the idea of transferring learning from one person to another, as put forth by Taylorism, with the aim of enhancing organizational efficiency, development, and performance. This dynamic process enables employees to swiftly adapt to changes and promotes the development of new behaviours and skills within the organization [9].

In the healthcare sector, prominent institutions such as the National Academy of Medicine (NAM), the National Institutes of Health (NIH), and the Agency for Healthcare Research and Quality (AHRQ) are advocating for healthcare organizations to transform into "learning healthcare systems" (LHSs). The LHS concept emphasizes the need for healthcare organizations to adopt a more systematic and data-driven approach to generate and leverage knowledge, ultimately improving the quality and value of the care they provide while fostering innovation [10].

Proficiency in organizational learning is imperative for attaining a high level of reliability in a dynamic healthcare environment [11]. Through the practice of organizational learning, healthcare teams can consistently deliver safe, efficient, and high-quality care in the midst of a complex and ever-evolving environment [12]. Nurses, the largest group involved in healthcare delivery, hold a critical role in establishing caring and therapeutic relationships with patients [13]. They serve as pivotal sources for knowledge transfer within healthcare organizations, making them instrumental in the process of organizational learning [13]. In China, primary care nurses are increasingly assuming healthcare responsibilities that extend beyond their traditional roles. Nurses assist physicians, provide clinical follow-up care and home nursing, and manage patients' electronic health records. This expanded role is particularly crucial in the context of an aging population, the growing

prevalence of chronic conditions and mental health issues, and new challenges like those posed by the COVID-19 pandemic [14]. Organizational learning is arguably important for the effective management of nurses during periods of transition [15].

Within the healthcare literature, researchers have extensively examined the antecedents, contextual factors, and mechanisms of organizational learning across multiple dimensions, including individuals, organizations, and the environment [16–18]. However, there has been relatively limited exploration of organizational learning outcomes [19]. Most existing studies focusing on the outcomes of organizational learning have centred around the hospitals [20, 21]. There is a dearth of information regarding organizational learning and its associated outcomes within primary care settings, particularly in developing countries such as China [22]. Furthermore, there is minimal information about the influence of organizational learning on primary care nurses' work performance and well-being in China.

This study bridges the existing knowledge gap by shedding light on the level of organizational learning within community health centres (CHCs) in urban China, a vital component of the country's primary care landscape. Furthermore, it analyses the relationship between organizational learning within CHCs and the well-being and work performance of primary care nurses as they adapted to change healthcare demands. These new insights inform policies and strategies aimed at enhancing the resilience and effectiveness of China's primary healthcare delivery in the face of dynamic challenges.

2. Methods

2.1. Study Design. This study conducted a cross-sectional, in-person survey of nurses working in CHCs in China from November 2020 to May 2021.

2.2. Study Setting and Sampling. This study gathered data from Shanghai, Shenzhen, Tianjin, and Jinan, where well-established primary care systems boast enhanced infrastructure and a cadre of primary care professionals. This information could prove valuable in steering further reforms in primary care across these cities and regions in China. Given the variations in practice size and patient volumes in the four cities, a convenience sampling approach was employed, resulting in 38 selected CHCs with 10 in Shanghai, 14 in Shenzhen, 8 in Tianjin, and 6 in Jinan [14]. For each CHC, all nurses on duty on the day when the researchers arrived were invited to participate in the survey. A total of 175 primary care nurses from 38 CHCs, with an average of 4–5 nurses per CHC, completed the nurse survey. The survey gathered information on the nurses' personal characteristics, self-directed learning, self-reported quality of care, organizational commitment, and work stress. Data were also collected from the directors of each CHC through a primary care organization survey, focusing on organizational learning and organizational characteristics.

To ensure data quality and reliability, stringent quality control measures were implemented at various stages of the survey. Initially, experts meticulously refined the questionnaire for clarity and precision, ensuring logical consistency throughout. A presurvey was conducted to identify and address any areas for improvement. During the data collection phase, surveyors underwent comprehensive training, while nurses were briefed on the questionnaire. Real-time support was provided to nurses, and on-site checks were carried out to verify the accuracy and completeness of the responses. Following the survey, a double-entry data entry method was employed to minimize errors, followed by thorough data cleaning procedures to enhance accuracy and ensure quality assurance.

2.3. Measures and Variables

2.3.1. Organization-Level Variables. Learning orientation can be considered the wellspring of core organizational values that influence the organization's propensity to generate and apply knowledge [8]. It plays a pivotal role in shaping the organization's satisfaction with its current operational theories, thereby affecting the extent of proactive learning [8]. A stronger learning orientation indicates a greater willingness and capacity for the organization to learn [23, 24]. Three organizational values regularly associated with the organization's inclination to learn are commitment to learn, open-mindedness, and shared vision [8].

Commitment to learn refers to the fundamental value held by an organization towards learning, representing the dedication and emphasis on fostering a learning culture. Open-mindedness refers to the organization's willingness and ability to question and challenge existing mental models, beliefs, assumptions, and routines. Shared vision entails a common and collectively agreed-upon direction or goal that guides the organization's learning and actions, providing a clear sense of purpose.

In this study, we adopted the Learning Orientation Scale developed by Sinkula et al. [8], with certain modifications to better suit the environment of primary care in China. Subsequently, we assessed organizational learning within 38 CHCs. Measured using a 5-point Likert scale (ranging from 1 "strongly agree" to 5 "strongly disagree"), specific items for each aspect are detailed in Table 1.

2.3.2. Nurse-Level Variables. As shown in Table 2, our measure of self-directed learning utilized three items from the study of Yang et al. [25], self-directed learning scale among nurses. Based on the previous research studies [26], the quality of care reported by nurses was assessed using the question provided in Table 2.

Drawing on the Allen and Meyer organizational commitment model, these were designated as "affective," "continuance," and "normative" commitment. Employees with strong affective commitment remain with the organization because they genuinely want to; those with strong continuance commitment stay because they feel a need to do

so; individuals with strong normative commitment remain committed because they feel a sense of moral or ethical obligation to stay [27]. Our modified and contextualized organizational commitment scale was based on Allen and Meyer [27], with six positively worded items listed in Table 2.

Work stress variables in Table 2 are based on Cavanaugh's concepts of challenge stressors and hindrance stressors [28]. Challenge stress refers to a series of stressors that positively influence employees' skill enhancement and career development, while hindrance stress refers to stressors that negatively affect employee career development and personal growth [29].

2.3.3. Control Variables. As shown in Table 3, control variables were collected, including nurse-level variables such as age, sex, education level, and years of working experience. In addition, organization-level control variables were gathered, consisting of types of organization ownership (government-managed CHCs and hospital-managed CHCs), accreditation status (accredited by national or provincial health authorities or not), and organization size (number of staff).

2.4. Ethical Considerations. The study was approved by the Biomedical Ethics Committee of the Medical Department of Xi'an Jiaotong University (No. 2020-1344). All methods that we used adhered to the accepted guidelines for ethical reporting.

2.5. Statistical Analysis. The analytic approach involved several stages. First, Cronbach's alpha coefficients were employed to assess the internal consistency of the scales. Descriptive statistics were then utilized to provide an overview of the sample characteristics and the main variables. The Spearman rank correlation coefficient was employed to explore the relationship between organizational learning and the four nurse-level variables. Subsequently, with nurse-level data nested within the organization-level data, we constructed four 2-level hierarchical linear regression models (nurses at level 1, nested within the CHCs at level 2) to investigate whether organizational learning of CHCs influence nurse-level variables [30]. The data were analysed using Stata 15/SE.

3. Results

3.1. Characteristics of the Participants. Table 3 presents the descriptive statistics on 175 nurses. The average age of nurses is 34.93 years, ranging from 22 to 61 years; most nurses were female, accounting for 98.29% of the sample, and 93.10% of nurses had attended junior college or college. Nurses had an average of 11 years of work experience. Their tenure ranged from 0.2 to 40 years. Among the CHCs, 60.53% were government-managed and 39.47% were under the management of public hospitals. In addition, 57.89% of CHCs were accredited by national or provincial health authorities.

TABLE 1: Organization-level variables and measurement items.

Variables	First-order factors	Measurement items
Organizational learning	Commitment to learning	Managers basically agree that our organization's ability to learn is the key to our competitive advantage
		The basic values of this organization include learning as a key to improvement
		The sense around here is that employee learning is an investment, not an expense
		Learning in my organization is seen as a key commodity necessary to guarantee organizational survival
		The organizational culture of our organization does not regard employee learning as a top priority ^a
	Open-mindedness	"Once we stop learning, the future will be in danger" is the consensus of this organization
		We have a clearly defined concept of the organization's positioning and future development
		Each department and section of the organization has a common organizational vision
		All employees of the organization are committed to the achievement of organizational goals
		Heads of departments and departments in the organization share their vision with their subordinates
Shared vision	The organization does not have a clear and articulated vision ^a	
	The employees of the organization feel that they are responsible for the future direction of the organization	
	The organization is not afraid of us to question its various assumptions about operation and management	
	Heads of departments and sections do not like to have their views questioned ^a	
	The organization considers it important to be inclusive of diverse voices	
		Our employees are encouraged to think beyond the norm and creatively
		The organizational culture of the organization does not emphasize continuous innovation ^a
		This organization places great importance on originality

Note. Items were measured using 5-point scales (1 = strongly disagree and 5 = strongly agree). ^aReverse-coded item.

Furthermore, 34.21% of CHCs had 35 or fewer employees, while 28.95% had more than 100 employees.

3.2. Reliability and Scores of Variables. Table 4 displays Cronbach's alpha for each variable scale, along with the mean and standard deviations of the variables. These variables include organizational learning (composed of three first-order factors) and four nurse-level dependent variables.

Reliability refers to the consistency and stability of results obtained when using the same measurement tool. In this study, the reliability of the measurement tools for variables was assessed using Cronbach's alpha. A higher Cronbach's alpha value indicates greater reliability of the scale. The research study suggests that a Cronbach's alpha value greater than 0.9 indicates very good reliability, while $0.7 < \text{Cronbach's alpha} < 0.9$ indicates good reliability. Cronbach's alpha of the Learning Orientation Scale was 0.88 (with commitment learning at 0.74, shared vision at 0.81, and open-mindedness at 0.72), the Self-Directed Learning Scale was 0.83, the Organizational Commitment Scale was 0.94, and the Work Stress Scale was 0.85. These Cronbach's alpha values collectively indicate a high level of internal consistency among the items and suggest that the measurement tools used in this study are reliable, providing consistent results across the variables assessed.

The average organizational learning score for the 38 CHCs was 4.09 out of 5, indicating a high level of organizational learning. Specifically, the mean score for commitment learning was 4.25, 4.07 for shared vision and 3.96 for open-mindedness out of 5. There were differences between the three components that constitute organizational learning: the average score for self-directed learning was 4.16 (SD 0.72), quality of care was 3.17 (SD 0.54), organizational commitment was 4.04 (SD 0.88), and work stress was 3.39 (SD 0.96).

3.3. Correlation Analysis. Table 5 presents the correlation matrix for the main variables. The findings reveal that organizational learning exhibits positive correlations with self-directed learning ($r = 0.179$, $P < 0.05$), quality of care ($r = 0.145$, $P < 0.10$), and organizational commitment ($r = 0.149$, $P < 0.05$). However, no significant correlations were observed between organizational learning and work stress. These results suggest that higher levels of organizational learning were associated with increased self-directed learning, improved quality of care, and greater organizational commitment among the nurses.

3.4. Multilevel Linear Analysis. Reliability diagnosis of the multilevel ordinal logit model was conducted by calculating the intraclass correlation coefficient (ICC), which ranges

TABLE 2: Nurse-level variables and measurement items.

Variables	Response categories	Measurement items
Self-directed learning	Likert 5-point scale 1 = strongly disagree and 5 = Strongly agree	You actively participate in all kinds of training and strive to improve the level of business and the quality of care You use your spare time to enrich your medical knowledge and improve your professional level You consciously and humbly learn from other highly skilled medical professionals
Quality of care	Likert 4-point scale 1 = not good 2 = moderate 3 = good 4 = excellent	How do you assess the quality of care you provide to patients within this institution?
Organizational commitment	Likert 5-point scale 1 = strongly disagree 5 = strongly agree	I have deep affection for the people and events of this organization I would be very happy to spend the rest of my career with this organization I feel obligated to remain with the organization I really feel as if this organization's problems are my own This organization has a great deal of personal meaning for me I do feel a strong sense of belonging to my organization
Work stress	Likert 5-point scale 1 = Strongly disagree 5 = Strongly agree	The number of projects and tasks I must complete at work is large The volume of work that I must accomplish in the allotted time is heavy

TABLE 3: Description of nurses and organizational characteristics.

Characteristics	Mean \pm SD (range) or <i>n</i> (%) (units)
Nurse level (<i>n</i> = 175)	
Age	34.93 \pm 7.79 (22–61) (years)
Sex

\leq 35	13 (34.21) (employees)
36–55	7 (18.42) (employees)
56–100	7 (18.42) (employees)
>100	11 (28.95) (employees)

Note. The nurse data nested within 38 CHCs. Organizational ownership: government-managed CHCs or hospital-managed CHCs. Accredited: accredited by national or provincial health authorities or not. Organizational size: number of all staff.

TABLE 4: Main variables, Cronbach's alpha, and questionnaire score.

Variables	Item numbers	Cronbach's alpha	Mean	SD
Organizational learning	18	0.88	4.09	0.52
Commitment learning	6	0.74	4.25	0.60
Shared vision	6	0.81	4.07	0.59
Open-mindedness	6	0.72	3.96	0.61
Self-directed learning	3	0.83	4.16	0.72
Quality of care	1	—	3.17	0.54
Organizational commitment	6	0.94	4.04	0.88
Work stress	2	0.85	3.39	0.96

Note. SD: standard deviation.

TABLE 5: Correlation matrix of the main variables.

Variables	Organizational learning	Self-directed learning	Quality of care	Organizational commitment
Organizational learning				
Self-directed learning	0.179**			
Quality of care	0.145*	0.272***		
Organizational commitment	0.149**	0.507***	0.266***	
Work stress	-0.105	0.018	0.076	-0.154**

Note. * $P < 0.10$; ** $P < 0.05$; *** $P < 0.001$.

from 0 to 1, to ensure the model's suitability for our analysis. If the ICC value exceeded 0.059, it indicated the necessity of performing a multilevel model for data analysis. The intraclass correlation coefficient (ICC) shows clustering effects, with the ICC values of 0.123 for self-directed learning, 0.060 for quality of care, 0.219 for organizational commitment, and 0.094 for work stress. These ICC values suggest that a significant portion of the variability in the dependent variables can be attributed to differences between CHCs. Using multilevel linear models is an appropriate

approach to examine how the nurse characteristics are influenced, not only at the individual level but also at the CHC level, variables.

Table 6 presents the results of the multilevel linear models examining the relationship of organizational learning on nurse characteristics in CHCs. The key organizational variable, organizational learning, shows a positive and significant association with self-directed learning ($\beta = 0.272$, $P < 0.05$) and quality of care ($\beta = 0.234$, $P < 0.05$). The association with organizational commitment was not

ICC		0.123		0.060			0.219				0.094	
AIC	(377.013)	375.851		(290.889)	287.867		(444.730)	448.611		(477.673)	480.625	

Note. β : coefficient; SE: standard error; ICC: intraclass correlation coefficient; AIC: Akaike Information Criteria. AIC values in parentheses represent the AIC of the null model. ** $P < 0.05$; *** $P < 0.001$.

statistically significant ($\beta = 0.265$, $P = 0.146$), and there was a negative but nonsignificant association with work stress ($\beta = -0.226$, $P = 0.175$). Among the control variables, none of the nurse-level variables (age, sex, education level, and years of working experience) show statistically significant associations with any of the dependent variables (self-directed learning, quality of care, organizational commitment, and work stress). Regarding organizational level variables, organizational ownership and accreditation do not have statistically significant associations with the dependent variables. However, organizational size showed a significant association with self-directed learning (36–55 employees: $\beta = 0.366$, $P < 0.05$).

The Akaike Information Criterion (AIC) values were computed for both the full models and the null models, which included only the intercept. The AIC value for the full model, including both organizational learning and control variables, is 375.851, while the AIC for the model considering only self-directed learning is 377.013. Similarly, the AIC value for the full model, including both organizational learning and control variables, is 287.867, whereas the AIC for the model including only quality of care is 290.889. Notably, the AIC values of the full models were lower than those of the null models, indicating that the full models provided a better fit.

On the contrary, the AIC value of the null model containing only organizational commitment (AIC: 444.730) is lower than that of the full model including organizational learning and control variables (AIC: 448.611). Similarly, the AIC value of the null model containing only work stress (AIC: 477.673) is also lower than that of the full model (AIC: 480.625). These findings suggest that incorporating organizational learning and other control variables did not enhance the fit of these models; instead, it worsened. This suggests that the variable of organizational learning may not significantly improve the explanatory power of these models.

Table 7 presents the results of the multilevel linear models examining the three first-order factors of organizational learning and their associations with nurse characteristics in CHCs. Commitment to learn shows positive and significant associations with self-directed learning ($\beta = 0.229$, $P < 0.05$) and self-reported quality of care ($\beta = 0.178$, $P < 0.05$), while it exhibits a positive, but not statistically significant, association with organizational commitment ($\beta = 0.207$, $P = 0.188$). There was a significant negative correlation between commitment to learn and nurses' work stress ($\beta = -0.326$, $P < 0.05$), suggesting that higher organizational commitment to learn is related to lower perceived work stress among nurses. Shared vision demonstrates a positive and significant association with self-reported quality of care ($\beta = 0.195$, $P < 0.05$). However, it does not show statistically significant associations with organizational commitment, self-directed learning, or work stress. Open-mindedness was only significantly and positively associated with self-directed learning ($\beta = 0.169$, $P < 0.10$). Overall, the results suggest that different dimensions of organizational learning (commitment to learn, shared vision, and open-mindedness) have varying impacts on nurse characteristics in CHCs.

4. Discussion

Our research findings revealed that 38 urban Shanghai, Shenzhen, Tianjin, and Jinan CHCs demonstrated a high level of organizational learning, with a particular emphasis on commitment to learn, followed by shared vision and open-mindedness. Nurse managers in New South Wales, Australia, stroke units also reported a high level of organizational learning culture [31]. In our study, strong organizational learning within these CHCs emerged as a significant predictor of nurses' self-directed learning and the quality of care they reported. There was no observed correlation between this organizational learning and nurses' levels of organizational commitment or work stress.

Organizational learning is viewed as a dynamic knowledge-based process, involving a fluid transition between various levels of action, spanning from individual to group, and further to the organizational level, and vice versa [32]. Therefore, the investigation into the relationship between organizational-level organizational learning and individual-level self-directed learning is of paramount importance. The previous research study has indeed examined various relationships between different variables and self-directed learning, including factors such as self-efficacy, organizational support, performance, and problem-solving ability [33–35]. However, there has been comparatively less emphasis on investigating the connection between organizational learning and nurses' self-directed learning.

Although not specifically focused on the nurse population, the four studies collectively offer valuable insights into the practices and impacts of organizational learning and self-directed learning across diverse contexts, yielding results consistent with this study: the first study explored the implementation of Senge's five disciplines of learning organization within an innovative motorcycle manufacturing company in Indonesia. It demonstrated that integrating these disciplines into daily work-life fosters self-directed learning among employees, emphasizing the importance of shared vision, personal mastery, team learning, and systems thinking [36]. The second study, involving a survey of 175 members of Civil Defence Emergency Preparedness Teams in South Korea, highlighted the positive influence of organizational learning on members' self-directed learning [37]. In the third study, which included 745 participants from 20 private universities, findings indicated a direct and positive relationship between organizational learning culture and self-directed learning [38]. Lastly, the fourth study focused on 521 public librarians in Seoul, Incheon, and Gyeonggi-Do, examining the impact of organizational learning readiness on their perceived self-directed learning ability. The study proposed strategies for enhancing organizational learning readiness to improve self-directed learning outcomes [39]. These studies collectively support the result of this study, emphasizing the significant role of organizational learning practices in promoting self-directed learning across various professional settings.

We defined self-directed learning as the ongoing enhancement of personal clinical expertise and medical knowledge. This underscores the critical importance of

TABLE 7: Multilevel linear models examining the association between organizational learning's three first-order factors and nurses' variables.

Three first-order factors of organizational learning	Self-directed learning			Quality of care			Organizational commitment			Work stress		
	β	SE	<i>P</i> value	β	SE	<i>P</i> value	β	SE	<i>P</i> value	β	SE	<i>P</i> value
Commitment to learning	0.229**	0.098	0.020	0.178**	0.070	0.011	0.207	0.157	0.188	-0.326**	0.123	0.008

Note. The control variables remain the same as in Table 6. * $P < 0.10$; ** $P < 0.05$.

fostering a culture of organizational learning within CHCs. Our study found that nurses working in CHCs with a high level of organizational learning, particularly in terms of commitment to learn, were more likely to report elevated levels of self-directed learning. This observation highlights the potential link between organizational learning culture and nurses' ability to take charge of their own learning and professional development. This research study can illuminate the mechanisms through which nurses can leverage their organization's knowledge resources to enhance their personal learning and professional development.

In a study conducted in 2022 among healthcare department employees in Pakistan, it was discovered that the presence of an organizational learning culture exerted a positive and substantial influence on employee performance [40]. Learning organizations provide nurses with the opportunity to enhance the feedback mechanism for staff performance [41]. Furthermore, the concept of organizational learning has long been recognized as a pivotal factor determining an organization's sustained performance [19]. The relationship between healthcare quality and performance is well-established [42], prompting an exploration of whether organizational learning can impact healthcare quality from a novel standpoint. While extensive research has delved into the factors influencing healthcare quality [43, 44], there remains a conspicuous dearth of comprehensive information concerning the connection between organizational learning and healthcare quality.

Although the literature review did not find exact evidence of the relationship between organizational learning and care quality, we found several studies on the correlation between organizational learning and patient safety. Patient safety culture is crucial within healthcare systems as it significantly impacts the quality of care provided. A study involving 101 oncology nurses from two large Saudi tertiary care hospitals found that organizational learning positively influences patient safety culture [45]. Another study aimed to examine safety culture among registered nurses in four tertiary care hospitals in Thailand. Findings revealed that continuous improvement in organizational learning positively impacts safety culture [46]. Recent research indicates that a hospital has effectively enhanced nurses' theoretical knowledge and stabilized their practical skills. This was achieved by utilizing a nurse training system grounded in the principles of a learning organization. The system encompasses strategies such as comprehensive training, continuous management, and team learning. Consequently, the hospital has seen a reduction in the incidence of adverse nursing events [47]. Overall, these studies highlight the importance

of promoting organizational learning for patient safety in healthcare settings. Our study revealed that nurses operating within CHCs characterized by a high level of organizational learning, especially in terms of commitment to learn and shared vision, are more inclined to report a high level of quality care. Consequently, this study offers a fresh perspective on enhancing the quality of care provided by nurses through the establishment of a learning organization.

Our study also introduced a novel perspective regarding the relationship between nurses' organizational commitment and organizational learning. Prior research has frequently indicated that organizational learning or specific dimensions encompassed within organizational learning significantly impact organizational commitment. For example, Yafang found a notable positive correlation between the presence of a "learning organization" and organizational commitment [48]. Darban et al. found that shared vision allowed nurses to align their activities with the organization's goals and direction, thereby enhancing their commitment to the organization [49]. On the other hand, studies conducted in China focusing on hospital nurses yielded the following findings: one demonstrated that training had a positive impact on organizational commitment, while another study revealed a positive correlation between nurses' job satisfaction, psychological empowerment, and organizational commitment [50, 51]. While there may be differences between hospital environments and primary healthcare environments, potentially leading to varying research outcomes, these two studies provide us with a hint that, at present, nurses may be more influenced by fundamental working conditions and resources, such as training opportunities, job satisfaction, and psychological empowerment, rather than organizational learning, regarding organizational commitment. In conclusion, the absence of a significant impact of organizational learning on the organizational commitment of primary care nurses represents a complex outcome. To gain a deeper understanding of this issue, further research is necessary to explore the interplay of these factors.

While the previous research study has predominantly focused on identifying factors associated with work stress, including but not limited to emotional exhaustion, depersonalization, personal accomplishment [52], working hours per week, and anxiety [53], most studies have concentrated on understanding which elements or stressors have negative effects on individuals. Not all stressors have adverse effects on individuals or organizations, despite increasing strains or demands. To yield positive outcomes, managers should aim to eliminate hindrance stressors while

concurrently introducing challenge stressors within the workplace [54]. Our study represents a relatively novel exploration into the relationship between organizational learning and work stress. We conceptualized work stress as a set of stressors that positively contribute to the enhancement of nurses' skills and career development. Our study findings indicate that, aside from the "commitment to learn" dimension, the organizational learning and the other two dimensions had no statistically significant impact on nurses' work stress. The lack of a significant influence of organizational learning on nurses' work stress in China's primary healthcare settings may be attributed to various factors. These factors could include cultural differences, organizational support, or specific job demands. However, this study underscores the importance of continued exploration of organizational learning's role in enhancing nurses' career development and the quality of care within the evolving landscape of China's primary care system.

In addition to the aforementioned interpretation within the context of the wider literature, the findings of this study are also of significance to other regions and globally. Research on "learning organizations" within the health sector is predominantly focused on high-income countries and hospital settings, with only limited studies examining primary healthcare facilities, especially in low- and middle-income countries [55]. This study, targeting CHCs in China, presents an empirical case illustrating a potential pathway to enhance the quality of care in resource-limited environments through improved organizational learning levels. It offers a model that can be replicated by countries with similar contexts.

Countries with similar healthcare constraints, such as resource limitations and high patient loads—common in regions including Cameroon where nurses face significant emotional strain due to heavy patient burdens—can benefit from the insights gained through this study [56, 57]. Specifically, the implementation of structured learning environments and continuous feedback mechanisms can be adapted to local contexts. Moreover, in other regions, it could further validate the effectiveness of organizational learning frameworks in different cultural or healthcare settings.

The benefits of adopting learning organization frameworks extend beyond developing countries. For example, a study in Canada found that such frameworks positively impact daily nursing tasks [58], corroborating the findings of this study that emphasize the importance of career development and supportive learning environments in enhancing medical service quality. These findings underscore the universal applicability of learning organizations in both developing and developed settings.

Since 2012, the United Nations General Assembly has called on governments worldwide to advance towards Universal Health Coverage (UHC). A pivotal recommendation for UHC is that countries engage in ongoing learning [55]. Research studies have confirmed that adopting learning organizations is recognized as a strategic approach to improve knowledge management and promote continuous professional growth within healthcare sectors globally [58].

Therefore, the results of this study should encourage global health policymakers to intensify their focus on and explore effective strategies for fostering an organizational learning culture, which could substantially contribute to achieve universal health coverage.

4.1. Strengths and Limitations. The following limitations should be noted when interpreting our findings: First, this study is cross-sectional, confirming associations between CHCs' organizational learning and nurse-level variables rather than establishing causation. Our research team is preparing to conduct in-depth longitudinal investigations focusing on organizational learning in CHCs in the next few years to explore the causal relationship between organizational learning and nurse variables. Second, we recruited 175 nurses from 38 CHCs in four large cities. The primary care organization in these cities, including infrastructure building and primary care professionals, is relatively well established. While our results provide valuable information for further primary care reform in these well-developed cities in China, they may not necessarily be generalizable to other primary care settings. Future research should explore the generalizability of our findings across diverse healthcare systems and contexts. Third, CHCs selection was based on convenience rather than randomness. However, during sampling, we considered variations in practice size, patient volumes, and CHC ownership in each city to enhance the relative representativeness of CHCs and nurses. This approach may have potentially compromised the representativeness of the sample and introduced additional biases. Future research endeavours should consider employing more rigorous sampling techniques to enhance the reliability of the findings. Fourth, despite implementing quality control measures, reliance on self-reported data may introduce response bias and subjectivity. Future research should develop context-based primary care quality indicators for objective data collection.

While we have acknowledged several limitations to this study, our research significantly narrows the understanding gap regarding organizational learning within primary care, especially in developing countries. It establishes a notable association between CHCs' organizational learning and primary care nurses. This study offers a fresh perspective on enhancing nurses' personal self-directed learning and improving the quality of care provided by nurses through the establishment of a learning organization. It identifies promising areas for further investigation, making a relevant contribution to the fields of primary care and healthcare quality improvement.

5. Conclusion

This research examined 38 urban CHCs, revealing a strong level of organizational learning, with a focus on commitment to learning, shared vision, and open-mindedness. This study also explores the relationship between organizational learning and the well-being and work performance of primary care nurses, broadening our understanding of the role

of organizational learning in primary care by highlighting its correlation with nurses' self-directed learning and the quality of care they provide. In conclusion, the positive correlation uncovered in this study suggests that strategic management reforms should focus on promoting a learning-oriented culture that can significantly improve nurses' self-directed learning capabilities and the quality of care provided.

The experience and results from this study, along with a thorough examination of the limitations inherent in various study designs, also could guide further, more refined research efforts. These further studies may examine whether there is a causal relationship between the level of organizational learning and nurse-level variables (such as self-directed learning and quality of care) in urban CHCs in China. In addition, they may also test whether the organizational learning level of primary care institutions in rural areas of China and its relationship with nurse-level variables exist. Both can help establish a solid foundation for further development of learning organizations.

5.1. Implications for Nursing Management. As China advances towards establishing a high-quality primary care system, the role of primary care nurses becomes increasingly crucial in addressing the challenges posed by the shortage of primary care physicians. It is essential that policies focus not only on structural inputs but also on reforming internal management practices. This study highlights the importance of establishing a culture of organizational learning, which is vital for effective nursing management in primary care settings within China.

First, evaluating organizational learning in 38 CHCs provides managers with a clear understanding of the current level of learning within the organization. This understanding enables them to develop targeted strategies for enhancement based on specific needs. To promote learning effectively, it is advisable to offer nurses' tailored learning plans and career development opportunities, such as regular training and team building activities.

Moreover, the presence of sustainable feedback learning loops relies on shared organizational visions, and the creation of these shared visions requires active participation [59]. To effectively promote organizational learning, nursing managers must recognize and empower nurses to drive these initiatives being critical, as their active engagement is necessary for success; they should concentrate on fostering shared visions that align with evolving healthcare needs; at the same time, managers should ensure that each nurse can get timely and constructive learning feedback and provide necessary support.

Third, scientific and medical advancements present a significant opportunity for healthcare institutions to embrace a learning organization culture [55]. According to a McKinsey report, artificial intelligence can significantly enhance the speed and accuracy of diagnostics, allowing practitioners to access more knowledge more rapidly and easily. This technology is poised to transform medical education by shifting the focus from rote memorization to innovation, entrepreneurship, continuous learning, and

interdisciplinary work. To achieve this, all frontline workers need to integrate AI into their workflows [60]. Managers can leverage this approach to improve knowledge acquisition among nurses, thereby enhancing their learning abilities, anticipating advancements in medical knowledge that can improve nursing practices, and elevating the quality of patient care provided by nurses.

Aim. To systematically map and identify key knowledge on organizational support for nurses' career planning and development. *Design.* Scoping review. *Methods.* Systematic electronic searches were carried out with the CINAHL, PubMed, Scopus, and Web of Science databases in May 2022. The searches were limited to scientific, peer-review papers that were published in English from January 2012 to May 2022. Data were extracted and synthesized and are presented in tables and text. The review was conducted following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. *Results.* We identified 1,400 papers and 28 met the inclusion criteria. Organizations recognized nurses' career planning and development in relation to the individual's professional development and the organization's need to promote high-quality services and workforce engagement. The organizational support included strategic work to ensure there were adequate resources and purposeful vacancies and a structured framework based on objective qualification criteria and equal assessment. Organizations focused on sharing knowledge, structured career planning, and interpersonal support. Support within the nursing profession and multilayered interprofessional collaboration were also important. *Conclusion.* Nurses' career planning and development was linked to their personal development and the organization's aims and required support from both fellow nurses and other professionals. *Implications for the Nursing Management.* Identifying the organizational structures and methods that are needed to support nurses' career planning and development can help nursing management to evaluate and develop strategies that improve the attractiveness of a nursing career and nurses' engagement.

1. Introduction

The growing global shortage of healthcare workers highlights both the need to promote nursing as an attractive career [1, 2] and the importance of engaging the nursing workforce [3]. Previous research has addressed nurses' desire for professional and career development [1, 4, 5]. Nursing careers are typically directed towards leadership, academic [6], or educational work [7] but previous knowledge on career development opportunities in bedside nursing is limited [1, 4]. Poor career prospects [4, 6] and

a lack of recognition [8] have decreased meaningfulness and satisfaction at nurses' work resulting in staff turnover [9, 10].

Hence, career planning and development (CP&D) is a topical issue for nursing workforce management [4, 6]. CP&D refers to a nurse's expectations and prospects for work goals, advancement, and progress in their career development [10, 11] based on continuing learning [10] and recognized expertise [4, 12]. Nurses' CP&D has been studied in relation to individual factors, namely, the inner motivation to select nursing as a career and developing their own excellence and progress in that career [1, 13]. The need for

nurse's autonomy [8, 14] and personal resources [15], own responsibility, and motivation for CP&D has been highlighted [16]. However, research has also identified nurses' unfamiliarity with CP&D [17] as well as their neglect for building relationships to advance their careers [10].

An important factor for nurses' CP&D is organizational support and organizations' role has been emphasized in promoting CP&D to ensure nurses' efficiency, engagement [18], and care quality [5, 10]. Based on previous research, health and social care organizations who are committed to their staff tend to support nurses' CP&D with systematic, long-term strategic management and structures [19, 20]. The role of organizations and managerial engagement [21] has also been emphasized in relation to ensuring informed career guidance for nurses as well as the return of CP&D to the benefit of the organizations [17].

Previous reviews on career development in nursing have covered nurses' career intentions [8, 14], professional development [22, 23], career success [15], career path options [12], and the implementation of clinical ladder programs [21]. Instead, knowledge on organizational support for nurses' CP&D has been fragmented and needs to be brought together to provide the basis for the evidence-based development of nurses' working lives. It has been unclear what are the means for promoting nurses' CP&D, and identifying them is needed for the coherent development and evaluation of CP&D in organizations. It is essential that versatile means are available to support employees, which contributes to the equal treatment of them and, above all, their individual career plans. The study is also needed to identify the knowledge gaps that need to be addressed by further research. Thus, the aim of this scoping review was to systematically map and identify key knowledge on organizational support for nurses' CP&D. The research questions were as follows:

- (1) How has nurses' CP&D been defined by organizations?
- (2) How do organizations support nurses' CP&D in general?
- (3) What methods do organizations use to support nurses' CP&D?

2. Methods

2.1. Study Design. We conducted a scoping review on studies that focused on organizational support for nurses' CP&D. The scoping approach was chosen, as it was suitable for mapping and summarising previous fragmented research evidence on the topic and it was able to identify key concepts and research gaps [24]. The review was carried out in the following five stages [24]: (i) formulate the research questions, (ii) search for the relevant studies, (iii) select the studies to include in the review, (iv) chart the selected studies, and (v) report the results. The review was reported following the Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR Checklist ([25], Supplementary file 1).

2.2. Search Methods and Selection and Evaluation of Studies. We identified the research questions based on preliminary literature searches and the PICO-structure where the population (P) was nurses, the intervention (I) was organizational means for CP&D, and the outcome (O) was career CP&D. Comparison or control (C) element was not suitable for his study. We carried out the electronic searches using the CINAHL, PubMed, Scopus, and Web of Science databases, which were the most relevant for the study topic. Following preliminary searches, we worked with an informatician to develop explorative search phrases that consisted of free words, fixed terms, and their combinations and synonyms for the two key fields of interests, nursing and career (Supplementary file 2). We limited the searches to scientific, peer-reviewed papers published in English from January 2012 to May 2022. The papers were included if they focused on nurses and organizations who supported their CP&D. The papers were independently selected by two researchers (HK and HL) who reviewed the titles and abstracts and the full texts. The eligible studies were included in the review.

The quality of studies was assessed to increase the transparency of the data [25]. Quality of empirical qualitative [26] and quantitative [27] and theoretical [28] studies was assessed according to the Joanna Briggs Institute's checklists and multimethod studies according to the criteria presented by Harrison et al. [29]. Evaluation of qualitative studies focused on ten criteria, quantitative studies on eight, and theoretical studies on six criteria. Each criterion received one or zero points. There were 13 evaluation criteria for multimethod studies each of which received 0–3 points (Supplementary file 3).

2.3. Data Analysis. We analysed the data by following the principles of inductive content analysis [30]. First, we tabulated the papers according to the year, location, aim, methods, scope of the nursing career, and main results (Tables 1 and 2). Then, we extracted the sentences and paragraphs that described nurses' CP&D and how patient care organizations supported it. The extracted material was then organized into groups based on the similarities and differences and named inductively based on their content. To abstract the data, we then brought the groupings together to form eight subcategories and three main categories (Table 3). Two researchers (HK and HL) carried out the analysis until the extraction phase. Then, it was finalized in collaboration with the entire research team. The analysis was conducted using NVivo v.12 software.

3. Results

3.1. Study Characteristics. The searches yielded 1,400 results; 58 full texts were read and 28 met the eligibility criteria and were included in the review as data (Figure 1). Of the selected papers, 14 were empirical studies; one used quantitative methods, ten used qualitative methods, and three used multiple methods. The other 14 were theoretical papers; seven were nonsystematic reviews, six were project reports, and one was a discussion paper. All the papers were

published between 2012 and 2022. Eleven of the studies were conducted in Europe, nine in North America, five in Asia, and three in Australia (Tables 1 and 2).

The overall quality of papers was moderate (Supplementary file 3). In 10 qualitative studies, the scoring by paper varied between 3/10 and 9/10 (6.9 points out of 10 on average). Scrutinised by the evaluation criteria, the highest points in them were achieved by the congruity between the research methodology and the interpretation of results and data-based conclusions (10 out of 10 studies). Lowest points were achieved by the description of philosophical starting points and influence of researchers (3 out of 10 studies). One quantitative study included in the data received an overall score of 4/8. The three multimethod studies achieved 10, 17, and 19 points out of 39. In them, research aims was most clearly reported (9 out of 9 points) and methodological justifications, sampling, recruitment, and analysis less clearly reported (0 out of 9 points). Theoretical papers achieved scoring from 4 to 6 out of 6 points. In them, expertise basedness was unclear in some papers. For both empirical and theoretical studies, the evaluation criteria were not fully applicable (Supplementary file 3).

3.2. Definitions and Rationale for Nurses' CP&D. The nurses' CP&D in an organization were defined and justified from individual and organizational points of views. These contents were interlinked and created a basis for CP&D (Table 3).

3.2.1. Individual Level: Increase in Personal Competency to Respond for New Work Challenges in the Organization. On an individual level, nurses' career planning was described as an intentional act that focused on their competencies and the kind of work that would support their career in the future [33]. Career development was described as an increase in the individual development of personal qualities [34], competencies [16], strengths and talents [35], role expansion, and professional development [36]. Challenges were increased [36, 37] and so was the authority that nurses needed to execute and prioritize new duties [37, 38] and the abilities they needed to deliver quality patient care [32]. The work needed to be challenging enough to drive career development [39, 40] and enable the individual to show creativity [34]. New or expanded roles needed to be documented in job descriptions [36] and job titles [37]. Advancing to higher positions resulted in larger salaries [36, 37]. Career development aimed to strengthen nurses' professional identity [41] and pride [38]. Nurses were respected by patients and the working community [37] and their power and authority in organizations [34], and their participation in organizational decision-making, had increased [41].

3.2.2. Organizational Interest: Resources for Improving the Quality of Care and Services. Nurses' CP&D reflected an organization's commitment to staff development [31] and was connected to successful recruitment [41] and retention [40]. Organizations that supported nurses' careers showed that they recognized and valued their staff's skills and experiences [39] and their readiness to develop nursing career paths, including their attitudes, efforts, efficacy, and commitment [16]. From an organizational point of view, CP&D improved their performance, motivation, and productivity [36] and this improved the quality and safety of care and services [16, 35, 42]. Thus, CP&D was seen as a medium for quality accreditation [38] and improvement [41] to support evidence-based practice [43] and research strategies [44]. Organizational support for nurses' CP&D increased work satisfaction [16, 32, 37], motivation, and retention [39, 41, 45]. Nurses with organizational career development opportunities were engaged in organizations [39] and being rewarded supported their career progress [46]. In addition, clear structures for nurses' career paths supported interprofessional collaboration in organizations [38].

3.3. Organizational Structures to Support Nurses' CP&D. The key organizational structures to support nurses' CP&D started from a strategic level in an organization and required a structured framework and continuous evaluation strategies to monitor success (Table 3).

TABLE 2: Selected studies.

Author(s), year, country	Aim	Methods (scope of career)	Main results or central content
Afriani et al. [16], 2021, Indonesia	To identify the relationship between institutional and nurses' readiness for change in implementing nursing career paths in health centres	Quantitative survey of 93 nurses in public health centres and statistical analyses (clinical nursing)	There was a strong positive relationship between institutional and nurses' readiness. Institutional readiness for change, such as superiors' attitudes and commitment, and nurses' readiness, were needed to implement nursing career paths in public health centres. The nurses considered both had reached a good level
Bramley et al. [35], 2018, UK	To describe the implementation and evaluation results of the bespoke chief nurse fellow programme for frontline junior clinical staff. This was designed to develop skills in innovation, leadership, improvement science, and change management	Theoretical paper: project report (nursing leadership)	The pilot programme had a positive impact on the nurses' professional development and enabled them to become familiar with an alternative career route
Chen and Haller [55], 2015, Canada	To examine the relationship between nurses' career burnout and career wellbeing and how career counsellors can improve their career wellbeing	Theoretical paper (clinical nursing)	Career counsellors can improve nurses' career wellbeing by enhancing effective coping skills and helping goal progress. Combining narrative and social learning career counselling approaches were suggested
Choo et al. [37], 2019, Singapore	To explore the role-transition experiences of assistant nurse clinicians after their first year of appointment	Qualitative primary care study. Interviews with 22 registered nurses and content analysis (clinical nursing)	Previous clinical experience eased the transition. Peer support, mentorship, and training in managerial skills were needed
Cooper et al. [43], 2019, UK	To outline how nursing, midwifery, and allied health professions had been supported to develop clinical academic roles and their contribution to research and innovation in care	Theoretical paper (clinical academic nursing)	Clinical academics needed organizational support to combine clinical and research activity. The hospital's strategic commitment to promoting research and evidence-based practice was important. Clinical staff needed predoctoral opportunities to become familiar with academic work. Work time and mentoring was needed to apply for funding in the postdoctoral phase
Duffield et al. [39], 2014, Australia	To evaluate a career development policy in South Australia, which increased the number of senior staff nurse positions and provided senior registered nurses with time away from clinical duties to undertake agreed projects	Qualitative hospital-based study with 54 senior staff nurses who participated in career structure arrangements and interviews. Analysis method not specified (clinical nursing)	The organization's policy increased the number of senior staff nurse positions and enabled senior RNs to get involved in strategic portfolio projects that aimed to improve organizational effectiveness and care quality. Nurses felt this new policy helped their career and skills and enriched their working lives

TABLE 2: Continued.

Author(s), year, country	Aim	Methods (scope of career)	Main results or central content
Esplen et al. [42], 2018, Canada	To describe a model of education developed based on the novice to expert specialty training framework and its success in offering structured oncology continuing education training to nurses, from undergraduate levels to continued career development in clinical settings	Theoretical paper: project report (clinical nursing)	The paper underlines the importance of nurses' continuing education and certification to ensure high clinical competency. An education institute developed oncology education, including mentorship for lifelong learning and a novice to expert framework with a credit system and a national certification exam. The learning institute partnered with nurse associations. The model notably increased oncology nurses' certifications
Faithfull-Byrne et al. [31], 2017, Australia	To describe a quality improvement project to promote nursing assistants to enrolled nurses	Theoretical paper: project report (clinical nursing)	A hospital and educational institution created a flexible career path for nursing assistants to become enrolled nurses. The two-year study programme included theory and clinical practice. The hospital's nurse educator coordinated the studies and nurse managers helped students to balance their work. Grants covered financial losses due to time away from work. The programme was an effective workforce development strategy for the hospital
Freeman and Gray [33], 2013, UK	To discuss the benefits of a career and development framework for infection prevention and control nurses, developed by a health service organization	Theoretical paper (clinical nursing)	The framework defined responsibilities and professional requirements from practitioner to consultant level, focusing on leadership, learning, evidence, research and development, and clinical practice. It helped individuals to progress their careers, employers, and managers to plan their workforce and mentors to providing support
Jangland et al. [54], 2021, Sweden	To evaluate the implementation of a multifaceted mentoring programme in a large university hospital and describe its value from the perspectives of newly graduated nurses, experienced nurses, and the hospital	Qualitative hospital-based study on 35 nurses, supervisors, and nurse managers, with interviews and thematic analysis (clinical nursing)	Mentors were senior nurses. The mentoring programme comprised research knowledge to guide nursing work, practical and situational guidance for clinical nursing, and group discussions. New nurses found the programme meaningful for their work wellbeing and senior support important in their clinical work. Acting as mentors offered senior nurses a new career opportunity
Jokiniemi et al. [47], 2020, Finland	To formulate, validate, and disseminate policies modelling nurses' career pathway from registered nurse (RN) to advanced practice nurse (APN)	Multiple methods: review, interviews, survey and expert group discussions (clinical academic nursing)	Three competence levels were modelled: RN, specialized nurse, and APN. Central elements in a national RN to APN policy were establishing and enabling new roles, developing education, enhancing appreciation, networking and collaboration, knowledge translation, and governing the roles

TABLE 2: Continued.

Author(s), year, country	Aim	Methods (scope of career)	Main results or central content
Lanada and Forde-Johnston [45], 2021, UK	To reduce variations and standardize job titles, job descriptions, and job plans for clinical nurse educators (CNEs) and identify the academic requirements and professional experience required of each band	Qualitative study with 12 CNEs and 11 senior nurses. Focus group interviews and comparative content analysis (clinical academic nursing)	Job titles, descriptions, and plans were reviewed and CNE roles standardized to reduce variations and inconsistencies. These aligned overall job summaries, teaching activities, and management responsibilities. CNEs were offered career advice and support in line with these career progression descriptions. Staff perceived the new roles as meaningful
Lees-Deutsch et al. [48], 2016, UK	To enable nurses, practitioners, and managers to distinguish between enhancing, expanding, or advancing practice. To clarify points of progression and integrate "advancement" into an acute medical setting	Theoretical paper (clinical nursing)	The paper presents a conceptual framework for nursing career advancement in acute medicine. The framework included five ascending levels of practice and distinguished enhanced, expanded, and advanced ones
Martens et al. [56], 2018, USA	To identify common experiences or barriers during the first year as certified registered nurse anesthetists (CRNAs) moved into management To identify the knowledge, skills, abilities, and resources needed to ensure a smooth and successful career transition	Qualitative study with 20 members of the American Association of Nurse Anesthesiology Interviews and qualitative analysis. (Nursing leadership)	CRNAs had often "fallen" into managerial roles without adequate managerial competencies. Transition support, mentorship, and education were important in the role. People skills were crucial in managerial work
McGhie-Anderson [46], 2017, USA	To gain an understanding of the social processes associated with the decision of diploma and associate degree nurses to advance academically	Qualitative hospital-based study with 15 diploma and associate degree nurses and 7 other nurses. Interviews and qualitative data analysis (clinical academic nursing)	Rewarding, motivating, and supporting were important factors for nurses' decisions to advance academically. Rewards and positive work environment motivated nurses to progress
Pacho et al. [57], 2023, USA	To present the implementation of a program in a medical centre to support ambulatory care nurses make the transition from direct care to clinical nurse coordinator roles	Theoretical paper: project report (nursing leadership)	The four-week programme combined a web-based toolkit, mentoring network, and shadow shifts. Programme evaluation reflected the nurses' satisfaction with the program and their desired professional advancement
Rahimi et al. [34], 2019, Iran	To investigate the factors affecting career development of nurses in Iran	Delphi study. Hospital-based with 48 nurses and nursing faculty members. Interviews and content analysis, questionnaires, and statistical analyses (clinical nursing)	Central factors affecting nurses' career development were specialization, professional development, and increasing their organizational power and influence
Reville and Foxwell [51], 2017, USA	To present a new competency evaluation tool, the Advanced Practice Palliative Nurse Competency Milestones, to provide a framework for its application and to describe the authors' experience with its use	Theoretical paper (clinical academic nursing)	The tool suggests five competence levels from novice to expert in nine areas of palliative competence

TABLE 2: Continued.

Author(s), year, country	Aim	Methods (scope of career)	Main results or central content
Roddam et al. [49], 2019, UK	To explore the perspectives of aspiring or active clinical academics and health care managers in the nursing, midwifery and allied health professions (NMAHPs) about the benefits, barriers, and enablers of engagement in these career pathways	Qualitative healthcare study focusing on NMAHPs. Workshop data and thematic analysis (clinical academic nursing)	An organizational structure and resources were needed to enable clinical academic career progress, including funding and permanent academic posts. Individuals' research capacity needed to be promoted and networks and mentoring played a central role
Ryley and Middleton [52], 2016, UK	To discuss the implementation of the Welsh Government's advanced practice framework into a Welsh University health board	Theoretical paper (clinical academic nursing)	The paper presents the five stages of the development of the advanced nurse practitioner role
Sandehang et al. [38], 2019, Indonesia	To investigate career mapping for nurses at a new hospital in Jakarta	Qualitative case study in hospital. Discussing CP&D with 8 registered nurses and 6 nurse managers. Content analysis (clinical nursing)	Career mapping aimed to match nurses with adequate skills with optimal work based on prerequisites set by the employer. Mapping focused on the educational level, work experience, and competency assessment. Some challenges were recognized, such as time limitations
Sattler et al. [40], 2021, USA	To describe the innovative nurse retention role implemented in the medical health system in the USA	Theoretical paper: project report (clinical nursing)	A medical health system developed a nurse retention role, including meetings with nurses, building collaborative relationships, revising clinical ladders, cultivating peer mentoring, creating a system-wide recruitment structure, and promoting recognition of effort. Participation in nursing career development increased, nurse turnover dropped significantly and financial savings were achieved
Sheikhi et al. [36], 2015, Iran	To explore nurse leaders' experiences of implementing the nurses' career advancement pathway program in Iran	Qualitative study in hospital with 16 nurse managers. Interviews and content analysis (clinical nursing)	First, shortcomings in performance evaluation were recognized as evaluations were not continuous, there was no agreement between the evaluation criteria and the nurses' job descriptions and evaluation was subjective. Second, they needed to pay attention to the point accumulation so that it did not exceed educational needs. Third, there was an advancement-latitude mismatch. Career advancement may lead to pay rises and higher positions but not role expansion and considerable changes in job descriptions
Smith et al., 2018 [44], Australia	To consider clinician researcher career frameworks. To propose a new pathway, integrating university and health service components to support research career progression within nursing and midwifery practice	Theoretical paper: discussion (clinical academic nursing)	A national researcher career pathway for nurses and midwives was proposed, which comprised six levels from research assistant to chair/clinical professor. Each level specified a title, level of qualification, Australian qualifications framework level, role expectations, and examples of role-specific skills

TABLE 2: Continued.

Author(s), year, country	Aim	Methods (scope of career)	Main results or central content
Thompson et al. [50], 2012, USA	To introduce a model emphasizing the importance of mentoring and/or coaching for the aspiring executive nurse leader	Theoretical paper (nursing leadership)	Nurses' career trajectories towards leadership roles can be supported by mentoring and coaching. Mentoring is support, role modelling, discussions, and reflections between a nurse and an experienced executive. Coaching is more orientated to targets and clients and about nurses growing into their new roles. When nurses aspire to executive positions mentoring and coaching can proceed in three phases: basic fundamental knowledge, experiential learning, and advanced system thinking
Tucker et al. [53], 2019, USA	To describe how knowledge translation tools were used to guide the implementation of a professional development and career planning program, developed and piloted in an urban Chicago hospital. The aim was to reduce the turnover of newly hired nurses and looking at how to make this a sustainable change	Theoretical paper: project report and commentary (clinical nursing)	Nurses planned their career with a program coordinator and received information on career developmental possibilities. The Alberta Context Tool collected information on the nurses' work environment, namely, the units' strengths and readiness for change. Programme implementation included assessing, monitoring, and evaluation. Educating and involving nurse managers was central. Nurse turnover decreased. Use of knowledge transition models, context assessment, and expert recommendations for implementing change strategies were important for sustainable change
Wasike et al. [41], 2019, UK	To examine the learning outcomes from a pilot career program developed to advance home care nurses' professional competencies and career planning	Multiple method study with 15 home care nurses. Questionnaires and statistical analyses, interviews, and thematic analysis (clinical nursing)	The six-month program comprised one-day workshops and particularly focused on leadership and quality improvement skills, potential career paths in home care, and conversation confidence. Nurses found the program beneficial for their practice, professional self-image, and planning career
Woolhough and Fielden [32], 2014, UK	To investigate the effects of a career development and mentoring programme on female mental health nurses' career and personal development. The study used a matched comparison group	Qualitative study in mental health nursing with 54 female mental health nurses: 27 who did and 27 who did not receive intervention. Interviews and thematic content analysis (clinical nursing)	The nurses who participated in the program experienced personal development outcomes. Participants progressed more in their career during the 18-month period than the control group

TABLE 3: Nurses' career planning and development (CP&D), organizational structures, and support methods.

Main categories	Subcategories	Groupings
Definitions and rationale for nurses' CP&D	<ul style="list-style-type: none"> (i) Individual level: target-oriented increase of personal competency to respond to new work challenges (ii) Organizational level: resource for improving care and service quality and workforce's commitment 	<ul style="list-style-type: none"> (i) Intentionally directing competencies and content of work (ii) Expanding role and professional development (iii) Strengthening professional identity and pride <ul style="list-style-type: none"> (i) Signalling respect for staff (ii) Improving performance (iii) Promoting nurses' commitment in organization

*CP&D = career planning and development.

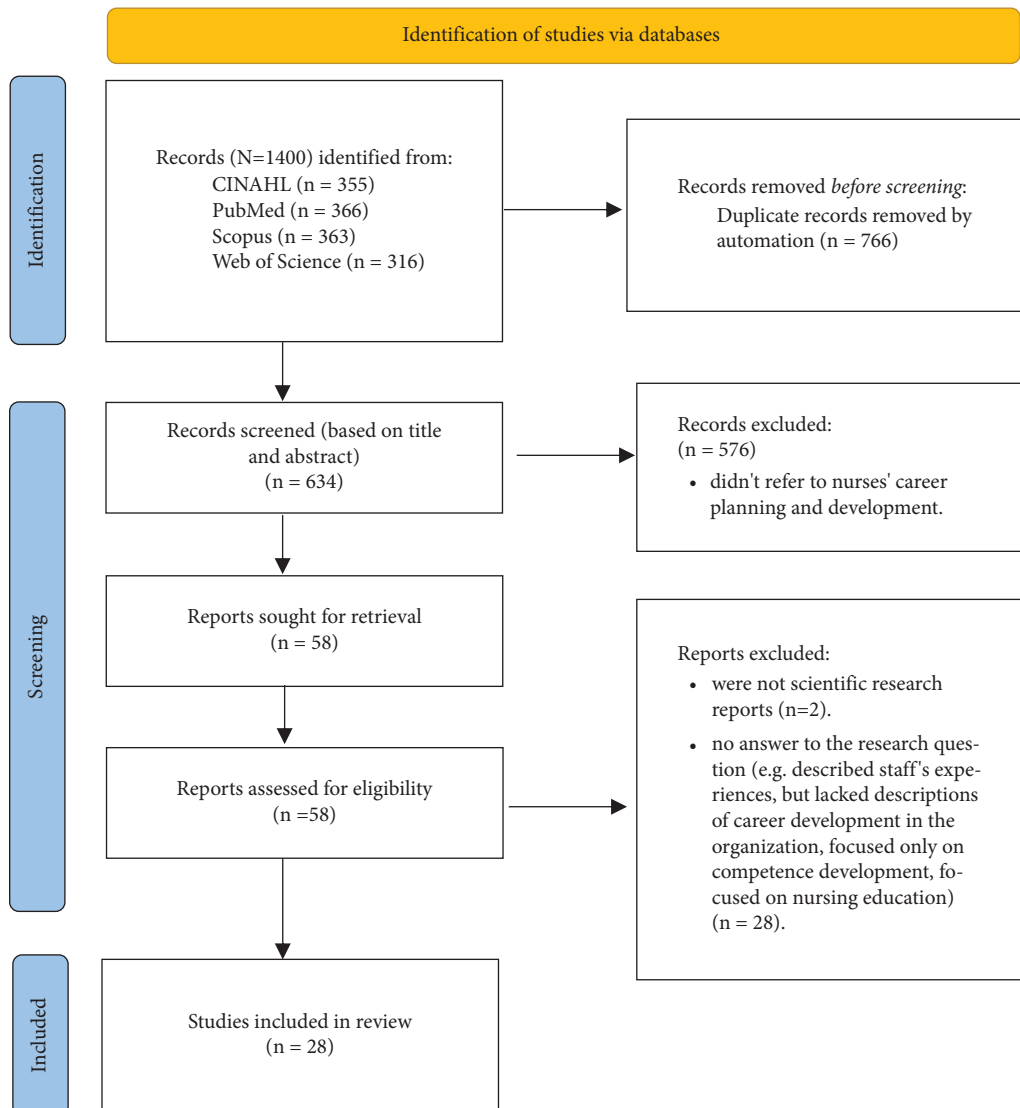

FIGURE 1: PRISMA flowchart.

3.3.1. Strategic Level Support for Nurses' CP&D in an Organization. Nurses' CP&D reflected an organization's values, aims and culture, and CP&D needed to be included in the organization's strategy. Future oriented, progressive organizations had a core interest in being committed to nursing staff [37, 43], creating different career opportunities [16] and promoting their career development [43, 46]. In addition, organizations were responsible for promoting the career development of nursing staff [38] and implementing national recommendations and standards to promote their career paths [16, 44, 47].

Recognizing nurses' CP&D was also seen as part of an anticipated strategic policy for workforce and competence needs in an organization, which aimed to match organizational tasks with the competencies needed by the workforce [33]. Matching required considering current staff competences and age structures [48] and reconsidering vacancies [45]. In addition, senior [39] and progressive positions for educated academic staff were needed to engage

them in organizations [49]. Matching also required evaluating changes in job descriptions and their effect on workload [38]. In addition, infrastructure for building organizational research capacity was required to support nurses' academic career progression in organizations, including research networks between universities and hospitals [49].

Organizational support for nurses' CP&D required strategic educational partnerships. This referred to planning and executing educational programmes in collaboration with healthcare and learning institutions [31, 38]. Programmes focused on staff re-education [31] and extended their competencies to respond to changing needs [33] and to the development and flexibility of nursing positions and new posts [43]. In addition, strategic educational partnerships included learning institutions that provided lifelong learning possibilities for staff [42].

Supporting nurses' CP&D through organizational strategies also included direct and indirect resourcing and

strategic investment. Direct resourcing included budgeting for cumulative salaries according to career progress [46], together with bonuses or other monetary compensation [38, 46]. In addition, supportive, rewarding systems referred to nonmonetary remuneration and included psychological payment for participating in organizational decision-making, progressing in their career [46] and social recognition activities [40]. Direct resourcing also included providing nurses with sufficient equipment to complete their new duties and professional responsibilities [39]. Indirect resourcing for CP&D referred to planning human resources to allow career development and providing sufficient permanent staff and substitutes to enable nurses to participate in education [31, 38, 39, 49]. In addition, vacancies and job description required constant reconsideration and updates so that they corresponded to nurses' career development, increased competencies, special nursing care duties [39], and research and developmental work [49]. In addition, mixed model vacancies between academia and services or public and private sectors supported CP&D [44]. Resourcing also focused on strategic investment for CP&D, as investment in education and competencies improved organizational effectiveness [39] and employees' engagement [49].

3.3.2. Structured Framework for Nurses' CP&D. The structured frameworks to support nurses' CP&D in organizations included nurse manager act as they played a crucial role in career stage mapping and identifying nurses' competencies [38, 50]. These were needed at both unit and individual staff levels [40, 48, 51] to determine nurses' competency levels based on prerequisites set by the organization [38]. At unit levels, updated overviews of available competencies were needed to evaluate how to respond to care needs and anticipate the requirements for future staffing and competencies. At the individual staff level, career stage mapping enabled nurse managers to address suitable responsibilities for staff members with adequate competencies [38, 52]. Career stage mapping consisted of considering the individual nurses' education level, work experience, and duration of work and their competency evaluation [38]. However, identifying nurses' competencies was challenging [49], especially with regards to tacit knowledge [48]. Thus, evaluation required optimal frequency and visibility and tested evaluation criteria tailored to the job description [36].

Standardized qualifications for all career stages were suggested to achieve systematic progress and fair evaluation [36, 44, 51]. Logical career trajectories [41] required clear job descriptions [37, 45] and identifying key knowledge, skills, behaviours, roles, and responsibilities [33] for each career phase. This included definitions for each competency level, from novice to expert [51]. Based on that, all individuals at the same career stage should have developed their skills, capacity, and knowledge to the same standards and have equal responsibilities [33, 52]. The benefits of structured career trajectories were twofold. First, they helped nurses to identify their career and progress opportunities and recognize their knowledge level and further training needs [33]. Second, structured career trajectories served as a tool for

nursing managers to evaluate the individual competencies of nurses and nursing staff [16, 51] and to design mentoring and educational programmes for organizations [33]. The standardization and implementation of a structured framework for nurses' career development needed to be evidence based and respond to the purpose of the organization [45]. They should be regularly updated [38] based on committee work in the organization [33] and involve strategic administrators [16] and human resource teams [45] and coordinators [16]. Implementation required nurse managers [33] and nursing staff to be educated about frameworks [53].

Various career opportunities and pathways in organization supported nurses' CP&D [38]. In clinical nursing, these opportunities included daily patient care [39], specialization in some field of nursing [54], and specific tasks in practice [33, 40, 42]. Career opportunities also included more academic options, such as advanced practice [33, 52], project work [39], clinical research [44, 49], and working as a nurse manager [37, 50] or educator [33]. In addition, peer mentoring was considered to be a career opportunity [54].

3.3.3. Evaluating and following up Nurses' CP&D. At an organizational level, constant evaluations and follow ups on implementing nurses' CP&D focused nurses' satisfaction on the existing structures for CP&D [32]. The structures that were evaluated focused on providing education and mentorship and collaboration with educational institutions [38]. In addition, evaluation was focused on outcomes of executed care and service. This referred to the goal of achieving high-quality care and services focused on how nurses could respond to care needs [38] and promote the image of the hospital [38].

3.4. Means to Support Nurses' CP&D. The key means to support nurses' CP&D were promoting their competencies, facilitating, and promoting their personal career planning and interpersonal support (Table 3).

3.4.1. Competence Promotion. Career awareness promotion and substance training supported nurses' CP&D. Nurses' career awareness was increased by publishing and presenting career options [49, 53] and success stories [49, 50] in organizations [39]. Career awareness was also promoted by providing nurses opportunities to get acquainted with certain careers, such as developmental work, education, or leadership in practice [35]. Such awareness eased the transfer into academic positions [37]. Substance training referred to nurses' opportunities for lifelong learning [34]. They included formal [37] and tailored educational programmes for staff on their career trajectory [35, 41, 49] and re-education by taking new degrees with the support of an organization [31].

3.4.2. Personal Career Planning. Portfolios [52] and personal career plans were used to support nurses' CP&D. Portfolios were documents, where nurses demonstrated their professional and academic accreditation, competence,

and capacity, continuing professional development, and readiness for career progress [52]. Personal career plans or individualized action plans [40, 50] referred to voluntary or compulsory [53] oral discussions [33] or written plans [53]. Career stage frameworks were used as templates for planning [33]. Oral plans involved personal discussions between staff members and nurse managers [45, 48] or with a career coordinator [53] or nurse retentionist. The aim was to identify each nurse's strengths, talents and goals [40], develop, and clarify their individual career prospects [33, 48] and evaluate yearly progress [48] and educational needs [33]. Personal career plans or portfolios were used to evaluate career progress [33, 48, 52].

3.4.3. Interpersonal Support. Interpersonal support for nurses' CP&D referred to support from leaders, mentors, networks, peers, and their work community. Career-oriented work environments [46] referred to organizational values and the crucial role played by nurse managers [31, 37]. These work environments were open and the professional ambitions of the individual nurses were respected [53]. Leadership support by nurse managers played a crucial role in guiding and supporting nurses [38, 40, 45] and career progress [16, 46], in line with organizational developmental policies [38]. The nurse manager's role was to provide opportunities for career progression by engaging nursing staff [39] and enabling them to participate in educational activities [43]. One-to-one career advice and support from the divisional recruitment and retention leads [45] and nurse retentionists [40] were pivotal.

Papers focused on different aspects of mentoring or coaching [50] that supported nurses' CP&D [32, 40]. These were mentoring for evolving career planning [35, 55], identifying different types of career trajectories [32, 35], supporting career transfer phases [40, 50, 54, 56, 57], following up career success [40, 43], and promoting lifelong learning [42]. Nurses' CP&D was mentored by nurse managers [32] and experienced supervisors [54]. The aim of all types of mentoring was to support goal achievement [32, 50], realistic aim setting, and periodical progress assessments [51]. Mentoring was informative [37, 43, 54, 56, 57], emotional, and psychological [37, 55]. Cognitive support [56] and guidance aimed to strengthen nurses' self-efficacy [38, 54], confidence [32, 41], and self-image [41]. Mentoring included discussions about challenges and ethical conflicts [54] that nurses had faced [37, 50]. Mentoring was carried out during regular meetings [35, 56], with reflective discussions [40] and feedback [56], to discover nurses' strengths and developmental needs [40]. Nursing networks and peer support provided interpersonal support for nurses' CP&D. Peers were crucial for sharing knowledge and providing emotional support [37, 40] within informal networks [49].

4. Discussion

Organizations recognized nurses' CP&D in relation to the individual's professional development and what the organization needed to do to promote quality services and workforce engagement. There were multiple levels of

support for nurses' CP&D. These included the organization's strategic work level, which ensured that resources and purposeful vacancies were available, and the structured framework level, which focused on objective qualification criteria and equal assessments. Different methods were needed to support nurses' CP&D opportunities, including ensuring that they were aware of career planning and providing them interpersonal support. CP&D was linked to an organization's aims. Support was needed within the nursing profession but also through multilayered interprofessional collaboration that was designed and implemented by organizations.

Nurses' CP&D in an organization provided mutual benefits for nurses, employers, and society as the individual and organizational level benefits of nurses' CP&D were strongly interlinked. They increased personal competencies to respond to work challenges and, therefore, the organizational capacity to achieve high-quality focused care and services ([5]). It seemed reasonable for nurses' employers to support their careers, as organizational support for CP&D contributed to the nurses' motivation and their experience of meaningful working life. It also promoted an employer's attractiveness and workforce retention. Despite the importance of nurses' CP&D, there has been a lack of studies, particularly empirical ones.

Nurses have a less clear and narrower career development trajectory than, for example, physicians [48]. Nursing careers often progress from clinical positions to leadership roles or academic tasks, while less attention has been paid to career development in bedside nursing. This is a conspicuous deficiency in nursing and healthcare services, from the perspective of the care quality development and the attractiveness of a clinical career. Patient care is known to be a central reason for choosing nursing as a career [1] and for nurses wanting to develop their careers in this area [39]. Moreover, career development that only focuses on academic and leadership paths is insufficient from a resource point of view, as the need for these roles is minor compared to the need for bedside professionals.

The results of this review emphasize nurses' CP&D in patient care organizations. However, nurses' CP&D is not limited to the boundaries of an organization but extends all the way to the societal need for a highly qualified nursing workforce and equal service provision for clients at a national level. Nurses also need equal treatment wherever they work. That is why national uniform models have been proposed to guide the steps in academic nursing careers [33, 47] and widely promote and standardize equal CP&D possibilities for nurses' in local districts and patient care organizations. These kinds of generic and acknowledged models would also need to cover bedside nursing and play important roles in helping people to choose nursing careers and inform and guide them when they do ([12]). However, generic career models are only part of the story. Regional differences in patient-nurse ratios need to be considered so that campaigns are applicable in districts and organizations. Nurses' trade unions and education play a key role in making CP&D models familiar. Thus, integrating career

development competencies and career planning in nursing and nursing leadership education would promote uniformity of nurses' career competencies and awareness.

Nurses' CP&D requires organizational structures and for individuals to play a proactive role. Nurses' organizations need to carry out strategic work on the career information and resources that are crucial. Individuals experience remarkable time and financial pressures during education ([22]). Employers who provide support to overcome these challenges need to implement multifaceted strategic planning and collaboration. These include building financial cooperation models [43] to, at least partly, cover educational expenses. Our study showed that organizational structures needed to focus on identifying equal opportunities to develop competencies and acquire qualifications, as well as provide resources. Clear career paths models and competency assessment criteria contribute to the objectivity and transparency of administrative decisions. However, it should also be noted that professionals who assess how competent personnel are need up-to-date evaluation skills [38] and appropriate competency assessment tools [51].

Even the best organizational structures do not guarantee career development without the individual's own contribution. Every nurse is responsible for their professional development and competencies [38] and plays a key role in their CP&D. Career pursuits require certain readiness [16], namely, awareness of CP&D possibilities, self-efficacy, motivation [38], and emotional readiness [16]. Not least, nurses need to show an appreciation of, and desire to, progress their career [55]. Organizational and individual readiness are known to be interlinked, as organizational support activities have improved nurses' readiness to progress in their careers [16].

Studies on nurses' CP&D had mainly been conducted using empirical qualitative methods, besides which many were theoretical project-based papers. Combining different studies and methods allowed us to map and summarise previous knowledge and provide an overview [24, 25] of nurses' CP&D in healthcare organization. It is noteworthy that the quality of the selected papers varied, particularly within qualitative studies. The strongest areas in them were the congruity between the methodology used and the interpretation of results, as well as data-based conclusions. The weaker areas of reporting concerned philosophical starting points and the researchers' influence on a study. Thus, quality appraisal was needed to increase the transparency of the data. It revealed methodological accuracy to enable reliable and evidence-based development of nurses' CP&D.

4.1. Study Strengths and Limitations. The limitations of this study were related to the review process [25], more specifically to literature searches and selection. Because career concepts are widely used in the nursing-related literature and to reach a reasonable number of search results, we had to focus the literature searches on titles of the papers. As a consequence, some relevant papers may have been unintentionally excluded. Also, although the literature

selections were carried out based on purposeful criteria and by two researchers, it is possible that some studies dealing with the topic remained unselected. In addition, we only included papers published in English, which may have biased our data.

5. Conclusion

Organizations need to see nurses' CP&D as beneficial, necessary for the development of professional nursing practice and a crucial part of the organizational goals needed to achieve high-quality patient care. In contemporary nursing, nurses' CP&D also increasingly contributes to an organization's attractiveness as an employer and to nursing as a career. Clear and transparent structures and models to support and enable nurses' CP&D are central and needed for equal career progression and meaningful working lives. At the same time, nurses' own ambitions and career awareness play crucial roles in CP&D, emphasizing the importance of integrating the topic of CP&D into clinical and leadership education. Further research is needed about the outcomes that nurses' CP&D deliver for their organizations and patient care.

6. Implications for Nursing Management

The growing shortage of nursing staff forces their leaders to develop new ways to promote the meaningfulness and attractiveness of nursing, where career opportunities are one central focus. Nurse managers play a key role in ensuring nurses' work engagement [58] and this study helps them to understand nurses' CP&D and its meaning for an employee and organizational benefits and what kind of structures and means are needed to support it. Moreover, the study opens up the key role of nurse managers in supporting nurses' CP&D at an individual level and in nurse communities. Eventually, nurses' CP&D supports the achievement of the overall goal in the organization.

Data Availability

The data used to support the findings of this study consist of scientific articles that can be found from electronic databases mentioned in the manuscript.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Background. Current research has mainly concentrated on the psychological facets of authentic leadership and the sense of psychological security it cultivates. **Aim.** This research assessed the perceived academic team leaders' authentic leadership and team members' psychological safety. **Methods.** Using a quantitative cross-sectional study, the study was conducted in 2022 using an online survey. A convenience snowball sample of 105 nursing faculty members was recruited from various Jordanian universities. **Results.** The nursing faculty highly praised their leaders' authentic leadership on a 5-point scale. Yet, they felt a lack of psychological safety for themselves. While the academic nursing team leaders were commended for their readiness to hear others' suggestions before making choices, they should work on resisting group influence. These leaders must convey their feelings openly and truthfully. Concerning their own psychological safety, the nursing faculty felt their distinctive abilities and talents were recognized and utilized when collaborating with team members, which was the most highly rated feature. Conversely, the least-rated aspects were holding mistakes against faculty members and having trouble requesting assistance from others. The nursing faculty's sense of security and comfort significantly impacts their psychological wellbeing. Interestingly, their level of psychological safety is found to have a significant but negative correlation with their marital status, providing a rich and new insight into psychological safety; married females with children are prone to more work burnout, which might lower their psychological safety. On the other hand, a positive and moderate correlation is observed between psychological safety and the size of the team they work with. Surprisingly, the team size is the only factor that predicts the psychological safety of nursing faculty members; this occurs by enhancing the team's creativity and learning behaviors. However, the model itself is not very effective and only accounts for a small portion (6.30%) of the variation in their psychological safety scores, suggesting other unmeasured factors likely play a more significant role in nursing faculty members' psychological safety, such as personality traits, stressors, and job satisfaction. **Conclusion.** The authentic leadership displayed by nursing team leaders does not directly impact the psychological safety of nursing faculty members. The study addresses a critical and contemporary issue within the nursing academic field, providing useful preliminary insights. However, its methodological limitations, including sample selection and the weak explanatory power of its model, suggest that further research is needed. The results highlight the urgent need for immediate interventions to improve the chaotic academic environment they are currently facing, such as enhancing workplace friendship and authentic communication and using entrepreneurial and nonauthoritative leadership styles. Future studies could benefit from diverse samples, longitudinal design, and deeper analysis of contributing factors to psychological safety.

1. Introduction

Academic institutions rely on faculty members to generate and share knowledge, as well as foster a sense of creativity and innovation in their students and society [1].

To fulfill these responsibilities, faculty members must feel psychologically secure. The evolving nature of academic environments necessitates the cultivation of psychological safety among faculty members [1, 2]. However, this cannot be achieved overnight; it requires the presence of

authentic leaders within academic teams who can establish a culture that encourages creativity and innovation [2–5].

In the realm of academic nursing and healthcare, a novel idea called authentic leadership has emerged [5]. Previous studies focused on the psychological aspects of psychological safety and authentic leadership [6–10], neglecting its application in nursing or academic environments. Several recent research studies have focused on the topic of authentic leadership and its relationship to the safety climate in nursing [4, 5, 11, 12]. These studies have also explored the psychological safety of staff members. However, research specifically examining the impact of authentic leadership on psychological safety was lacking. It is important to mention that authentic leadership is usually addressed from the perspectives of positive outcomes; however, it has negative outcomes as well, such as negative workplace behaviors such as bullying, incivility, and staff burnout [13]. In the current research, we assumed that authentic leadership has positive outcomes; yet, the exact reasons behind the positive outcomes of authentic leadership, such as commitment, trust, and engagement of employees in nonacademic organizations, remain uncertain [11, 13–21], which may be linked to the psychological wellbeing of nursing faculty members [22]. Employees experienced a heightened sense of purpose and fulfillment when guided by leaders who demonstrated authentic leadership. Yet, their day-to-day feelings of happiness and overall psychological safety remained largely unchanged [11, 13–21].

The leadership research has been critiqued for lacking contextual understanding; thus, this study would help faculty members and academic administrators understand the effects of authentic leadership on various outcomes, such as the current concept of faculty members' psychological safety [6–10]. As a senior faculty member and previous university administrator in Jordan, similar to other faculty members around the world, I attest that we are struggling with the consequences of the COVID-19 pandemic, such as our worsened financial burdens and the marginalized psychological safety, warranting immediate interventions as we are the role models for our current students who are the future nurses.

Authentic leadership is a leadership style demonstrated by individuals with strong moral principles who accept the consequences of their choices and base their judgments on lasting values rather than temporary gains [4, 5]. In today's ever-changing work environments, especially in academia, authentic leadership is a crucial aspect of individual and organizational behavior [3–5]. At an individual level, it refers to workers who uphold high integrity standards and have the potential to be authentic leaders [3–5]. On an organizational level, it is essential for leaders, particularly those in higher management, to embody authentic leadership [3–5]. Embracing authentic leadership, regardless of the level, promotes employees' psychological safety, which is defined as employees feeling comfortable sharing their thoughts, admitting errors, and being themselves at work without fear of negative consequences [6, 7]. There is a collective understanding that the workplace values

openness, allows room for learning from mistakes, and accepts each individual's true self [6, 7]. In turn, psychological safety prevents harmful behaviors and negative consequences, like medical errors [3–5]. Professionals, including nursing faculty members, continuously strive for their rights and ideal work environments [3–5].

Academic nursing leaders' authentic leadership in Jordan was linked to knowledge sharing within the team and nursing faculty members' creativity [3]. Another study was conducted in Jordan to explore the humble leadership of academic leaders and its effect on the psychological safety of faculty [4]. Moreover, a comparative nursing study in Jordan explored the relationships between the concepts of authentic leadership and the safety climate. However, it did not specifically focus on the psychological safety of staff members [5]. The study found that military hospitals in Jordan had higher levels of authentic leadership among nurses and a generally positive perception of the safety climate. In contrast, government hospitals had a negative safety climate [5]. The current study is the first to link the perceived academic team leaders' authentic leadership and team members' psychological safety in Jordan.

1.1. Research Questions. To my knowledge, the topics investigated in nursing and academic nursing settings have never been the subject of a global investigation before this one. This study assessed nursing faculty members' perceptions of their academic team leaders' authentic leadership and their own psychological safety. The investigation at hand aimed to uncover the following: (1) how do nursing faculty members perceive the authentic leadership qualities of their academic nursing team leaders? (2) What are the perceptions of nursing faculty members regarding their own sense of psychological safety? (3) Does the perceived academic nursing team leaders' authentic leadership predict nursing faculty members' psychological safety? The current study's findings will be utilized to build leadership initiatives that uphold the authentic leadership of academic nursing leaders and establish inclusive work environments to enhance the psychological wellbeing of nursing faculty members.

1.2. Background. In the current dynamic work environment, it is essential to have leaders who create psychologically safe environments [3–7]. This is crucial for fostering creativity and adaptability at the individual, team, and organizational levels, even in academic settings [3]. The acquisition of authentic leadership skills is essential as it fosters a sense of psychological security within the workplace [7–10, 14], including academic settings. Due to the ongoing changes in our academic environments, which call for transformative leadership [4], this study has chosen to investigate authentic leadership instead of focusing on humble, autocratic, and democratic leadership [4]. Authentic leadership is essential for effective work environments and beneficial outcomes, including the psychological safety of the workforce [4–10, 14], especially for our academic faculty members at universities. Authentic leadership improves staff's self-efficacy, job satisfaction, retention, interdisciplinary

teamwork [13, 15], work engagement [11, 16–21], organizational productivity, and citizenship [12, 21, 22]. In the clinical setting, authentic leadership results in high-quality and safe healthcare [4, 21] and safe medication practices [23]. Nonetheless, there is a lack of sufficient research, particularly when it comes to how authentic leadership helps in establishing psychological safety within the nursing profession [5].

Authentic leaders possess qualities that make them trustworthy, optimistic, ethically sound, skilled in navigating change, productive, and capable of assisting their team members [4, 11, 18, 19, 21, 22, 24–26]. In his book, Bill George [27] outlines essential behaviors for an authentic leader as (1) “purpose,” which facilitates the opportunity for passion, (2) “values,” which facilitate behaviors that are aligned to values, (3) “relationships,” which facilitate the importance of building strong relationships with team, (4) “self-discipline,” which facilitates consistency in good and hard situations, and (5) “heart,” which facilitates the benefit for displaying compassion and empathy for team’s well-being. Moreover, authentic leaders have the following traits: (1) “self-awareness” includes accepting one’s talents and weaknesses and showing tolerance for how they may influence others, (2) “balanced processing” involves examining pertinent information from different perspectives before making decisions, (3) “relational transparency” involves expressing emotions or encouraging others to do so to foster trust, and (4) “internalized moral” refers to acting following one’s moral principles [4, 17, 21, 22, 24–26, 28–32].

Because psychological safety is a part of the safety climate [3–5, 11, 12], a positive team climate is a critical driver of psychological safety and would occur when leaders demonstrate supportive behaviors [3]. A psychologically safe work environment, including academic settings, is a product of positive leadership styles, such as transformational leadership and authentic leadership [33, 34] and professional nursing practices [33]. Authentic leaders have the power to foster a sense of psychological safety among their teams by promoting the right attitudes and behaviors. To establish a psychologically safe environment for faculty members in academic nursing, authentic leaders can empower other potential leaders within the team and ensure that the necessary behaviors are reinforced [3].

Creating conducive work atmospheres and establishing clear boundaries are essential for nurturing the mental wellbeing of nursing faculty members [35]. These studies highlight the importance of leadership actions that enhance psychological safety, including recognizing and utilizing the individual strengths and abilities of faculty members, refraining from holding past errors against them, and fostering a collaborative environment where seeking assistance from team members is encouraged [7, 10].

In Jordan, Elrehail et al. [2] conducted a study in universities to measure the effect of transformational and authentic leadership on innovation. Even though it was not about psychological safety or academic nursing settings, Elrehail et al. [2] found that authentic leadership did not have an impact on innovation. In contrast, transformational leadership and innovation were

positively correlated. Contrary to Elrehail et al. [2], Alzghoul et al. [36] found that authentic leadership positively impacts the work environment, creativity, and productivity in Jordanian telecommunication companies. The work environment’s climate mediates the relationship among authentic leadership, creativity, and job performance [36].

To sum up, when academic nursing leaders wholeheartedly embrace authentic leadership, there is a greater chance that nursing faculty members will feel psychologically secure. If faculty members do not feel psychologically safe, the long-term viability of academic settings is in jeopardy. Faculty members are increasingly mindful of the kind of work environments they desire, as well as their role in educating students.

2. Methods

2.1. Design. An online survey was conducted using a quantitative cross-sectional approach. While not incorporating experiments, cross-sectional surveys were employed to examine different environments and choose participants based on the topics of interest and their outcomes. This design is generally straightforward to execute and cost-effective, and it provides initial insights to guide the development of more sophisticated future research [37]. Moreover, unlike other observational approaches, such as longitudinal designs, cross-sectional studies do not track individuals over an extended period [37]. Nevertheless, it is important to note that the cross-sectional design cannot establish causation between variables [37].

2.2. Participants and Settings. In Jordan, there are a total of 12 undergraduate nursing programs, each led by the dean. Assisting the dean in their academic duties are the vice dean as well as the assistant dean for student affairs, the assistant dean for quality management, and the heads of the departments. It is worth noting that informal leaders also play a role in these programs.

The study’s general population comprised Jordanian nursing faculty members, with the target population being those from various universities. The accessible population consisted of nursing faculty members from the selected universities. To gather data, the researcher utilized a non-probability convenience snowball sampling technique was used. Convenience sampling is a nonprobability method through which individuals are selected based on their availability at the time of data collection. Snowball sampling is a nonprobability method in which the ongoing recruitment process depends on who the current participants already know. Both sampling techniques result in self-selection bias, preventing generalizations of the results to the whole population of participants. For instance, the nursing faculty members selected for the study were from the same university as the current researcher, which could introduce a self-selection bias. This means that individuals with specific characteristics may be more inclined to participate in the research compared to others.

Using the personal and schools' Facebook and own WhatsApp, a total of 105 nursing faculty members from two government and two private universities resulted in an 84.67% response rate, though this sample was not representative of the general population of nursing faculty members in Jordan and the target population of nursing faculty members in Jordanian universities. Despite the inability to determine the exact number of leaders or rating groups, this sample size of 105 was selected from a pool of 124 potential participants.

To ensure the statistical validity of the study, the well-known Thorndike's formula, $N = 10(k) + 50$, where k is the number of variables and 50 cases are added to account for the attrition rate, was employed to determine the necessary sample size [37]. The two major variables in this study were the perceived academic nursing team leaders' authentic leadership and the psychological safety of the nursing faculty members. Accordingly, $N = 10(2) + 50$, a minimum of 70 participants was required for this study [37]. However, a total of 105 nursing faculty members were successfully included in the study.

To accurately measure the psychological safety of nursing faculty members, the study required participants to meet certain criteria. It was required that they were actively working as nursing faculty members at a university's nursing school for a minimum of one year, as this would ensure a more precise evaluation of their leaders' authentic leadership, given that psychological safety tends to improve with increased work experience. Moreover, they were expected to show competence in utilizing technological tools to participate in the online survey.

2.3. Research Ethics. The study was authorized by the Institutional Review Board (IRB), where the author is currently working. The study was assigned the reference numbers 2/1/20/2021 (October 18, 2020) and 11/8/2021/2022 (July 25, 2022). Nursing faculty members were informed that their participation in the survey indicated their consent, and they had the option to skip the online survey if they wished. There were no conflicts of interest; however, selection bias is always accompanied by nonprobability sampling.

Ethical behavior and privacy protection are critical in online surveys. With online data collection, there is a need for robust consents that focus on future data sharing [37]. That is, there is a need to disclose the privacy policy. Since it is my own work, I described what personal demographics were collected and how the survey results will be shared. Data were kept anonymous using codes, and their email addresses were not collected in the dataset. Data were also kept confidential by securely storing data and ensuring that only the author had access. Moreover, faculty members were assured that the results were shared exclusively with nursing leaders at the specified universities in order to maintain confidentiality.

2.4. Data Collection. The survey had the following three sections: a 16-item authentic leadership perception assessment scale, a 7-item psychological safety scale, and nine

academic sample characteristics. The survey was hosted on Google Forms from March 10th, 2022, for ten days, and it was designed to allow for one submission.

The researcher announced the study on her Facebook and WhatsApp, allowing participants to decide whether to take part and encouraging them to share the survey link with their friends and contacts. The current researcher began by introducing the study and allowing participants to choose whether they wanted to take part. The survey was then conducted online in English, which is the official language of nursing education. The online survey has detailed invitation letters, contact information, and a declaration of voluntary participation and consent to participate.

Before making it publicly available, I conducted a pilot run of the survey to check for its suitability and applicability of the scales in the Jordanian academic environments. The survey was sent by WhatsApp to ten colleagues, with no necessary changes needed. Once everything was in order, I shared the survey link on the Facebook pages of the Faculty of Nursing and my colleagues. Nursing faculty members who participated in the online survey were considered to have given their consent, and they were encouraged to invite others to take part as well. To ensure maximum participation, a reminder email was sent to nursing faculty members after five days, reminding them to complete the survey only once.

2.5. Instruments. Since the current sample consisted of nursing faculty members teaching in English, the tools were used in their original language. However, a preliminary study was conducted to test if the tools could be used effectively in the Jordanian academic environment, and the results were positive.

The authentic leadership perception assessment tool was the Authentic Leadership Questionnaire (ALQ) [31]. In October 2020, the Mind Garden Institute gave authorization to use the ALQ, which was copyrighted in 2007 by Avolio et al. [26]. The ALQ, a 16-item survey, utilizes a 5-point Likert scale to measure responses. These responses range from strongly disagree (1) to strongly agree (5). The ALQ consists of the following four different categories: self-awareness (items 1, 5, 9, and 13), an internalized moral (items 2, 6, 10, and 14), balanced processing (items 3, 7, 11, and 15), and relational transparency (items 4, 8, 12, and 16). These four dimensions are constantly reported in many recent research studies [4, 5], and meta-analytic and systematic reviews [13, 15] reported authentic leadership and psychological safety concepts. For instance, statements in the ALQ may include examples like leaders acknowledging their weaknesses or their actions align with their values.

To calculate scores, the results of relevant items are averaged, resulting in a total score and subscale scores. In terms of scoring, high authentic leadership is indicated by a score of four or higher on the Likert scale, while a score of three or below represents poor authentic leadership [38].

The ALQ has been utilized in different types of organizations and cultural settings. It has been employed to examine various aspects, including work environments

[8, 14] and team performance [3]. The ALQ has been studied in organizations of different sizes and levels, and its psychometric model has been analyzed in multiple countries [23]. The original tool has predictive validity [31]. The reliability coefficient of the ALQ scale remains consistent with previous studies [4], at 0.95.

Edmondson [6] developed a scale consisting of seven statements to measure psychological safety. Participants were asked to rate their agreement on a scale from 1 to 5, ranging from strongly agree to strongly disagree. Some examples of statements included in the scale are “when I make a mistake on this team, it tends to be held against me” and “team members feel comfortable discussing problems and challenging issues.”

I utilized the scoring method developed by Sexton et al. [38] to assess authentic leadership. A score of four or higher on a 5-point scale indicated high psychological safety, while a score of three or below indicated poor psychological safety. The original tool has been found to have convergent validity [6]. In this study, the instrument's Cronbach's alpha was 0.71, slightly lower than the 0.76 reported in Wang et al.'s previous study [7].

The sample characteristics that were measured included gender (male and female), marital status (single married), age (≤ 34 years and > 34 years), time commitment (full time and part time), level of education (Baccalaureate, Master's degree, or more), presence of official accreditation and quality initiatives in the employer organization (yes and no), tenure (indicating how long an employee has worked for an organization) (≤ 4 years, > 4 years), team size (≤ 15 members and > 15 members), and sector type (governmental and private). The inclusion of variables such as time commitment and team size was made based on the current researcher's perspectives on the concept of psychological safety.

2.6. Analyses of Data. Before commencing the analysis, the data underwent extensive data-cleaning procedures to eliminate any erroneous information. That is, online surveys are often associated with inaccuracies caused by respondents who rush through the survey and select the first response without considering its content, as well as those who intentionally provide nonsensical feedback; these responses should be eliminated. Furthermore, outliers were identified, and histograms were created to evaluate the data. It was concluded that there were no notable deviations present. Most of the questions in the online survey were formulated in a manner that motivated respondents to provide answers, thereby ensuring the absence of missing data [37].

The independent variables in this study were the characteristics of nursing faculty members and their perception of their academic nursing team leaders' authentic leadership. The dependent variable was the psychological safety of the nursing faculty members [37]. To answer the first and second research questions related to concepts measured in the current study, authentic leadership and psychological safety were treated as interval variables; thus, descriptive statistics, including means, standard errors of the means, medians,

interquartile (IQR), range, and 95% confidence interval (CI) of the mean, were generated using SPSS version 25 [39]. The third research question assessed whether the perceived academic nursing team leaders' authentic leadership predicts nursing faculty members' psychological safety using the general linear model (GLM) with an alpha level of 0.05. The GLM is an extension of linear regression that can be used with a wide range of types of data while allowing for flexible modeling choices and diverse responses, resulting in robust predictions [37]. Prior to running the GLM, the assumptions of normality, linearity, sphericity, and independence associated with a linear regression model were assessed, and no significant deviations were observed [37].

3. Results

The majority of the nursing faculty members consisted of married women ($N = 72$, 68.60%; $N = 81$, 77.10%), ranging from young to middle aged as they aged less than 34 years ($N = 87$, 82.90%). Nursing faculty held Master's degrees or higher ($N = 67$, 63.80%) and were employed full time ($N = 98$, 93.30%) in governmental universities ($N = 80$, 76.20%) that were accredited ($N = 99$, 94.30%) and focused on quality improvement ($N = 97$, 92.40%). These faculty members had an above-average tenure of four years or more ($N = 73$, 69.50%) and worked in teams of varying sizes, with over fifteen members on average ($N = 55$, 52.40%). However, the ideal collaborative team size is typically between four and eight members (Table 1). The sample characteristics are similar to those of nursing faculty members working in higher education organizations in Jordan.

3.1. Perceived Team Leader's Authentic Leadership. Nursing faculty members in the study generally rated their academic nursing team leaders as having high levels of authentic leadership (based on the scoring of Sexton et al., 2006) [38]. For the whole sample, the nursing faculty members rated high (agreed) the authentic leadership of their academic nursing team leaders (mean = 3.65 and mean SE = 0.08). In academics, authentic nursing leaders were perceived to listen to the ideas of others before making decisions (mean = 3.90 and mean SE = 0.10). On the other hand, authentic nursing leaders need to learn how not to allow the group to pressure them (mean = 3.45 and mean SE = 0.11). They should also learn to openly share their feelings with others (mean = 3.46 and mean SE = 0.11) (Table 2).

3.2. Perceived Team Members' Psychological Safety. Based on the scoring of the study in [38], high psychological safety scored four or higher, while poor psychological safety scored three or below. For the whole sample, the nursing faculty members rated their psychological safety poorly (mean = 3.10 and mean SE = 0.06). The highest-rated nursing faculty members' psychological safety item was that they felt their unique skills and talents were valued and utilized when working with team members (mean = 3.54 and mean SE = 0.09). However, the lowest-rated nursing faculty

TABLE 1: Nursing faculty members' characteristics (N = 105).

Characteristics	N (%)
<i>Gender</i>	
Male	33 (31.40)
Female	72 (68.60)
<i>Marital status</i>	
Single	24 (22.90)
Married	81 (77.10)
<i>Age</i>	
≤34 years	18 (17.10)
>34 years	87 (82.90)
<i>Time commitment</i>	
Full-time work	98 (93.30)
Part-time work	7 (6.70)
<i>Level of education</i>	
Baccalaureate degree (clinical instructor)	38 (36.20)
Master's degree or above (faculty members)	67 (63.80)
<i>Accreditation initiatives in organizations</i>	
Yes	99 (94.30)
No	6 (5.70)
<i>Quality initiatives in organizations</i>	
Yes	97 (92.40)
No	8 (7.60)
<i>Number of tenures at work</i>	
≤4 years	32 (30.50)
>4 years	73 (69.50)
<i>Team size at work</i>	
≤15 members	55 (52.40)
>15 members	50 (47.60)
<i>The sector of work</i>	
Governmental	80 (76.20)
Private	25 (23.80)

members' psychological safety items were holding mistakes against the faculty member (mean = 2.97 and mean SE = 0.10) and having difficulty asking others for help (mean = 2.97 and mean SE = 0.11) (Table 3).

3.3. Predictors of Perceived Team Members' Psychological Safety. Before addressing the third research inquiry, correlations were documented. The psychological safety of nursing faculty members demonstrated a significant, unfavorable, and moderate correlation with their marital status ($r = -0.204$ at an alpha of 0.05). In addition, it exhibited a significant, favorable, and moderate correlation with the size of the team ($r = 0.255$ at an alpha of 0.01).

The GLM indicated that the perceived authentic leadership of academic nursing team leaders did not influence the psychological safety of nursing faculty members. The size of the team was the only factor that predicted the psychological safety of nursing faculty members ($B = 2.044$ and p value = 0.040). The model was not significant ($F(df = 12) = 1.57$, p value = 0.112, and $R^2 = 0.171$, Table 4), and it explained only 6.30% of the variance in the mean score of nursing faculty members' psychological safety. This result suggests that other unmeasured factors likely have a more significant role in promoting nursing faculty members' psychological safety.

4. Discussion

This research examined the variables and predictors that influence how nursing team leaders are seen as authentic leaders by their faculty members and how this affects the psychological safety of the nursing faculty members. Surprisingly, the perceived authentic leadership of academic nursing team leaders did not have an impact on the psychological safety of nursing faculty members, which goes against what I had anticipated.

4.1. Perceived Team Leader's Authentic Leadership. Nursing faculty members perceived their academic nursing team leaders as highly authentic; this high rating of leaders is similar to that of Hassan and Din [1] and Lee et al. [11]. Authentic leadership should be consistently demonstrated, as it is associated with numerous beneficial outcomes for employees, such as increased job satisfaction and commitment [21]. These outcomes may also extend to nursing faculty members.

The most crucial quality displayed by academic nursing team leaders who are viewed as genuine is their willingness to listen to others' ideas before making decisions, similar to Alzghoul et al. [36]. This attentive listening cultivates a participatory approach to decision-making, empowering faculty members to contribute their innovative thoughts [1, 40], which in turn cultivates a feeling of psychological security [41]. This collaborative decision-making process also nurtures a constructive team dynamic grounded in mutual trust and psychological safety [40, 41].

The lowest mean of perceived academic nursing team leaders' authentic leadership was that the leader did not allow the group to pressure them. In the academic nursing landscape, team leaders often face the challenge of maintaining their authentic leadership. A key aspect is their ability to resist undue pressure from the group they lead. Navigating the hectic environment of academia, all academic leaders must shoulder significant responsibilities in managing their own stress and conflicts, as well as those experienced by their team members. Thus, it is crucial to prevent burnout among both leaders and faculty, a factor that research has shown can mediate the influence of authentic leadership on nurses' decisions to leave their roles [11, 19, 20]. Preventing burnout is particularly relevant for nursing academics.

Regrettably, our nursing team leaders in academia refrained from openly expressing their emotions to others. This type of behavior should be reduced and avoided in order to improve academic outcomes. However, it is natural for people to reveal only emotions that match their resolve, as supported by Purwanto et al. [42]. This is an essential component of one's psychological wellbeing [42].

4.2. Perceived Team Members' Psychological Safety. Nursing faculty members reported experiencing a concerning lack of psychological safety, consistent with findings from previous studies [43]. Psychological safety is a critical factor for both employee wellbeing and organizational

TABLE 2: Nursing faculty members' perceptions of their academic nursing team leaders' authentic leadership (N = 105).

Items	Mean	Mean (SE)	Median	IQR 25 th -75 th	Range	95% confidence interval	
						Lower	Upper
(1) My leaders can list three of their greatest weaknesses	3.65	0.11	4	3-5	4	3.42	3.89
(2) My leaders' actions reflect their core values	3.71	0.11	4	3-5	4	3.48	3.94
(3) My leaders seek others' opinions before making up their own minds	3.70	0.11	4	3-5	4	3.47	3.93

success [43], so this deficiency is problematic. Our academic leaders must, therefore, strive to cultivate an environment of trust and security where nursing faculty can thrive and achieve new heights. Building this foundation of trust relies on authentic engagement and decision-making within the academic nursing realm. Therefore, authentic leaders should resist external pressures and encourage open expression of thoughts and emotions. Ideally, academic leaders will be reliable and dedicated to the welfare of their staff [43], such as the nursing faculty members in our case. When faculty feel their unique capabilities are valued and utilized by their team, they experience a sense of psychological safety [3, 6], which allows them to fulfill their essential roles in teaching, research, and management and to contribute innovative and creative ideas, akin to Abu Rabia [35].

In contrast, nursing faculty members felt uneasy because their superiors in the academic nursing world would use their mistakes against them. They also faced difficulties in getting help from others. These results indicate a lack of trust and teamwork in the academic nursing field. When there is no trust, people hide their thoughts and avoid admitting their errors, fearing consequences [43]. However, when professors feel safe, they are more likely to address their wrongdoings openly. Trust is the essential basis for building a secure and encouraging environment.

4.3. Predictors of Perceived Team Members' Psychological Safety. Correlations indicated that the psychological well-being of nursing faculty members was significantly, negatively, and moderately linked to their marital status. This discovery is noteworthy and original. This result contradicts Xia et al. [44], who reported no differences in the self-psychological safety maintenance of nurses during the COVID-19 pandemic based on the marital status. Given that most of our participants were married women who work as nursing faculty members, we could cautiously infer that single female nursing academics may experience a higher level of psychological safety. This is because married women, particularly those in troubled marriages, are more prone to psychological issues that have a detrimental impact on their

sense of safety. It is worth noting that working women in Jordan face significant financial burdens due to shared household responsibilities.

In addition, female nurses bear the primary responsibility for managing their families, particularly when it comes to raising children. The cultural norms largely influence this situation in the Arab region, where men have limited involvement in household tasks. This result is consistent with Cañadas-De la Fuente et al. [45], who reported that married females with children are prone to more work burnout, which is expected to lower their psychological safety, which may apply to nursing faculty members.

The psychological safety of nursing faculty members correlated with the team size, supported by Albritton et al. [46]. They revealed a minimum team size of 9-10, close to the current team size, at which team psychological safety and learning behaviors become critical for team effectiveness. Effective team size promotes a sense of psychological safety at the team level. In turn, a team's belief in a safe and trusted environment is promoted, implying more brainstorming, critical thinking, effective problem solving and decision-making, better job performance, and creativity [36].

Per predictors, contradictory to my expectations, the GLM indicated that the perceived academic nursing team leaders' authentic leadership did not predict nursing faculty members' psychological safety (contradictory to Anugerah et al. [47] and Maximo et al. [48]). This result is consistent with the results of a study conducted in Jordan about academic nursing team leaders' authentic leadership and its relation with knowledge sharing among the team and nursing faculty members' creativity [3]. Authentic leadership did not predict knowledge sharing within the team or nursing faculty members' creativity [3]. Moreover, Chaudhary and Panda [49] reported that psychological safety failed to transfer the impact of authentic leadership on work engagement and creativity. Even though the prediction model was insignificant, which is believed to be related to confounding variables, the current researcher still strongly believes in the roles of authentic leaders in their team members' psychological safety. The insignificant model calls for studying noninvestigated variables that may have a role

in promoting faculty members' psychological safety, such as individual personality traits, job satisfaction, or external stressors. More specifically, personality traits are an individual's distinctive character or qualities over time. As the healthcare and educational environment is complex and customer centered, multiple competing stressors, such as workload, shortage of staff, and time pressures, result in many negative consequences, such as job satisfaction and turnover [50]. The authors reported that the personality of the staff, including faculty members, will likely play a significant role in team dynamics, especially particularly when they are under pressure. Staff responses to stressors and, in turn, their job satisfaction are influenced by their personalities [50], regardless of the type of stressors and their magnitudes.

The study findings suggest that nursing faculty members' perceptions of their team leaders' authentic leadership did not significantly influence their sense of psychological safety. This result aligns with Elrehail et al.'s [2] observation that authentic leadership had no impact on innovation within Jordanian universities, which may also apply to psychological safety, as it is closely linked to creativity and innovation. However, this finding differs from the conclusions of Alilyani et al. [13] in Saudi Arabia, who found that authentic leadership positively and directly influenced team effectiveness, nurses' work engagement, and psychological safety. Obviously, authentic leadership and psychological safety are presented in their unique organizational, cultural, and county contexts.

Accounting for the county context, for example, given the significant changes taking place in higher education institutions, particularly in terms of quality and accreditation efforts on national and international levels, academic nursing settings in Jordan are being influenced by various forms of leadership. These alternative leadership styles, such as entrepreneurial and nonauthoritative leadership, have an impact on nursing academics [51], along with energizing workplace friendship and authentic communication. In addition, leadership that prioritizes knowledge and fosters innovation in academic settings is crucial, as is supportive leadership [11, 19, 20, 52] that encourages creativity [11, 19, 20, 51, 53]. These different leadership approaches are necessary in the ever-changing and unpredictable academic work environment.

Considering the unique organizational context, the size of the team was the only factor that affected the psychological safety of nursing faculty members although the impact was not significant. It is worth noting that a larger team could potentially help our nursing faculty members overcome their perceived lack of psychological safety. In such a scenario, they would be more inclined to support each other, especially when facing criticism for their mistakes. Albritton et al. [46] revealed a minimum team size of 9-10, close to the current team size, at which psychological safety becomes critical for teamwork. This result adds to the nursing authentic leadership literature; that is, the common demographic variables linked to nursing authentic leadership are age and experience. For example, Puni and Hilton reported that junior nurses perceive their work supervisors as authentic leaders [54].

4.4. Limitations and Implications for Research. Additional research is necessary to explore various aspects of the topic at hand. For instance, it would be beneficial to conduct further studies on how marital status affects the psychological wellbeing of nursing faculty members. It has been observed that single female faculty members tend to feel more secure in this regard. However, it is important to note that the data collected for this study were limited in scope, and as it was obtained from only two governmental and two private nursing schools, using the convenience snowball sampling method might not be representative of all nursing faculty members in Jordan.

Furthermore, the snowball inclusion technique employed in the study also restricts information regarding the number of individuals approached to participate, as well as the number of organizational units or managers involved. Moreover, while using convenience and snowball samples is practical, they are prone to selection biases and potential systematic errors, limiting their representativeness and generalization [37].

The use of cross-sectional design is a major limitation in the current research as it is difficult to establish cause-and-effect relationships. It is only a snapshot; thus, it cannot be used to analyze behavior over a period or establish long-term trends [37], such as those related to authentic leadership and psychological safety.

It is also worth mentioning that the findings may have limited applicability to other countries, as the data were collected specifically in Jordan. As such, it would be valuable to conduct further research in different cultural settings, as academic environments in Jordan, particularly within nursing, tend to be highly collectivist and hierarchical, with a significant power distance culture, as seen in previous studies [7, 8, 14].

Future research could benefit from a more diverse random sample and deeper analysis of psychological safety underlying factors. Furthermore, the researchers should consider alternative research designs, such as qualitative methods and longitudinal design, to overcome the limitations of the current cross-sectional design. In addition, there is a need to investigate different types of nursing leadership in relation to the psychological safety of nursing faculty members. Understanding why the authentic leadership of academic nursing team leaders did not support psychological safety is crucial. The insignificant prediction model mandates studying other nonstudied variables that could influence faculty members' psychological safety, such as job satisfaction and tenure staff commitment, individual personality traits, or external stressors. Mediation studies can provide insights into how the authentic leadership of academic nursing team leaders impacts the psychological safety of nursing faculty members. Furthermore, validation studies can explore additional dimensions of authentic leadership that are associated with psychological safety beyond self-awareness, internalized morals, balanced processing, and relational transparency [53].

4.5. Implications for Education and Practice. In Jordan, the academic nursing settings have a culture of high-power distance, which is hierarchical and collectivist. [7, 8, 14]

Such professional hierarchy is a barrier to psychological safety; faculty members would have limited freedom to speak and be themselves, contrary to leaders in higher positions. This is consistent with our sample reporting of insecurity because their superiors in the academic nursing field would hold their errors against them. Our faculty members also faced challenges in seeking assistance from others. These behaviors demonstrate a deficiency in trust and collaboration fueled by the high-power distance environments, supported by Edmondson [6] and De Smet et al. [3].

Hierarchical and collectivist cultures contribute to negative outcomes, such as workplace bullying and incivility [8]. High power distance cultures have certain traits, such as limited access to information for those in authority, the use of power to establish social order, division of the work environment into classes with restrictions, and a focus on outcome rather than quality of treatment and relationships [8, 14]. To mitigate the impact of this culture in academic nursing settings, it is important to develop low power distance cultures, supporting our nursing faculty members reporting that they feel psychologically safe when their unique skills and talents are valued and utilized when working with team members, calling for authentic leadership behaviors.

Hierarchical and collectivist cultures should be transformed into low-power distance cultures. The latter can be achieved by promoting independence, minimizing inequality, considering the balance of power to prevent inequality, and viewing power as a means of accessibility that changes frequently [8, 14]. By creating low-power distance cultures, bullying and incivility can be reduced in academic work environments [8, 14]. In addition, academic nursing team leaders should learn authentic leadership, as it supports the psychological safety of their faculty members [7, 9, 10].

Starting by decreasing the hierarchical and collectivist cultures, it is essential to improve the psychological safety of our nursing faculty members; it is crucial to create positive working conditions in academic settings [35]. It is important to distinguish between healthy and dysfunctional work environments. By cultivating a healthy work environment, we can support the wellbeing and engagement of nursing faculty members, fostering a sense of trust and belonging [35].

The psychological safety among nursing faculty members can be enhanced through many leadership interventions [7, 10]. Called “practical enablers of psychological safety,” O’donovan and Mcauliffe [55] reported that assessing these enablers is the first step in developing and maintaining staff’s psychological safety. In healthcare, these enablers were grouped according to the following five themes: priority for patient safety, improvement or learning orientation, support, familiarity with colleagues, status, hierarchy and inclusiveness, and individual differences [55]. In academic settings, these enablers could be an improvement or learning orientation, support, familiarity with colleagues, status, hierarchy inclusiveness, and individual differences.

The current study reveals that these faculty members feel a sense of appreciation and recognition for their abilities and contributions, similar to other studies [3, 6]. Authentic academic nursing team leaders must foster and maintain such leadership behaviors, reflecting improvement, support, and inclusiveness of psychological safety enablers. Conversely, nursing faculty members express concerns about their errors being used against them and find it challenging to seek assistance from others, demonstrating status and hierarchy psychological safety enablers [3, 55]. Authentic academic nursing team leaders should promptly address these instances of low-rated psychological safety, as they hinder the establishment of a supportive and secure environment, demonstrating the support, familiarity with colleagues’ psychological safety enabler, and inclusiveness while addressing individual differences [6, 55].

5. Conclusion

The nursing faculty perceived their academic nursing team leaders to display strong authentic leadership, but they felt that their own psychological safety was lacking. Interestingly, the level of authentic leadership exhibited by the team leaders did not have any impact on the psychological safety of the faculty members. The only factor that predicted the psychological safety of the nursing faculty members was the size of the team they worked with. However, this model was ultimately deemed insignificant, stressing the need for further research related to some unstudied variables, such as individual personality traits, job satisfaction, or external stressors.

Authentic leadership initiatives are necessary to establish favorable working conditions for nursing faculty. It should be noted that the cultivation of psychological safety cannot be achieved in a short time.

Further investigation involving a diverse and extensive pool of participants should be conducted across various nations and cultures, utilizing different leadership styles and research methodologies, such as qualitative research, to enable a deeper understanding of the reasons why the perceived authentic leadership of academic nursing team leaders did not have a predictive effect on the psychological safety of nursing faculty members [56, 56].

Data Availability

The data used to support the findings of this study are available on request from the corresponding author. The data are not publicly available due to privacy or ethical restrictions.

Ethical Approval

The Institutional Review Board (IRB) of the Hashemite University, Jordan, approved the study; the reference numbers are 2/1/20/2021 (Oct. 18, 2020) and 11/8/2021/2022 (Jul. 25, 2022). In the invitation letter, participants were informed that they were providing their consent by submitting the survey. It was emphasized that participation in

the study was entirely voluntary, allowing participants to withdraw at any point. Only codes were used to identify participants to ensure anonymity, and their email addresses were not retained in the dataset. The data remained confidential as they were securely stored on the researcher's computer.

Consent

A written statement was clearly stated on the front page of the survey.

Conflicts of Interest

The author declares that there are no conflicts of interest.

Authors' Contributions

MTM did the whole work.

Acknowledgments

The researcher thanks the nursing faculty members for their input in the current study.

Background. During a public health crisis, such as the COVID-19 pandemic, nurse leaders coordinate timely high-quality care, maintain profit margins, and ensure regulatory compliance while supporting the health and wellbeing of the nursing workforce. In a rapidly changing environment where resources may be scarce, nurse leaders are vulnerable to moral injury; however, organizational effectiveness may help to buffer moral challenges in healthcare leadership, thereby fostering greater moral resilience and reducing turnover intention. **Aim.** To understand mechanisms by which perceived organizational effectiveness contributes to nurse leaders' moral wellness (i.e., moral injury and moral resilience) and thereby effects work outcomes (i.e., engagement, burnout, and turnover intention). **Methods.** A cross-sectional survey of nurse leaders ($N = 817$) from across the United States was conducted using a snowball methodology, independent t -tests, and structural equation modeling to examine theoretical relationships among moral injury, moral resilience, and organizational effectiveness. **Results.** Higher ratings on every facet of perceived organizational effectiveness were significantly related to greater moral resilience ($p < 0.001$ for all t -tests) and lower moral injury ($p < 0.001$ for all t -tests) among nurse leaders. Structural equation models indicated both moral resilience and moral injury were significant mediators of the relationship between organizational effectiveness and work outcomes. Moral resilience and moral injury significantly mediated the effect of organizational effectiveness on burnout. Moral resilience was also a significant mediator of the relationship between organizational effectiveness and moral injury. **Conclusion.** Dismantling organizational patterns and processes in healthcare organizations that contribute to moral injury and lower moral resilience may be important levers for increasing engagement, decreasing burnout, and reducing turnover of nurse leaders.

1. Introduction

In public health crises, nurse leaders and frontline nurses are faced with health-related situations, which may overwhelm their capacities to address them [1]. The COVID-19 pandemic is the most recent example in the history of a global public health crisis, which severely strained existing public health infrastructure, taxed hospital resources, and degraded

an already tenuous workforce [2–5]. During these situations, nurse leaders have a vital role in upholding organizations' missions and values, while concurrently leading staff through rapidly changing environments [6]. This requires not only deft skills in communication, leadership, compassion, and resolve but also an ability to prioritize wellbeing and resilience for themselves and their frontline staff. Nurse leaders must support the provision of high-quality care and

represent frontline staff at the organizational level, all while serving as ethical role models [7]. During the COVID-19 pandemic, the challenges nurses faced at the point of care were highlighted [8]. However, the toll the pandemic took on nurse leaders was largely underreported. Many nurse leaders' work occurs "behind the scenes," and as such, their voices and experiences are underreported in the literature with limited acknowledgment by their organizations ([9]—in press) and, therefore, are poorly understood.

1.1. Moral Injury. Nurse leaders must navigate a myriad of ethical and moral challenges and adversities that may cause moral suffering and contribute to burnout, which can lead to turnover intention and moral injury (MI) [10, 11]. These experiences may be particularly heightened amid a public health crisis [8, 9]. When moral suffering is conceived as a continuum, MI is viewed as the most corrosive type of moral suffering ([12], p. 52–76; 2023). MI occurs when persons perceive that they or others have violated their moral core producing symptoms, such as stress, burnout, and turnover intention [13]. Often, it includes betrayals or transgressions by self or others, particularly financial and administrative leaders [4], and can be associated with post-traumatic stress disorder, suicide ideation/attempts, and other mental health symptoms [2, 14]. Among nurses, studies have shown clinically significant MI symptoms (>36) among frontline nurses given their high-intensity work environment(s) and physical/emotional strain that comes with providing patient care [15, 16]; however, the degree of MI among nurse leaders in these situations is largely unexplored. Frontline nursing staff are not experiencing the burden of the pandemic alone [8]; the impact on nurse leaders is likely also significant. A 2022 survey by the American Organization for Nursing Leadership (AONL) found that emotional health of staff and retention are two of the three top challenges nurse leaders were facing in response to the pandemic. Of the AONL survey respondents, 38% of the nurse leaders are "maybe" or "definitely" leaving their roles, of which 43% identified the reason as burnout/exhaustion [17].

1.2. Moral Resilience. Moral resilience (MR) is "the capacity of an individual to restore their integrity in response to moral adversity" ([12], p. 68). Moral resilience encompasses personal integrity, relational integrity, buoyancy, self-regulation/awareness, moral efficacy, and self-stewardship [18]. Moral resilience has been posited as a protective resource that can reduce the detrimental effect of moral suffering [19]. A strengths-based approach, MR, has been shown to be inversely related to MI [16] and moral distress [5]. Higher levels of moral resilience are inversely correlated with stress, anxiety, and depression [5] and decreases in burnout and turnover intention [10]. Understanding the relationship of MR in response to potentially morally injurious events during a pandemic can illuminate opportunities for prevention and intervention.

1.3. Organizational Effectiveness. Nurse leaders are in a precarious position, balancing staff, and personal wellbeing while also meeting regulatory requirements and organizational expectations [20]. During a public health crisis like the COVID-19 pandemic, leaders depend upon the organization's structures, processes, and governance mechanisms to achieve desired outcomes. Organizational effectiveness (OE) is a complex measure of how well an organization maintains and delivers on its mission and services, supports personnel, and establishes a culture of employee commitment and satisfaction [21]. In contrast, less effective organizations are characterized by reduced professional autonomy and perceived value within the organization, and greater exposure to circumstances that violate and eventually erode integrity and moral capability [22]. During the pandemic, OE was constrained and contributed to symptoms of MI. A study of nurses, physicians, advanced practice providers, and others showed that facets of OE contributed to both MI and MR [16]. As organizational effectiveness was degraded, symptoms of MI increased, and MR decreased [16].

Foreshadowing the pandemic, the National Academy of Sciences, Engineering, and Medicine (NAEM) established goals for healthcare systems to assess the impact of system demands on employees and improve employee wellbeing [23]. A contributing factor to clinician wellbeing includes practicing in alignment with ones' professional values and working in an environment that enables ethical practice [24]. Cultivating an ethical climate that fosters wellbeing and MR is a challenge that requires a multipronged approach at both the individual and organizational levels [4, 25, 26]. Leading organizations, such as NAEM [23], the U.S. Surgeon General [27], the National Institute for Occupational Safety and Health [28], and the United Nations [3], have identified key priority areas, which include mental health support for healthcare providers and frameworks for systemic change, further echoing the call for action within healthcare institutions. The adoption of these recommendations in the United States and globally was in its infancy when the pandemic began in March 2020. Effective strategies for expanded occupational health and safety that support frontline staff and nurse leaders require further scientific inquiry [29]. Therefore, the purpose of this study was to examine the following four research questions among a sample of nurse leaders in the United States in the aftermath of the COVID-19 pandemic.

- (1) Are there differences in MR and MI based on whether nurse leaders rate different facets of OE as high or low during a public health crisis? Is nurse leaders' perceived OE associated with differences in MR and MI?
- (2) Does the effect of OE on work outcomes during a public health crisis (i.e., engagement, burnout, and turnover intention) operate through its negative effect on MI among nurse leaders?
- (3) Does the effect of OE during a public health crisis on work outcomes (i.e., engagement, burnout, and turnover intention) of nurse leaders operate through its positive effect on MR?

- (4) Does the effect of OE on MI operate through its positive effect on MR among nurse leaders during a public health crisis?

2. Methods

2.1. Study Design, Setting, and Participants. We conducted a cross-sectional survey via Qualtrics with a sample of nurse leaders from across the United States who were practicing during the COVID-19 pandemic (2020–2022). Using snowball sampling, we recruited nurse leaders in the United States, leveraging members of the American Organization of Nurse Leaders (AONL) to recruit its members, as well as the PI's professional networks (Figure 1). Participants were recruited via email and other communications sent by AONL and the research team, inviting them to complete the online survey. Participants were encouraged to share the survey with other nurse leaders within their networks. Data were collected from August through November of 2022. Inclusion criteria were as follows: (1) serving in a nurse leader role, as defined by the following categories: Chief Executive Officer, Chief Nursing Officer/Chief Nursing Executive, Chief Operating Officer, Vice President, Director, Manager, Specialist/Coordinator, Clinical Staff, Dean/Professor, Consultant, Vendor, or Other Nurse Leader; (2) practicing since at least 2019; (3) living in the United States; and (4) over the age of 18 years. Qualitative data obtained via open-ended questions from this survey were analyzed and published separately [9]. Elements of those data are described in the discussion to further contextualize and explain the quantitative findings. The Johns Hopkins Institutional Review Board deemed this study to be exempt; survey completion implied consent to participate.

2.2. Variables

2.2.1. Demographics and Work Characteristics. All demographic and work characteristic covariates were categorical; therefore, each was dummy coded for inclusion in preliminary regression analyses and final path analyses. Age included five categories; education had three categories; and religion had five categories. For all analyses, role was recoded into the following three categories: nurse manager (reference group), executive, and other nurse leader. Race included five categories; primary work population included three categories; and time in current role had six categories.

2.2.2. Organizational Effectiveness. OE was measured via 18 items adapted from a prior study involving HCWs during the pandemic [16]. The process for adapting the scale involved literature review, input from nurse leaders practicing during the pandemic, and responses from an AONL-sponsored focus group. The original items ($N=10$) were included in addition to eight new items that were specific to nurse leaders during the COVID-19 pandemic. Participants rated items from 1 (not at all effective) to 5 (extremely

effective). An exploratory factor analysis using principal axis factoring was conducted. A single factor was extracted, which explained 57.91% of the variability in the items. All communalities were greater than or equal to 0.50. All factor loadings were greater than or equal to 0.70. The exploratory factor analysis provided evidence for the construct validity of the scale. The total score was computed by taking the mean of all items, whereby higher scores indicate higher OE. The Cronbach's alpha reliability for this sample was 0.96.

2.2.3. Moral Injury. The Moral Injury Symptoms Scale-Healthcare Professionals (MISS-HP) comprises 10 items rated on a scale from 1 (strongly agree) to 10 (strongly disagree) to assess MI symptoms [15]. The total score is computed by summing the items, with scores ranging from 10 to 100; higher scores indicate higher MI. The Cronbach's alpha reliability for our study was 0.71.

2.2.4. Moral Resilience. The Rushton Moral Resilience Scale-16 (RMRS-16) is a 16-item scale rated on a 4-point Likert scale from 1 (disagree) to 4 (agree) to assess moral resilience [30]. The scale is divided into four subscales as follows: (1) response to moral adversity; (2) personal integrity; (3) relational integrity; and (4) moral efficacy—each of which includes four items. The total RMRS score was computed by averaging item responses, where a higher score indicates greater moral resilience with scores ranging from 1 to 4. Overall reliability for the total RMRS in our study was 0.85.

2.2.5. Work Engagement. We used a modified 8-item version of the Utrecht Work Engagement Scale-9 (UWES-9) [31]. Participants rated frequency on a scale from 1 (never) to 6 (always, everyday). Total score was computed by averaging the items, where higher scores indicate greater work engagement, and scores range from 1 to 6. Reliability for our study was 0.91.

2.2.6. Burnout. We used a 4-item scale validated by Profit and colleagues [32] to measure emotional exhaustion as a component of burnout. Items were rated on a scale from 1 (strongly disagree) to 5 (strongly agree). The total score was configured by averaging the four items, subtracting 1, and multiplying by 25 such that scores range from 0 to 100 where higher scores indicate higher burnout. Cronbach's alpha for our study was 0.90.

2.2.7. Turnover Intention. Turnover intention was measured using the 3-item "leave job" subscale developed by Dotson and colleagues [33]. Wording was changed from "nursing" to "nursing leadership" to make items more relevant to the population. Items were rated on a scale from 1 (strongly disagree) to 5 (strongly agree). The score was computed by averaging the three items; higher scores indicate higher turnover intention. Cronbach's alpha for our study was 0.93.

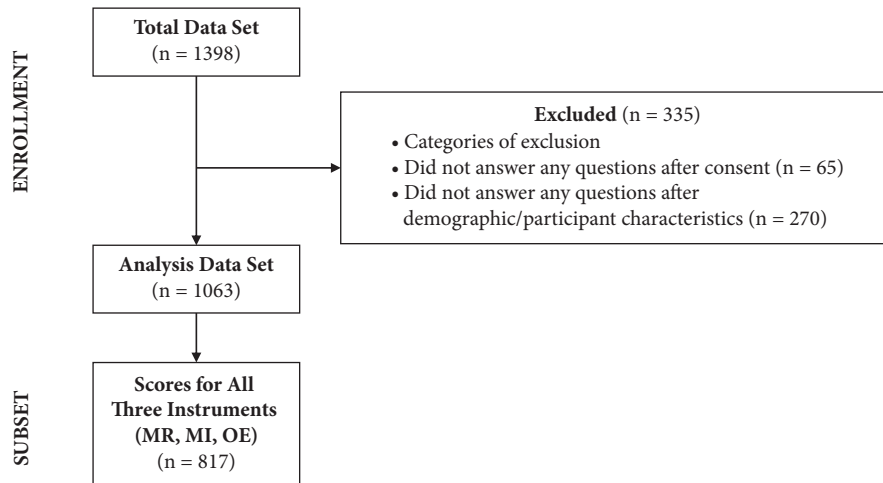

FIGURE 1: CONSORT diagram.

2.3. Statistical Methods. Data were analyzed using STATA Release 18 (StataCorps; College Station, TX). Frequency analyses were run to describe the overall sample. We began by recoding the OE facets so that low OE = not at all/slightly/moderately effective and high OE = very/extremely effective to assess relationships to moral resilience and MI. We then used independent *t*-tests with each of the 10 facets of OE as independent variables and moral resilience and MI as dependent variables. We reported the Cohen's D effect size for each *t*-test.

Structural equation models (SEMs) were generated to estimate complex models with multiple mediation effects, while controlling for other hypothesized relationships to circumvent any potential bias. We tested three mediation relationships: 1) organization effectiveness > moral resilience > work outcome; (2) OE > MI > work outcome; and (3) MR > MI > work outcome. We ran separate models for each work outcome (burnout, work engagement, and turnover intention) because the theoretical relationships between these variables were not the primary focus of this analysis. Goodness-of-fit indices used to evaluate the overall model were the chi-square test, RMSEA, p-close, CFI, and TFI. Guidelines for what represents a good fit included were as follows: (1) a chi-square value that is not statistically significant; (2) RMSEA values of ≤ 0.06 [34, 35]; (3) P-close values of greater than 0.05 since this is a test of whether RMSEA is significantly greater than 0.05; and (4) CFI and TFI values of ≥ 0.95 [34, 35].

We used the *medsem* command in Stata, a post-estimation command run after estimating each model, to generate estimates of each indirect (mediation) effect and associated standard error and used bootstrapping [36]. The *medsem* command also generates effect sizes for the indirect effect referred to as RIT and RID [37]. The RIT effect size is a ratio of the indirect effect to the total effect and is interpreted as the percentage of the effect of the independent variables on the dependent variable (direct effect) that goes through the mediator. RID is a ratio of the indirect effect and

the direct effect, and it is interpreted as the proportion larger the indirect or mediation effect is as opposed to the direct effect.

Before running the SEM models, we ran preliminary simple linear regression analyses to determine which demographic and work characteristics to use as covariates for each outcome (i.e., MR, MI, work engagement, burnout, and turnover intention) in the path analyses. Any of these variables that were significantly related to an outcome at this stage were included as a predictor of that variable in the path analysis.

3. Results

3.1. Participants. The study included a total sample of 1063 nurse leaders from across the United States, of which 817 individuals completed online surveys for MR, MI, and OE, and this was our final analysis sample for this study. Of the 817 individuals who completed all three surveys, 90.1% were females and 89.3% were White. Most leaders (84.8%) were between 36 and 65 years of age and had graduate degrees (86.6%). The race and ethnicity of this nursing leader sample was largely White (89.3%) and non-Hispanic (95.6%). Over half (58.9%) worked with adult patients, and 31.6% reported being in their current role for less than three years (Table 1). The three main roles held by the participants were as follows: Chief/VP (24.8%), Director (32.2%), and Manager (29.4%).

3.2. Relationship of OE with MR and MI. A series of independent *t*-tests with Cohen's D effect sizes were conducted to examine whether there were differences in MR and MI between nurse leaders who rate different facets of OE as high or low (Table 2). For every facet of OE, nurse leaders who rated their organization as high on that facet experienced higher moral resilience ($p < 0.001$ for all *t*-tests) and lower MI ($p < 0.001$ for all *t*-tests) than nurse leaders who rated their organization as low on that facet. All effect sizes were in

TABLE 1: Demographic characteristics of nurse leaders ($N = 817$).

Greater than 20 years	45	5.5

the medium to large range (absolute values = $|0.47|$ – $|0.91|$), indicating that all are likely important contributors to nurse leaders' wellbeing. One facet, an environment that promotes speaking up about concerns without fear of retaliation, stood out with relatively high effect sizes for both moral resilience (Cohen's $D = 0.68$) and MI (Cohen's $D = -0.91$). The facet, "protocols for filling staffing needs when current staff have fulfilled their assignments", was most strongly related to nurse leader's MR (Cohen's $D = 0.72$). Facets that were most strongly associated with MI (absolute values of Cohen's $D < |0.70|$) included the following: (a) forums with leaders to whom I report to share concerns (Cohen's $D = -0.76$); (b) pathways for requesting ethics consultation or advice (Cohen's $D = -0.77$); and (c) an environment that promotes speaking up about concerns without fear of retaliation (Cohen's $D = -0.91$).

3.3. Path Analysis of the Relationships of OE, MR, and MI with Work Outcomes

3.3.1. Identifying Covariates. Preliminary simple linear regression models were run to determine whether any of the demographic or work characteristics were associated with one of the outcomes of the path analysis models. Potential covariates examined included the following: age, gender, LGBTQ identity, education, religion, occupational role, race, ethnicity, work population, work setting, and length of time in current role. Outcomes for these simple linear regressions included the following: MR, MI, work engagement, burnout, and turnover intention. Covariates that were significantly related to MR included the following: age, education, role, race, work population, and tenure in role. Those covariates significantly related to MI were age, education, religion, and role. Covariates that were significantly related to work engagement included the following: age, education, role, and work population. The following covariates were significantly related to burnout: age, education, and role. The covariates that were significantly related to turnover intention were age

and role. We included covariates that were related to an outcome as covariates for that outcome in the path analyses (A, B, and C).

3.3.2. A: Path Analysis for Work Engagement. SEM was used to simultaneously test our three competing mediation hypotheses for work engagement (i.e., (1) OE- > MR- > work engagement; (2) OE- > MI- > work engagement; and (3) MR- > MI- > work engagement) (Figure 2). The covariates included for each outcome variable in the model are listed in Figure 2. All goodness-of-fit indices indicated a good fit for the overall model (Table 3). All main direct paths in the model were statistically significant (Table 4).

The following is a summary of the hypothesized mediation effects for the path analysis for work engagement.

We examined whether moral resilience mediated the relationship between OE and work engagement controlling for the other predictors in the model. The indirect or mediating effect was statistically significant, $\text{coeff} = 0.05$, $\text{se} = 0.01$, and $p < 0.001$. The RIT effect size indicates that 14% of the effect of OE on engagement is mediated by MR.

We examined whether MI mediated the relationship between OE and work engagement controlling for the other predictors in the model. The indirect or mediating effect was statistically significant, $\text{coeff} = 0.04$, $\text{se} = 0.01$, and $p < 0.001$. The RIT effect size indicates that about 12% of the effect of OE on engagement is mediated by MI.

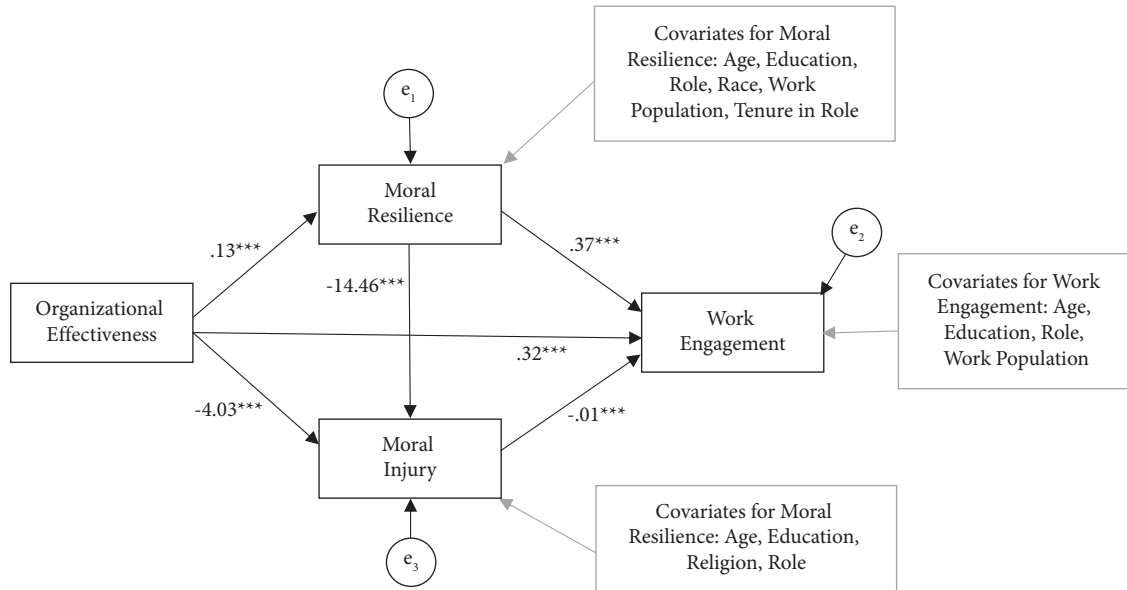

We examined whether MR mediated the relationship between MI and work engagement controlling for the other predictors in the model. The indirect or mediating effect was statistically significant, $\text{coeff} = -1.95$, $\text{se} = 0.23$, and $p < 0.001$. According to the RIT effect size, 33% of the effect of OE on MI is mediated by MR.

3.3.3. B: Path Analysis for Burnout. Next, SEM was used to simultaneously test our three competing mediation hypotheses for burnout: (1) OE- > MR- > burnout; (2) OE- > MI- > burnout; and (3) MR- > MI- > burnout. The

TABLE 2: Association of low vs. high OE with MR and MI.

Item	OE		Moral resilience			Moral injury		
	Low	High	N	M (SD)	p	N	M (SD)	p

OE -> MR -> MI	-7.18	1.32	<0.001	0.32	0.47

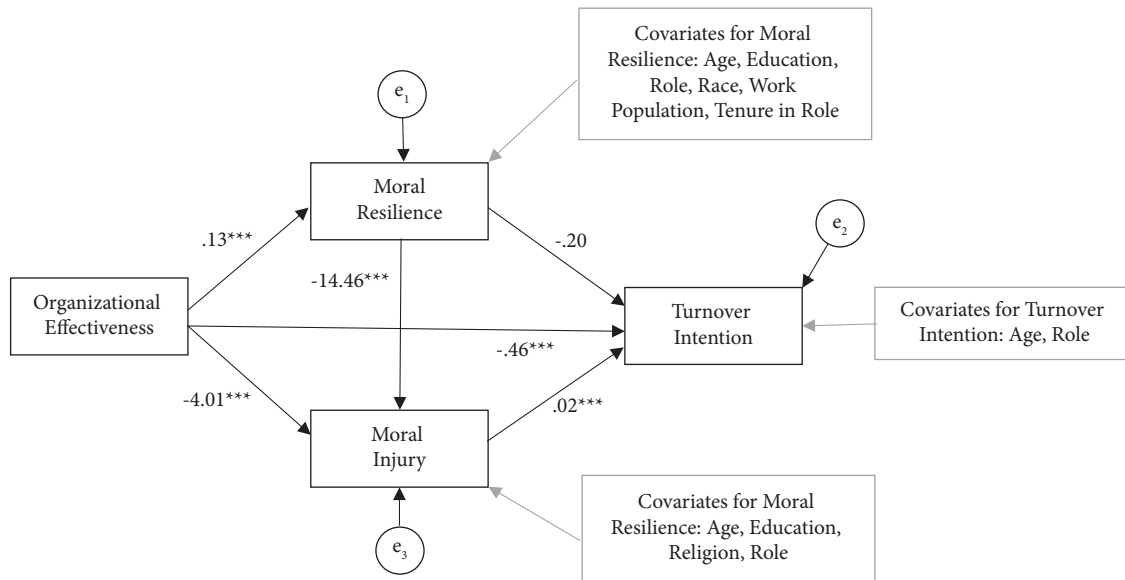

We examined whether MR mediated the relationship between OE and burnout controlling for the other predictors in the model. The indirect or mediating effect was statistically significant, $coeff = -2.05$, $se = 0.40$, and $p < 0.001$. The RIT effect size indicates that 20% of the effect of OE on engagement is mediated by moral resilience.

We examined whether MI mediated the relationship between OE and burnout controlling for the other predictors in the model. The indirect or mediating effect was statistically significant, $coeff = -2.04$, $se = 0.40$, and $p < 0.001$. The RIT effect size indicates that about 20% of the effect of OE on engagement is mediated by MI.

We examined whether MR mediated the relationship between MI and burnout controlling for the other predictors in the model. The indirect or mediating effect was

statistically significant, $coeff = -7.18$, $se = 1.32$, and $p < 0.001$. According to the RIT effect size, 32% of the effect of OE on MI is mediated by MR.

3.3.4. C: Path Analysis for Turnover Intention. Finally, SEM was used to simultaneously test our three competing mediation hypotheses for turnover intention: 1) OE->MR->turnover intention; 2) OE->MI->turnover intention; and 3) MR->MI->turnover intention. The covariates included for each outcome variable in the model are listed in Figure 4. All goodness-of-fit indices indicate a good fit for the overall model (Table 3). All main direct paths in the model, except for moral resilience to turnover intention, were statistically significant (Table 6). The following is a summary of the hypothesized mediation effects.

Indirect mediation effects:
 OE -> MR -> Turnover Intention, Coeff = -.03, p = .130
 OE -> MI -> Turnover Intention, Coeff = -.09, p < .001
 OE -> MR -> MI, Coeff = -.33, p < .001.

FIGURE 4: Path analysis of the relationship among OE, MR, MI, and turnover intention of nurse leaders (N= 799).

OE -> MR -> MI	-0.33	0.07	<0.001	0.17	0.20
				0.62	1.66

We examined whether MR mediated the relationship between OE and turnover intention controlling for the other predictors in the model. The indirect or mediating effect was not statistically significant, $coeff = -0.03$, $se = 0.02$, and $p = 0.130$.

We examined whether MI mediated the relationship between OE and turnover intention controlling for the other predictors in the model. The indirect or mediating effect was statistically significant, $coeff = -0.09$, $se = 0.02$, and $p < 0.001$. The RIT effect size indicates that about 20% of the effect of OE on engagement is mediated by MI.

We examined whether MR mediated the relationship between MI and turnover intention controlling for the other predictors in the model. The indirect or mediating effect was

statistically significant, $coeff = -0.33$, $se = 0.07$, and $p < 0.001$. According to the RIT effect size, 62% of the effect of OE on MI is mediated by MR.

4. Discussion

The goal of this study was to explore the relationship between OE and work outcomes, such as engagement, burnout, and turnover intention among U.S. nurse leaders, considering MI and MR in hypothesized pathways. We found that all facets of OE significantly contributed to MR and MI, as demonstrated by medium/large effect sizes, indicating a strong link between OE and nurse leaders' moral

wellness (MI and MR). These findings parallel those of a previous study with frontline nurses, which found 9 of the 10 facets of OE significantly contributed to both MI and MR [16]. Nurse leaders, particularly during a crisis, must prioritize staff wellbeing while also meeting regulatory mandates, financial objectives, and other organizational priorities to remain competitive in their professional environments. The inability to advocate for staff needs due to organizational change erodes leaders' integrity and their ability to navigate workplace challenges [38]. This is consistent with other studies that suggest that OE is predictive of MI symptoms and can be modified to reduce the detrimental impact [16, 19]. As noted in our previously published qualitative work, nurse leaders used open-ended survey questions as an opportunity to describe OE and its impact on ethical decision-making, which are referenced below to provide supporting context for key findings.

The facet of OE most strongly correlated with nurse leaders' MR was having protocols for addressing staffing needs when current staff have fulfilled their assignments. During the COVID-19 pandemic, shortages of nurses and other healthcare workers created difficult ethical challenges related to the allocation of scarce human resources. When filling staffing gaps, a common practice is to ask those already working to work overtime, which creates tension between leaders and staff who feel overworked. In the open-ended questions, leaders described this dilemma, *"middle-level management was drug through the mud during the pandemic. We received the pressures from both above and from our staff, and nothing was ever enough"* (Clinical Staff Leader). When healthcare organizations have clear protocols to avoid this conflict, MR is amplified; when protocols are absent, MR can be eroded, particularly when resources are constrained by a public health crisis. Another leader expanded on the lack of guidance and support in making ethical decisions, *"there is little support to make one feel confident in making decisions and the fear of getting in trouble is always looming over my head. Little guidance given, never any clear guidelines but always judged after the fact"* (Nurse Manager). These sentiments align with organizations like AONL, who are advocating for greater investment in nursing administration research to strengthen the provision of clear protocols and guidance for nurse leaders to utilize within their institutions [39]. Likewise, using an ethical framework for human resources allocation can make explicit the ethical tradeoffs that are necessary and illuminate the rationale for them [40].

Nurse leaders felt excluded from organizational decisions regarding staffing during the COVID-19 pandemic, which contributed to feelings of disempowerment and distress. Open-ended comments, such as *"directions come from above that are polar opposite of what I have voiced, and my teams are feeling. This adds to additional challenges and stress"* (Clinical Director), illustrated this concern. Executive leaders responsible for OE and outcomes may have adopted a "command and control" response rather than a collaborative, inclusive process for decision-making that equitably included nurse leaders. When nurse leaders are excluded from decision-making or their expertise and feedback are

seemingly disregarded, trust is inherently broken [4, 41]. From this research, we posit that when nurse leaders are involved with staffing and nursing care delivery decisions (especially during a pandemic), and when there are clear and transparent protocols for addressing surges in care, their moral efficacy, response to moral adversity, relational integrity, and self-stewardship are amplified. When nurse leaders are properly resourced and engaged in decision-making, their ethical commitments and wellness are maximized and trust is fostered. As a matter of justice and fairness, asking people who are already depleted to fill staffing gaps creates threats to relational integrity with their team and their ability to live their core values, such as respect for persons, fairness, and equity. Having protocols and processes that honor employee boundaries and commitments without coercion or retribution, especially during a public health crisis, can potentially relieve the moral suffering of both nurse leaders and frontline nurses [13].

Trust has consistently been identified as a key factor in mitigating the negative impact(s) of ineffective work environments on nurses. A qualitative analysis by Nelson et al. [4] yielded evidence, which supports the need for organizational infrastructure and supports from leaders to rebuild broken trust in the workplace. They offered the following five key remedies for rebuilding trust: (1) counseling/emotional support; (2) peer-to-peer support; (3) education and ethical support; (4) wellness offerings; and (5) spiritual/faith support. Given the nature of MI, rebuilding organizational trust may be an important element in restoring integrity and sustaining the nursing workforce, especially in the aftermath of a pandemic [42]. Models such as the Reina 3 Cs for trust building offer leaders a roadmap for identifying where trust is being built and broken and specific behaviors that are needed to sustain or rebuild it when it is broken [41].

The facets of OE that were most strongly associated with MI included the following: a) a lack of forums with other leaders to share concerns; b) an environment that prohibits voicing concerns for fear of retaliation; and c) the absence of pathways for requesting ethics consultation or advice. Taken together, these items suggest that nurse leaders' MI is decreased when there are strong and safe paths of communication within the leadership structure where they can share ethical concerns and obtain support for ethical decision-making from peers and experts. When nurse leaders lack psychologically safe space to share concerns, trust can erode, and MI symptoms may ensue. Although nurse leaders are outspoken advocates for patients and staff, their expertise is undervalued and nursing voices are often silenced, *"they (organizational leaders) don't want to hear criticism and you can't fix problems if all you hear is silence. Nurse leaders should not just hold a seat at the table, they should feel free to express ideas and concerns"* (Clinical Educator). In contrast, leaders who had a voice and contributed to decision-making felt supported and prepared for the ethical challenges brought by the pandemic. *"I truly believe that our organization has all of the disciplines at the table when making decisions and we were prepared to continue to lead through a crisis with strong integrity and professionalism"* (Clinical Director). These

findings suggest that innovative, trustworthy structures, and processes are required to create the conditions for nurse leaders to be heard, understood, and their expertise valued.

Lack of access to ethics consultation or advice has the potential to intensify MI symptoms, especially when nurse leaders are grappling with complex and uncertain ethical questions for which there are no easy answers [43]. During the COVID-19 pandemic, ethical issues were no longer episodic but rather imbedded in everyday reality. Lacking skills or processes to systematically address these issues via dialogue with others likely resulted in the accumulation of moral residue [44]. Over time, unresolved ethical issues can contribute to feelings of moral ineffectiveness, moral suffering including symptoms of MI, and compromised integrity. Whitehead et al. [45] found that moral distress was negatively correlated with ethical workplace climate among a sample of 592 clinicians. The highest sources of moral distress were watching patient care suffer due to lack of continuity and poor communication among care team members [45]. Strengthening access to ethics consultants, creating proactive mechanisms to identify ethical concerns, and fortifying ethics education for nurse leaders may help mitigate these types of negative consequences. Doing so may also strengthen the relational integrity of the entire team [24, 44].

Both MR and MI were mechanisms through which OE was associated with work engagement and burnout. Higher levels of OE were associated with greater MR and less MI, which was in turn related to better work engagement and less burnout. Previous research has demonstrated that OE is inversely related to MI [24]. The inverse relationship between MR and burnout has also been confirmed in other kinds of research [10]. In addition, an intervention to increase elements of MR was related to increases in work engagement [30]. This research builds upon the previous research outlined by examining a more integrated model of how these constructs are related to one another. This suggests there are several intervention points that are likely to amplify the impact on outcomes, such as work engagement and burnout.

When considering both MR and MI as mechanisms through which OE impacts turnover intention, MI was a more important mediator of OE on turnover intention. Previous research has found an inverse relationship between MR and turnover intention [10]; however, constructs were not previously examined in a larger statistical model with OE. One nurse manager described an organizational culture of blame and its impact on their mental and moral wellness and ultimately their decision to leave. *“The organization I left was unforgiving. The (leadership) was very into blame, ‘fix it’ and unsupportive. I was rung out. I had nothing left. It was horrible to leave the wonderful team I had worked so closely with through the pandemic, but I had to leave that hospital... or mentally implode”* (Nurse Manager). These types of cases may cause leaders to seek a position elsewhere, regardless of their MR, where they may be better supported to make decisions in alignment with their values. The exodus of nurse leaders postpandemic has led to a concerning trend that further threatens the sustainability of the U.S. nursing workforce [42].

In addition, when organizations were more effective, nurse leaders reported greater MR, and this mechanism was associated with lower MI. Thus, some of the effects of MR on work outcomes are indirect through its relationship with MI. Specifically, greater OE is associated with greater MR and lower MI, which is thereby related to higher work engagement, less burnout, and lower turnover intention. This is consistent with other findings that demonstrate the role of MR as a protective resource to decrease the detrimental impact of OE in key areas [10]. This does not imply amplifying workers’ tolerance for unethical situations but to restoring their moral efficacy to choose what is in alignment with their values and commitment to acting in integrity-preserving ways. As such, in cases where perceived OE is low, MR tends to be lower and may contribute to higher turnover intention. Our previous work also found that greater MR was associated with lower MI [24]; however, this study expands on those findings by how MR may mediate the relationship between OE and MI.

4.1. Limitations. This study did have limitations that should be considered when considering interpretation and generalization of the results. This was a convenience sample; thus, respondents may have been those who were particularly interested in OE and wellbeing during the pandemic. That said, recruiting via AONL, a national organization, and encouraging participants to share the initiation with others did result in representation from all 50 U.S. states. This, in addition to the large sample size, makes it likely that the sample is reasonably representative of nurse leaders in the United States. Whether these findings are relevant in other countries is beyond the scope of this study but warrants further investigation. The study was cross-sectional in nature; therefore, we could not establish the time-order relationships of mediational relationships. For that reason, we have done our best to ground the proposed paths in prior research and theory. In addition, all data were self-reported and, thus, relationships may be inflated due to common method variance.

5. Conclusion

Nurse leaders are experiencing MI symptoms related to OE. Healthcare organizations must focus on dismantling institutional structures and processes that negatively impact the moral wellbeing of leaders. MR and MI are both important pathways through which OE impacts workplace engagement and burnout. In other words, OE is related to increased MR and decreased MI, which may influence greater work engagement and less burnout among nurse leaders. However, to achieve these more favorable outcomes, nurse leaders’ moral suffering must be given sustained attention. Promoting a work environment that enables voicing concerns without fear of retaliation is a critical starting point for fostering respect and trust needed to ultimately retain nurse leaders in their positions. Future research should strive to understand the dynamic interplay of investments needed to create healthier work environments for both nurse leaders and frontline nurses collectively [46, 47].

Aim. This study aims to explore contributing factors, impacts, and strategies to address perioperative nursing shortages. **Background.** Health facilities worldwide are experiencing nursing shortages, especially in specialty fields such as perioperative nursing. **Evaluation.** This integrative review is reported according to the PRISMA guidelines. The title, abstract, and full article screening, as well as the quality appraisal process, were performed by two independent reviewers, with a third for disagreement. This review focused on empirical and theoretical research published from 2013 to 2023 using databases including CINAHL, Embase, Emtree (via OVID), Medline (via EBSCOhost), Scopus, Web of Science, ProQuest Dissertations and Theses Global, Overton, and GreyNet. **Key Issues.** This study thoroughly reviewed 84 articles. The perioperative domain confronts significant staffing challenges due to increased demand, lack of experienced nurses, insufficient new entrants, high turnover, and an aging workforce. Notably significant are the deficiencies in recruiting new nurses and the elevated turnover levels, potentially amendable issues. The shortages negatively impact the remaining nurses, patient care quality, and hospital revenue. Strategies to address perioperative nursing workforce challenges include promoting the specialty to undergraduate nursing students, bolstering recruitment efforts, and retaining experienced perioperative nurses. However, none of the studies examined in this review adopted a comprehensive approach. Furthermore, the effectiveness of these strategies relative to one another remains uncertain due to a lack of reliable measurements. **Conclusion.** Perioperative nursing faces considerable challenges, including an aging workforce, limited new recruits, and high turnover rates. Present strategies primarily prioritise workforce preparation over supporting current staff. Mitigating the perioperative nursing shortages requires comprehensive approaches integrating preparation, recruitment, retention, and retirement plans. In addition, these strategies must be adapted to the diverse regulatory environments of different countries, recognising the absence of a one-size-fits-all solution to perioperative nursing shortages globally. **Implication for Nursing Management.** Perioperative nursing managers are vital in reducing shortages.

1. Background

Nursing shortages are a severe global problem [1–4]. Worldwide, the World Health Organisation (WHO) report estimated a shortage of 5.7 million nurses by 2030 [5]. The shortage is most acute in the poorest nations, particularly in sub-Saharan Africa, where the shortage is exacerbated by substantial migration from poorer to wealthier countries, driven by salary gaps and recruitment initiatives in developed nations [6, 7]. High nurse turnover and problems

with retention compound nursing workforce shortages [2, 8–13]. In the United Kingdom (UK), the Nursing and Midwifery Council reported that 27% more nurses are leaving the profession than joining [2]. Worldwide, studies report turnover rates from 12% to 44.3% [10, 13, 14] and intention-to-leave rates from 42.9% to 94% [15–17]. An aging population also contributes to nursing shortages [1, 18–22]. Reportedly, 25%–55% of the nursing population in Australia and the United States (US) are 50 years and above [21, 23, 24]. Globally, the WHO has reported that, as

of 2020, 17% of the 27.9 million nursing workforce is 55 years or older, indicating that they are expected to retire by 2030 [5]. Associated with the aging process, the growing prevalence of chronic diseases necessitates more preventative and complex surgical interventions, increasing the demand for perioperative nurses [25, 26].

The perioperative nursing sector faces recruitment challenges due to its historical background, regulatory frameworks across various nations, and distinctive characteristics. Despite being the first recognised nursing specialty in the late nineteenth century [27, 28], it has been suggested that perioperative nurses often struggle to assert their role, facing perceptions of being mere assistants to surgeons [29, 30]. Moreover, in some countries such as Spain and Turkey, perioperative nursing still lacks official recognition [31, 32]. Regulations in certain countries also pose barriers to entering the perioperative nursing specialty. While specialty nurses can be employed at different levels in Sweden and Greece [31] and nurses with experience in the intervention fields can practice in those areas in Portugal and Finland [31, 33], specialised postgraduate training is required for perioperative nurses before employment in countries such as Norway, Belgium, Lithuania, Netherlands, Poland, Slovenia, Germany, Switzerland, Brazil, China, Japan, and Canada [27, 31, 34–40]. In countries such as Spain and Turkey, highly centralised policy restricts the free-flowing labour market [31, 41]. The demanding nature of perioperative nursing may further deter potential recruits. Perioperative nursing is unique due to its rapid pace, involvement in complex procedures, reliance on advanced technical equipment, and quick patient turnover [4, 29, 42, 43]. Amidst the commitment to patient safety in a fast-paced and intricate setting [44, 45], perioperative nurses often face numerous hazards, including noise [46], chemicals, radiation, waste anaesthetic gases, disinfectants, surgical smoke, sharp objects, and bloodborne pathogens [44, 47, 48]. Moreover, stressors such as night shift demands, unforeseeable events, excessive workloads, and insufficient resources can lead to burnout among perioperative nurses [49]. The need for specialised skills and extensive orientation periods add to the complexity and costliness of training in perioperative nursing. Perioperative nurses require specialised critical care skills [50–52]. In addition to fundamental theoretical knowledge, they must possess advanced technical and cognitive abilities, such as anticipating patient needs, adapting to evolving situations, and efficiently handling unexpected events [53]. Therefore, it usually takes six to twelve months of orientation for new nurses to attain proficiency in their perioperative nursing roles [54, 55]. The extensiveness and length of training time make perioperative nursing one of the costliest specialties to train [22, 56]. The expense of training a perioperative nurse is believed to exceed that of general nursing, which can cost up to \$88,000 per nurse [12, 57].

Within healthcare settings, nursing shortages can compromise the whole healthcare system. A shortage of nurses in a department leads to heightened workload and stress levels among the remaining nurses, leading to emotional exhaustion, burnout, and job dissatisfaction,

ultimately impacting the quality of nursing care [7, 58, 59]. In the general nursing area, reviews have suggested a significant correlation between inadequate staffing levels and adverse patient outcomes [60, 61]. In the perioperative setting, research by Lee et al. [4] highlights a close relationship between nursing shortages and reduced quality of patient care. For example, an observational study carried out in postanesthesia care units in Greece found that the incidence of hypoxaemia was significantly higher in understaffed units [62]. Nursing shortages can cause notable workforce instability, marked by higher turnover rates among nurses, leading to increased expenses associated with recruitment and training of replacements [7].

There has been abundant literature focusing on staffing shortages, primarily within the broader nursing field. A previous literature review by Ross [63] delved into factors contributing to nursing shortages and proposed solutions to mitigate them. Another systematic review pinpointed the following four primary contributors to nursing workforce shortages: policy and planning impediments, barriers to training and enrolment, causes of nursing staff turnover, and the stress and burnout experienced by nurses [58]. Regarding mitigating strategies to reduce nursing shortages, a systematic review by Park and Yu [64] evaluated the effectiveness of policies addressing nurse shortages. As examined in a systematic review by Mohamed and Al-Hmairat [7], nurse residency programs emerged as promising educational interventions for nurturing competent new nurses and enhancing retention rates. Regarding the perioperative setting, a literature review by Willemsen-McBride [52] revisited preceptorship and suggested ways to enhance existing orientation programs. However, as most reviews focus on the general nursing landscape, there is a notable gap in exploring the staffing issues in the perioperative setting. Given the complexities involved in maintaining adequate staffing levels in perioperative environments, an integrative review was conducted. This study aimed to systematically explore the negative impacts, causal factors, and potential solutions related to shortages in perioperative nursing personnel. The Human Resource for Health and Action Framework was employed to structure and synthesise the information gathered. This framework, endorsed by the WHO, provided a robust framework for organising insights on human factors in healthcare [65, 66].

1.1. Objective. This integrative review aimed to explore contributors to the international perioperative nursing shortage. Strategies and initiatives to address perioperative nursing shortages and the potential impacts of shortages in this setting were also investigated.

1.2. Review Question. The main review questions are as follows:

What are the contributing factors and impacts of the perioperative nursing shortage worldwide? What strategies are used to address the shortages in the perioperative nursing workforce?

Using the Population, Prognostic Factors, and Outcome framework [67], the elements of the questions are framed as follows.

1.2.1. Population. This study includes all perioperative nurses and undergraduate nursing students. Undergraduate nursing students were included to enhance understanding of how perioperative nurses are recruited into this specialty.

1.2.2. Prognostic factors. Factors contributing to the perioperative nursing workforce shortage.

1.3. Outcomes of Interest

- (1) Factors contributing to workforce levels: recruitment, retention, and turnover.
- (2) Impacts of workforce shortages: at the patient level—quality of patient care and patient safety; at the organisational level—hospital revenue; and at the staff level—work and life quality, work satisfaction, health issues, and burnout.
- (3) Strategies to address workforce shortages.

2. Methods

This review used an integrative approach to assimilate both empirical and theoretical research [68–70]. This review followed the five steps of an integrative review: problem identification, literature search, data evaluation, data analysis, and presentation [71]. The search was reported according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement [72].

2.1. Search Strategy. The search included the following databases: CINAHL, Embase, Emtree (via OVID), Medline (via EBSCOhost), Scopus, and Web of Science. Grey literature was sought via ProQuest Dissertations and Theses Global, Overton, and GreyNet. Key terms with MeSH headings included MH “perioperative nursing”, MH “operating room nursing”, MH “postanaesthesia nursing”, “surgical nurse”, “anaesthetic nurse”, (MH “recovery room”) AND (MH “nurses+”), “instrument nurse”, MH “personnel selection”, MH “personnel turnover”, “nurse recruitment”, “nurse retention”, “shortage of nurses”, “personnel staffing and scheduling+”, “nurse supply”, and “intention to leave”. Complete search strategies across all databases are provided in Supplementary File (available here) 1.

2.2. Inclusion and Exclusion Criteria. The search sought experimental and nonexperimental primary research studies of any design, policies, and reports published in English from January 2013 to June 2023. The inclusion criteria and excluding conditions for studies are outlined in Table 1.

2.3. Screening. The search process adhered to the flow diagram outlined in the PRISMA statement [72]. In the initial search phase, articles identified from targeted databases were

exported to EndNote. Following this, duplicate entries were removed from the imported search results. The data were then forwarded to Rayyan for comprehensive screening, covering titles, abstracts, and full articles. Two independent reviewers conducted title and abstract screening according to predefined inclusion and exclusion criteria. In instances of disagreement, a third reviewer was consulted to reach a consensus. Full-text screening followed a similar procedure, with two independent reviewers assessing the articles and a third resolving any discrepancies. In this round, the identified articles underwent screening of both abstracts and full articles by two reviewers, with a third reviewer consulted to ensure consensus was reached.

2.4. Data Extraction. A data extraction form was devised to gather key elements and details from the chosen articles, which was piloted before implementation. This form encompassed categories such as “Author/Date/Country”, “Sample/Population”, “Study Method/Theoretical Framework”, “Contributing Factors and Negative Impacts of Shortages”, and “Strategies to Mitigate Shortages”. The primary reviewer extracted relevant data from the articles based on the predefined categories and entered it into the corresponding columns. The extraction process differed based on study type: themes identified from qualitative studies and reports were extracted, whereas descriptive data information was extracted from quantitative studies. The second reviewer examined the extracted data to confirm consensus.

2.5. Quality Appraisal. The Quality Appraisal for Diverse Studies (QuADS) tool was used to appraise the included 58 primary research articles due to its applicability for multi or mixed-methods design [73, 74]. The QuADS tool contains a checklist of 13 items with answers rated from 0 (lowest quality) to 3 (highest quality). Although the tool does not allow ranking the quality of studies as low, moderate, or high, the percentage of the maximum achievable score may indicate the quality of the appraised studies [73]. Two reviewers conducted appraisals independently, and disagreements were resolved through discussion. One reviewer was an author of an included article [75] and was purposefully not assigned to appraise this study.

Two viewers independently used the Quality Improvement Minimum Quality Criteria Set (QI-MQCS) [76] to evaluate the quality of the 26 quality improvement articles, with a third reviewer to resolve disagreements. Questions answered “met” scored “1” [76]. The total score of each article was added up, and a percentage based on a total mark of 16 was calculated.

2.6. Data Synthesis. The synthesis of data was meticulously structured and organised in alignment with the Human Resource for Health and Action Framework, a comprehensive model designed to foster the sustainability of the workforce by devising strategies to address critical workforce challenges such as inequitable staff distribution, insufficient

TABLE 1: Eligibility criteria.

	Included	Excluded
PFO	(i) Instrument/circulating nurses (ii) Anaesthetic nurses/Nurse anaesthetists (iii) Postanaesthetic care unit nurses (iv) Perioperative nurses in management and education (v) Nurse surgical assistants (vi) Perioperative nurse practitioners (vii) Perioperative ancillary nurses (viii) Undergraduate nursing students involved in perioperative nursing programs	(i) Retired perioperative nurses (ii) Nurses working in other specialties
Prognostic factors	Factors contributing to shortages in perioperative nursing	(i) Pandemic issues (ii) Natural disasters (e.g., fire) (iii) War, unstable political national environment (iv) Non work-related personal issues
Outcomes	(i) Workforce levels: recruitment, retention, turnover (ii) Impacts of workforce shortages: patient level-quality of nursing care and patient safety, organisational level-hospital revenue, staff level-burnout, work and life quality, job satisfaction, health issues, etc. (iii) Strategies to address workforce shortages	(i) Critical condition of the patients (ii) Hospital revenue loss by other factors

skills and knowledge, elevated turnover rates, and diminished motivation [65, 66]. This framework serves as a guiding platform in navigating the complex terrain of workforce management within the perioperative nursing domain. The findings of the study were methodically condensed and categorised according to the three fundamental components of the framework: entry, current workforce, and exit, as illustrated in Figure 1. Each component represents a distinct phase in the lifecycle of the workforce, encompassing recruitment and onboarding processes, the ongoing management and development of the existing workforce, and the transition and departure of staff from the workforce [65, 66]. This systematic synthesis provides a structured approach to understanding the multifaceted challenges and opportunities within perioperative nursing workforce dynamics, thereby facilitating the development of effective interventions and strategies to address these complexities.

3. Results

This review encompassed 84 articles, as illustrated in Figure 2 of the PRISMA flowchart [72]. Most articles included in this review were conducted in the US (56/84, 67%). The remainder was conducted in Sweden (7/84, 8%), Australia (5/84, 6%), Canada (3/84, 4%), Iran (3/84, 4%), Turkey (2/84, 2%), and only one study (1% each) from the following: China, Finland, Ghana, Greece, Iceland, Norway, South Korea, and Spain. Most articles (58/84, 69%) comprise primary research using descriptive or observational designs, such as cross-sectional correlational surveys. The remaining 26 articles are quality improvement reports (26/84, 31%), primarily based in the US. The characteristics of the included 84 articles are included in the Study Characteristics Table (Supplementary File 2).

The critical appraisal results of the selected articles are presented in Supplementary File 3. The QuADS appraisal (part 1) reveals that 13 primary research articles (13/58, 22%) scored above 80% of the maximum score (39), 18 articles (18/58, 31%) scored between 60% and 79%, and the remaining 27 articles (27/58, 47%) scored below 60%. Appraisal of the 26 quality improvement reports using the QI-MQCS tool (part 2) resulted in 6 articles (6/26, 23%) scoring within 80–100% of the maximum score (16), 11 articles (11/26, 42%) scoring 60–79%, and 9 scoring below 60%. Although most of these reports scored higher than 60% (17/26, 65%), essential aspects of quality improvement reports such as study design, comparators, data source, adherence, and health outcomes are missed, which impacts the completeness of these reports [76, 77].

3.1. Shortage Levels. Limited information regarding the extent of shortages was observed in the selected articles. In the US, the Association of periOperative Registered Nurses (AORN) conducts annual surveys to examine compensation disparities, job satisfaction levels, potential turnover rates, and factors contributing to perioperative nurses' intentions to leave their positions [8, 78–85]. Notably, the ten AORN

survey reports are the sole studies among the selected articles that provided data on vacancies. Over the ten years from 2013 to 2023, the surveys reported that the vacant percentage of full-time perioperative nursing positions rose from 3.1% to 18%, and the percentage of managers who claimed a moderate to crisis level of nursing shortages ranged from 37% to 73% [8, 78–85]. Conversely, we found a lack of data concerning perioperative nursing shortages in other countries.

3.2. Impacts of Perioperative Nursing Shortages. This review identified nursing shortages in the perioperative setting as an impact on the quality of patient care, nurse satisfaction, and health service revenue. Quality of patient care is generally affected by negative impacts on the remaining nurses due to understaffing, such as fatigue and burnout, which can lead to reduced job involvement and increased errors that harm patients [86]. A Turkish correlational study found that work-related stress may negatively impact safety attitudes by 20.2% [50]. An observational study of 2207 participants in Greece reported that the incidence of adverse events among patients was significantly higher and of higher severity in highly understaffed versus sufficiently staffed departments [62]. Another US survey covering 1693 perioperative nurses discovered that inadequate staffing in the perioperative settings caused missed care due to miscommunication and lack of preparation [87]. Some studies considered the financial impact of perioperative nursing shortages. In some hospitals, perioperative departments generate substantial revenue [88]. Financial loss is associated with delaying or cancelled surgeries due to a lack of nursing staff, as reported by the AORN surveys [8, 83–85], and the high turnover cost of US\$65,000–\$120,000 for a perioperative nurse, according to a US quality improvement report [89].

3.3. Contributing Factors and Mitigating Strategies to Perioperative Nursing Shortages. In alignment with the Human Resources for Health and Action Framework [65, 66], a comprehensive examination was conducted to discern the factors contributing to and potential strategies to alleviate perioperative nursing shortages. This evaluation was structured around the framework's three pivotal phases: entry, current workforce, and exit. Each phase was meticulously scrutinised to identify primary themes indicative of the challenges and opportunities within perioperative nursing. The synthesis of these themes is presented in detail in Table 2, providing a comprehensive overview of the landscape surrounding perioperative nursing shortages and potential avenues for intervention.

3.3.1. Entry (Workforce Preparation). Workforce preparation encompasses strategic planning aligned with market needs, acquiring knowledge and skills through education and recruiting individuals into specialised roles within the field [65, 66]. This review revealed an imbalance between the demand for and the supply of

FIGURE 1: Human Resource for Health and Action Framework. Adapted from the human resource for health and action framework [65, 66].

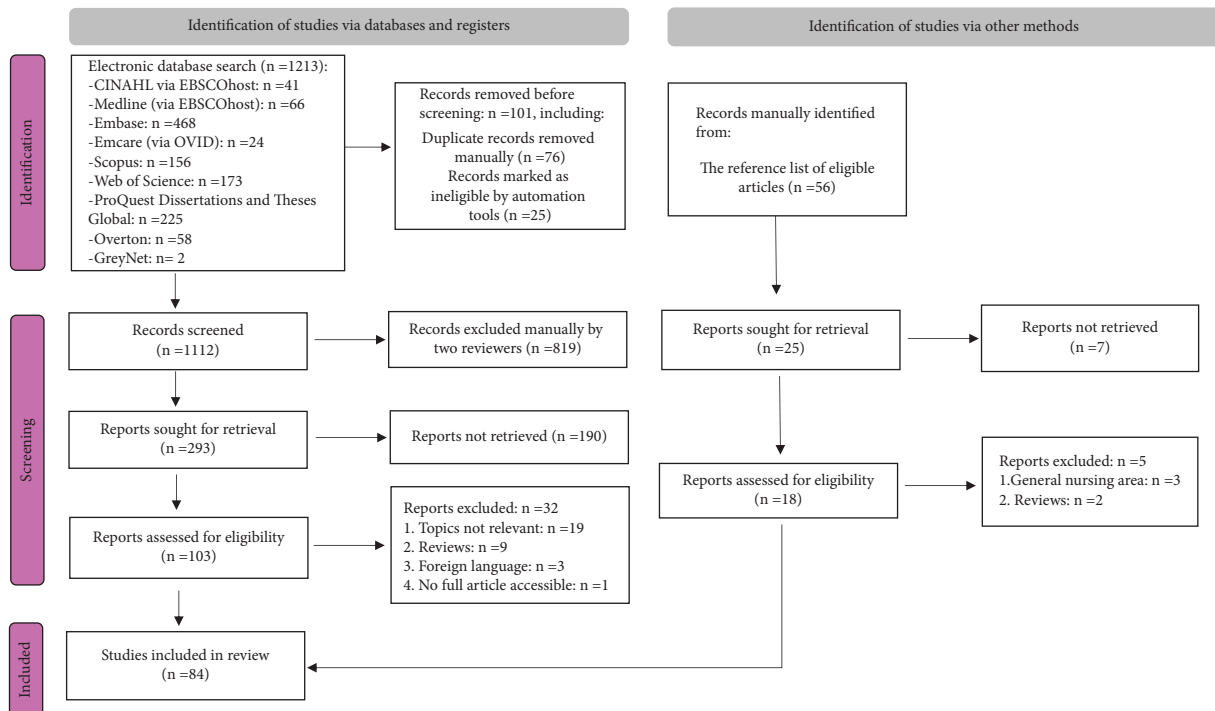

FIGURE 2: PRISMA flowchart [72].

perioperative nurses. The evidence indicates an increasing demand for perioperative nursing professionals. Almost 50% of the respondents to the AORN surveys in the US between 2013 and 2023 claimed increasing surgical activity in their facilities [8, 78–85]. Studies in the US [20, 85, 90, 91] and Spain [26] suggested that increasing demands for nurses are driven by an aging population requiring more frequent and intense surgical interventions. However, the availability of qualified perioperative nurses appears to be falling behind. The AORN surveys reported that only 3-4% of newly graduated nurses entered the perioperative setting annually [8, 78–85]. Likewise, additional studies included in the review found that the majority of nursing graduates opt for familiar nursing specialties, such as medical-surgical wards, instead of perioperative areas that were not generally offered during their undergraduate programs [12, 20, 22, 55, 56, 88–111].

The general practice of not recruiting newly graduated nurses into the perioperative specialty is another issue that further expands the gaps in meeting the demand. Particularly in the US, multiple quality improvement reports suggest a practice of not hiring new nursing graduates among perioperative nursing managers [43, 88, 92, 93, 105, 112–114]. Management’s concern about a general lack of experience or understanding of perioperative nursing among graduate nurses was reported [43]. Authors of a quality improvement report identified that allowing novice nurses to develop critical thinking skills in medical-surgical units also decreases the probability of nurses transferring to perioperative areas once they are fully adapted to medical-surgical specialty [88]. This review highlighted various initiatives to alleviate staffing shortages, primarily concentrating on preparing and recruiting perioperative personnel. In the US, recruiting experienced nurses from other specialties and providing them with perioperative orientation was a frequently used

TABLE 2: Summary of contributing factors and strategies to address the perioperative nursing shortages.

Entry (Workforce Preparation)	
Planning	(-) An aging population leads to increasing demand for perioperative nurses (-) General lack of experienced/qualified perioperative nurses
Education	(-) No perioperative nursing programs for undergraduate nursing students (-) Lack of placement spaces in hospitals (-) Lack of perioperative nursing faculty in universities (+) Universities increasing faculty and providing perioperative nursing electives/programs for undergraduate students (+) Perioperative nursing educational programs for novices with health service: academic partnerships
Recruitment	(-) Not recruiting newly graduated nurses (+) Active hiring of newly graduated nurses (+) Recruiting and training experienced nurses from other specialty
Current Workforce (Enhance Workforce Performance)	
Supervision	(+) Yearly surveys to monitor job satisfaction and intention to leave (e.g., AORN surveys)
Compensation	(-) Insufficient salary/rewards for the roles and training, and compensation/salary topped out for senior nurses (+) Appropriate salary matching job roles, recruitment incentives, and retention bonus
Lifelong learning	(-) Lack of continuous training and chances for professional development (+) Continuous training opportunities (+) Having access to career advancement opportunities (+) Empowerment, autonomy, delegation of leadership, and governance (+) Career planning and customised training (+) Competitive working environment
System support	(-) Working environment with hazards that could lead to physical or psychological damage to staff (-) Various issues with management that lead to job dissatisfaction among staff (-) Inconsistent guidelines and protocols (-) Inadequacy of precautions (-) Facility budget constraints (-) Staffing staff feel no connection to the facility (+) Organisation level: stability, secured job, and resolving organisational issues (+) Increasing planned funding and providing adequate resources (+) Managers sufficiently trained in their roles, providing strong support, reducing hazards, and promoting staff wellbeing in the department
Exit (Managing Attrition)	
Migration	No evidence was found in the selected articles
Career choice	(-) New job opportunities in other organisations that could expand the nurses' skills and knowledge (-) Leaving the healthcare profession
Health and safety	(-) Musculoskeletal disorders due to aging or physical demands of the job (-) Poor workplace-related mental wellbeing (+) Developing practices or positions that require less physical exertion (+) Wellness programs focusing on health promotion and lifestyle, as well as reducing hazards (+) Readily accessible newer technologies to reduce physical strain (+) fewer call hours, shorter shifts, and flexible scheduling (+) Establish organisational policies, professional standards, and guidelines to prevent psychosocial hazards
Retirement	(-) Mass retirement due to an aging workforce (+) Supportive leadership and health promotion programs to improve job satisfaction and preserve the ability to remain on the job

Note: “(-)” indicates contributing factors to perioperative nursing shortages; “(+)” indicates strategies to resolve nursing shortages.

strategy to fill vacancies in the perioperative section [8, 78–85, 93, 98, 101, 113, 115–117]. Furthermore, five reports highlighted that certain facilities enlist new nursing

graduates into the specialty through on-the-job training initiatives, such as perioperative nurse residency programs [43, 92, 93, 112, 113]. Also, a trend for universities to embed

perioperative nursing exposure programs for baccalaureate nursing students through health service-academic partnerships was evident [12, 20, 55, 56, 89–98, 100–112, 118]. One perioperative immersion program was designed for high school students [93].

Perioperative nursing programs successfully encouraged interest in entering the perioperative specialty and saved costs in orientation [22, 56, 88, 90, 91, 93–97, 100, 102–104]. It is reported that between 38%–100% of nursing students exposed to the perioperative setting entering the specialty after graduation [90, 94, 103, 105, 111, 113]. Specialty programs can help students make informed decisions about their career direction [106], with high retention rates (70%–100%) after two years recorded in four of the quality improvement reports [92, 93, 112, 119]. Studies from the US and Australia suggested that nursing students with perioperative exposure and guided learning can demonstrate practical skills in this specialty, with improved self-efficacy and confidence than those without [56, 88, 95, 96, 101]. The perioperative training and immersion programs also have benefits for hospital costs. Ten of the 26 quality improvement reports indicated that hospitals could save half of the costs in orienting a novice by employing newly graduated nurses with perioperative experience [56, 88, 93–96, 101, 103, 107].

3.3.2. Current Workforce (Workforce Performance). The articles examined in this study underscored that elevated nurse turnover significantly contributes to shortages within the perioperative nursing workforce. In the US, the AORN surveys reported that perioperative nursing turnover increased from 25% in 2016 to 59% in 2022; respondents who expressed intention to quit increased from 11% to 34% from 2013 to 2022 [8, 78–85]. Another study noted a consistent turnover of 12.8% to 13.6% between 2016 and 2017 [119]. In addition, a report indicated that approximately half of perioperative nurses exit the specialty within two to three years, often due to the extensive orientation requirements [88]. Intention to leave rates were reported as 20% in a Spanish study [26], 42.9% in an Iranian study [15], and deemed “high” in a South Korean study involving 193 perioperative nurses [120].

According to the Human Resource for Health and Action Framework, elevated turnover rates and leaving intentions are associated with supervision, compensation, system support, and learning opportunities within healthcare institutions [65, 66]. Constant supervision, such as implementing a routine monitoring process, can offer insights into the progress of key elements of human resource strategies [65, 120], but this beneficial practice has not been extensively adopted within healthcare systems. Besides the annual AORN survey [8, 78–85], other countries did not use similar benchmarking. Dissatisfaction with compensation is a contributing factor to perioperative nursing shortages. The ten AORN surveys identified that dissatisfaction with compensation increased from 17% to 52% from 2013 to 2022 [8, 78–85]. Salary was identified as a factor leading to the highest dissatisfaction among participants in two cross-sectional studies, one in Spain and one in the US [26, 121]. Dissatisfaction with compensation

was also evident in two other studies [122, 123]. Lack of professional development opportunities can also lead to staff leaving their current positions, as reported by a focused ethnography of perioperative nurses in the US [124]. In Iceland, a cross-sectional study revealed that nurses provided opportunities for further training and education in another department or organisation were more likely to consider leaving their current position [125]. The foremost issue causing staff dissatisfaction, intentions to leave, and turnover is the inadequate organisational or managerial support to mitigate the risks of physical and mental health damage to the perioperative nurses. According to 23 articles in this review, organisations failing to provide a safe working environment or culture for perioperative nursing staff is a common issue leading to nurse turnover worldwide [8, 49, 75, 78–85, 118, 120, 122–134]. Potential factors posing physical and mental health damage to perioperative nurses in the workplace include environmental hazards such as biological, chemical, and radiation exposures [134], continuous physical exertion [82], and intense work demands requiring constant mental focus [120]. In addition, the persistence of negative behaviours such as incivility and bullying remains a significant challenge in the perioperative settings [20, 75, 122]. These behaviours encompass various forms, such as verbal abuse [120] and depersonalisation [26], along with instances of exclusion and mistreatment by colleagues and management [122, 132]. Lack of support or recognition from management also contributes to staff attrition [8, 80, 82–85, 118, 122, 123, 125, 128, 133]. Failing to provide flexible working hours also contributes to staff turnover. An average of 17.3% of AORN survey respondents reported dissatisfaction with working hours [8, 80, 82–85]. While a cross-sectional study in the US claimed that flexible scheduling was available to only 39% of 2121 perianaesthesia nurses [133], participants in another US qualitative study described a lack of proper breaks during long working hours [123]. Other issues that lead to nurse turnover associated with the system include budget constraints [8, 80–85], short of resources [75], lack of consistent guidelines and protocols for clinical practices [131], nursing staff not feeling connected to the hospital [118], and nurses being socially detached [120, 135].

Multiple strategies were identified to reduce turnover among the current workforce. Three Swedish descriptive studies [122, 126, 136] and two US-based phenomenological studies [118, 128] suggested that well-functioning leadership is vital to the success of other workforce strategies. Two studies recommended the importance of a healthy and safe work environment to job satisfaction and wellbeing among perioperative nursing staff [26, 75]. The significance of teamwork in the perioperative working environment was supported by a qualitative study in Norway [137], a correlational study in the US [138], and a focused ethnography in Canada [124]. Furthermore, an Iranian correlational study of 350 perioperative nurses identified a close association between professional communication and professional commitment [139]. A Swedish qualitative study identified that nursing staff who are provided with sufficient opportunities for career

advancement have less intention to leave [136]. A high level of job satisfaction was reported in a cross-sectional study among perioperative nurses with higher certificate levels [121] and perioperative nurses who receive skill training [140]. In addition, the AORN surveys recommended the need for improvement in compensation [8,78–85]. Another correlational study stressed the importance of empowerment to staff retention [141]. Other suggested strategies to encourage retention include adequate staffing and resources [133], flexible hours, a supportive climate, and low-strain work to reduce health issues [135].

3.3.3. Exit (Attrition). Nurse attrition can be attributed to migration, retirement, health issues, or a change of career [65, 66]. This review found that mass retirement, health issues, and career changes lead to perioperative nursing attrition, but evidence of migration is not identified. Projected retirement among perioperative nurses is concerning. The retirement rate of perioperative nurses responding to the AORN surveys remained at an average rate of 34% between 2013 and 2023 [8, 80–85]. Another cross-sectional survey among 2121 perioperative nurses in the US found that a projected mass retirement (58%) was expected by 2020 [133]. A Spanish cross-sectional study identified that 20% of perioperative nurses will retire in 2024 [26, 118, 134, 142]. Health issues are also a critical factor for perioperative nurse attrition. Studies conducted in the US and Sweden identified that self-rated health and musculoskeletal disorders are associated with nurses leaving the profession [118, 126]. Change of career is another factor leading to nurse attrition. The ten AORN surveys identified perioperative nursing attrition due to new job opportunities or leaving the healthcare profession at a rate of 23.5% and 2%, respectively [8, 80–85]. A cross-sectional study in the US reported that nurses who can expand their skills and knowledge in other units or organisations are more likely to consider leaving their current position [125]. This review found limited evidence on strategies for managing attrition specifically. Participants in a phenomenological study targeting older nurses in the US reported fear of having to retire when their health deteriorates [118]. Strategies to help retention of older nurses include supportive leadership and health promotion programs to preserve their ability to remain on the job [118]. These strategies were also suggested in a Swedish qualitative study of 955 perioperative nurses [135].

3.3.4. Overall Impression of Recommended Strategies. The strategies outlined in the chosen articles primarily focus on single dimensions, with a few incorporating multiple dimensions. Nonetheless, none of the studies employ comprehensive mitigation strategies, and there is a lack of reliable measurement tools to determine which strategies are more effective than the others. Although some articles in the review suggest coordinated recruitment and retention strategies to address current perioperative nursing shortages [8, 78–85, 90, 91, 93, 98, 101, 113, 115–117, 143], these strategies were not evident in the selected articles.

4. Discussion

Perioperative nursing shortages have been, and will continue to be, a challenge for health services over many years. According to a cross-sectional study in the US, the perioperative workplace was the least favourable among eleven nursing work environments [144]. This finding may be attributed to the fact that perioperative nurses face a greater risk of physical and mental injuries compared to general ward nurses, given the nature of their work environment and job responsibilities [118, 134, 142]. Perioperative nurses are often exposed to multiple physical and psychological stressors [45, 145]. This environment is known for its high demands, stress, and pressure [50, 51], requiring intense focus, expert knowledge, and swift action related to surgical procedures and patient safety [120]. In this high-risk environment, perioperative professionals frequently encounter the dilemma of ensuring patient safety amidst the rapid pace and intricate nature of modern surgical procedures [29, 146]. Multidisciplinary bullying and lateral violence persist, contributing to moral distress and potential mental health issues among perioperative nurses [29, 122]. The ongoing prevalence of burnout and mental exhaustion among perioperative nurses can significantly diminish their resilience and elevate their intentions to leave their positions [45, 122].

The review findings point out key factors affecting the perioperative workforce, such as rising demand for nurses, limited recruitment into the specialty, high turnover, and retirements. Significantly, while the increasing demands on nurses and the aging workforce are unpreventable, limited recruitment and high turnover emerge as factors that can be modified. Staffing preparation appears to lag due to a lack of undergraduate programs offering perioperative nursing training. Since its inception, perioperative nursing training initially adhered to a doctor-centric, hospital-based approach [29, 52]. However, in the 1980s, many hospital-based diploma nursing programs were either closed or shifted to baccalaureate degree programs, resulting in the omission of perioperative nursing from the curriculum [20]. Many universities are also discouraged from building up the curriculum as perioperative specialty not being a prerequisite for registration, lack of faculty with perioperative experience [90], time constraints, and shortages of local placements [29, 92]. Academic-practice teams may face obstacles when starting an immersion program, such as getting support from administrators and preceptors, coordinating schedules, managing time constraints, and dealing with limited staff and resources [91]. Consequently, nursing students typically graduate with minimal or no exposure to perioperative nursing [29]. Lack of immersion in the perioperative nursing role, primarily involving observation without hands-on experience, was linked to a decrease in the number of graduate nurses seeking positions in the perioperative specialty [55]. The high nurse turnover and elevated intention-to-leave rate among the perioperative nursing workforce are significant concerns. Factors contributing to perioperative nursing workforce turnover, as identified in this review, appear to be environmental, cultural, and managerial, highlighting implications for the

wellbeing of perioperative nurses. It cannot be overstated that high-quality healthcare relies on healthcare practitioners' health, general wellbeing, and safety [147, 148]. Factors influencing the wellbeing of perioperative nurses include workplace culture, career development, work-life balance, and compensation [47, 142, 147]. However, a case study conducted in the UK declared that the wellbeing of the staff was either not a priority or not taken seriously by their employers [42]. The wellbeing crisis in health care has been identified as a key concern by many stakeholders [147–149]. The People Plan launched in both the US and the UK emphasised the importance of and proposed initiatives for looking after the health and wellbeing of healthcare employees [147, 150]. Psychological wellbeing is now a government priority in the workplace in Australia, with national standards and legislation established regarding workplace behaviours [151, 152]. A recent UK study with a three-round Delphi technique identified that actions to support the wellbeing of nurses should focus on the organisational level rather than public policy and research [147].

This review underscores the adverse effects of perioperative nursing shortages on existing staff, patient care quality, and organisational finances. These shortages contribute to staff fatigue and burnout, possibly lowering work engagement, escalating disruptive behaviours like incivility and bullying, and increasing the likelihood of errors jeopardising patient safety. In consequence, perioperative understaffing leads to further nursing turnover and subsequent financial loss in recruiting and training new staff [9]. Even the lowest rates (15–18%) of nursing workforce shortages disrupt hospital operations and increase hospital costs; a higher rate of nursing shortage may lead to substantial revenue loss and decreased quality of patient care for the healthcare system [10].

This review extensively explores strategies to alleviate the shortage of perioperative nurses. However, these strategies are mainly focused on the workforce preparation and recruitment phase. These strategies include offering perioperative nursing electives in undergraduate programs and orientation programs for newly graduated nurses or nurses from other specialties. While these training programs are beneficial for attracting and retaining new perioperative nurses, they may have drawbacks. The majority of articles advocating for educational programs are centred on the US, which limits the generalisability of this approach. In the US, nursing is the only healthcare profession with multiple entry-level educational pathways [153]. This concept may be applicable in countries such as the US, New Zealand, Australia, India, Sweden, and Greece, where specialty training can commence at various educational levels [29, 31, 93, 154–157]. However, it may not be the same in Portugal, where specialty skills can be acquired through localised training, and in countries such as Belgium, Poland, and the Netherlands, where postgraduate education is a prerequisite for entering the specialty [31]. In Spain, centralised workforce planning poses obstacles to specialisation programs for nurses, particularly as perioperative nursing remains unrecognised [31]. In Turkey, nursing holds a lower social status [158], and within perioperative nursing,

the roles are limited to instrument and circulating nurses. Certification in this specialty requires two years of experience although specialised master's and doctoral programs are also offered [32].

Enhancing perioperative nursing recruitment via educational programs requires various factors to be considered. The success of training programs reportedly depends on the inclusion of all stakeholders, such as executive leaders, nursing managers, educators, preceptors, and students themselves, as suggested by two US-based quality improvement reports [22, 88]. Using a standardised course can help reduce local orientation cost and time, such as Periop 101: A Core Curriculum [43, 55, 56, 89, 101, 107, 112–114, 119], suggesting the need for similar programs globally. Facilities should weigh the drawbacks of solely focusing on recruiting and training new perioperative nurses. Many universities and local facilities lack the capacity to accommodate a surge in trainees [25]. AORN surveys indicate that experienced perioperative nurses often quit due to the strain of continuously training newcomers [8, 78–85]. Also, younger registered nurses were found to change employers faster than older nurses [25]. Reportedly, the turnover rate of perioperative nurses is between 13% and 75% in their first three years working in this specialty [88, 123, 159].

The retention of currently employed perioperative nurses is crucial, given the established link between the staffing of competent nurses and the quality of patient care. The knowledge and skills of senior nursing staff are a valuable resource in the perioperative department [29, 160]. As in other specialties, experienced perioperative nurses build up their knowledge, critical thinking, and extensive skills from years of experience and professional growth [160, 161]. The benefits of retaining these experienced perioperative nurses include saving costs in training new recruits [160], maintaining the stability and intellectual property of this nursing population, achieving high-quality patient care and having experienced mentors to guide students and novices [21, 150]. Strategies to manage perioperative nursing attrition, especially for nurses nearing retirement age, are understudied as per the selected articles. It has been indicated that perceptions about older perioperative nurses among nursing managers are often negative, according to qualitative studies conducted in Europe [162] and Australia [163]. Making this group of perioperative nurses active even postretirement could potentially help reduce the shortage levels. A scoping review in 2018 found that nurses' intentions to work after retirement ranged from 18.3% in Singapore to 73.2% in Australia [164]. The personal preference for delaying the retirement age, together with the intention of the government to raise the retirement age, for example, from 65 years to 67 years by 2028 in the UK, can be a promising solution for narrowing the nursing shortage gaps [165]. It was suggested that the retention of retirement-aged nurses be integrated into the national nursing workforce planning and workplace wellbeing policies [166].

This review highlights the importance and necessity of regular and routine monitoring of staffing issues within healthcare systems [65, 66]. Besides the ten AORN survey

reports, which provided detailed insights into the contributing factors to shortages in the perioperative nursing workforce in the US, none of the other studies identified similar measures. Nonetheless, even with regular monitoring, the situation may vary in other countries. For instance, in Iceland, the turnover rate could be markedly different from that in the US, as nurses in certain specialties may not have the option to change workplaces without leaving their specialty or country despite having a high intention to leave [125]. In Spain, nurses are assigned according to healthcare authorities' planning and redistributive policies, which might drive nurses to explore job opportunities overseas, thereby exacerbating the nursing outflow [31, 168].

Programs such as the Magnet Recognition Program® can be used to help the retention of the current perioperative nurses. The Magnet Recognition Program®, established by the American Nurses Credentialing Centre in 1981, focuses on the establishment of professional organisational characteristics and achieving high job satisfaction for nurses [169]. Up to 2022, 591 hospitals in the US [170] and eight non-US hospitals hold Magnet® designation, three of which are in Australia [171]. Improved job satisfaction and reduced nursing turnover were reported by two Australian articles [172, 173]. Another cross-sectional study among Magnet®-employed nurses in Australia indicated a high level of job satisfaction and intention to stay in a better working environment than their international counterparts [171]. Internationally, multiple articles reported similar results [174–177]. A systematic review covering 17 papers supported the positive effect of Magnet® designation on the professional nurse practice environment, leading to reduced burnout, higher satisfaction, improved quality of care, and decreased intent to leave among Magnet® nurses [178]. This program, however, was not highlighted in the selected articles of the current review. It is suggested that health organisations consider this program or establish similar programs that fit local facilities.

5. Conclusion

This study examines the global shortage of perioperative nursing professionals, identifying key contributing factors such as high demand for surgical services, limited new entrants, and high turnover rates. While challenges like aging demographics are beyond control, interventions targeting workforce preparation and recruitment are proposed. However, limited evidence supports the retention of current perioperative nursing staff, with most focus on identifying contributing factors. Furthermore, the lack of comprehensive solutions and comparative assessments underscores the necessity for additional research. Extensive, practical, and adaptable approaches are crucial, particularly given the diverse regulatory landscapes across countries.

5.1. Implication for Nursing Management. The finding of this review highlighted the critical importance of perioperative nurses' wellbeing in relation to nursing retention. Increasing evidence suggests that effective leadership is critical to any

multidimensional workforce planning strategy [21, 150]. As nursing managers shape the culture of a unit, perioperative nursing managers play a critical role in resolving staffing issues associated with workplace culture [11]. Any change initiatives, such as culture change, begin with management as the critical change agent [11, 179, 180]. They influence the professionalism of staff as role models [181]. The role of perioperative nursing managers in monitoring nursing turnover trends and evaluating the implications of workforce change has been emphasised, as less frequent monitoring may miss warning signs of workforce issues [167]. With support and resources from the organisation, nursing managers play an essential role in establishing a civil and collaborative work atmosphere and providing opportunities for staff development [148]. Based on a good understanding of human development as per Maslow's theory [182], managers providing career planning guidance to nursing staff according to their characteristics and level of experience is highly valued [183]. As effective leadership is critical to the success of the department, perioperative nursing succession planning should include perioperative nurse managers [161]. In addition, perioperative managers also have their own challenges [1, 2, 184, 185]. Besides "on-the-job training" opportunities [181], they should have continual access to various forms of support, ongoing education and training throughout their tenure as leaders [185], career planning, and continuous professional development so that they can support the workforce and address challenges [184]. The US has required specialty certification for perioperative managers as a standard of care to lead the transformative changes [181]. It is recommended that similar programs be used in other countries to allow perioperative leaders to acquire the knowledge and skills in their roles.

5.2. Indication for Further Research. Research on retaining older perioperative nurses as they approach retirement age is lacking. There is a need to understand their career plans, desired retirement age, and other factors affecting retirement decisions. In addition, while this review included 84 studies, the evidence varied in quality and utilised limited study designs. Furthermore, there is a lack of research or quality improvement programs employing coordinated methods and reliable measurement tools to address perioperative nursing shortages.

Data Availability

Data sharing is not applicable to this article as no new data were created or analysed in this study.

Additional Points

This review's strength lies in its rigorous and reliable study process, encompassing diverse data sources and study types and two reviewers' involvement in article selection and quality appraisal. However, restricting the language to English may have resulted in excluding relevant studies in other languages. In addition, the majority of studies was conducted in the US, potentially limiting the generalisability of findings to other countries.

Ethical Approval

Ethical approval was not required because the review drew upon literature within the public domain.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Background. Improving the recruitment and retention of healthcare workers in the continuing care sector is critical to ensuring adequate care for older adults, which was highlighted following the COVID-19 pandemic. **Purpose.** The purpose of this study was to understand the perceptions of prospective registered nurses about working in the continuing care sector and identify workplace attributes that attract prospective nurses to the sector. **Methods.** A sequential mixed methods study was conducted with nursing students at Ontario Tech University. Focus groups ($n = 14$) asked students to comment on views about working in the continuing care sector, and job attributes that may attract them to the sector. Focus group data were analyzed using thematic analysis. Subsequently, a cross-sectional survey asked students to respond to elicited choice job scenarios that varied job attributes. The job attributes were shaped by the focus group interview data. To assess respondent's preferences, the survey data ($n = 139$) were analyzed to generate willingness-to-pay (WTP) values for each job attribute. **Results.** Focus group interviews suggested that fair compensation, optimal client-to-staff ratios, unionized work environments, comprehensive benefits packages, and flexible work arrangements were important job attributes. In survey results, 18.0% expressed interest in working in the continuing care sector compared to 75.5% in acute care. Regression analysis suggested that higher amounts of paid vacation (WTP: -5.983 ; 95% CI: -13.749 and -0.037) and higher risk of injury (WTP: 0.684 ; 95% CI: 0.124 and 1.208) were associated with work in the continuing care sector. **Impact.** Continuing care workplaces can attract nurses by offering flexible options such as part-time positions and paid vacation and by taking actions that can mitigate the risk of workplace injury, violence, and abuse. Nursing students should be shown the positive aspects of working with older adults and dispel negative perceptions about the continuing care sector. Further research is needed to understand the preferences for work and risk perceptions among currently employed nursing staff.

1. Introduction

Globally, the recruitment and retention of healthcare workers in the continuing care sector is an increasingly significant challenge [1, 2]. Continuing care in Canada describes a complex system which includes delivery of all services provided by long-term care, home care, and home support (e.g., nursing homes, long-term care, and supportive living facilities), and combines aspects of both health and social services [3]. Typically, this is an undervalued workforce within Canadian society [4]. During the best of times,

the continuing care sector has experienced difficulty recruiting and retaining healthcare workers [5–7]. It has been suggested that the sector suffers from a workforce crisis, where staffing levels are never high enough to meet demands [8]. Recruitment and retention challenges have been linked to workplace attributes, including staffing ratios as high as 1 worker to 40 clients, wages that are at market minimums, and precarious and part-time work [8–10].

Another important workplace attribute in the continuing care sector is workplace safety. A Canadian study found that more than 40% of institutional continuing care

workers experience physical violence on a daily basis [11]. Understaffing, inappropriate resident placement, frequent and infrequent work, night shift work, lack of communication, and lack of collegial support have all been cited as causes of workplace violence [8, 11]. The perception that there are workplace risks, whether they exist or not, leads to challenges in recruitment for the continuing care sector, and the experience of safety risks on the job makes retaining staff difficult.

Workplace safety came to the fore during the COVID-19 pandemic, with the Canadian continuing care sector being hit particularly hard by the disease, with devastating effects for residents, families, and the workforce. According to early 2021 data, continuing care facility residents accounted for more than 60% of COVID-19-related deaths in Ontario [12]. Other resources have estimated that between 62% and 82% of deaths due to COVID-19 have been among residents of continuing care facilities, and 5 of 7 Ontario healthcare workers who have died from COVID-19 were personal support workers in the sector [4]. Low staff levels, part-time workers operating in multiple sites, lack of testing, and lack of personal protective equipment have been blamed for preventable COVID-19-related deaths in the sector [4]. These unfavourable working conditions contribute to job dissatisfaction in the continuing care sector, exacerbating the recruitment and retention crisis.

Nurses are critical healthcare providers who can best meet the growing demands imposed on the healthcare system by an aging population [13]. Unfortunately, clinical placements in continuing care facilities have frequently been unsatisfactory and/or unsettling for undergraduate nursing students, discouraging them from working in the continuing care sector in the future [14]. Understanding the perspectives of working in the continuing care sector is essential to ensure that nurses in this field have the necessary support and resources to provide quality care to their patients. Nurses face many challenges on the job, such as complex patient needs, increases in absenteeism, worsened mental health, overtime hours, and a high level of emotional labour [15, 16]. These challenges highlight the need for healthcare organizations to implement policies and practices that support the well-being of healthcare workers. This, in turn, can improve the quality of care delivered to patients.

Improving retention and recruitment efforts is critical to attracting new nurses to the field in order to service the increasing population over the age of 65 in need of healthcare services [15]. It is estimated that Canada will need to increase its healthcare workforce (across different sectors) by 80% by 2040 [17] to keep up with the current demand. The national turnover rates currently range from 8.8% to 37.0%, with variations depending on the nursing specialty and geographical location [18]. A high turnover rate in the nursing workforce can lead to lower quality of care, increased costs, and decreased patient satisfaction [18]. Increasing wages is one solution to recruiting and retaining a nursing workforce, but there may be other workplace attributes that can be utilized to attract and retain workers. These attributes include benefit packages, vacation time, staff-to-client ratios, safety, and more [4, 8–11]. Currently,

there is limited research highlighting preferable work attributes within prospective nurses, especially in the Canadian continuing care sector, indicating a gap and need for research in this area.

The purpose of this study is to understand the perceptions that prospective registered nurses have about working in the continuing care sector and the workplace attributes that could attract prospective nurses to the sector. This study addresses the following research questions: (1) What are the major concerns of prospective nurses about working in the continuing care sector during and after the COVID-19 pandemic? and (2) What workplace attributes could attract prospective nurses to the continuing care sector?.

2. Materials and Methods

2.1. Design, Setting, and Participants. A sequential exploratory design was completed for this mixed-methods study [19]. The qualitative descriptive methodology was used first through focus group interviews, followed by quantitative survey methodology. The quantitative survey instrument was built based on the qualitative data that were previously collected during the focus group interviews. Participants were recruited using the convenience sampling method. Nursing students who were included in the study were enrolled at the University, where the research team was employed. The study interviewed nursing students to understand the perceptions they have about how to retain and recruit healthcare workers in the continuing care sector. Subsequently, an original survey instrument was used to elicit preferences for job attributes [20]. All persons who participated in the study were enrolled in the Bachelor of Science Nursing program at Ontario Tech University in Oshawa, Ontario. The four-year program is offered in collaboration with Durham College, and students have a practicum placement focused on the care of older adults in year 1 of their studies. The nursing program at Ontario Tech University is committed to offering students state-of-the-art learning environments, experience with leading-edge technology, and support praxis through clinical placements and simulation, positioning students for a successful career in healthcare and other sectors. The program had 840 enrolled students in the 2022/23 academic year.

This study was reviewed and approved by the Research Ethics Board at Ontario Tech University, Oshawa, ON, Canada (REB #16402).

2.2. Focus Groups: Data. A semistructured interview guide [21, 22] (see Supplementary Materials-Appendix A) was constructed by the research team for the focus groups. The focus group data collection was carried out between the University's fall semester of 2021 and the fall semester of 2022. Students were recruited via e-mail and asked to reach out to the research team to express interest in participating in the focus groups. One member of the research team (LG) hosted each focus group to maintain consistency. Interaction and discussion between participants were encouraged as much as possible. Focus groups were held

virtually via Google Meet. Prior to each focus group, the researcher explained the purpose of the study, that participation was voluntary, the student's right to withdraw at any moment, that all data collected would be kept confidential, and that all identifiers would be removed. Before the online focus group began, each participant provided informed verbal consent. A demographic datasheet was completed by each attendee once informed consent was collected. The focus groups were audio and video recorded and transcribed verbatim. Transcripts were cleaned and all identifiers were removed prior to being shared with the remainder of the research team. Two members of the research team (DR and JM) reviewed the deidentified transcripts for familiarity prior to analysis. Data saturation was reached after 6 focus groups. Each focus group involved 2–4 students. The final focus group sample consisted of 14 participants.

2.3. Focus Groups: Data Analysis. Braun and Clarke's thematic analysis [23] was used to derive overarching themes from the focus group transcripts, highlighting relevant workplace attributes to inform the development of an elicited choice survey, a form of stated preference survey [24]. The data were carefully examined to identify patterns and latent level themes, which refer to underlying ideas not immediately apparent in the data. This process resulted in the development of a coding system. To ensure intercoder reliability [25], two researchers independently generated an initial code list in Microsoft Word and discussed it, reaching over 80% agreement [26]. The initially drafted codes were further developed into themes and subthemes after a rereading of the transcript data and subsequent discussions between DR and JM. A draft coding system was then provided to three other researchers (LG, CO, and MR) who applied the coding system to the transcript data, and through iterative team discussions, reached consensus on the coding system. The coding system was developed deductively and inductively. Our interview guide included specific workplace attributes derived from our review of the literature (e.g., compensation, workplace safety, vacation time, and benefits), and these same categories were incorporated into our initial codebook. However, given the lack of research on workplace preferences in the continuing care sector, we allowed for additional themes to be grounded in the raw data extracted from the focus group transcripts. Data analysis was conducted in English, the same language in which the focus groups were conducted.

2.4. Survey: Data. An online cross-sectional survey (see Supplementary Materials-Appendix B) was used to collect self-report data from students in the nursing program at Ontario Tech University during the fall 2022 semester. The survey was inspired by the work of Wiswall and Zafar, who used a survey instrument to study preferences for workplace attributes in a sample of undergraduate students at New York University [20]. Our survey consisted of the following five sections: a demographic section followed by four sections of hypothetical job scenarios. The demographic section

collected data on year of study, age, gender, cumulative grade point average (GPA), plans postgraduation, whether they intend to work in the continuing care sector postgraduation, as well as postgraduation salary expectations. The remaining sections each contained eight job scenarios, with each scenario consisting of three job offers. The job offers differed by four attributes in each scenario. Participants were instructed that each attribute was identical across the job offers. We varied the job offers by the following attributes: hourly wage, percentage wage increases per year, vacation time, benefits, staff-to-patient ratio, patient acuity, hours worked per week, part-time option, unionized work environment, consistent shift hours, training and development opportunities, probability of being fired, and risk of workplace injury. Job attributes that were deemed most important to the participants in the focus group interviews were used in the construction of the job offers used in the survey. Other job attributes were inspired by those highlighted in the literature. Each of the offers was varied by four attributes at a time, and the values of the attributes (e.g., hourly wage) were designed to be as realistic as possible. We used new hire and union packages [27, 28] from local government-funded facilities and expert opinion from professionals in the continuing care sector in Ontario, Canada to develop realistic job attributes and variations in the attributes. Further details about how the job scenarios were constructed are provided in Supplementary Materials-Appendix C.

The survey allowed participants to provide elicited choice probabilities, which permitted respondents to show uncertainty about their preferences [24]. Participants were asked to rank each of the three hypothetical job offers in each scenario by assigning a percentage likelihood of choosing the scenario. Participants were informed that all values must sum to 100. Examples of these job scenarios are provided in Table 1. The survey data were extracted from the Ontario Tech University secured survey program (LimeSurvey).

2.5. Survey: Data Analysis. First, we estimated descriptive statistics for all variables in the demographic section of the survey. Following from Wiswall and Zafar [20], for our main analysis we estimated the log-odds of choosing each job as a function of the difference levels in job characteristics between job choices. To ensure the log-odds representation of our outcome variable, we made slight adjustments (adding or subtracting by 0.0001) to probabilities that were either 0 or 1. This was necessary because without these adjustments, the log transformation would not be valid. To account for the measurement error introduced when people round their choice probabilities to units of 5% or 10% during self-reporting of preference data, we utilized a least absolute deviations (LADs) estimator. Unlike the ordinary least squares estimator, which minimizes the squared differences between observed and predicted values, the LAD estimator minimizes the absolute differences. This approach increases the robustness of estimates by mitigating the impact of outliers and measurement errors [24].

TABLE 1: Example choice scenarios.

Section A	Hourly wage	Annual percentage increase in earnings	Average work hours per week for full-time	Work flexibility: is part-time available?
<i>Example</i>				
Job 1	\$35.36	2%	35	Yes
Job 2	\$35.94	2.5%	40	No
Job 3	\$34.00	3%	44	Yes
Section B	Hourly wage	Probability of you being fired or laid off from the job in the next year	Union vs. nonunion environment	Staff-to-patient ratios
<i>Example</i>				
Job 1	\$38.97	1%	Union	1 : 61
Job 2	\$38.33	3%	Nonunion	1 : 90
Job 3	\$38.48	7%	Union	1 : 56
Section C	Hourly wage	Amount of vacation of paid time off	Shift work/rotation/preferable hours	Opportunity for training and development
<i>Example</i>				
Job 1	\$36.54	4 weeks	Consistent shifts	\$2,208
Job 2	\$39.00	3 weeks	Rotation shifts	\$3,996
Job 3	\$40.93	2 weeks	Consistent shifts	\$3,956
Section D	Hourly wage	Available benefits and pension package	Risk of injury on the job	Patient acuity
<i>Example</i>				
Job 1	\$36.84	13%	6.2	Stable
Job 2	\$36.67	10%	13.7	Moderate
Job 3	\$40.63	9%	24.8	Complex

We estimated a separate model for each participant who responded fully to each of the job scenarios. During the survey, participants were presented with 32 different scenarios and were asked to assign probabilities to three job options in each scenario. Since job 1 was used as the base case in each model, each participant had $32 \times 2 = 96$ unique observations. Job 1 was used as the reference case in each model, so 64 observations per participant were used in the regression model. We obtained coefficient estimates by averaging coefficients for each job attribute across participants. To perform inference, we used block bootstrap resampling, repeating the estimation process 5,000 times by randomly drawing participants (with replacement) from the sample. We then calculated the 95% bootstrap confidence intervals using the 2.5th and 97.5th percentiles of the resampling distribution. We also presented these results as individual-level willingness-to-pay (willingness-to-accept) statistics. All regression analyses were performed using R version 4.1.2. LAD estimates were generated by using the LAD function from the L1pack package [29].

3. Results

3.1. Focus Groups: Participant Characteristics. The focus group participants consisted of 14 Ontario Tech University nursing students; 3 (21.4%) male and 11 (78.6%) female (Table 2). Most focus group participants were under the age of 30 and represented a variety of ethnicities. Four participants had previous experience working in a continuing care setting.

3.2. Focus Groups: Data-Derived Themes and Codes. The findings from the focus groups revealed three important themes: (1) workplace attributes that support recruitment, (2) workplace attributes that support retention, and (3) perceived risks and fears related to work in the continuing care sector (Table 3).

A recurring theme among the focus group responses was *the work attributes of the workplace perceived to support recruitment* and thereby were enticing to the prospective nurses. Participants discussed attributes including adequate compensation, a preference for a unionized environment, the importance of comprehensive benefit packages, appropriate client-to-staff ratios, and work schedule flexibility. Client-to-staff ratios were raised several times by the participants, across all three themes in different ways. Students were concerned about the high patient-to-registered nurse ratios and the fact that high ratios increase the physical and emotional demands of nursing, limit one's ability to form personal relationships with clients, and may place nursing staff in situations which pose ethical dilemmas.

The second occurring theme among the focus group responses was *the work attributes that support retention*. These attributes reflect elements that are aimed at keeping the individuals employed over longer periods of time. Elements included a comprehensive orientation period which included information on roles, responsibilities, and expectations. Participants also highlighted staffing complements

as a means of retention, with importance on the ratio and number of staff that form the care team, and the nature of the roles (personal support workers, registered practical nurses, and registered nurses). Additional elements cited were opportunities for continued growth and education along with skill development, the ability to form relationships with the clients, and working in an environment in which there were positive working relationships and support from both colleagues and management.

The final theme that emerged from the focus group responses was *the perceived risks and fears related to working in the continuing care sector*. Participant responses reflected both real and perceived risks and fears about working in the continuing care sector including the potential for abuse and violence towards the RN as well as towards the patients, and being engaged in situations that promoted or reinforced low standards of care which would lead to ethical and moral dilemmas. Furthermore, participants were concerned about the potential of knowledge and skill decay of acute care level skills if one was to spend a significant amount of time within the sector. The potential for burnout was a perceived risk, and participants spoke separately of the perceived fear of the physical and emotional toll of the work, including the potential for injury, and the nurse as martyr framework that pervades nursing as giving when you have nothing left to give, or giving and caring with little to no attention to one's own needs. The potential for understaffing and inadequate skills' mix of staff was a concern, along with a concern about the availability of the proper technology and equipment to properly function. Lastly, participants raised concerns about

TABLE 3: Focus group's data-derived themes, codes, and selective illustrative quotes.

Theme	Code	Illustrative quote
Workplace attributes that support recruitment	Adequate compensation	"Wage compensation is important for me"
	Unionized environment	"Unionized environment is very important"
	Benefits	"I would like to work full-time when I get a job because of benefits"
	Client-to-staff ratio	"We don't have enough time because there just two of us to take care of 15 people in the morning, we have to get six people up. You don't have enough time to do much"
Workplace attributes that support retention	Work flexibility (personal choice)	"You need to know what you're going to be working on and it needs to be predictable set of shifts"
	Orientation	"I'm told what my job expectations are and if I have someone to guide me as to how to do my duties and teach me, those are things I look for in an orientations that can prepare me for success in my job"
	Staffing complement	"I'll say the issues with staffing, for example, if they have adequate staff so that there's no burnout. I work in a long-term care, we get burnt out. We work so many hours because people don't show up for work. So I'd like a workplace that has adequate staff"
	Continued education, training, and skill development	"I'm looking for a place to build a career in. So for me I would like opportunities for advancement, you know if I wanted to take a specialty or move up then I want to be able to stay within the same organization"
	Personal relationships with clients	"So in my experience, it's just the relationships that you get to make with residents again because you're seeing the same people, you know, daily or weekly"
	Reliable and supportive coworkers/management	"So I agree with everybody that the main thing is respect for the employee, so respect for me as an individual, but also a group. If I feel like management cares about me, then I care about the job more"

Theme	Code	Illustrative quote	
Perceived risks and fears related to work in the continuing care sector	Abuse and violence	<p>“A risk of injury and verbally, emotionally, and trauma, I think that is very important to have security in place. You want more to minimize any kind of injury, like physically, verbally, and emotionally”</p>	
	Ethical and moral dilemmas	<p>“It doesn’t allow you to actually provide adequate care for a patient because, for one thing, in the back of your mind you’re concerned about getting all your meds done, but you’re not actually getting to analyze”</p>	
	Knowledge and skill decay	<p>“It’s really easy to forget, really simple things”</p>	
	Burnout	<p>“The workload in the nursing home is too much”</p>	
	Understaffing and poor skill mix	<p>“We don’t have enough time because they’re just two of us to take care of 15 people in the morning, we have to get six people up. You don’t have enough time to do much”</p>	
	Physically and emotionally demanding work	<p>“I would be most concerned about the risk of injury. I think I would try to have a job that is on the lower side of risk of injury”</p>	
	Working in public vs. private long-term care homes	<p>“Because sometimes you have to think a little selfish and think of things that benefit you and if you have a family, that can benefit your family, take vacations, have time for yourself to just relax, away from work”</p>	
	Availability of resources	<p>“But like as soon as it came down to making a profit, a lot of standards went out the window or they try to get away with like sweeping it out of the door, really quietly”</p>	
			<p>“My previous placements, when I asked where the suction is, and where the crash cart is they’re like “oh, we don’t have one””</p>
			<p>“...If you see someone who’s had a stroke and they clearly need way more care than they’re getting, it’s difficult to not be able to do anything”</p>

working in private or for-profit environments versus public care facilities, as many perceive public care facilities to be professionally enticing.

3.3. Survey: Participant Characteristics. Table 4 shows that 139 participants completed the demographics section of the survey. This represents approximately 20% of the four-year collaborative nursing program. The survey included 46 first-year students, 23 second-year students, 36 third-year students, and 34 students in their fourth or fifth year. Of the participants, 16 (11.5%) identified as male and 120 (86.3%) identified as female, gender nonconfirming, or other. Most participants were under 30 years old, which is typical for university-age students. Ontario Tech University uses a 4.3 GPA scale. The average cumulative GPA of the participants was 3.4 (SD = 0.451), equivalent to a B+. Out of the total participants, only 25 (18%) expressed interest in working in the continuing care sector after graduation. Most participants intended to seek full-time employment after graduation, with an average salary expectation of \$65,654.14 (SD = \$22,741.98).

3.4. Regression Analysis. Of the 139 participants in the survey, 67 fully responded to each of the job scenarios in the survey. We limited our regression analysis to the 88 participants who did not miss more than one job scenario in each of the four sections. In Appendix D, Table A1 in the Supplementary Materials, we compare the demographic characteristics of those included in the regression analysis with those who were excluded. Gender, choice of nursing sector, cumulative GPA, and salary expectations were similar across these groups. While none of the differences between the groups were statistically significant (p values >0.1), those who were included in the regression analysis tended to be older, in higher years of study, and more likely to report working full-time after graduation.

Table 5 shows our regression estimates. We interpret the sign of these estimates since the magnitudes are difficult to interpret. Thus, higher hourly wages, wage increases per year, part-time options, unionized environment, vacation time, consistent shifts, and training and development were positive predictors of the hypothetical job preference. Meanwhile, hours worked, probability of being laid off, staff-to-client ratio, risk of injury, and patient acuity were negative predictors of hypothetical job preference.

Table 6 shows the willingness-to-pay (WTP) estimates. These can be interpreted as the increase in hourly wages needed for prospective nurses to accept an undesirable workplace attribute, or wages nurses are willing to forgo for a desirable attribute. Only vacation and risk of injury had statistically significant WTP estimates. On average, respondents were willing to forgo \$5.98 in hourly wages for a one-week per year increase in paid vacation time. While this estimate suggests respondents highly valued paid vacation, our data were consistent with a wide range of WTP values (95% CI: -13.749 and -0.037). On average, respondents needed to receive an increase of \$0.68 in hourly wages to accept a 1% increase in the risk of injury (95% CI: 0.124 and 1.208).

4. Discussion

This study aimed to explore the views of aspiring registered nurses regarding employment in the continuing care sector. Focus group interviews conducted with nursing students revealed key job attributes for recruitment, including fair compensation, optimal client-to-staff ratios, unionized work environments, comprehensive benefit packages, and flexible work schedule arrangements. Client-to-staff ratios were brought up several times during the interviews, and students highlighted the effect these have on nurses' ability to provide safe and compassionate care. Participants were also concerned about the real and perceived risks of working in the continuing care sector, including the potential for abuse and violence toward healthcare workers and patients. There was also an expressed concern about the skill and knowledge decay, particularly while working long-term in the continuing care sector.

These perspectives on workplace attributes informed the development of a survey of nursing students at Ontario Tech University, particularly the hypothetical job scenarios. Although there was considerable variation in the individual preferences expressed in the survey data, two attributes more consistently stood out as important to prospective nurses: paid vacation and risk of injury. The preference for jobs with

TABLE 5: Survey regression analysis results.

longer periods of paid vacation aligns with the emphasis on workplace flexibility and work-life balance that arose during the focus group discussions. Similarly, the preference for jobs with lower risk of injury reflects the concerns expressed about safety in the continuing care sector.

Few previous studies have explored the preferences for workplace attributes in the continuing care sector or the views of prospective nurses. One study conducted in South Korea surveyed recently graduated nurses on the importance of different workplace attributes. They found that salary, working conditions, and organizational climate were the most important factors when choosing a workplace [30]. Studies conducted in other countries (such as Australia, South Korea, the United States, the United Kingdom, China, and France [13, 31–39]) have focused on the perspectives of nurses already working in their continuing care sectors and the factors that contributed to their decisions to leave the sector. These studies highlighted job security [31, 32], workplace safety [33, 34], favourable work hours [13, 31, 35–37], paid vacation [36, 37], recognition of work [38], and sick leave [32, 34, 39] as important workplace attributes. These studies show some overlap with the factors identified in our data, but other factors may have emerged given differences in context and differences in career stages. Further research in the Canadian context on the views of practicing and later career nurses is needed to understand

how preferences for workplace attributes may evolve later in their careers.

Our focus group and survey data also indicate a lack of enthusiasm for working in the continuing care sector. Specifically, we found that only 18% of survey respondents expressed interest in working in this sector after graduation. This is striking in contrast with the 76% who showed interest in working in acute care. Previous research has identified a similar apprehension. For example, the study conducted in Australia noted that only 8% of undergraduate nursing students chose to work with older adults, and this preference further declined throughout their studies [40]. Another survey of nursing students conducted in the United States found that while attitudes toward working with older adults improved over the duration of their studies, working with this population consistently ranked last for workplace preferences [41].

The results emphasize that ageist views and stigma towards the continuing care sector are prevalent within an undergraduate nursing population. Nursing education programs (both at the Bachelor level and Diploma level) need to work to actively to address these views to improve the recruitment of healthcare professionals into the continuing care sector. Several solutions to these problems have been suggested in the literature, including curricula reviews to ensure that there is a focus on the needs of older adults,

access to role models who can positively promote work in the sector [42], practicum experiences in the continuing care sector [41], and integrating gerontology focused simulations into nursing programs [43]. Focus on spreading out practicum experiences throughout the duration of a degree or diploma would be important as this could assist students in connecting continuing care with early-level learning and increase student's understanding of the complexity of continuing care. Concerns about skill decay in the continuing care sector may also be reinforced by the curricula that focus on the technical aspects of nursing, which may direct prospective nurses to the acute care sector [42]. Overall programs could focus on student attitudes toward older adults as well as highlighting the skills required of those nurses working in the sector, and the opportunities that are available (e.g., gerontology certificates and the use of technical skills specific to continuing care).

More research is needed on multilayered educational interventions to better understand how to support students who enter the continuing care sector after graduation. It is important to go beyond just studying student attitudes toward elderly populations, as it is unclear if attitude alone is the main factor influencing work location.

Workplaces within the continuing care sector also have a role in addressing the perception of working in the sector. The creation and promotion of work environments that allow staff to exercise their full scope of practice (for registered nurses and registered practical nurses) would allow for both caring relationships and the use of technical skills. Furthermore, workplaces that provide patient-to-nurse ratios that allow for the development of caring relationships may ease negative perceptions concerning workload. High registered nurse-to-patient ratios also limit the opportunity to work to one's full scope of practice and may limit the roles and responsibilities that registered nurses take on within the sector. Educational organizations can play their part by highlighting the potential for practicing to one's full scope of practice during practicum experiences.

Workplaces in the continuing care sector can attract prospective nurses by providing flexible work options, including part-time positions and paid vacation. In addition, it is important for these workplaces to take measures to reduce the actual or perceived risks of workplace injury, violence, and abuse. This is especially important after the COVID-19 pandemic, which may have exacerbated perceived risks. Some evidence suggests that risk-averse nurses tend to overestimate the risks associated with their job [44]. Further research is necessary to understand the risk perceptions of both prospective and currently employed nursing staff [45]. Currently, there is a lack of studies examining interventions aimed at addressing workplace risk perceptions.

4.1. Limitations and Strengths. In the study, there were several limitations that should be taken into consideration. First, the focus group sample size included 14 participants interviewed during six different focus group meetings. Despite the small focus group sample size, the aim of our qualitative descriptive study is to achieve transferability of

study findings with the goal of providing an initial understanding of the phenomena of interest and their implications. Second, our survey was not implemented with a randomized sample of nursing students. While randomization helps to minimize bias and increase the generalizability of the results, it was not feasible in our study environment. We have made efforts to highlight the characteristics of our sample to aid in assessing external validity. Third, 51 survey respondents who did not complete the job attributes section were excluded from the main quantitative results. These nonrespondents were mostly younger students in earlier years of study. The views of third-year and fourth-year students may be more relevant for understanding the perspectives of prospective nurses, as they are closer to entering the job market. However, our findings may be less applicable to students in the earlier stages of their studies. Fourth, it is important to acknowledge that the study focused exclusively on nursing students. While this allowed for a specific examination of this group, it also means that the findings may not be applicable to other healthcare professionals or currently employed nurses. More research is required to investigate the experiences and perspectives of these additional groups.

Our study had several notable strengths. First, we successfully integrated qualitative results into the design of the quantitative survey, creating an integrated mixed methods study. Second, we used hypothetical job scenarios to eliminate biases that arise when analyzing actual job choices made by workers. Realized job choices can be influenced by employer preferences and job availability, rather than true worker preferences [20]. Third, this study aimed to pilot an approach for understanding healthcare professional preferences regarding workplace attributes in Canada. It could serve as the initial step towards gaining a deeper understanding of how continuing care workplaces can attract healthcare professionals. Despite being an initial step, this study should still provide valuable insights to employers in the continuing care sector.

5. Conclusions

Cross-sector wage competitiveness remains crucial for the continuing care sector to attract and retain healthcare professionals. However, this study emphasizes additional workplace attributes that employers in the sector should consider when recruiting and retaining prospective nurses. Employers should prioritize creating a flexible work environment that allows healthcare professionals, including registered nurses, to work to their full scope of practice. In addition, workplaces need to address the real and perceived risks of injury, abuse, and violence that influence labour market decisions. Nursing curricula and postsecondary faculty engagement in nursing education play a key role in addressing negative perceptions about the sector, which may be unintentionally reinforced by the current curricula (for example, relegating continuing care sector placement to initial practicum experiences). Nursing faculty should consider opportunities that explore the complexity of work in the long-term care sector. These may include simulations

focused on providing care to dementia patients [46], structured field experiences across programs with long-term care homes [47], and case studies that raise the nuanced and professional-based issues that are reflected in this paper (e.g., advocating for care standards and negotiating opportunities to work to full scope). Nursing education research is required in this area to demonstrate the effectiveness of these types of initiatives on student attitudes toward the sector. These efforts may expose nursing students to the positive aspects of working within the continuing care sector and with older adults while simultaneously working to dispel negative perceptions about the continuing care sector.

Background. In addition to the usual difficulty of managing human capital in any organization, healthcare institutions have other problems to solve arising from the circumstances and the very nature of the work they perform, such as the ethical pressure on staff, emotional exhaustion, the distribution of work shifts, or the general shortage for nurses. In many cases, this situation has an impact on the quality of care. **Objective.** The main objective of this research is to compile, in a single document, human resource practices that help health centre managers improve results in terms of performance and quality of care, as well as avoid the intention of abandoning the job, specifically related to the work of nurses. **Methods.** To this end, a systematic literature review has been performed based on 229 papers published in the Web of Science database, from which the practical implications for nurses proposed by these authors have been extracted. **Results.** The main results suggest that developing affective commitment helps to improve organizational performance and enhance patient safety culture. Furthermore, improving communication and meaningfulness of work, recognition by superiors, or job flexibility would improve the quality of outcomes, for the work of nurses. **Conclusions and Implications for Nursing.** Stimulating normative commitment, reducing excessive control, and paying attention to job burnout and job stress help combat the intention of voluntary turnover or leaving the job, especially in the case of nurses.

1. Introduction

Healthcare faces a considerable challenge regarding the management of human resources [1, 2]. The World Health Organization (WHO) has already remarked, in the WHO's World Health Report [3], the worrying shortage of staff and management difficulties in healthcare. More recently, the Sustainable Development Goals Report of the 2030 Agenda [4] warns about the lack and unequal distribution of staff in health institutions.

Human resource management (HRM) in the healthcare sector has become an arduous task for the managers of these institutions, as in addition to the usual problems that can arise in any organization, there are others derived from the type of work that is carried out [5, 6], such as shift work, care pressure, emotional exhaustion, and work ethic. In any

organization, it is essential that employees are aligned with the organizational goals, and in healthcare institutions, this aspect is even more important, as it is the healthcare professionals who are in direct contact with patients, and their involvement, empathy, and motivation will largely determine the quality of the medical care [7–9].

The singular characteristics of this sector have generated a great deal of research related to healthcare organizations [10, 11]. Amongst the approaches mainly employed, two main categories can be distinguished. On the one hand, the research describes specific cases of HRM in healthcare organizations in a particular location and subject to particular circumstances: Asian nurses in US hospitals [12], nurses in US hospitals [13, 14], Dutch cases [15, 16], Canadian staff nurses [17], and China's circumstances [18]. On the other hand, there is an investigation that addresses the different

factors considered in the conceptual model underlying this research [19], such as human resource management [9, 20], job satisfaction [21, 22], organizational commitment [23–25], staff turnover [12, 26], risk of burnout [27, 28], or insufficient availability of qualified nursing staff [10, 13, 29, 30].

Published research has described and developed these issues, linking them to different organizational factors such as managers' leadership styles [31, 32] or psychological contract fulfilment [33, 34]. The latter's link to organizational and professional commitment has also been analysed [25, 35], and other concepts such as trust, performance, or productivity emerge from it. In fact, organizational commitment (OC) is positioned as one of the most important elements in the management of human resources in healthcare [23, 36].

As can be seen, there are many factors and interrelationships in the management of human resources in healthcare institutions that are also present in other organizations, perhaps taking on greater importance in these due to their nature and circumstances.

Therefore, there appears to be a high level of interest in the subject and a significant production of literature; however, as far as the authors are aware, the analysis of OC in HRM in the health sector has never been addressed from a practical perspective. In this sense, the aim of this research is to bring together in a single document the practical implications resulting from the different techniques and dynamics of HRM in healthcare institutions in which OC plays an essential role. This research will help all managers understand what factors moderate the OC of their employees (particularly nurses) and how they affect the performance and quality objectives in their organizations. It also presents causes and possible solutions to avoid the negative consequences of low OC in institutions. We also believe that this publication will provide the scientific community with interesting insights into OC in healthcare institutions and with reference to the practical implications to be adopted, which can be a starting point for future research.

2. The Review

Organizational commitment (OC) can be described in terms of the personal benefit of the functions performed, the autonomy to perform the job tasks, and the strategic management assumed by the employees [37]. In particular, according to Fadillaha et al. [38], OC describes employees' willingness to accept organizational goals and to cope with work. In this way, it encompasses a series of behaviours that lead them to make efforts for the good of the institution, to accept its values, and to long for permanence in the institution [39]. In this sense, Sena [40] goes a step further and incorporates aspects such as the desire to work well for the organization and have the pride of belonging to it.

Based on the above, and despite the existence of contrasting theories on OC [41–48], it can be observed that most authors agree with the three components proposed by Meyer and Allen [49, 50], i.e., continuance commitment, affective

commitment, and normative commitment. These postulates are positioned as the starting point of this research; it is considered that OC is a key element in the achievement of objectives by organizations. This approach motivated us to explore the practical implications of achieving OC in healthcare organizations. Continuance commitment is based on the embeddedness caused by small investments that have developed over time [51]. Affective commitment is linked to psychological rewards such as recognition or support shown by peers that lead to identification with the organization and acceptance of its values and goals [52]. Finally, normative commitment relates to the worker's own values and his or her responsibility for his or her workplace ethics [51]. In this sense, Top et al. [53] highlight the importance of affective and normative commitment in the development of organizational trust, also highlighting the need for further research in this area.

Ultimately, organizations must have committed members if they are to thrive or even survive [54], and to this end, HRM activities have the potential to influence an employee's level of OC and, consequently, their retention [55]. This is valid in all areas and fields of activity. In healthcare, continuance commitment is considered one of the critical aspects due to the high turnover of staff, finding several types of research that related HRM to OC [56, 57]. Thus, Mousa and Puhakka [58], in the Egyptian setting, delved into the relationship between responsible leadership and organizational inclusion, concluding that an environment of respect, equality, and fairness in the workplace contributes positively to the development of affective, normative, and continuance commitment of physicians. Conversely, Ramoo et al. [59], in the Malaysian setting, established that there is a direct relationship between age and continuance commitment of nurses, although it also depends on external factors such as labour market opportunities.

Affective commitment also has a clear particularity for healthcare as it is positively related to job satisfaction and trust in the organization [16]. In that sense, Shipton et al. [9], in the context of several Dutch hospitals, argued that by performing roles that evoke deeply held values, such as excellent patient care and concern for others, line managers can have a positive effect on staff attitudes.

Furthermore, normative commitment has also been extensively addressed in the healthcare literature, where it is related to various aspects such as demographics, gender, background, age, and type of institution. In this sense, Gambino [60] established that the strongest indicator of the intention to remain in the position of nurses is normative commitment, which is also reinforced in the function of the age of the workers; he therefore recommends promoting normative commitment in younger nurses.

Finally, also in relation to OC, Rodríguez-Fernández et al. [19] proposed a model that explained the effects of OC on healthcare institutions (Figure 1). They argued that, from a transformational leadership approach, OC becomes fundamental to achieve the high levels of performance and quality required in health-related workplaces. For this reason, they placed it in a central place amongst the aspects to be taken into account for the achievement of the

FIGURE 1: Model of organizational commitment. Source: Rodríguez-Fernández et al. [19].

objectives of these organizations. Another important aspect is job satisfaction, which is postulated as the main factor for improving OC, both normative and affective, and, in turn, avoids negative consequences such as the intention to leave the job. Similarly, certain moderating factors such as stress and burnout directly attack job satisfaction, negatively influencing it and thus OC, jeopardising the achievement of key objectives in healthcare institutions such as high performance and quality service to patients.

The model in Figure 1 provides an essential reference point to guide the process of this research. The systematic literature review undertaken represents a significant contribution to the study of OC in the context of healthcare organizations. This review brings together the range of practical implications detailed in previous research, comprehensively addressing all relevant factors that are usually dealt with individually. Other literature reviews on this topic have been developed previously. These include the longitudinal study by Freese et al. [33] on the impact of organizational changes on psychological contracts; the systematic review by Lu et al. [30] on job satisfaction of hospital nurses; the longitudinal study on OC and mental health [61]; or the systematic review on burnout syndrome in nurses [62]. No reviews have been previously found on the practical implications related to OC in healthcare institutions.

3. Methods

A systematic literature review of a sample of publications from the Web of Science (WoS) database has been carried out. To find a cause-effect relationship between OC and the objectives and consequences in healthcare organizations, the “model of organizational commitment” by Rodríguez-Fernández et al. [19] has been used.

3.1. Materials. The study has followed PRISMA 2020 guidelines for screening, selection, extraction, and data acquisition [63]. The search strategy is detailed in Figure 2, which explains the step-by-step process.

The documents analysed came from the Web of Science (WoS) database. The filters were established according to the criteria of the participants. The first restriction applied was the publication deadline, which was set to 31 December 2023. A preliminary scan was carried out to find the words that best represented the object of study. Publications containing these words in the title, abstract, author keywords, and keywords plus were filtered. For this, the following formula was used: (“organizational commitment” or “organizational commitment”) and (“health institutions” or “health system” or “healthcare” or “healthcare” or “health”). The search was restricted to the following indexes: Science Citation Index Expanded (SCI-EXPANDED), Social Science Citation Index (SSCI), Emerging Sources Citation Index (ESCI), Art and Humanities Citation Index (A&HCI), Conference Proceedings Citation Index-Social Science and Humanities (CPCI-SSH), Book Citation Index (BKCI), and Science Citation Index Expanded (CCR-EXPANDED). The year of publication was not limited, for the purpose of having the largest number of publications associated with this subject. To include the most recent publications that have not yet achieved the corresponding scientific impact, the number of citations received was unrestricted.

As a result of the search, a total of 559 manuscripts were obtained from WoS. After this first selection, the authors, individually, proceeded to discard those publications whose subject matter did not correspond to the purpose of the research or which, although of interest, did not provide practical implications related to OC in healthcare institutions. By using unique WoS, no duplicate papers were detected. A total of 275 documents were extracted from this

FIGURE 2: Sample analysis of practical implications for organizational commitment in health institutions and flowchart based on PRISMA 2020. Source: prepared by the authors. WoS (Web of Science).

first filter. Subsequently, the authors applied a second filter to extract those documents with practical implications, in line with the model used in this research—“model of organizational commitment” by Rodríguez-Fernández et al. [19], resulting in a sample of 229 documents (Figure 2). In the application of both filters, all authors agreed on the same number of excluded papers. Finally, the ATLAS.ti version 9 application was used for the literature review. This tool allows for the organization and categorization of large volumes of textual data, as well as, through the coding and development of the themes, the thematic analysis [64].

4. Results

The practical implications identified under each of model’s headings are detailed as follows.

4.1. Organizational Commitment. In terms of works related to organizational commitment, 78 papers have been found. Amongst practical implications that have a general impact on OC, the following stand out: (a) when nurses in managerial positions are seen by their teams as effective and trusted transformational leaders, there is an improvement in their commitment to the organization, as well as an increase in worker effectiveness and productivity [65]; (b) the design and implementation of strategies and practices in HRM foster OC, which in turn improves well-being, happiness at work, and performance within the organization [66]; (c) in addition to the intrinsic needs of workers, the quality of the physical infrastructure and work environment are key factors in increasing OC [67]; and (d) nursing managers should take measures to reduce workload and improve remuneration and job autonomy to enhance OC [68].

Publications with practical implications related to affective commitment have highlighted the following issues: (a) increased affective commitment implies growth in job performance [69], and for the case of nonprofit organizations, it is also considered a key factor [70]; (b) increased affective commitment increases patient safety culture [71]; (c) it has been detected in organizations that high levels of affective commitment hinder the occurrence of job burnout [72]; and (d) employee training and development has a moderating effect on the growth of affective commitment [15].

With respect to normative commitment, the results suggest that (a) with regard to turnover intention, in the case of nursing jobs, improving job quality helps to avoid resignations [73]; (b) with regard to improving levels of *normative commitment*, and generating greater commitment, it is necessary to foster loyalty and obligation in healthcare settings and nursing schools [60]; and (c) in relation to the performance of healthcare staff, Gorgulu and Akilli [74] suggest that there is a positive and significant relationship between levels of normative commitment and job satisfaction displayed by workers, indicating how efforts made to reduce job burnout and psychologically supportive dynamics will improve motivation to provide better care.

It is noteworthy that another type of commitment analysed in the theoretical model, continuance commitment, has not been reflected in specific practices in the context of healthcare and no evidence of proposals or practical experiences has been found.

4.2. Moderating Factors: Job Satisfaction, Stress, and Burnout. The sample of publications presenting practical implications related to moderating factors such as job satisfaction, stress, and burnout consists of 45 papers. There has been a great proliferation of research focused on nurses. Suggestions [75]

recommend that nurse executives support collegial solidarity in healthcare settings, in particular, by reducing stress, strengthening teamwork and communication, and thereby making the organizational climate more positive. In the study conducted by Tourigny et al. [76], moderating factors are highlighted for their practical importance for healthcare in general and for nurse management in the case of Japan and China in particular. Similarly, nurses' job satisfaction could be increased by promoting organizational and professional commitment and reducing occupational stress, role conflict, and role ambiguity [77]. In this sense, the authors in [78] adds, in the case of paediatric nurses, that, in addition to the above, it is necessary to provide support to alleviate turnover intention. Additionally, Perez [79] points out the significant cost of the loss of knowledge when employees decide to leave. In summary, burnout must be combated through interventions [80].

Furthermore, nurse managers should support burnout management with the provision of psychological employment [81] and practice responsible leadership by promoting a culture of inclusion [82]. Organizational culture should be geared towards prioritising workers' mental health, which requires improving communication skills and proactively engaging with teams to set and address wellness goals [61]. Burnout prevention plans, with a focus on social support, should be developed to improve nurses' quality of life and increase the care they provide [62]. Fragoso et al. [83] propose the reduction in work demands to prevent burnout, while Tripathy et al. [84] and Babatope et al. [85] suggest the enhancement of work-life balance practices, reduced burnout, and support from supervisors to increase job satisfaction. Management strategies that empower nurses for professional practice may be helpful in preventing workplace incivility and ultimately burnout [86]. Structural empowerment generates positive workplace outcomes; these outcomes relate to increased job satisfaction, increased OC, adoption of innovative behaviours, and reduced burnout and turnover [18, 87, 88]. Recently, Khatatbeh et al. [89] performed a systematic review and critical analysis of measures used to evaluate nurses' burnout and quality of life. Finally, applying resonant leadership in healthcare organizations can reduce employee burnout and prevent stress-related illnesses. It is also associated with a greater sense of belonging and OC [90].

4.3. Objectives: Performance and Quality. In the organizational commitment model that serves as the structure of this research, the organization's objectives focus on achieving high levels of performance and quality of care. A total of 35 papers have been analysed, which, in generic terms, try to apply HR practices that foster communication, work significance, and appreciation of superiors in order to increase OC and consequently the quality of services [91, 92].

In particular, it is recommended that managers and policy makers develop and implement supportive and nurturing strategies that improve organizational culture (emotional climate and collaborative relationships), which should lead in a reasonable time to more positive perceptions of the quality of healthcare [93, 94]. It is also suggested

by Khera et al. [95] that health centres should measure performance in terms of the implementation of programmes that detect financial difficulties.

An imperative objective, according to Attia et al. [96], is to create a positive environment in intensive care units (ICUs) to increase staff satisfaction and efficiency by promoting quality of care, with special attention to junior staff.

Nurses also have a very important role in the analysed documents as a majority of authors consider them a stakeholder group on which management improvement should be focused. In particular, the proper establishment of work shifts is considered a measure of OC that would result in better performance of the nurses [97].

Nevertheless, managers should conduct professional training courses for nurses to improve the quality-of-service delivery [98]. In particular, the main implications for nursing education and practice are that educators and clinical mentors should work collaboratively to bridge the gap between theory and practice, thereby improving the quality of the clinical experience of these students, as proposed for China and elsewhere [99].

Along the same line, Hsu and Kernohan [100] recommend further research with different groups of nurses in a wider variety of work settings to examine the strengths and weaknesses of nurses and to develop appropriate strategies for the quality of their working lives. Research could seek to obtain objective measures of nurse performance rather than self-report measures [101].

4.4. Implications for Nursing and Health Policy. The consequences of the proposed model, considering its practical implications, are mainly based on improved performance, job satisfaction, and reduced turnover [102]. Some authors refer to structural empowerment leading to positive workplace outcomes such as increased satisfaction, greater commitment, adoption of innovative behaviours, and reduced burnout and turnover [87].

Organizations that need to adapt to changing environments should implement a strong employability culture, because such stimulates employability orientations amongst employees and, at the same time, decreases turnover intentions [103]. Monitoring and adopting measures that eradicate the experience of threats or violence by workers, as well as exposing physicians to less control over the pace of work, can prevent turnover intentions [104]. Workplace discrimination is associated with physicians' job turnover, career dissatisfaction, and contemplation of career change [105].

As regards nurses, it is important to pay attention to nurses' job burnout and job stress to improve job satisfaction and OC and to provide support to alleviate turnover intention [78]. Awareness of flexible work systems, OC, and quality of life needs to be reflected in interventions to reduce the turnover intention of health nurses [106]. It has been shown that healthcare organizations with greater investments in their nursing human capital are more likely to demonstrate lower levels of turnover of their registered nurses [107]. This has been corroborated by a recent mapping study on nurses' changing work practices performed by Salma and Waelli [108].

As for nurse leadership, authors such as Dahinten et al. [17], Alkarabsheh et al. [14], Lei et al. [109], or Orłowska and Laguna [110] assert that they should utilise a variety of organizational, structural, and psychological empowerment strategies that are important for their job satisfaction and potentially for the quality of patient care and turnover. Finally, as pointed out by Cooper-Thomas and Poutasi [111] and Rodríguez-Fernández [112], it is necessary to adequately adjust the person-position-organization triangle, which is key to avoid the intention to leave the organization.

5. Discussion

This study explores the influence of organizational commitment on performance and quality of care in healthcare settings, with a specific focus on nurses. It discusses the practical implications found in a systematic literature review, which suggests that effective OC can significantly improve both nurses' well-being and patient care outcomes.

The findings highlight that transformational leadership, effective communication, and recognition by superiors are essential to foster OC. Therefore, human resource management in the health sector becomes a challenging task for managers in these institutions. In these cases, employees must be aligned with the goals of the organization, as healthcare professionals will largely determine the quality of the healthcare provided [7–9].

Noteworthy, the present research demonstrates that there are numerous factors and interrelationships between human resource management and healthcare, something also reflected in previous studies [31–35].

In the organizational commitment model that serves as the structure for this research (Figure 1), the organization's objectives focus on achieving high levels of performance and quality of care, and OC is positioned as a key aspect, which is supported by research. These aims indicate that, in generic terms, HRM practices that promote communication are applied to increase CO and service quality [91, 92].

Numerous publications with practical implications related to affective commitment have been found to highlight its positive relationship with job performance [69] and an increase in patient safety culture [71]. This relationship becomes inverse in relation to occupational burnout [72]. However, employee training and development have a moderating effect on the growth of affective commitment [15].

Regarding normative commitment, and in line with the analysis conducted, there is a positive and significant relationship between levels of job satisfaction and the former [74]. This leads to improved job performance and low levels of turnover intention [73], so it seems advisable to foster loyalty and commitment in both healthcare settings and nursing schools [60, 113].

No evidence has been found in continuance commitment of proposals or practical experiences to promote this type of commitment. It should be noted that in the model on which this study is based [19], continuance commitment did not appear as representative, which confirms its correct approach.

The studies analysed indicate that transformational leadership, HRM practices, and both intrinsic and extrinsic factors have a positive impact on increasing CO. In particular, when nurses in managerial positions are perceived by their teams as effective and trusted transformational leaders, an increase in staff efficiency and productivity is observed, as well as an improvement in their commitment to the organization [65]. Furthermore, the implementation of HRM strategies and practices not only fosters OC but also improves well-being, happiness at work, and overall performance. Factors such as the intrinsic needs of workers, the quality of the physical infrastructure, and the work environment are key elements in increasing CO [67, 68].

Regarding job satisfaction, burnout, and stress as moderating factors, the results agree with Green et al. [80], who state that it is crucial to combat them with specific interventions. According to Tripathy et al. [84] and Babatope et al. [85], improvement of work-life balance practices and support from supervisors can increase job satisfaction. Velando-Soriano et al. [62] point out that burnout prevention plans with a focus on social support should be developed, which will improve nurses' quality of life and, consequently, the care they provide. Furthermore, the application of resonant leadership in healthcare organizations can decrease employee burnout and prevent stress-related illnesses [90].

Finally, the effective implementation of human resource practices aimed at promoting CO, and thus improving the quality of patient care and reducing the turnover rate of healthcare staff, shows significant variations between different healthcare settings. These differences are largely dependent, for example, on whether the health institution is publicly or privately owned, as well as on the geographical and cultural context in which it is located. In this regard, it is observed that nurses in the private sector and in rural areas more frequently consider leaving their posts compared with those working in the public sector and urban areas [66, 114]. Resource-constrained environments, however, create barriers that include shortages of skilled personnel, inadequate infrastructure, and limited access to continuous training [67, 115]. These barriers can negatively affect the implementation of HR practices aimed at fostering OC. In more developed contexts where resources are not a significant constraint, the challenges focus more on resistance to change and institutional bureaucracy [116]. In these environments, despite the availability of resources, rigid policies and lack of flexibility may impede the adoption of new HR practices that are essential to improve CO and, consequently, quality patient care. Therefore, to overcome these challenges, it is essential that HR interventions are designed and adapted considering the specific characteristics of each healthcare setting.

5.1. Practical Implications. The concept of organizational commitment amongst nurses has been studied in various hospitals, with a focus on its impact on healthcare quality and patient safety. In Mexico, a study on the dominant culture amongst nurses in a public hospital revealed the need

for consensus on values, attitudes, and behaviours to strengthen and develop hospital organizations [117]. In Catalunya, Spain, a study on nursing governance and its impact on perceived quality showed a positive correlation between patient satisfaction and safety with the work of nurses and their commitment to the organization [118]. In the United States, research has explored the relationship between work engagement, burnout, and organizational commitment amongst nurses, with findings suggesting that job crafting and work engagement can mediate the relationship between participation in decision-making and intentions to leave the organization [119]. In Brazil, a study on leadership in intensive care units found that the relationship between nurses and doctors was more favourable in public hospitals with a more collaborative leadership style [120]. These studies highlight the importance of fostering a positive organizational culture and commitment amongst nurses to improve healthcare quality and patient safety.

5.2. Other Studies on Healthcare in Addition to Nursing.

In addition to research on the organizational commitment of nurses in healthcare institutions, the literature has also addressed other healthcare-related work sectors, mainly physicians. Leadership behaviour has been shown to have a positive influence on the organizational commitment of physicians [121, 122], a finding that coincides with the results presented in this study for nurses. Research by Gokce et al. [123] related to the organizational commitment expressed by physicians in public and private healthcare providers is consistent with the results of our research, which show that there are a positive and significant relationship between perceived organizational support and affective and normative commitment and an insignificant relationship between perceived organizational support and continuance commitment.

However, there are also some differences in relation to the factors that enhance OC in doctors and nurses. Individual support from leaders and colleagues is positioned as elements that most positively influence the OC of physicians, while nurses improve their OC when they increase their degree of autonomy and do not feel overly monitored or overwhelmed at work [124, 125]. In summary, research shows that physicians have lower levels of CO than other health professionals, influenced by more work-related aspects, employment, and age [125].

5.3. Limitations and Future Research. As concerns the limitations of the present work and further research, we have delved into human resource practices in the health context, with a particular focus on nursing. However, it is necessary to recognise that our findings have inherent limitations. For instance, sector specificity may limit the generality of the findings to other contexts or populations. Furthermore, the use of additional databases could give as a result a larger number of papers. Furthermore, bibliographic bias could arise due to not using certain sources, Scopus, for example, which could lead to over-reliance on a particular perspective or ignoring relevant research that could challenge the

assumptions of the study. However, the WoS database is highly valued in the scientific community due to its exhaustiveness and quality in indexing high-impact scientific journals in various disciplines.

In general terms, for future research it would be of interest to (1) study how the relationships between professionals and teams in healthcare impact key factors on organizational commitment and (2) apply the model used in this article to other healthcare groups for a holistic approach. Based on the results of this work referring to OC in future research, we will be able to follow up on new publications where nursing management is crucial in improving health. Regarding affective commitment, future research can be enriched with works that analyse the effects of its growth on patient safety, burnout occurrence, and the moderating effect of nurses' training and development. Regarding normative commitment, future research will analyse the relationship between nurses' job satisfaction and their improvement in daily motivation.

Finally, the inclusion of Magnet hospitals in the study of the applicability of this model can result in interest for an upcoming paper as these types of organizations present, amongst other benefits, better work environments, higher nurse job satisfaction, less burnout, and decreased intent to leave [126].

6. Conclusions

As noted above, this paper applies a previous theoretical model on organizational commitment in healthcare to the case of nurses.

The increase in OC is positioned as a key factor in achieving the objectives set by organizations, an effect that becomes even more transcendental in healthcare institutions. In the systematic review of the literature related to practical implications, the relevance of the high status of nurses, the importance of adequate human resource management, and the convenience of adequately covering the intrinsic and extrinsic needs of workers have been highlighted. Appropriate workload management, remuneration, and autonomy are also positioned as good practices to improve CO.

Organizational commitment can be divided into affective, normative, and continuance commitment. In the 229 articles analysed, there is little presence of practices related to improving continuance commitment. However, issues related to affective and normative commitment are sufficiently represented.

Affective commitment is the most present in the research and is positioned as key in nonprofit and healthcare organizations. It helps improve patient safety culture and decreases the occurrence of burnout, amongst other effects. Employee training and development have moderating effects on this commitment. It can be added that affective commitment implies an increase in job performance, specifically for the work of nurses.

To enhance normative commitment, loyalty and obligation need to be fostered in healthcare settings and schools. Job satisfaction favours normative commitment; hence,

leaders should orient their human resource policies to reduce job burnout, encourage communication, increase flexible working hours, avoid excessive control, and, in short, generate a suitable environment for performance.

Job satisfaction, stress, and burnout are presented as moderating factors in achieving high levels of commitment. The authors highlight how these elements become more important in jobs related to healthcare in general and nursing work in particular, mainly due to the importance of the loss of knowledge when an employee decides to leave, and the negative influence that inadequate human resource management can have on patient care.

Health organizations aim to improve their performance levels and quality of care. HR practices for nurses that foster communication, job satisfaction, appreciation of superiors, and appropriate work environment will provide higher levels of CO, which will result in increased recognition of the work and improved patient care.

Data Availability

This study has followed PRISMA 2020 guidelines for screening, selection, extraction, and data acquisition. The documents analysed came from the Web of Science (WoS) database.

Ethical Approval

There are no ethical issues related to this research. No humans or animals have been used to carry out the work under study in this article.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

The authors are very grateful to the University of Malaga for their continued support. The funding for the open-access charge was provided by the University of Malaga/CBUA.

Background. Although retaining new nurses is imperative for the future of the nursing profession, it remains a challenging task in the healthcare industry. Understanding the career journey of new graduates as they transition from students to nurses is vital. However, longitudinal studies investigating the factors influencing retention during this period are lacking. **Aim.** The aim of this study is to identify the influencing factors and develop a longitudinal prediction model for new graduate nurse retention. **Methods.** A secondary data analysis was conducted using the New Nurse e-Cohort Study dataset from two survey periods, November–December 2020 and February–March 2022. The participants were categorized into either retention or turnover groups based on their turnover experiences. A decision tree based on classification and regression tree (CART) analysis was utilized. **Results.** Of the total 586 participants, 463 (79%) were in the retention group. The CART model highlighted that new nurses' retention was significantly associated with younger age, higher readiness for practice (clinical problem-solving) during the nursing program, lower transition shock (such as confusion in professional values, loss of social support, and conflicts between theory and practice), and a higher person-environment fit (person-job fit). The predictive accuracy of the CART model was 79.7%. **Conclusion.** To retain new nurses, nursing educators and hospital managers should collaborate to prepare nursing students for actual practice, offer support during organizational socialization, and foster healthy professional values for competence in the workplace. **Implications for Nursing Management.** Transforming the educational strategies of nursing programs and hospital management policies is imperative to ultimately enhance the retention of new graduate nurses.

1. Introduction

Accounting for over 50% of the global health workforce, there are approximately 28 million nurses worldwide [1]. New and experienced nurses are essential to the profession's future, but retaining them within the healthcare industry continues to be challenging. As a result, by 2030, there is expected to be a shortage of 5.9 million nurses [1], leading to a vicious cycle of far-reaching consequences on patient ratios, staff dissatisfaction, occupational stress, burnout, and staff retention issues, ultimately compromising patient safety and the quality of care [2, 3]. Turnover is especially a problem among new graduate nurses; up to 30% and 57%

leave within their first year and by the end of their second year, respectively [4]. New nurse turnover represents a loss of human and financial resources for the healthcare workforce, which is particularly problematic given the prevailing global shortage of nurses [5]. Preventing the exodus of new nurses is crucial; specifically, it requires developing an understanding of how new nurses adapt to new roles, from students to nurses [6], the reasons for the exodus, and multifaceted solutions to prevent it.

The first year of employment is the period for nursing students to grow and adapt as competent professional nurses. The successful transition to practice is an important factor that determines the retention of new nurses [7].

During the transition, new nurses confront numerous challenges, such as a theory-practice gap, overwhelming workload, difficulties in interpersonal adaptation with co-workers, confusion in professional identities, lack of nursing competency [8], and work-life imbalance [8, 9].

Previous studies have contributed to understanding the diverse factors related to the reasons for new nurse turnover and recommended policy strategies to retain them in practice. New nurses' turnover reasons appear to increase in a poor working environment [10, 11] and when nurses experience workplace bullying [12] or violence [13]. In addition, low resilience with less empowerment [11], low job satisfaction [13, 14], and high job stress [15] provoke high turnover intention. However, as previous studies focused on the relationship between these factors and turnover intention rather than actual turnover, there is insufficient evidence to determine whether the reported factors really predict nurse turnover in practice settings.

Focusing on the factors leading to the retention of new nurses is more effective than identifying the factors involved in turnover; a positive approach not only controls problems but also goes beyond elimination and leads to a healthy work environment and better work life quality in the nursing profession [16]. In addition, identifying and enhancing retention factors can create a positive organizational environment that encourages new nurses to continue to work, leading to improved quality of nursing and patient safety [17]. Brook et al.'s systematic review [18] indicated that interventions aimed at retaining new nurses, including residency programs [19] and transition programs [20], have been relatively successful. However, the duration for intervention effects to manifest, ranging from 27 to 52 weeks, is relatively long, and sustaining the intervention during this period requires additional staffing and resources [18]. This raises doubts about the feasibility of implementation in countries with limited resources and support. In fact, out of the 53 studies included in the abovementioned systematic review, 52 were conducted in high-income countries such as the USA, Australia, the UK, and Canada [18].

Other descriptive studies have identified several organizational and personal factors that positively affect the retention intention of new nurses, including organizational culture, empowering leadership, organizational socialization [21], the meaning of work, organizational commitment, professional self-image [22], clinical competency, and grit [23]. To ascertain the factors influencing the actual retention of nurses, it is necessary to confirm whether retention intention translates to actual retention. Yet, similar to studies on nurse turnover, most nurse retention studies have identified a relationship between relevant factors and retention intention, not actual retention [24, 25]; thus, whether the factors affecting retention intention also affect retention is unclear. Therefore, to address the global nurse shortage, it is imperative to identify universally applicable factors influencing the retention of new nurses and formulate appropriate strategies [26].

Despite knowledge of their importance, the factors influencing the retention of new nurses have rarely been studied longitudinally. Most previous studies have focused on the experiences of new nurses after employment using

cross-sectional data [5, 8, 27], thereby limiting their predictive abilities. To understand the retention factors of new graduate nurses, their transition from students to nurses should be examined using longitudinal data. A previous study reported in-depth results by longitudinally analyzing the factors affecting the transition shock caused by the conversion of students into practicing new nurses; however, whether these factors eventually lead to the retention of new nurses has not been confirmed [6].

Therefore, we aimed to identify the factors influencing new graduate nurse retention, utilizing decision tree analysis to uncover the following two key aspects: the anticipatory socialization factors of nursing students and the organizational socialization factors of new graduate nurses based on Scott's 2008 model of new graduate nurses transitioning into the workplace [28] (Figure 1).

1.1. Conceptual Framework. The model proposes that anticipatory and organizational socialization experiences concurrently influence the successful transition of new nurses into the workplace [28]. According to this model, the transition of new nurses into the workplace is characterized by the following three phases of progression: anticipatory socialization, organizational socialization, and socialization outcomes. Anticipatory socialization refers to the educational or personal characteristics of a student who is preparing to start work as a nurse, such as age, gender, and educational preparation. Organizational socialization refers to all experiences that new nurses have after beginning work, such as work stressors, preceptorship, orientation, and person-environment fit. Socialization outcomes refer to negative or positive outcomes depending on new nurses' perceptions of practice, the organizational education program provided, personal conditions, and work environment. Dissatisfaction with work and career can lead to turnover, while satisfaction leads to retention.

2. Materials and Methods

2.1. Study Design and Data Source. A longitudinal study was conducted using the datasets of the first and second surveys of the New Nurse e-Cohort Study [29] in South Korea (Figure 2). The New Nurse e-Cohort Study is a longitudinal panel study that tracks senior nursing students for three years to identify factors influencing the successful transition to new nurses. The panel was constructed in 2020, with the second and third surveys conducted in 2022 and 2023, respectively. The data for the first survey were collected from November to December 2020, when all participants were senior nursing students. The data for the second survey were collected from February to March 2022, the year after the participants had graduated. The second survey was conducted when participants had experience working as new graduate nurses.

2.2. Study Sample. We included 637 (75.6%) participants out of 842 senior nursing students aged 20–29 who were scheduled to graduate in 2021 and take the national nurse

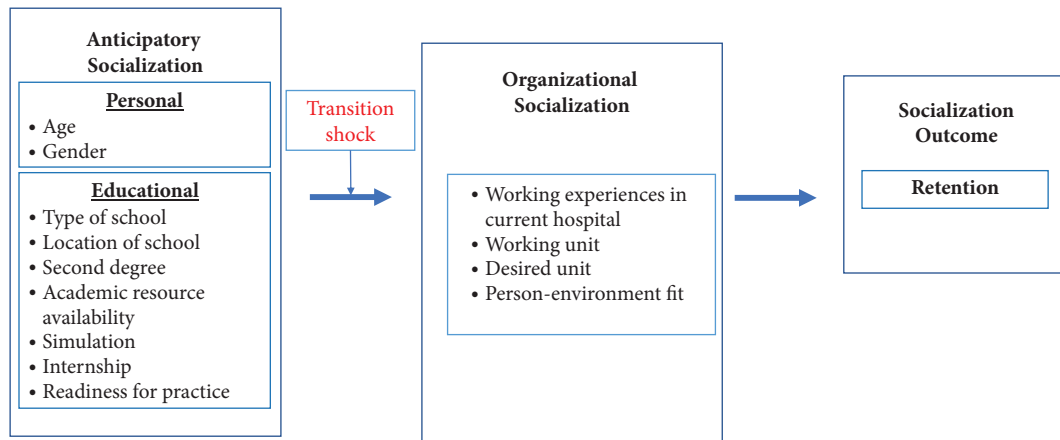

FIGURE 1: Conceptual framework to predict retention among new nurses based on Scott's model (2008) of the transition of new graduate nurses into the workplace.

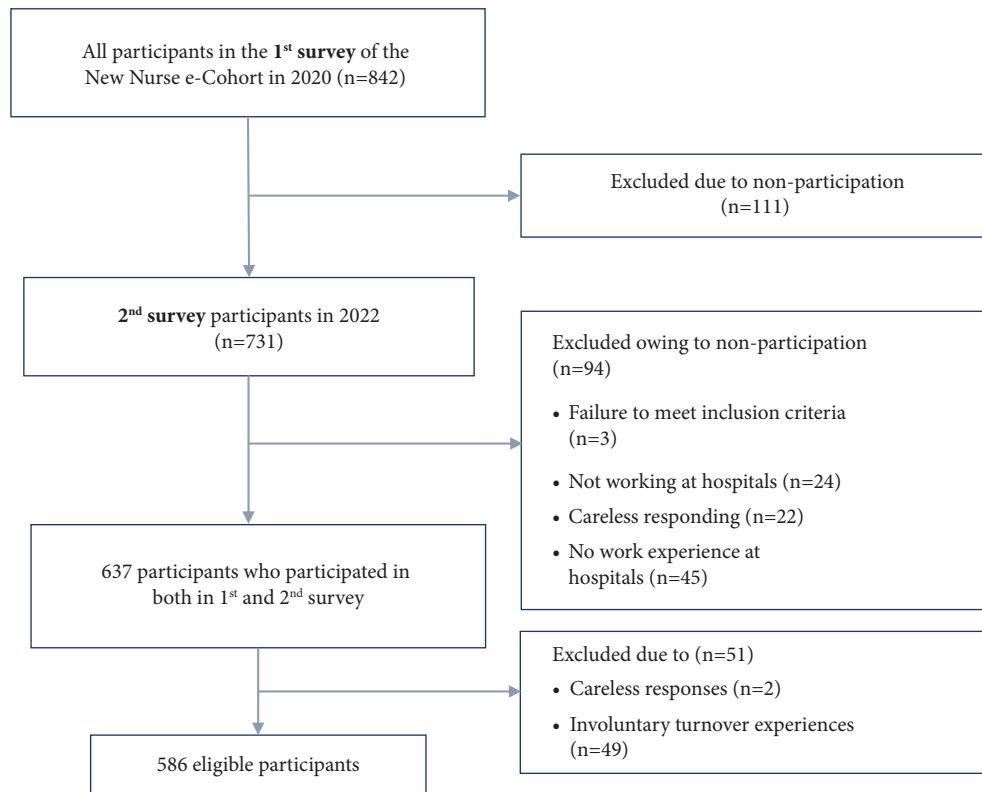

FIGURE 2: Flow diagram of participant selection.

licensure examination that year and who reported having worked in hospitals at the time of the second survey in 2022. Among them, 586 were included in the final analysis after excluding 49 with involuntary turnover experiences and two with careless responses. In the original study [29], additional consent for secondary data analysis was requested at the time of initial data collection, and only the data of participants who agreed to secondary data analysis were used in this study.

2.3. *Measurements.* Factors affecting retention were allocated to one of two categories based on Scott's model [28].

2.4. *Anticipatory Socialization*

Personal factors included participants' demographic characteristics (age and gender).

Educational factors included information related to the participants' prelicensure nursing education, including

the type and location of the school, second degree program, internship experience, availability of academic resources, and simulation education. Academic resource availability was measured by asking one yes/no question as follows: “have you been able to use any materials from the school library?” Simulation education was measured by asking another yes/no question as follows: “have you received simulation education?” Readiness for practice was assessed using the comfort and confidence section of the Casey-Fink Readiness for Practice Survey [8]. This self-report questionnaire consists of 20 items divided into the following four subscales: clinical problem-solving, learning techniques, professional identity, and trials and tribulations. Participants rated each item on a 4-point Likert scale, ranging from 1 (strongly disagree) to 4 (strongly agree). The average score across all items is used as the scale score, where a higher score indicates greater readiness for practical application. Cronbach’s α was 0.69 at the time of the instrument’s development [8] and 0.83 in our study.

2.5. Organizational Socialization. Organizational socialization included information related to the first job experience at a hospital after graduation, including work characteristics (number of months worked, working unit, placement in desired unit, and number of preceptors), transition shock, and person-environment fit.

2.5.1. Transition Shock. Transition shock was measured using the Transition Shock Scale for newly graduated nurses [30]. This 18-item self-report questionnaire contains the following six subscales: conflict between theory and practice, overwhelming workload, loss of social support, shrinking relationships with coworkers, confusion in professional nursing values, and incongruity in work and personal life. The items are rated on a 4-point Likert scale ranging from 1 (strongly disagree) to 4 (strongly agree). The mean of all items is considered the scale score, with a higher score indicating higher transition shock. Cronbach’s α was 0.89 at the time of the instrument’s development [30] and 0.89 in our study.

2.5.2. Person-Environment Fit. Person-environment fit was measured using person-job and person-organization fit perception scale [31]. This eight-item self-report questionnaire contains the following two subscales: person-job and person-organization fit. The items are rated on a 5-point Likert scale ranging from 1 (very little) to 5 (very large extent). The mean of all items is considered the scale score, with a higher score indicating better person-environment fit. Cronbach’s α was 0.86 at the time of the instrument’s development [31] and 0.89 in our study.

2.6. Socialization Outcome

2.6.1. Retention. Retention of new graduate nurses was assessed using a self-report questionnaire developed by our research team; during the second survey, participants were

asked if they had experienced a voluntary change in workplaces since the first survey. Depending on their answers, the participants were divided into retention and turnover groups.

2.7. Ethical Considerations. This study adhered to the guidelines outlined in the Declaration of Helsinki [32], and approval to conduct a secondary data analysis was obtained from the Institutional Review Board of Yonsei University Medical Center (approval no: 4-2023-0854). All data were anonymized before being shared with the research team.

2.8. Data Analysis. The descriptive characteristics of the sample were computed using means and standard deviations for continuous variables and frequencies for categorical variables. Differences between the retention and turnover groups were assessed by *t*-tests and χ^2 tests. Statistically significant variables ($p < 0.05$) in the univariate analysis were entered into the multivariate logistic regression analysis to develop the decision tree model. Decision tree analysis is a machine-learning technique [33] that provides a sequential and hierarchical path to an outcome variable from independent variables and demonstrates the retention probability given the specific values of the independent variables in the path. A decision tree based on classification and regression tree (CART) analysis was used to investigate the factors related to the retention of new graduate nurses. CART is an explanatory technique used mainly to identify data structures by splitting the data into segments that are as homogeneous as possible with respect to the dependent variables [34]. A classification model was constructed from the entire sample to create the largest tree structure with a minimum of 100 and 15 parent code and child node samples, respectively. K-fold cross-validation, with the value set in a 10-fold cross-validation sampling method, was used to address possible overfitting. The area under the receiver operating characteristic curve was calculated to assess the predictive performance of the decision tree for the retention of new graduate nurses. Statistical analyses were performed using SPSS Statistics for Windows version 26 (IBM Corp., Armonk, NY, USA).

3. Results

3.1. Participant Characteristics. Data from the 586 participants are presented in Table 1. A total of 463 participants (79.0%) had no job turnover experience since starting their first nursing job at a hospital. Regarding anticipatory socialization factors, the mean age of the participants was 24.8 ± 1.3 years, and the majority (91.0%) was women. Overall, 82.6% of the participants had graduated from university and most attended nursing schools located in the capital area (52.6%). Only 4.3% of the participants had achieved a second degree, 68.3% had academic resources available, and 97.6% had experience with simulation education. Of the participants, 91.3% had not undergone an internship at a hospital when they were nursing students. The mean readiness for practice score at the time of

Loss of social support		2.17 ± 0.73	2.12 ± 0.70	2.37 ± 0.79	-3.481 (0.001)
Shrinking relationships with coworkers		3.10 ± 0.64	3.05 ± 0.62	3.28 ± 0.69	-3.497 (0.001)
Confusion in professional values		2.84 ± 0.65	2.77 ± 0.64	3.10 ± 0.62	-5.063 (p < 0.001)
Incongruity in work and personal life		2.72 ± 0.78	2.65 ± 0.75	2.97 ± 0.81	-4.042 (p < 0.001)
Person-environment fit		2.69 ± 0.77	2.75 ± 0.75	2.45 ± 0.81	3.861 (p < 0.001)

TABLE 1: Continued.

Variables	Categories	Total (586) Mean \pm SD or n (%)	Retention (n = 463) Mean \pm SD or n (%)	Turnover (n = 123) Mean \pm SD or n (%)	χ^2 or t (p)
Person-job fit		2.78 \pm 0.80	2.85 \pm 0.77	2.55 \pm 0.88	3.748 (p < 0.001)
Person-organization fit		2.60 \pm 0.88	2.66 \pm 0.87	2.36 \pm 0.90	3.364 (0.001)

graduation was 2.86 (SD = 0.31) on a 4-point scale. Among the subscales, "professional identity" ($M = 2.94$, $SD = 0.43$) was highest, followed by "learning technique" ($M = 2.92$, $SD = 0.55$), "clinical problem-solving" ($M = 2.88$, $SD = 0.77$), and "trials and tribulations" ($M = 2.73$, $SD = 0.35$).

In terms of socialization factors, the mean working experience at the current hospital was 8.3 (SD = 3.9) months. Of the participants, 54.8% worked in a general ward and 57.4% were assigned to the unit they desired. The highest number of participants (62.7%) answered that one instructor had educated them during the new nurse orientation period. The mean score of transition shock was 2.82 (SD = 0.47) on a 4-point scale. For the subscales, "shrinking relationships with coworkers" ($M = 3.10$, $SD = 0.64$) was highest, followed by "overwhelming workload" ($M = 2.97$, $SD = 0.62$), "confusion in professional values" ($M = 2.84$, $SD = 0.65$), and "conflict between theory and practice" ($M = 2.81$, $SD = 0.54$). The mean person-environment fit score was 2.69 (SD = 0.77) on a 5-point scale. The participants perceived that "person-organization fit" ($M = 2.60$, $SD = 0.88$) was lower than the "person-job fit" ($M = 2.78$, $SD = 0.80$).

3.2. Differences in the Groups' Characteristics. Compared with the turnover group, those in the retention group were statistically significantly younger ($M = 24.7$, $SD = 1.2$; $p = 0.18$), with higher scores for clinical problem-solving ($t = 2.029$, $p = 0.044$) and professional identity ($t = 2.230$, $p = 0.027$) on the readiness for practice scale. Simultaneously, they had lower transition shock ($t = -4.978$, $p < 0.001$) and higher person-environment fit ($t = 3.861$, $p < 0.001$) scores for all subdomains (Table 1).

3.3. CART Analysis for New Graduate Nurses' Retention. The variables ($p < 0.05$) from the univariate analysis were entered into the CART model. Figure 3 depicts the final decision tree analysis model for predicting new graduate nurse retention, ultimately generating five layers and seven nodes. Based on the conceptual framework [28], in terms of anticipatory socialization, readiness for practice and age were significant; for organizational socialization, transition shock and person-environment fit were substantial. The most important discriminating factors were as follows in the descending order: (sub) confusion in professional values of transition shock, (sub) clinical problem-solving of readiness for practice, age, (sub) person-job fit of person-environment fit, (sub) loss of social support of transition shock, and (sub) conflict between theory and practice of transition shock. Ten groups were identified, six of which had higher percentages of retention than the root node (boxes with red lines in Figure 3). Newly graduated nurses who scored lower than 3.38 for confusion in professional values and higher than 2.21 on clinical problem-solving were younger than 27.5 years; those who scored higher than 2.13 on person-job fit showed a higher retention rate. Otherwise, among the newly graduated nurses, those who scored higher than 3.38 on confusion in professional values, higher than 3.25 on loss of social support and lower than 2.83 on conflict between theory and practice showed higher retention.

We evaluated the quality of this model's performance using the receiver operating characteristic curve, which yielded an area under the curve of 0.700 (95% confidence interval of 0.636–0.750) and accuracy of 79.7%. This indicated acceptable diagnostic accuracy (exceeding 0.7) [35].

4. Discussion

To the best of our knowledge, this is the first study to identify educational factors from among school and organizational socialization factors in the workplace associated with the retention of new graduate nurses based on Scott's transition model [28]. Previous studies have found that the organizational-level working environment and personal-level transition shock are predominant factors influencing new nurses' turnover intentions [6, 11, 12]. Our study contributes to existing knowledge by examining the relationship between anticipatory (readiness for practice) and organizational (transition shock and person-environment fit) socialization, which are factors that affect actual turnover and retention. Compared to previous research, using decision tree methods provided an opportunity to review a wide range of factors affecting retention and also revealed the logic behind a retention or turnover decision. The CART model shows that retention is mainly related to the younger age group, higher readiness for practice (clinical problem-solving) in the nursing program, lower transition shock (confusion in professional values, loss of social support, and conflict between theory and practice), and higher person-environment fit (person-job fit).

In this study, approximately 21% of the newly graduated nurses reported that they had experienced job turnover since starting work at a hospital after graduation. According to a recent nationwide study in South Korea, the turnover rate of early career nurses with under three years of experience was 26.7% [36]. Another study using longitudinal panel data reported that 25% of new graduate nurses in South Korea left their jobs within the first year [37]. Considering that the average length of experience for our participants was approximately eight months, these results are consistent with our study. Considering South Korean hospitals generally provide an average of three to six months of training [38], new nurses who turn over within a year will have about six months of clinical experience. The quick turnover of new nurses necessitates more frequent recruitment processes, which cause additional financial burdens for staffing and training and hamper patient outcomes [36, 37].

Considering that the CART model ranked the features based on the Gini coefficient [34], confusion in professional values (a subdomain of transition shock) was ranked first. Our results are consistent with the findings of previous studies on nursing students [39, 40] and nurses [41, 42] indicating that higher professional values result in lower turnover intention. Feng and Tsai [43] found that when conflict occurs between the organizational value of pursuing work-centered nursing and professional value of pursuing patient-centered nursing, new nurses experience high levels of stress and confusion regarding professionalism. These results suggest that advancement of professional values may

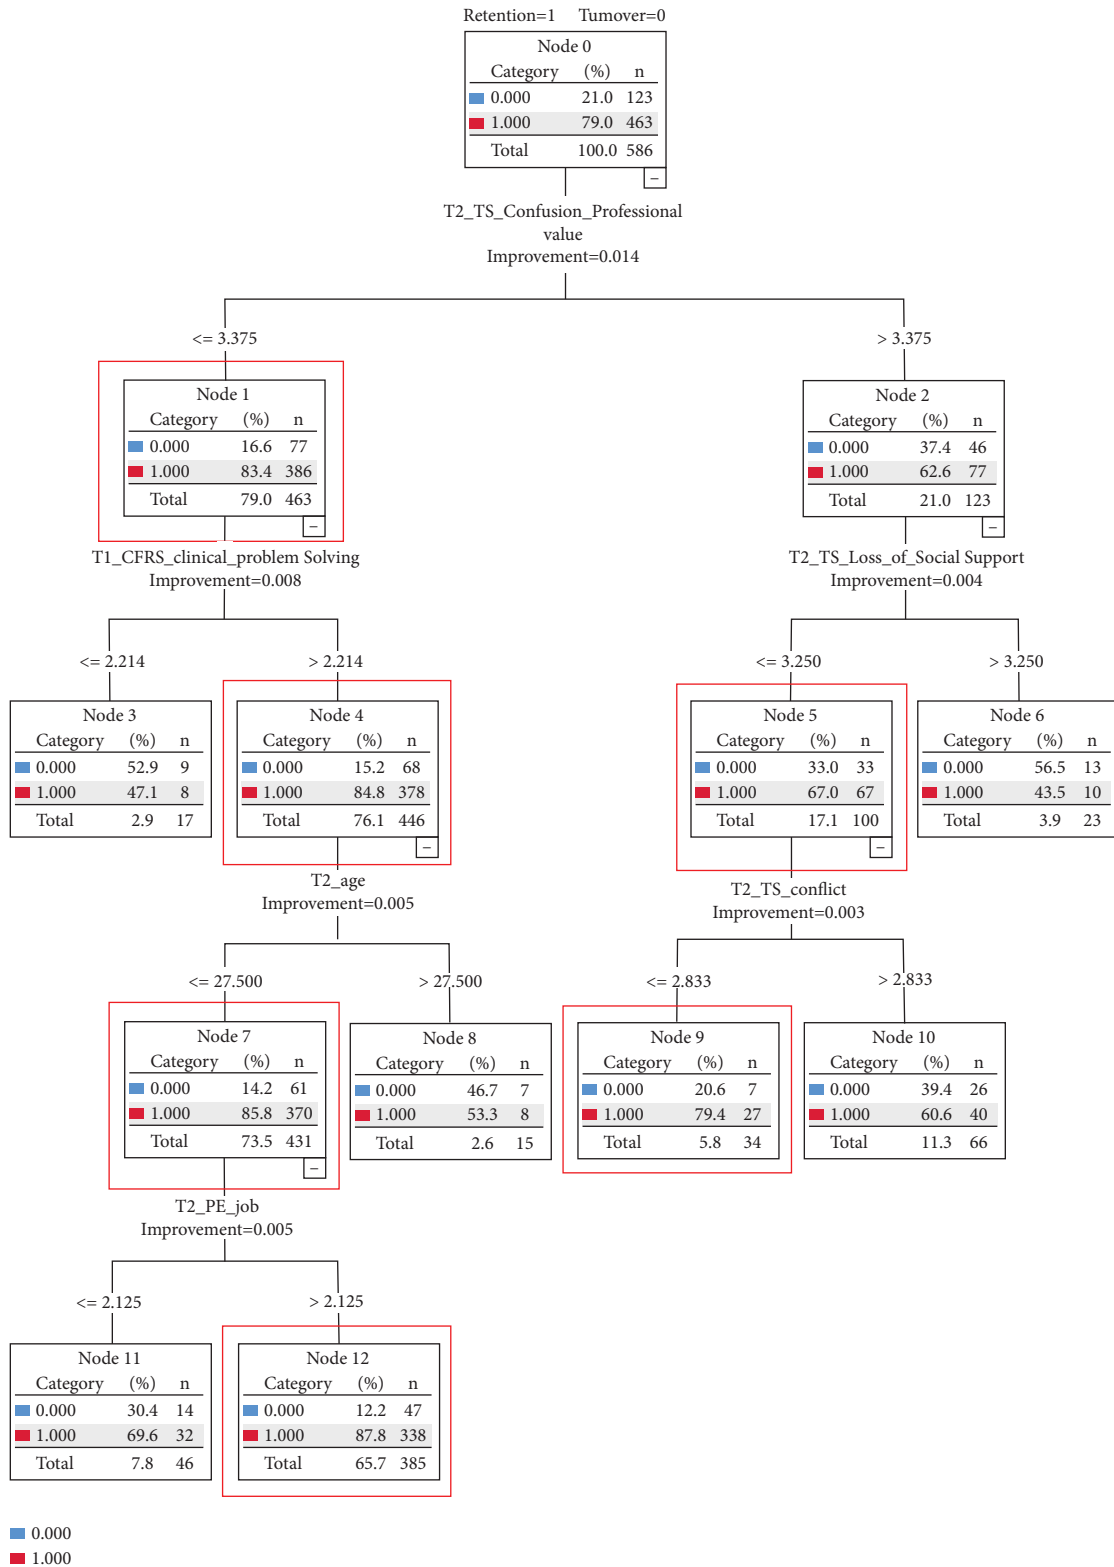

FIGURE 3: Classification decision tree analysis of the relationship between students and new nurses' characteristics.

increase the retention of new nurses by raising their sense of professionalism [41]. Based on these results, professionalism values can be claimed as a crucial factor in the retention of new nurses [44].

An interesting finding is that the participants who had confidence in clinical problem-solving when they were nursing students tended to remain in their jobs as new nurses. Problem-solving skills are a core competency of

professional nurses, who need to continuously identify patients' health problems and make clinical judgments in patient care [45, 46]. Nurse educators should pay attention to the problem-solving ability of new graduate nurses during the transition, optimize the new nurse orientation program, and conduct a series of training sessions using situational simulation and new media technology to improve their clinical reasoning [46].

Regarding age, this study's findings are contrary to those of previous studies that found that young nurses were more inclined to leave their work [10, 36, 47, 48]. According to Bae et al. [36], life events, including pregnancy and childbirth, increase actual turnover among nurses aged 20–35 years. A possible reason for this is the characteristics of our sample. Unlike previous studies, our study included only new graduate nurses in the 22–29-year age range, who had worked less than a year and were still in transition. Previous studies have reported that the age of senior nursing students is negatively correlated with their learning outcomes; confidence in managing multiple patients [49] and nursing skill competency [46] decrease as age increases. Considering that confidence and competence on the learning curve are likely to grow with experience [50], we cannot confirm the effect of age on the retention of nurses. This is because we followed up within a year of graduation, which is a very early career stage with an expectedly unstable transition process. Further studies are required to verify the relationship between age and retention over time.

Another noteworthy finding of this study is the positive relationship between person-job fit and retention, which affects the turnover of new graduate nurses. The more suitable the person-job fit, the more likely it is that new nurses will remain. Person-environment fit has been repeatedly identified as a predictor of turnover or turnover intention in the literature [51, 52]. It is possible that a good fit between the job and organization leads to higher job satisfaction, empowerment, and work engagement [51, 53, 54]. Person-job fit occurs when the staff's knowledge, skills, and abilities match work demands and the work performed meets their needs [55]. This suggests that hospital administrators and nurse managers should consider nurses' characteristics, needs, and values before assigning work and departments to enable them to perform to their full potential. In addition, they should provide nurses with precise and detailed job descriptions, and educational opportunities for updating skills and knowledge to continuously improve their work abilities.

In addition, participants with relatively low professional values were influenced by social support. This finding indicates that even if professional values are not strong, there is a high possibility of retention if strong social support is received. Social support is a job resource that facilitates employees' work motivation, involvement, and engagement, promoting wellbeing [56]. Previous studies have reported that well-supported nurses in hospitals show a higher intention to stay [11, 22]. Therefore, to retain new nurses, who face difficulties with unfamiliar work, unskilled interpersonal relationships, and the unestablished value of their profession [7], nurse managers,

coworkers, and supervisors should pay more attention to them at the organizational level. Support activities, such as peer support, collegiality fostering programs, and mentorship, can help new nurses alleviate job stress and promote personal meaningfulness and health and wellbeing at work and ultimately help them find the professional value [57, 58].

This study has several limitations. Despite the internal validation through CART analysis demonstrating excellent accuracy, the generalizability of the model would benefit from external validation using additional databases from different settings or populations. In addition, using convenience sampling resulted in a sample that was predominantly female and consisted of college graduates. This may lead to a lack of diversity. To address this limitation, future research should focus on employing more representative sampling methods, such as random or stratified sampling, to ensure a more diverse and inclusive participant pool. Furthermore, the variables in this study were measured using self-report, which may introduce potential biases or inaccuracies. To improve the robustness of future studies, it is recommended that readiness for practice and organizational socialization be assessed by third-party sources such as nursing faculty, preceptors, or supervisors. This approach provides a more objective and comprehensive evaluation of these factors, thereby enhancing the reliability and validity of the research findings.

5. Conclusions

We developed an internally validated decision tree model based on six factors to predict new graduate nurse retention using longitudinal data. This was accomplished by applying a conceptual framework with Scott's transition model for new graduate nurses in the workplace. The prediction algorithms and results of this study will contribute to transforming the educational strategies of undergraduate nursing programs and management policies of hospitals to enhance the retention of new graduate nurses. To retain new nurses in practice settings, nursing educators in schools and managers in hospitals should cooperate to prepare nursing students for practice, provide support to experience success in the organizational socialization process, and cultivate healthy professional values to grow as competent nurses in the workplace.

Data Availability

To ensure the confidentiality of the participants' personal information, the datasets are not publicly available.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

TL and YJ contributed to conceptualization, methodology, and formal analysis; TL contributed to supervision, project administration, and funding acquisition; YJ and YY

contributed to visualization; YJ, TL, and YY wrote the original draft and contributed to reviewing and editing. All the authors have read and approved the final manuscript.
