Aim. This research study aims to examine the professional quality of life (ProQOL) among healthcare workers (HCWs) in Pakistan during the fourth wave of COVID-19. **Background.** Under intense pressure to fight the coronavirus disease 2019 (COVID-19) pandemic, HCWs are more likely to experience psychological problems. Numerous investigations carried out in the past at various points during the pandemic have shown that COVID-19 has had important detrimental effects on HCWs. However, there are many unknowns with regard to ProQOL for HCWs. **Methods.** This is a cross-sectional study conducted with Pakistani HCWs who performed their duties during the fourth wave of COVID-19. Data were collected between January 1 and March 31, 2022. A total of 258 HCWs took part in the study evaluating ProQOL. The significance level was <0.05 . **Results.** Most respondents were males (79.1%), and 20.9% were females. The scores of secondary traumatic stress (STS), burnout (BO), and compassion satisfaction (CS) were 24.03 ± 3.79 , 19.18 ± 2.92 , and 35.29 ± 4.37 , respectively. Compared with higher-income groups, HCWs with lower incomes were significantly ($P < 0.001$) more likely to experience psychological issues. Males had lower BO and STS than female HCWs ($P < 0.001$). Similarly, doctors had a lower STS than nurses ($P < 0.05$). HCWs who worked hours per day longer had a heavier STS ($P < 0.001$). **Conclusion.** This study shows low BO levels, moderate CS levels, and STS levels among HCWs. HCWs with lower salary were at a higher risk of mental distress due to the pandemic. HCWs who worked for long hours and had less income had more STS and BO. HCWs who were dissatisfied with their works had poor CS. **Implications for Nursing Management.** It is supposed that these results may help HCW managers to improve job satisfaction and rewards while reducing working hours and workload to improve the ProQOL of HCWs fighting COVID-19. The government should focus on the mental health of HCWs, enhancing their satisfaction and allocating sufficient resources.

1. Introduction

The novel coronavirus disease 2019 (COVID-19) pandemic rapidly spread over the world, causing a threat to public health [1]. SARS-CoV-2 mostly affects and causes more damage to the respiratory system [2, 3]. On March 11, 2020, the World Health Organization (WHO) proclaimed COVID-19 to be a pandemic after the first case was discovered in Wuhan, China, in December 2019 [4]. This virus takes 2 to 14 days to incubate, and symptoms typically start

to manifest during this time [5]. On December 23, 2022, the disease infected 651.9 million confirmed cases of COVID-19, including 6.65 million deaths, across the world, as reported to the WHO [6]. The pandemic affected both developed and developing nations, with India, Brazil, and United States of America (USA) suffering greatly from its effects in terms of mortality and morbidity [7]. In a little period of time, the total number of confirmed cases in emerging or low-resource nations significantly increased. The world economy, particularly China and surrounding developing

countries such as Pakistan, Iran, India, Bangladesh, and Afghanistan, is becoming more at risk from COVID-19 [8, 9]. Pakistan has a low- to medium-level economy and 197 million inhabitants, making it a country with a high population density. In Pakistan, from 3 January 2020 to 13 December 2022, there were 1.57 million confirmed cases of COVID-19 with 30,635 deaths, according to the WHO [10]. COVID-19 is known to cause both physical and psychological problems in HCWs [11]. HCWs, such as physicians, nurses, and paramedics, are fighting the pandemic on the frontlines. As is frequently the case, medical staffs coping with such widespread epidemics are susceptible to psychological stress and changes in mood, which impact their health [12].

Healthcare professionals are involved in a variety of tasks, including isolating patients and preventing and controlling infections [13, 14]. In addition, they were at a greater risk of infection during patient care [15]. Although frontline HCWs primarily focus on preventing transmission and caring for COVID-19 patients, the pandemic's effects on mental health and their consequences cannot be underestimated [16]. Healthcare professionals are more frequently experiencing mental health issues such as anxiety, insomnia [17–21], and burnout syndrome (BS) [22]. Meanwhile, stress was a common problem for nurses fighting COVID-19 [23]. During the COVID-19 epidemic, the mental workload of nurses rose [24]. The physical and mental health of nurses may suffer when they work under conditions that raise their risk of infection, pressure, and workload, when there are not enough resources available, and when they have to carry out more physical and psychological labor [25]. The debate over how the COVID-19 epidemic has affected mental health conditions has uncovered glaring gaps in the information that is currently available on the frequency of depression, anxiety, and sleep disturbance amongst HCWs. Therefore, it is essential to identify the mental health burden and deal with it appropriately [26].

Even before the pandemic, there were high levels of burnout and exhaustion among HCWs in Pakistan. According to a cross-sectional study on burnout among 179 HCWs in emergency rooms, 42.4% of them showed emotional fatigue [27]. A study conducted in 2019 that evaluated 118 surgical residents in Karachi discovered that women had greater emotional exhaustion (49.2%) than men did (50.8%). In addition, married individuals showed higher degrees of personal fulfilment and sleep deprivation than single individuals did [28].

A study conducted in six hospitals in Pakistan using the PHQ-9 and GAD-7 scales to evaluate 400 healthcare workers during the first wave of COVID-19 revealed that 21.8% of them had moderate-to-severe anxiety or depression [29]. Similar results were found in a study conducted on 398 healthcare workers from Punjab, where the prevalence of anxiety and depression was 21.4% and 21.9%, respectively [30]. A study of 87 HCWs during the second COVID-19 wave found that 54% of participants experienced psychological fatigue, 77% experienced depersonalization, and 31% experienced low personal accomplishment. These symptoms were all linked to a history of COVID-19 infection or contact

with patients who had such a history [31]. As of January 27, 2021, a third-wave novel SARS-CoV-2 variant from the UK, also known as B.1.1.7, had been identified in over 64 countries, including Pakistan. With an average of 100 individuals dying away in Pakistan every day, this B.1.1.7 variant is linked to a higher risk of death than other variants, implicating more burdens on healthcare professionals [32]. In Pakistan, higher levels of burnout were observed in the COVID-19 fourth wave, likely as a result of the pandemic's cumulative physical and emotional repercussions; however, much is still not entirely clear at this time [33]. It is important to comprehend the long- and short-term effects of CS, BO, and SCS in a lower-middle-income nation such as Pakistan. These effects include decreased healthcare quality, an increase in errors, and a decrease in ProQOL, low job satisfaction, and significant costs [33, 34]. However, during the fourth wave of the pandemic, Pakistan did not routinely report on the prevalence of CS, BO, and STS in HCWs. Therefore, in light of the fourth wave of the COVID-19 outbreak, the purpose of our study is to evaluate the levels of the contextual variables depressive concerns, BO, CS, and STS among HCWs in Pakistan.

2. Methods

2.1. Study Design and Participants. To learn more about the experiences of frontline HCWs caring for patients with COVID-19, a cross-sectional study was carried out. The study was conducted at two governmental health institutions, namely, Ayub Teaching Hospital and Combine Military Hospital Abbottabad, Pakistan. The inclusion criteria for participation in this study were as follows: (1) voluntary participation in the study; (2) healthcare workers on the frontline against COVID-19; and (3) healthcare workers with direct bedside care experience involving COVID-19 patients. Exclusion criteria were as follows: nonfrontline HWCs involved in scientific research, teaching, and hospital administration [13]. Because there were nurses characterized by different levels of experience at least 5–10 times as many variables were represented in the sample size [13]. The current study included 20 variables. A total of 286 questionnaires were collected, 258 questionnaires were included for the final data analysis after those that did not match the requirements were removed.

2.2. Measures and Instruments. The relevant published articles and scientific literature on COVID-19 were examined to create a structured questionnaire [13, 26]. The questionnaire was administered in the English language, which is the official language of Pakistan. Three different sections were made in the questionnaire used: (1) sociodemographic information; (2) healthcare worker work conditions and COVID-19 pandemic-related aspects; and (3) mental health conditions [13]. The demographic features comprised of HCWs are their gender, marital status, age, work experience, educational attainment, the infection status (COVID-19) of friends or family members of the HCW, the number of night shifts worked per week, the number of working hours during

the epidemic, job satisfaction, pay satisfaction, and work load [13]. The ProQOL Scale was used to measure ProQOL. The ProQOL Version 5 was the instrument used; it consists of 30 items organized into three subscales: burnout (BO), compassion satisfaction (CS), and secondary traumatic stress (STS). The following items were used to test CS: 3, 6, 12, 16, 18, 20, 22, 24, 27, and 30. Items associated with burnout (items 1, 4, 8, 10, 15, 17, 19, 21, 26, and 29 of the ProQOL tool) and STS (items 2, 5, 7, 9, 11, 13, 14, 23, 25, and 28) were included in order to quantify CF. A 5-point Likert scale was used to record responses to these questions, with 1 indicating never, 2 very rarely, 3 sometimes, 4 often, and 5 indicating very often [35]. In published papers, the ProQOL shows high validity and reliability [36, 37]. According to Cronbach's alpha values of 0.89 for CS, 0.83 for BO, and 0.78 for STS in the primary research study, the ProQOL tool was considered reliable. Therefore, a Cronbach's alpha of 0.80 or higher is regarded as particularly desirable for all aspects [38]. The healthcare worker participants were contacted by WhatsApp, and they were informed about the study's purpose and the researchers' interest in the research topic. The hospital administrators providing respondents who were battling COVID-19 were contacted to discuss the goal of our investigation. Those who were not medical professionals and did not finish the assessment were excluded from this survey.

2.3. Data Collection. Data were collected between January 1 and March 31, 2022. Google Forms software was used to generate a survey, and the link to it was distributed via WhatsApp. Since every question was needed, only surveys that were completely filled out were collected, ensuring that there were no missing data. The healthcare worker assisted in distributing the surveys individually and through WhatsApp groups. It took approximately 10–15 min to complete the questionnaire.

The combined military hospital in Abbottabad's Ethical Research Committee gave its approval to the current study (CMH Atd-ETH-78-Paed-23). To participate in our online survey, respondents had to assent (accept or deny) to the informed consent declaration on the first page.

2.4. Statistical Analysis. Data collected from respondents were directly deposited in Google Worksheets and later transfer into Microsoft Excel and SPSS 22.0. The data analysis, which was based on the quantitative analysis, combined descriptive and inferential statistics. Descriptive statistics (univariate analysis) were performed for each main variable of the study, whether it was an independent or dependent variable, using frequency counts, percentages, and mean \pm standard deviation (SD). The socioeconomic characteristics of the individuals and variables associated with HCWs were examined using the chi-square test. The ProQOL manual states that the responses to items 1, 14, 15, and 17 should be reversed to become (1 = 5) (2 = 4) (3 = 3) (4 = 2) (5 = 1). The ProQOL was at a low level in the end, with sum answers of ≤ 22 and a moderate level with sum answers of 23–41; the ProQOL was at a high level, and the sum answers were ≥ 42 [35]. The significance level was < 0.05 .

3. Results

3.1. Demographic Characteristics. A total of 258 healthcare workers (204) (79.1%) were males, and 54 workers (20.9%) were females. Regarding marital status, 31.3% were single, and 68.7% were married. Regarding age, 50% were 18–30 years old, 43% were 31–40 years old, and 6.97% were > 40 years old. On the basis of education, 32.6% had graduated, and 65.1% had postgraduate or above education. Moreover, 2.3% were senior medical students in the last stage of their undergraduate studies. In this study, 76.7% of the participants were physicians, 10.5% were nurses, 11.6% were technicians, and 1.2% were assistants. Furthermore, we found 5.8% of participants from the infectious disease department, 9.3% from the surgical department, 3.5% from the ICU, 15.1% from internal medicine, 16.3% from emergency, and 50% from other departments. Among all participants, 37.2% were satisfied with their monthly salary, 29% were not satisfied, 6.9% were very satisfied, and 26.7% were normal. Regarding work burden, 44.2% showed a heavy work burden. The time interval of duty shown by the participant included 38.3% working for 8 h per day, 57% working for 9–12 h per day, and 4.6% working for 12 h per day as clinical frontline staff, as shown in Table 1. In addition, 34.9% of HCWs had 2 night shifts per week, 20.9% had 1 night shift per week, and 10.5% had 3 night shifts per week. Here, we found that 61.3% of HCW families were infected with COVID-19, and 68.6% of HCW lives were affected by COVID-19, as shown in Table 1.

3.2. Prevalence of ProQOL in Healthcare Workers. The healthcare workers' average scores for CS, BO, and STS were categorized into low, moderate, and high groups. The mean scores \pm standard deviation (SD) was as follows: CS was 35.29 ± 4.37 , while BO and STS were 19.18 ± 2.92 and 24.03 ± 3.79 , respectively. These results indicate that healthcare workers generally experience low levels of STS and moderate levels of CS and BO. Specifically, the results reveal that healthcare workers reported moderate levels of compassion satisfaction (60.5%) to low levels (20.9%), low levels of STS (48.8%) to moderate levels (40.3%), and moderate levels of burnout (48%) to low levels (39.5%). Details are shown in Table 2.

3.3. Factors Related to HCWs' ProQOL. In univariate analysis, general data were used as independent factors and anxiety, depression, BO, STS, and CS were used as dependent variables, and the findings demonstrated that HCW age, marital status, number of working hours per day, workload, and job satisfaction were associated with STS; workload, job satisfaction, and salary satisfaction were associated with BO and CS ($P < 0.05$; Table 3). Chi-square analysis was performed, and it showed that males possessed lower anxiety, depression, STS, and compassion satisfaction than female HCWs ($P < 0.001$). Single HCWs had a lower burnout risk than married HCWs ($P < 0.006$). HCWs aged 18–30 had heavier STS than HCWs aged 31–40 and ≥ 41 ($P < 0.001$). Physicians had lower anxiety and depression,

STS, and compassion satisfaction than nurses, technicians, and assistants ($P < 0.05$). The HCWs who worked in the emergency department, ICU, and internal medicine department had higher levels of burnout, anxiety, and depression than those who worked in other departments or units ($P < 0.05$). Those with 1–5 years of work experience had a larger percentage of moderate STS than those with more than 5 years of work experience ($\chi^2 = 13.738$, $P = 0.008$). Working hours per day (h) longer, the STS was heavier ($\chi^2 = 46.748$, $P < 0.001$). When the job was more satisfied, the HCWs had lower anxiety and depression ($\chi^2 = 15.020$, $P = 0.005$) and secondary traumatic stress ($\chi^2 = 9.526$, $P = 0.009$). In addition, the HCWs had more

satisfaction by monthly salary, and they had poor levels of burnout, anxiety, depression, STS, and CS ($P < 0.001$) (Table 3).

4. Discussion

The current findings demonstrated that during the COVID-19 pandemic, HCWs had a high frequency of self-reported sociodemographic and psychological issues. The prevalence of anxiety, depression, burnout, and general psychological issues varied significantly among different types of healthcare employees. This research revealed several sociodemographic factors associated to HCWs to help officials and policymakers establish policies and improve HCW facilities. Due to their frequent use of empathy, extended exposure to secondary trauma, and work environment, healthcare practitioners are likely to feel depression, anxiety, burnout, and secondary traumatic stress [39]. In addition, the constrained resources and numerous healthcare needs during this time may raise the possibility of compassion fatigue. This evidence has increased the risk of psychological distress due to the pandemic.

According to our research, HCWs had to moderate degrees of anxiety and depression, whereas high levels of depression signs and symptoms were found in Indian healthcare professionals who were classified as having moderate-to-severe depression symptoms (22% of them) [40]. During the COVID-19 pandemic, HCWs who scored higher on fatigue, melancholy, anxiety, and stress also had a greater fear of contracting coronavirus [41]. In China, healthcare professionals and nurses experienced symptoms of despair, anxiety, insomnia, and discomfort two months after the first identified COVID-19 case [42]. Managing COVID-19 patients led to increased anxiety and reduced health-related quality of life [43]. Frontline healthcare workers with moderate-to-severe depression and anxiety symptoms saw a decline in their overall quality of life [40].

According to our research, medical staffs that have been exposed to the COVID-19 pandemic might experience both positive and negative psychological consequences. According to the results, STS and burnout were frequent, although levels of CF varied from moderate to high. While greater levels of CS and less CF were detected in HCWs who reported feeling highly content with their salaries, less BO was seen in HCWs who reported feeling highly satisfied with their earnings ($P < 0.05$). Similarly, during the pandemic, 72.5% of nurses were satisfied with their current job, while 73.6% of nurses were satisfied with their pay [44]. Less BO was experienced by nurses who were satisfied with their pay, while higher CS and less CF were seen in nurses who were highly satisfied with their jobs [13]. During the COVID-19 epidemic, similar findings were reported in Ecuador, where medical staff experienced mild to moderate burnout and CF [45]. Similar findings were made by Jordan et al. in their study, which revealed that high-income nurses had a low incidence of CF [46]. According to Tian et al., nurses who were dissatisfied with their salaries had higher BO [47]. In addition, in the study reported by Niu et al., nurses who reported having low job satisfaction were more likely to

suffer from CF, which is consistent with our findings regarding job satisfaction [13].

The results of this study showed that STS scores were greater than the crucial value, as well as higher than those of Turkish nurses prior to the pandemic and Italian nurses during the pandemic [48]. The signs and symptoms of STS can include anxiety, sleeplessness, and intrusive thoughts [49]. Patients with COVID-19 are more likely to experience mood swings, irritability, and grief [13]. HCWs who interact with these patients could feel a great deal of psychological pressure. It has been discovered that nurses fighting the pandemic are more likely to have symptoms of somatization [50]. As a result, it is essential to care about HCWs and STS, offer social and psychological support, promote a healthy team culture, and engage in proper exercise to lessen the pandemic's negative effects on HCWs.

In this study, HCWs with excessive workloads exhibited higher levels of BO and STS ($P < 0.001$), as well as substantially lower CS levels. According to certain research and our study, nurses who work a lot are more likely to experience STS, which lowers job satisfaction and BO [51]. In a 2020 study with 506 Spanish healthcare professionals, 94% showed moderate-to-severe compassion fatigue, 84% showed moderate-to-severe burnout, and 84.4% of the entire sample showed moderate-to-severe compassion satisfaction [52]. Burnout and secondary traumatic stress were more severe in physicians than in nurses. In addition, nurses had higher levels of compassion satisfaction. Another Spanish study of 973 healthcare professionals revealed that 90.6% had high levels of compassion satisfaction, noting that this trait is more common in people between the ages of 35 and 55 and that nurses outnumbered physicians even though nurses were more prevalent [53].

The study's findings showed that the COVID-19 pandemic significantly increased the burden of psychological issues among various healthcare professionals. The results imply that exposure to negative information about the pandemic may be linked to a higher risk of psychological issues. Participating in frontline work appears to be a significant risk factor for anxiety, sleeplessness, and psychological issues in general [54–56]. These results suggest the implementation of measures that go beyond saving patient lives with COVID-19 psychosocial interventions and support for healthcare workers, which will help us better understand the impact of pandemics on psychological health among HCWs. Early in the pandemic, support for transient psychological issues, including anxiety and depression, is required, along with evidence-based psychosocial therapies. Furthermore, stress should be placed on self-relaxation training, regular exercise, and a healthy lifestyle.

4.1. Limitations of the Work. This study has certain limitations, even if it adds empirically to the conversation about the ProQOL of HCWs. First, because the study was performed online, self-selection bias could have been a factor. Considering that a convenience sample was used, it is not possible to extrapolate the findings to other situations because they may not accurately represent the population. This

study was cross-sectional in design and evaluated ProQOL at a single moment in time within the particular era and COVID-19 pandemic scenario, care must be taken when interpreting the data. As the number of COVID-19 cases continued to rise in Pakistan during the fourth wave, hospitals faced increasing strain from the influx of patients. Government policies proved ineffective due to public indifference. Notably, the private sector hospitals in Pakistan outnumber government-run facilities, and they have a larger contingent of healthcare professionals, particularly physicians and doctors, compared to nurses and other healthcare providers. Consequently, during the fight against COVID-19, physicians had to take on the frontline roles compared to nurses and other professionals following suit [57]. In addition, there is a significant gender disparity in the healthcare workforce, with a higher proportion of men compared to women, largely attributed to the country's ongoing struggle for women's empowerment and education. This gender imbalance is especially prominent in roles such as nursing and nursing assistants, where men dominate the positions [58]. Another limitation of the study is its cross-sectional design, as the pandemic has since subsided and the study cannot capture the long-term impact on the mental health of these frontline healthcare workers. To address this, it would be advisable to conduct a longitudinal study to track the evolution of the mental health symptoms assessed in this research over time.

5. Implications for Nursing Management

Prior to fighting the epidemic, it is essential to teach HCWs about patient knowledge, epidemic control and preventive techniques and to build personal resiliency. Programs for stress management and peer social support are also essential to lower BO and STS levels, and they should offer efficient interventions to increase HCWs' satisfaction levels. The foundation of the healthcare system's physical and mental health must be protected; thus, governments must take the necessary action. Financial subsidies and rewards from the government are advised to increase work satisfaction for HCWs. According to our research, structural empowerment techniques can be developed by hospital administration and HCWs to improve HCWs' psychological empowerment. We also advocate for the development of counseling services, assistance, and programs to support HCWs' psychological well-being. These measures will help preserve a strong team culture.

6. Conclusion

The HCWs have moderate levels of compassion satisfaction, secondary traumatic stress, and low levels of burnout. High levels of perceived susceptibility and severity, as well as elevated psychological distress, are present in HCWs battling COVID-19. Healthcare professionals' levels of anxiety and CF may be impacted by professional contextual factors (poor income and lengthy hours). HCWs with a heavy workload and little pay had more severe depression and STS. The administration of the hospital must to keep a low degree of

burnout, increase CS levels, manage STS levels, and provide HCWs with a good work environment. Further research studies with different research approaches and different low-resource sceneries are suggested to address the professional quality of life level.

Aim. This study examined the mental health of nurse managers in the Kingdom of Saudi Arabia. *Background.* The COVID-19 pandemic has affected the physical and mental health of senior nurses, including effects of shortages of staff and medical supplies. However, no study has examined this topic among nurse managers in the Kingdom of Saudi Arabia despite their exposure to mental stress during the pandemic. *Methods.* A cross-sectional design was used to investigate the levels of depression, anxiety, stress, and general psychological distress among nurse managers in Saudi Arabia. Data were collected August 2023 to February 2024. The main tool was the reliable and validated Arabic translation of the Depression, Anxiety, and Stress Scale (DASS-21). Data collection was performed using an online platform. IBM SPSS software was used for data analysis. The data was analysed using multiple regression to examine the relationship between the dependent (outcome) and independent (predictor) variables. A significant *p*-value was set at 0.05. *Results.* Stress and general psychological distress were the most common problems among nurse managers in the post-COVID-19 era. Individual educational attainment was the only significant predictor of anxiety, stress, and general psychological distress. Moreover, the nationalities of nurse managers were correlated with stress outcomes. *Conclusions.* Nursing managers are very likely to suffer from stress and general mental health problems in cases of exposure to crises. They may find the results of this study useful in understanding the factors that may play a role in the development of mental health problems during clinical work. Different strategies can be considered to alleviate depression, anxiety, and stress among managers, including the proper delegation of tasks. Top-level management and healthcare stakeholders should give special considerations to the nationality and education level upon selecting nurse managers at different levels. *Implications in Nursing Management.* Policy makers involved in planning care for healthcare professionals may find this study valuable in planning for future pandemics by developing a strategy that could reduce stress and psychological distress.

1. Introduction

The role of care managers has become increasingly important since the advent of COVID-19 as competent care management can mitigate many of the problems that nurses face [1]. Hospital management by nurse managers has been found to be associated with staff shortages, crisis management, and related psychological problems [2]. Several factors put the physical and mental health of caregivers at risk from COVID-19, including shortages of staff and medical supplies, a lack of personal protective equipment (PPE), and limited hospital beds [3]. Nurse managers also struggle with physical and mental health problems [1]. COVID-19 has

presented a challenge to hospital managers as increasing demand for care was accompanied by workforce shortages and crisis management. The mental health of nurse managers can be compromised by demands of providing emotional support, managing medical supply and Personal Protective Equipment (PPE) inventories, and supporting team members during pandemics [4–6]. In addition, the lack of previous experience in dealing with pandemics and the lack of effective preparation by the respective authorities or policy makers could also contribute to the management challenges [1, 2]. The reasons given for the scale of the problem were the complex and expensive diagnostic procedures and therapeutic equipment and application

methods, combined with the need for more staff and the shortage of hospital beds, as well as disproportionate management for the allocation of resources and the lack of a standard program for the preparation and response phase, alongside inadequate staff training and practice and the varying experience of health managers, which made the situation more difficult for nurse managers and their subordinates [2, 3, 7].

To date, no study has examined the mental health of nurse managers in the Kingdom of Saudi Arabia (KSA) in this context, despite their exposure to psychological stress during the pandemic. The pandemic lasted for more than three years, and professionals have continuously taken precautions to contain it. It is believed that it is appropriate to assess the mental health of nurse managers since they have continuously provided managerial guidance and control during and after the pandemic, and the resulting stress can increase the risk of mental health problems. Hence the need for this study, which could potentially reveal the extent of the problem and possible measures to mitigate it in the clinical setting.

The COVID-19 pandemic has had a significant impact on the mental health of adults and children alike [8]. Nearly 50% of the respondents to a US survey had recently experienced anxiety or sadness, and 10% felt that their mental health needs were not being met [8]. The rates of anxiety, depression, and substance-use disorders have increased since the epidemic began [9]. People with mental illnesses or disorders that are worsened by COVID-19 were found to be more likely to die than people without mental illnesses [8]. Mental illness has become an important research topic, and researchers are developing strategies to diagnose, prevent, and treat them [8, 9].

Evidence suggests that infected individuals are more likely to develop mental illness or disorders, including posttraumatic stress disorder [9]. The symptoms associated with long COVID-19 can affect brain functioning and mental state [8, 9]. In particular, the presence of COVID-19 may be associated with cognitive and attention deficits (brain fog), anxiety, depression, psychosis, seizures, and suicidality [8].

There is a potential threat to the health and wellbeing of leaders of hospitals and healthcare organizations (including leaders in nursing) due to increasing demands for restructuring of infection control systems [8]. Therefore, it is necessary to examine the psychological state of leaders in nursing in the post-COVID-19 era. Such information could help in the future design and development of health system policies that address staff wellbeing. The study objectives were to investigate the levels of depression, anxiety, stress, and general psychological distress among nurse managers in the post-COVID-19 pandemic era and to explore factors that affect their psychological profiles.

2. Methods

2.1. Study Design, Population, and Settings. This study used a cross-sectional survey design. Participants were recruited from June to November 2023 using convenience sampling.

The software G*Power Online 3.1.9.4 was used to determine the sample size needed based on a previous study investigating ethical leadership of nurses with a moderate effect size of 0.65 [10]. With a power of 80% (0.8) and a significance level of 0.5, the required sample size was 76 participants. Taking into account the possibility of 20% attrition after 2 months, the total sample size for the study groups was 92 participants. The criteria for participation in the study were age >18 years, employment in a public hospital as a nurse manager (e.g., nursing directors, heads/supervisors of nursing departments, and ward managers), and the ability to speak Arabic or English. The participants were recruited from all regions of the Kingdom of Saudi Arabia.

2.2. Measures. A wide range of sociodemographic information was collected from the participants, such as age, sex, marital status, employment, and level of education. Data were collected online by a trained research assistant. Informed consent forms were provided to all eligible participants after an explanation of the study procedure was given.

The Arabic version of the Depression, Anxiety, and Stress Scale (DASS-21) was used to assess symptoms of depression, anxiety, stress, and general psychological distress [11–13].

The DASS-21 test contains 21 items and three subscales: depression, anxiety, and stress [11, 14]. With the exception of general psychological distress, which comprises all 21 items, all three subscales had seven items each. Each construct is measured with four-point Likert scale (0–3) representing frequency, where 0 represents “never,” 1 represents “sometimes,” 2 represents “often,” and 3 represents “almost always.” Based on the total number of items on each subscale, the total subscale scores range from 0 to 21 [15]. Multiplying each of the subscale scores by 2 gives a score similar to that of the DASS-42 [15]. Depressive symptoms were considered normal for scores of 0–9, moderate for scores of 10–13, severe for scores of 14–20, and extremely severe for scores of 20+. The stress subscale ranges are 0–14, 15–18, 19–25, 26–33, and 34+, with 0–14 indicating normal symptoms, 15–18 indicating mild symptoms, 19–25 indicating moderate symptoms, and 26–33 indicating severe symptoms [16]. Anxiety scores of 0–7 indicate fairly normal anxiety, 8–9 indicate mild anxiety symptoms, 10–14 indicate moderate anxiety symptoms, and 15–19 indicate severe anxiety symptoms [16].

The instrument has been translated into over fifty different languages and has been shown to be valid for assessing the constructs of depression, anxiety, and stress [17]. However, the construct of general psychological distress was also reported [18]. This confirms the existence of a two-factor model in its construct. DASS-21 has been psychometrically tested in diverse populations, including various racial groups with internal consistency ranging from 0.74 to 0.84 [19], clinical groups, and communities, with equally acceptable concurrent validity and internal consistency reliability [20], and nonclinical samples of adults (0.80–0.91) for the three constructs of depression, anxiety, and stress

[17]. Similarly, it was found to have internal consistencies of 0.72, 0.72, and 0.76 for depression, stress, and anxiety among the Internally Displaced Persons [18]. For this study, the Arabic and English versions were used. Finally, the four respective constructs in this cohort had an internal consistency of 0.82, 0.72, 0.61, and 0.50 for general psychological distress, stress, depression, and anxiety, respectively.

2.3. Ethical Considerations. Ethical approval was obtained from the Institutional Review Board of Jouf University with reference number 6-11-44. The study was carried out in accordance with the Declaration of Helsinki and in strict compliance with its principles. All subjects participating were provided with the necessary information about the study to provide informed consent and had the right to terminate participation at any time without penalty.

2.4. Data Analysis. The statistical software IBM SPSS version 20 (IBM Corp., Armonk, NY, USA) was used for data analysis. The level of significance was set at $p < 0.05$. Age, sex, marital status, employment status, and educational status were analysed using descriptive statistics of frequencies and percentages. Multiple regressions using the standard method were used to evaluate the predictive relationship between the independent variables (age, sex, marital status, education, and employment) and the dependent variables (symptoms of depression, anxiety, stress, and general psychological distress). The analysis was carried out based on the domains of DASS-21, so four different regression analyses were carried out and are presented as models 1, 2, 3, and 4. The results are presented as unstandardized coefficients (B) with standard error (SE), confidence intervals, R^2 values, and significance values.

Due to the categorical nature of marital status and employment, dummy variables were created. Age and education were treated as continuous variables because they were categorical variables with five levels of ordering. The three outcome variables of depression, anxiety, and stress symptoms were treated as categorical variables. Preliminary analyses were conducted to ensure the assumptions of linearity, homoscedasticity, and normality using scatter plots and residuals [21].

The Q-Q plot was examined for kurtosis and skewness to determine whether the data were normally distributed. A rectangular distribution of residuals against the predicted value was used to assess the assumption of homoscedasticity [22]. Several other checks were conducted, including the adequacy of the samples, the assumption of singularity, multicollinearity, and correlation examination.

Data cleaning was conducted for the entered data to identify any discrepancies between them and the raw data and ensure the accuracy of the analysis [23]. The data were checked against a printout for five datasets and were compared with descriptions when systematic errors were detected to identify missing data. The mean, standard deviation, frequencies, minima, and maxima were used to determine extreme values for continuous variables.

Incorrect data entries were indicated by unexpectedly low values in the minimum column [24]. The questionnaires were kept confidential in one drive.

3. Results

The majority of the study population was between 35 and 44 years old. A bachelor's degree was the most widely reported qualification of the nurse managers. High proportions of the participants were Saudi nationals (93.6%), married (77.1%), and employed full time (92.7%) (Table 1).

As shown in Table 2, multiple regression analysis was utilized to assess levels of anxiety, stress, depression, and general psychological distress after controlling for age, sex, marital status, education, and employment status. Models 1, 2, 3, and 4 showed variance of 8.0, 3.8, 9.4, and 8.7 for anxiety, depression, stress, and general psychological distress, respectively. However, only stress and general psychological distress reached statistical significance. The only variable that made a significant contribution to the development of anxiety was the level of education ($B = -1.60$, SE 0.62, 95% confidence interval (CI) $-2.83, -0.38$, $p < 0.05$). Individual nationality ($B = 2.48$, SE 1.07, 95% CI 0.35, 4.61) and educational level ($B = -1.78$, SE 0.78, 95% CI $-3.32, -0.25$, $p < 0.05$) were predictors of stress. Finally, education had predictive power for general psychological distress ($B = -4.83$, SE 1.79, 95% CI $-8.38, 1.28$, $p < 0.05$).

4. Discussion

To our knowledge, this is the first study to look at the psychological profile of nurse managers in the post-COVID-19 era in KSA. Factors that can contribute to the development of mental health problems among nurse managers were also examined. This study shows that stress and general psychological distress appear to be the most common problems among nurse managers in the healthcare sector. The individual level of education was the only significant predictor of anxiety, stress, and general psychological distress. It was also found that the nationality of the nurse managers correlated with stress.

Corroborating with similar studies, evidence have shown that healthcare professionals suffer from a range of mental health problems due to a lack of equipment and work overload, which may have an impact on the quality of care [25, 26]. This study found that educational level and individual nationality contribute to the development of stress, while education alone has predictive power for general psychological stress. Education has been shown in the literature to be a significant predictor of mental health (depression, anxiety, and stress) [25, 27]. In other words, marital status, gender, and monthly working hours were significant predictors of mental health [25]; however, they were not in this study. Therefore, further quantification is needed.

Stress has been reported to be a common problem among nurses and may be due to staff shortages, poor working conditions, inadequate management support, and

TABLE 1: Demographics.

high workload [28]. Furthermore, an association has been found among nurses between COVID-19-related work stressors and psychological distress [29–31]. Studies have also reported that nurses with lower educational qualifications are more stressed than those with higher qualifications [32]. The literature also shows that a lower level of

psychological stress can be correlated with a higher level of education, and vice versa [33]. Anxiety is also widespread among nurses with lower academic qualifications [34].

The emergence of COVID-19 has posed a threat to the health system and led to structural, environmental, and administrative changes or requirements that have continued

into the post-pandemic period. Therefore, the stress and general psychological distress in this study are not unusual. Evidence has shown that chronic stressors have affected people worldwide and across all sections of society, and without a doubt, the COVID-19 pandemic has been a contributing factor [35]. As a result, it may have provoked a crisis of unprecedented proportions in public mental health [35, 36].

The COVID-19 interventions have required all people to stay indoors and maintain physical distance in any situation (including in hospitals) or when they are out for any purpose [36]. The prevalence of common mental disorders such as depression, anxiety, and stress has been expected to increase in the post-COVID-19 pandemic period due to the long-term effects of restrictive measures such as quarantine and social distancing, as well as the socioeconomic consequences [37]. In an event of such magnitude as the pandemic, the impact on mental health can be long-lasting [37].

Physical and emotional exhaustion and fear of infection among nurses further aggravate their fears [38]. There has been a huge impact on people's mental health as well as on all current activities as a result of the aforementioned interventions [36]. In particular, positive mental health outcomes were associated with organizational support, readiness, safety, and materials and resources [38]. Evidence has shown that the health consequences of nurse management may be similar to those faced by front-line nurses [38].

The COVID-19 pandemic posed a resource challenge for many institutions, and nurse managers had the responsibility of managing human and equipment resources [38]. Nursing care managers in particular are responsible for making decisions regarding staff and patients, planning care, and supervising the nurses who provide this care [38]. They may have been impacted by uncertainty related to COVID-19 management because practical measures were constantly changing.

In KSA, nurse managers comprise both local people and expatriates. However, a study has shown that occupational stress is widespread among expatriates [39]. Therefore, it should not be surprising that stress is reportedly associated with nationality. Furthermore, psychological distress, anxiety, and stress are significantly correlated with education. This result is in line with the study by Golubic and colleagues [32], who found that nurses with a lower level of education experienced more stress at work compared to those with a college degree. A lower level of education could also be correlated with the development of anxiety, and according to Bjelland et al. [40], a higher level of education appears to protect against anxiety.

Similarly, studies have shown that there is a positive correlation between higher education and lower psychological stress [33]. The level of education alone could be a predictor of general psychological distress. Therefore, it is not surprising that general psychological distress is

significantly correlated with educational levels in the present study. Notably, only 12.8% of the study participants had post-graduate degrees.

4.1. Limitations. One of the limitations of this study is that the sample size was small, which could limit the generalizability of the results. Furthermore, the cross-sectional nature of this study limits our ability to infer causality and provides only a partial picture of the situation. As data were collected using a self-report questionnaire, the results cannot be interpreted with certainty. Therefore, an in-depth study using a mixed methods design that incorporate a qualitative component should be carried out to find out more about the mental health problems associated with COVID-19.

5. Conclusion

Although this study had limitations, it contributes to our understanding of mental health outcomes. Stress and general psychological distress appear to be the main mental health problems among nurse managers. It was also found that individual nationality and level of education play important roles in the development of anxiety, stress, and general psychological distress. The results of this study can raise nurse leaders' awareness of the levels of anxiety, stress, and depression and help to provide psychological support programs to improve nurses' mental health during the pandemic. Therefore, policy makers should develop a blueprint for monitoring the mental health of facility managers in public health facilities. Furthermore, healthcare institutions should ensure that more professionals with higher education be appointed as care managers. Managers should delegate tasks to junior staff as a strategy to deal with some work-related stressors.

Introduction. Shifting care from hospitals into community-based settings is a major policy goal internationally. Community health services in England currently face the greatest workforce shortages of all sectors, threatening the feasibility of this policy. Moreover, little is known about the extent of variation in community workforce provision regionally and how this relates to determinants of need. **Aim.** To analyse regional variation in the community services workforce in England between 2010 and 2021. **Methods.** We obtained NHS workforce statistics data on the number of nurses and nursing support staff providing community services at each NHS organisation in England, from March 2010 to November 2021. We aggregated the organisation-level data to both regional and national levels, which enabled us to maintain consistent units of analysis across the decade. To examine longitudinal trends and regional variation in workforce provision, we calculated the number of staff per 100,000 population aged 65+ in each region and each period. We then graphed and summarised the variation and examined the correlations with levels of deprivation and rurality. **Results.** There was a twofold variation in community services workforce provision between English regions. In November 2021, the number of staff per 100,000 people aged over 64 ranged from 300 in the South West to 697 in the North West. Most regions experienced a reduction in provision between 2010 and 2021, with a 21.2% reduction nationally. East of England experienced the largest reduction of 39.3%, whilst London experienced a 2.1% increase. In November 2021, regions with more deprived populations had higher workforce provision and regions with a larger proportion of residents living in rural areas had lower workforce provision. **Conclusions.** The size of the community services workforce has fallen relative to population needs, contradictory to the policy priority to enhance care in the community. There was substantial regional variation in the size of the workforce, which has persisted throughout the decade. Workforce provision was higher in more deprived areas but lower in rural areas, potentially impacting equitable access in rural areas.

1. Introduction

Healthcare workers have a fundamental role in the functioning of health systems, yet it is predicted that there will be a global shortage of 18 million health workers by 2030 [1]. England's National Health Service (NHS) is facing the greatest workforce crisis of its history [2], with workforce shortages across all health and care system staffing groups putting services under significant strain. The biggest shortfall

of staff is seen in nursing [3, 4], and recent figures have shown that the number of nurses leaving the NHS is at an all-time high [5].

Within the NHS in England, the adult community nursing workforce plays a crucial role in addressing the population's health needs in their homes and local communities, ideally reducing the need for hospital admission. They contribute to the provision of a diverse range of services, including long-term condition management,

reablement, wound care, and palliative care. Community health services currently account for approximately 10% of the NHS budget and deliver 100 million patient contacts each year [6].

In line with the goals of health systems internationally, the NHS Long Term Plan reaffirmed the long-standing policy objective of shifting care from hospitals to community-based settings [7], to be achieved by strengthening the provision and efficiency of community services. Moreover, the Fuller report envisages an important role for community nursing services in delivering more integrated care, working with staff in primary care to deliver a wider range of integrated services outside hospitals [8].

An effective community care workforce is required to deliver these plans. Due to the range of services provided by community health services, the workforce is comprised of a range of healthcare professionals, with 73% of those providing direct patient care being nurses and related nursing support roles [9]. However, community health services have been identified as the area experiencing the greatest shortage of nurses in England [10]. Whilst the number of full-time equivalent (FTE) registered nurses working in adult hospital care has increased by around 24% between 2011 and 2021, the number working in community nursing and health visiting has declined by 7% over the same period [11], with the number of community matrons and district nurses declining by 47% [12]. The challenges facing community nursing are so great that they have led to the development of a forthcoming strategic national community nursing plan aiming to strengthen capacity in the community nursing workforce [13]. This forthcoming plan is, however, much delayed.

Whilst the extent of community nursing workforce shortages has been assessed at a national level [11, 12], little is known about how workforce provision varies across the country. Equitable provision of health care is central to the founding principles of the NHS. In recent years, the NHS has committed to stronger action on health inequalities [7], by addressing unwarranted variation in healthcare provision and the relative disparities in access to services [14]. However, the vast majority of research to date has focused on primary and secondary care, with very little evidence on community health services [15]. Inequalities in the regional distribution of the community services workforce could prevent equitable access to services, impact patient experience and outcomes, and widen health inequalities. Regional variation in the community services workforce will also affect the ability of local systems to respond to the policy requirements to deliver a greater proportion of care in the community [8]. Examining whether the provision of these services varies across the country is a vital first step in understanding the sources of variation in care provision.

Social determinants of health are widely recognised as key drivers of health outcomes, health inequalities, and increased healthcare expenditures [16, 17], with environmental and socioeconomic determinants often shown to be the most influential factors determining health [18, 19]. The NHS aims to distribute the resources available to deliver care across geographical areas in a way that takes into account

such differences in the need for care [20]. Therefore, examining whether the regional variation in the community services workforce is associated with known drivers of need will provide important data to facilitate the development of meaningful workforce plans, which take account of local needs. We would expect to see higher workforce numbers in areas of deprivation or rurality if services are provided according to need, for example, because people living in rural areas have a higher reliance on community care due to difficulty accessing other healthcare services [21].

In this study, we aim to analyse the trends over time in the size of the community nurse and nursing support workforce in the English NHS between 2010 and 2021. Second, we aim to examine the extent of regional variation and whether this variation is related to two expected determinants of population need: deprivation and rurality [15, 16]. We focus on community nurses and the related nursing support workforce providing community health services to adults, as these services face increasing demands both from an ageing population with increasingly complex healthcare needs and from the introduction of new care models designed to boost out-of-hospital care [7, 22]. Therefore, this analysis will highlight areas with less adequate staffing and ones which may require specific remedial support. This will also give further insights into the factors affecting the ability of the NHS to meet its commitments to tackle inequalities in access to care and provide insights into potential targets for intervention, such as targeted recruitment and regional schemes to attract new staff [23].

2. Materials and Methods

2.1. Research Design. To examine the trends in the scale and regional variation in community nursing and nursing support workforce provision, we conducted a descriptive longitudinal study. The units of analysis were the whole of England or the seven NHS Commissioning Regions. The analysis presented in this study is part of a larger study aiming to better understand community services in the English NHS and their role in avoiding hospital admissions [24]. The analysis was designed by all authors in consultation with our patient and public involvement panel and following discussions with stakeholders in NHS England.

2.2. Data

2.2.1. Workforce. We obtained data from NHS Digital on the number of FTE nurses and nursing support staff listed as delivering community healthcare services, employed by each NHS organisation in England. The data cover the period from 31 March 2010 to 30 November 2021. Data are available on a quarterly basis for the first seven years of the series (31 March 2010 to 31 March 2017) and monthly thereafter (30 April 2017 to 30 November 2021).

The data are taken from NHS workforce statistics, which are extracted from the NHS human resources and payroll system [25]. It is possible that NHS organisations have opened, closed, or merged over the study period, with staff being transferred between organisations. We aggregated the

organisation-level data to both regional and national levels, which enabled us to maintain consistent units of analysis across the decade. Regions were classified as the seven NHS England commissioning regions [26].

The NHS workforce statistics data contain the number of FTE staff employed at all NHS organisations working in the speciality of community services. The data contain two main staff groups: “Nurses and health visitors” and “Nursing support staff,” distinguishing between registered and un-registered nursing staff. Registered nurses are clinically qualified healthcare practitioners on the Nursing and Midwifery Council register who have graduated from an accredited training programme [27]. Registered nurses coordinate, plan, and deliver patient care. Nursing support staff include Healthcare Assistants and Nursing Associates, who assist clinical staff in the care of patients, but who do not have professional registration. Due to this study’s focus on community services provision for older adults, we excluded nursery nurses, children’s nurses, and health visitors as these roles provide services exclusively for children. We also excluded nurses and nursing support staff working in the specialities of Community Learning Disabilities and Community Mental Health services as they serve different populations.

Independent Healthcare Providers play a significant role in the community health service sector in England, but data from non-NHS providers are sparse. To determine the size of the workforce delivering care outside of the NHS, we obtained data from NHS Digital on the number of nurses and nursing support staff working at Independent Healthcare Providers. This data collection began more recently and is therefore only available for the period of 30 September 2015 to 30 September 2021. Data for staff employed by Independent Healthcare Providers are only collected at six-month intervals throughout the series. Due to the way that the data are collected and the data sharing agreements in place, it is not possible to attribute this workforce to regions, so we presented this at the national level only.

2.2.2. Population Statistics. We obtained midyear population estimates of the usual resident population in an area covered by each Clinical Commissioning Group in England from the Office for National Statistics, for the period 2010 to 2020 [28]. Clinical Commissioning Groups were clinically led statutory NHS bodies responsible for the planning and commissioning of healthcare services for their local area. We interpolated these midyear estimates linearly between years to generate estimates for all quarters or months, to correspond with the workforce data availability. Population figures for 2021 were not yet available at the time of writing, so we used estimates from 2020. Clinical Commissioning Groups were assigned to NHS regions using mappings from the Office of National Statistics [29]. From these, we calculated annual counts of the population aged 65+ residing in each NHS region and nationally. This population was chosen because contact rates with community staff increase significantly following age 65, with this being the primary population served by the adult community workforce we examine [30].

2.2.3. Deprivation and Rurality. For each region, we calculated the proportion of the region’s aged 65+ population that lives in the most deprived quintile of lower layer super output areas in England, based on the index of multiple deprivation [31]. England is divided into 32,844 lower layer super output areas (LSOAs), which represent a geographical hierarchy designed for the reporting of small area statistics, with a mean population of 1,500 [32]. We then linked LSOAs to Clinical Commissioning Groups, which were then assigned to NHS regions using mappings from the Office of National Statistics [29]. We also calculated the proportion of a region’s aged 65+ population that lives in rural areas using the rural-urban classifications of LSOAs [33]. Urban areas are defined as the connected built-up areas identified by Ordnance Survey mapping that have resident populations above 10,000 people, and rural areas are those with fewer than 10,000 people or are open country side [34].

2.3. Data Analysis. To examine how the size of the national community service nursing and nursing support workforce has changed over the decade, we presented the longitudinal trends graphically and using summary statistics. We first examined the longitudinal trend over time in the total FTE NHS adult community nurse and nursing support workforce nationally, from March 2010 to November 2021. To examine whether the numbers of nurses and nursing support staff have kept pace with population growth, we also examined this longitudinal trend per 100,000 population aged 65+.

To examine the scale and regional variation in workforce provision, we then presented longitudinal trends in the total FTE NHS nurse and support workforce per 100,000 population aged 65+ in each of the seven NHS regions. This indicates how regional workforce capacity has changed over time, accounting for the size of the populations served.

We presented the number of adult community nurses and nursing support workforce at Independent Healthcare Providers nationally, in terms of both the total FTE and FTE per 100,000 population aged 65+.

Finally, at the regional level, we examined the relationship between the size of the community nurse and nurse support workforce (adjusted for the size of the region’s population aged 65+) and two expected determinants of the population need: the level of deprivation and rurality. Specifically, we estimated Pearson’s correlation coefficients between the number of FTE community nurses and nursing support staff per 100,000 population aged 65+ and (i) the proportion of a region’s aged 65+ population that live in the most deprived quintile of national LSOAs and (ii) the proportion of a region’s aged 65+ population living in a rural area. The size of the FTE workforce observed at our most recent time point, 30 November 2021, was used in these analyses. We also used univariate linear regressions to estimate the association between the size of the community services workforce and (i) the level of deprivation and (ii) the level of rurality. From these regressions, we then calculated the expected level of workforce per aged 65+ population for each region given its level of deprivation or rurality.

3. Results

3.1. National Trends in Community Nursing and Nursing Support Staff Workforce. Figure 1 presents the national trends in the number of FTE adult community nurses and nursing support staff employed in NHS organisations from March 2010 to November 2021 (raw numbers and per 100,000 population aged 65+). The size of the workforce decreased substantially during the first half of the decade, with a reduction of 7,400 (14%) total FTE staff between March 2010 and its lowest point in June 2015. When accounting for changes in the size of the older population served, there were 608 FTE staff per 100,000 population aged 65+ in March 2010 (Table 1). This fell by 24.7% to 458 staff per population by June 2015.

Whilst the number of staff started to rise during the second half of the decade, the growth in the size of the workforce since its low point in 2015 did not keep pace with population growth. As of November 2021, there was an average of 480 staff employed per population (Table 1). This figure is 21.2% lower than at the start of the series in March 2010.

In September 2015, Independent Healthcare Providers recorded employing a total of 5,450 FTE nurse and nursing support staff in adult community health service roles, equivalent to 56 FTE per 100,000 population aged 65+ nationally. This means that the size of the workforce reported by Independent Healthcare Providers was approximately 12.2% of the 459 staff per population employed by NHS organisations in September 2015. The number of staff employed by Independent Healthcare Providers had increased by 9% to 61 staff per population nationally in September 2020, which is equivalent to 13.1% of the 465 staff per population employed by NHS providers on that date.

3.2. Regional Trends in Community Nursing and Nursing Support Staff Workforce. There are stark regional differences in the size of the community nursing and nursing support workforce (Figure 2). Every year, there was around a twofold difference between some regions in the number of FTE staff employed per 100,000 population aged 65+. As of November 2021, there were 697 staff per population in the North West compared with just 300 in the South West of England (Table 1).

Regions experienced relatively similar rates of growth in the size of the population aged 65+ (Table 1, column 6), but much more variable changes over time in FTE staff numbers (Table 1, column 3). Regions therefore experienced vastly different trends in workforce per population over the period we examined. Most regions experienced a fall in staff in the first half of the decade to various extents (Figure 2), as seen in the national trends (Figure 1). However, London did not experience this initial drop, with workforce numbers instead staying relatively stable up until 2017 when they began to increase, resulting in a 2.1% increase in workforce per population across the period we examine. Conversely, the East of England experienced the most dramatic drop in workforce numbers at the start of the decade, with workforce

numbers then remaining low for the rest of the period. The size of the workforce in the East of England fell from 542 to 329 staff per population between 2010 and 2020, representing a 39.3% reduction in workforce provision. London was the only region where the size of the workforce kept pace with the growth in the size of the older population served. All other regions saw reductions in the size of their workforce per population over the period we examine, ranging from -15.4% in the North West to -39.3% in the East of England.

3.3. Regional Workforce and Deprivation. Deprivation levels vary substantially across the regions of England. In the South East, 5.8% of the population aged 65+ reside in the most deprived quintile of national LSOAs, compared to 26.2% of the aged 65+ population in the North West (Table 1). There was a strong positive correlation between the regional FTE workforce per 100,000 population aged 65+ and the proportion of this older population living in the most deprived LSOAs (Pearson's correlation coefficient = 0.81, p value: 0.028), as of November 2021. Regions with a greater proportion of their aged 65+ population living in deprived areas had higher levels of staffing (Panel 1, Figure 3), as demonstrated by the strong positive gradient observed in the line of best fit. Most regions fit this trend relatively closely except London and the North East and Yorkshire. London has 198 more staff per population than expected from the univariate regression, whilst the North East and Yorkshire has 82 fewer staff per older population than expected given the region's deprivation levels.

3.4. Regional Workforce and Rurality. The proportion of people residing in rural areas also varies across the regions of England. In the predominantly urban region of London, just 0.3% of the population aged 65+ reside in a rural area (Table 1). The South West has the highest levels of rurality, with 37.7% of the population aged 65+ residing in a rural area. There was a strong negative correlation between the regional FTE workforce per 100,000 population aged 65+ and the proportion of the older population living in rural LSOAs, as of November 2021 (Pearson's correlation coefficient = -0.88, p value: 0.008) (Panel 2, Figure 3). The East of England and the South West are the two most rural areas, with over one-third of their older populations living in rural LSOAs. These regions had just under half the workforce per population compared to the two least rural regions, London and the North West.

4. Discussion

4.1. Summary of Findings. Nurses play a vital role in promoting equitable and essential care, yet workforce shortages and inequitable geographical distributions of staffing pose challenges for health systems across the globe [35]. Most evidence to date has focused on understanding the nursing workforce in acute settings rather than nursing in the community. An effective community nursing workforce is required to support the delivery of the new models of care designed to enhance care provided outside of hospital, yet

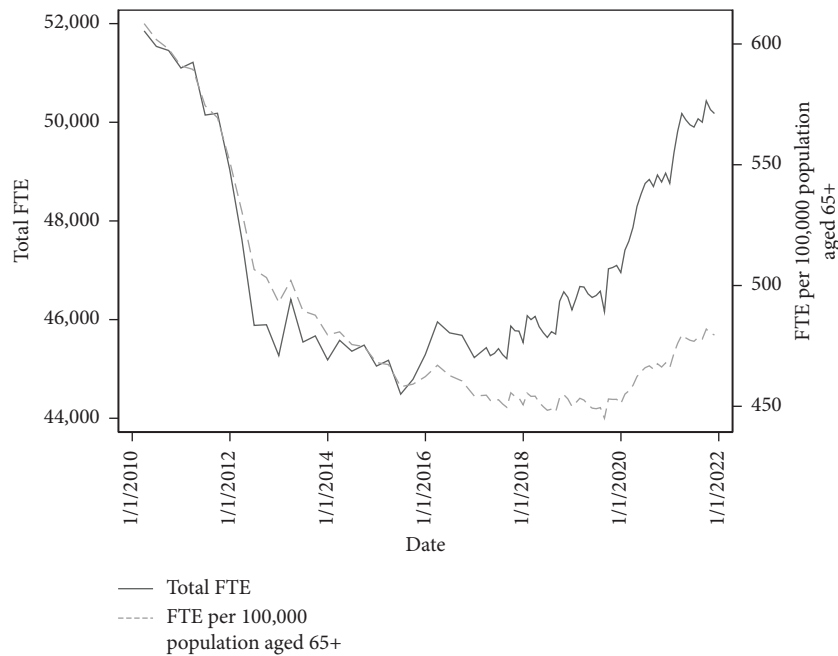

FIGURE 1: National trends in adult community nurse and nursing support workforce, total FTE, and FTE per 100,000 population aged 65+.

little is known about trends in the community services workforce within the English NHS and how this varies across the country. Our analysis demonstrates how the community nurse and nursing support staff workforce has changed over time in England, how it varies regionally after accounting for the size of the potential populations served, and how workforce provision is related to two factors expected to reflect higher levels of need amongst the population: deprivation and rurality.

There was a significant decline in the first half of the decade in the number of nurses and nursing support staff providing adult community health services in NHS organisations. Although there was growth in staffing in the later part of the decade, the number of FTE staff was still lower in 2021 than in 2010 after adjusting for the size of the population aged 65+ served. The growth in the size of the workforce since its plateau in mid-2015 has failed to keep pace with population growth, resulting in 21% fewer FTE staff per population at the end of the series in November 2021. In addition to population growth, patient complexity and need are also known to have increased during this period [36], meaning that the demands placed on the workforce have likely grown even further than is reflected by simple population counts.

Some of this initial decline may have been a result of the “Transforming Community Services” programme, which was implemented in March 2011 and required Primary Care Trusts (PCTs) to separate their provider and commissioning responsibilities for community services [37]. In response, the provision of community services was transferred to a range of organisations. The majority was transferred to NHS organisations through the creation of standalone NHS Community Trusts or merged with existing Acute or Mental Health NHS Trusts. The remainder was transferred to

organisations outside of the NHS, such as voluntary and independent sector providers [38]. However, the resulting shift of some staff to Independent Healthcare Providers is unlikely to have been large enough to fully explain the decline seen within NHS organisations. Whilst we do not have data on the Independent Healthcare Provider workforce before September 2015, we find that the total size of their community nurse and nursing support workforce recorded is just 12% of the NHS workforce during the period we can observe, at around 5,450 FTE staff in September 2015. The recorded Independent Healthcare Provider workforce was therefore not large enough to account for the observed reduction of 7,400 FTE staff employed by NHS organisations from March 2010 to June 2015.

We find stark variations in the levels of adult community nurses and nursing support workforce in different areas of the country. There was a twofold difference in the number of FTE staff between regions after controlling for the size of the older populations they serve. Regions also experienced different trends in their workforce over the series. Whilst staffing levels per 100,000 population aged 65+ remained relatively consistent across the series in London, this was the only region not to experience a decline in the size of its NHS workforce after adjusting for population growth. FTE adjusted for population size was 2.1% higher in London at the end of the series, whereas the East of England experienced a reduction of -39.3% in the size of its population-adjusted workforce.

Regional variations in the size of the adult community nurse and nursing support workforce are strongly patterned according to the level of deprivation experienced by the regions’ populations. Deprivation is a key determinant of community service need [30], so this suggests that regional variations are warranted as they correlate closely with this

TABLE 1: Community nurse and nursing support staff workforce and population size and characteristics.

Region	FTE staff			Population aged 65+			FTE staff per 100,000 population aged 65+			The proportion of aged 65+ population living in rural areas in November 2021	
	Mar 2010	Nov 2021	Change (%)	Mar 2010	Nov 2021	Change (%)	Mar 2010	Nov 2021	Change (%)		
East of England	5,609.23	4,260.93	-24.04	1,035,031	1,295,979	25.21	541.94	328.78	-39.33	7.50	34.92
London	5,804.98	7,284.70	25.49	893,928	1,098,453	22.88	649.38	663.18	2.13	13.08	0.26
Midlands	9,977.09	10,277.59	3.01	1,661,849	2,030,374	22.18	600.36	506.19	-15.69	16.87	25.94
North East and Yorkshire	10,742.15	9,160.58	-14.72	1,428,503	1,681,146	17.69	751.99	544.90	-27.54	23.16	24.03
North West	8,724.48	9,167.87	5.08	1,059,811	1,316,247	24.20	823.21	696.52	-15.39	26.17	11.37
South East	6,659.30	6,210.24	-6.74	1,424,852	1,770,422	24.25	467.37	350.78	-24.95	5.83	24.86
South West	4,334.71	3,815.70	-11.97	1,018,242	1,271,398	24.86	425.70	300.12	-29.50	7.37	37.68
England total	51,851.94	50,177.60	-3.23	8,522,216	10,464,019	22.79	608.43	479.53	-21.19	14.47	23.46

FIGURE 2: Regional trends in adult community nurse and nursing support workforce, FTE per 100,000 population aged 65+.

indicator of need. However, the magnitude of this difference is striking and is contrary to the inverse care law, which has been shown to exist in many other care settings [39]. For example, the provision of general practitioners in an area has previously been found to be inversely related to the deprivation of the population [40]. This suggests that, unlike other healthcare sectors, the community workforce aligns better with deprivation, at least at the regional level. There are also some regions for which this variation is not well explained. London, for example, appears to be an outlier to this trend, having a much higher FTE workforce per population relative to its deprivation levels. This would suggest London may be most able to prioritise the expansion of community services following the recent policy agenda.

Whilst workforce provision follows a positive relationship with levels of deprivation, we find that regional variations are inversely related to rurality. This is in part because deprivation and rurality are themselves moderately negatively correlated. However, if rurality was independently positively associated with workforce provision, we would not expect the regional variation to follow deprivation levels only. A survey of community nurses found that teams serving predominantly rural areas covered an average area of a 17-mile radius compared to 10 miles in urban areas [41]. It has therefore been argued that rural areas require more staffing to account for additional travel distances and the resulting lower proportion of overall time spent with patients associated with serving more remote areas and dispersed populations [42]. Furthermore, people living in rural areas have a higher reliance on community care due to difficulty accessing other healthcare services [21]. However, we observe the opposite relationship when examining workforce provision across England; the two regions with

the largest provision of adult community nurses and nursing support workforce per head are those with the lowest proportion of their older population living in rural LSOAs. Our results suggest that populations in rural areas may face inequalities in access to, and provision of, adult community services. This in turn could compound the inequalities in access to other healthcare services known to exist in rural areas, particularly in secondary care, with travel time to the nearest hospital double for people residing in rural compared to urban areas [21].

4.2. Comparison with Previous Research. We are not aware of any published analyses of the regional variation in the distribution of the adult community nurse and nursing support workforce. Our findings are, however, in line with existing research that has demonstrated the existence of inequalities in the distribution of healthcare workers internationally. Studies have demonstrated inequalities in the density and distribution of nurses between countries [43, 44] and at a subnational level within 58 countries [45]. However, these studies did not focus specifically on community nursing. Previous studies have also found substantial subnational geographic variation in the distribution of general practitioners internationally [46–48] and within the English NHS [49, 50]. The previous finding that fewer general practitioners are employed in practices in more deprived areas in England [40] contrasts with the findings of our study, where we find the opposite relationship between adult community workforce provision and deprivation. This suggests that the community workforce may align better with deprivation, in contrast with the primary care workforce.

Previous descriptive analysis of NHS workforce statistics shows that the number of nurses and nursing support staff working in acute adult care settings in NHS hospitals increased by 24% nationally, between December 2011 and December 2021 [11], whilst the number working in either community or health visiting decreased by 7% nationally. However, importantly, these analyses combined adult and children's community services, did not account for population growth, and did not examine regional variations as we did in this study.

Recent studies have assessed the trends in the size and composition of the wider primary care workforce in the English NHS. Between 2015 and 2019, there was a 2.9% increase in the total workforce employed at general practices per 1,000 patients, combined with an expanding skill mix of the general practice workforce [51]. The number of practice nurses per 1,000 patients remained fairly constant, but there was an increase in the number of advanced nurse practitioners [51]. However, this study only examined the primary care workforce from 2015 onwards, which is the period from which we observe the size of the community workforce to begin to increase again following a decrease in the first half of the decade.

The number of staff employed at general practices was also found to vary between regions of England [52]. The lowest number of primary care staff per 1,000 patients was

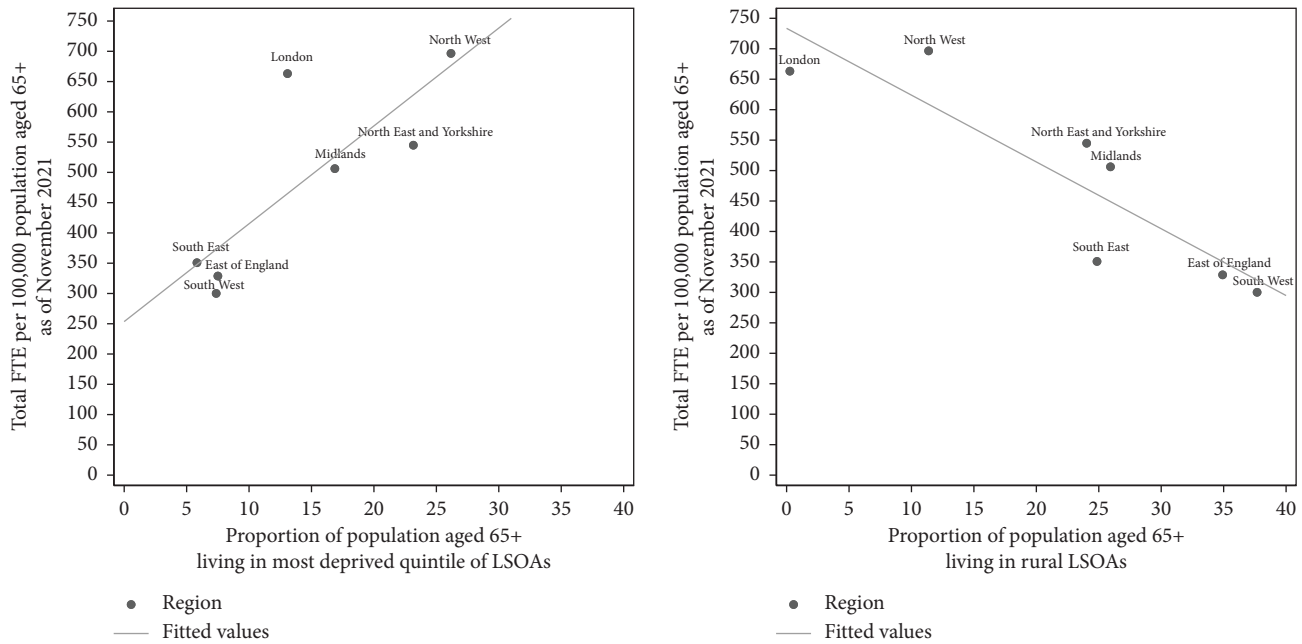

FIGURE 3: Relationship between adult community nurse and nursing support workforce size and deprivation and rurality.

seen in the London and South East regions of England [52]. Whilst we do not examine all types of community health service staffing, we do find the South East to be amongst the regions with the lowest community nurse and nursing support workforce. The regions with the highest number of primary care staff were those in the South West and North East [52]. We also show that the North East of England had levels of community nursing and support staff above the national average.

4.3. Strengths and Limitations. This is the first national and regional analysis of trends in the number of nurses and nursing support staff employed to provide adult community services in NHS organisations in England. Previous research has focused on either the entire NHS nursing workforce employed across all care settings or only subsets of the community services workforce, such as district nursing, and none have assessed regional variations in the community services workforce. None have examined geographical variation, or how provision relates to deprivation and rurality. We have a long time series containing over 10 years of data, which covers several important policy changes implemented in community health care.

Whilst most community healthcare services are provided by NHS organisations, a proportion is provided by Independent Healthcare Providers. We present data on the number of nurses and nursing support staff providing adult community services recorded by Independent Healthcare Providers nationally. These data are not available for the full period that we have access to data from NHS organisations, starting instead from September 2015. Furthermore, there is an agreement with some Independent Healthcare Providers that data will not be disaggregated below the national level; therefore, we are unable to examine the regional differences in community services provision from Independent

Healthcare Providers. It is therefore possible that the regional distribution of the adult community nurse and nursing support workforce employed by Independent Healthcare Providers could explain some of the observed regional variation in the NHS community workforce that we detect. However, the reported size of the workforce employed by Independent Healthcare Providers is not large enough at the national level to explain the reductions in the NHS workforce observed during the period we examine.

Due to how NHS workforce data are collected by NHS Digital, we are unable to capture the wider allied healthcare professional and medical workforce employed in the community setting. However, 73% of clinical staff providing community services are nurses or nursing support staff, so we can capture the majority of the workforce providing care in this setting [9].

5. Conclusions

The size of the community nurse and nursing support workforce has fallen relative to population needs, contradictory to the long-standing policy priority of enhancing care in the community. There was substantial regional variation in the size of the workforce, which has persisted throughout the decade. Workforce provision was higher in more deprived areas, but lower in rural areas.

These results focus on the nursing and nursing support workforce as data on alternative roles such as doctors and allied health professionals were unavailable. However, this remains an important avenue for future research and should be the focus of future data collection efforts. Furthermore, the need for consistent units of analysis required us to aggregate the data to the regional level; however, there may be wider inequalities at smaller geographical area levels [51, 52].

5.1. Implications for Nursing Management. Boosting out-of-hospital care through increased investment in community health services has been a key policy goal of the NHS for several years. Similarly, the NHS Long Term Plan committed to more action on health inequalities by addressing unwarranted variation in care provision. The findings of this study highlight the need for further action towards addressing community health services nursing workforce shortages nationally and particularly in rural regions, where levels of provision are lower than urban counterparts, potentially preventing equitable access for rural populations.

The failure of size of the workforce to keep up with population growth means that the community nursing workforce will be more stretched and under more pressure than ever before. Therefore, the insights gained from this study in terms of the scale and patterns of inequalities can be used by policymakers to effectively plan nurse recruitment and retention programmes and improve the sustainability and equity of community health services.

Data Availability

NHS workforce data are publicly available here, at one level of aggregation higher than we utilise: <https://digital.nhs.uk/data-and-information/publications/statistical/nhs-workforce-statistics>. We were provided with a longitudinal community services specific subset of these data upon request from NHS Digital. All other datasets are publicly available, and sources are cited throughout the manuscript.

Ethical Approval

Study registration: Proportionate University Research Ethics Committee (UREC) approval granted from The University of Manchester UREC. Registration number: 2022-15310-25431.

Background. Registered Practical Nurses (RPNs) are considered a critical component of high functioning nursing and interprofessional care teams. Therefore, it is important to ensure that RPNs feel valued within their roles within acute care settings. High acute care demands in tandem with unsupported workplace environments can lead to increased levels of job dissatisfaction, burnout, and ultimately impact retention. Identifying and examining the barriers and facilitators that enable RPNs to be optimally equipped within acute care are critical towards ensuring success in their role. In this study, we explore the experiences of RPNs and perspectives of nurse leaders on RPN integration into an acute care setting. **Methods.** A mixed method study among RPNs ($n = 10$) and nurse leaders ($n = 10$) was conducted. This included administration of the Assessment for Collaborative Environments (ACE-15) tool to measure interprofessional integration, collaboration, and teamwork. Semi-structured interviews were also held with all participants to explore both the lived experiences of RPNs in the acute care environment and the perspectives of nurse leaders who had supported the onboarding and integration of RPNs. **Results.** Our inductive content analysis identified 5 themes: preintegration process, nursing team dynamics, RPN role clarity, challenges to RPN integration, and benefits to RPN integration. ACE-15 data showed no significant differences in the level of teamness and internal disagreement between RPNs and nurse leaders ($t(17) = 0.37$ and $p = 4.60$). RPNs reporting a higher level of teamness described a more positive integration experience than those who reported a lower level of teamness. **Conclusion.** The integration of a new role to existing teams brings both benefits and challenges which are experienced uniquely by RPNs and nurse leaders. Nurse leaders can utilize findings of this study to better prepare their staff and units for the integration of new roles into their models of care.

1. Introduction

A shortage in nursing capacity within acute care settings continues to burden the Ontario healthcare system [1]. As a result, nurses are experiencing higher levels of burnout, while patients are experiencing compromised levels of quality patient care [2]. To alleviate burdens due to nursing staffing shortages, new nursing care delivery models are being implemented [3, 4]. Such models include the reintroduction of Registered Practical Nurses (RPNs) into acute care [4].

In Ontario, Canada, nursing is one profession with multiple categories which include Registered Practical Nurse (RPN) and

Registered Nurse (RN). The main distinction between RNs and RPNs is foundational education. While RNs and RPNs acquire similar nursing knowledge, RNs study for a longer period of time, allowing for a greater depth and breadth of foundational knowledge [5]. In Ontario, a two-year diploma is required for RPNs and the nursing curriculum consists of courses such as basic human anatomy, practical nursing theory, and practical skill labs. RNs usually complete a four-year post-secondary university nursing program. Although there are significant areas of overlap for the two categories of nurses, differences in responsibility can be identified in terms of the depth, breadth, and scope of involvement with patient care [6]. RPNs are employed

in various settings including long-term care, hospitals, and community settings.

The additional educational requirements over the years have enabled RPNs to increase skills in clinical training, thereby expanding overall scopes of practice [7]. Furthermore, the literature has identified that RPNs are considered a critical component of high functioning nursing and interprofessional care teams [3, 8]. Therefore, it is important to ensure that RPNs feel valued within their roles within acute care settings.

High acute care demands in tandem with unsupported workplace environments can lead to increased levels of job dissatisfaction and burnout, and this ultimately impacts retention [9]. Identifying and examining contributing factors that enable RPNs to be optimally equipped within acute care are critical towards ensuring success in this role.

Over time, hospitals try to respond to changing workforce demand environments by adjusting their models of care. Our acute care centre is one such example. In the 1990s, our organization was an RN and RPN staffed hospital. The RPN role was more task-based at this time and RPNs worked under the supervision of an RN. During this time, the organization phased out the RPN role in preference of an exclusively RN staff. In response to changing demands including staff shortages, the RPN position has been reintroduced. While the RPN role has been reintroduced, it is important to be mindful that the RPN role has evolved over the past 30 years, with much more autonomy in practice. Furthermore, role evolution has resulted in overlapping scopes of practice with the RN role. Therefore, it is essential to understand the challenges and opportunities presented with the integration of the RPN role into the acute care setting.

Our study explores the experiences of the RPNs as they were reintegrated into our acute care setting. In particular, we evaluated how RPNs adjusted to work within an acute care setting that was previously all RN staffed through exploring the barriers and facilitators to practice. We also explored the perspectives of Nurse Leaders (NLs) including Clinical Leader Managers (CLMs), Clinical Educator-Nursing (CE-Ns), and Charge Nurses (CNs) in order to identify current and potential strategies which would best support the transition of RPNs to the acute care environment. Moreover, our study aimed to identify what strategies increased confidence and readiness to care for various patient assignments across differing units. Findings from the perspectives of RPNs and NLs were synthesized in order to present a fulsome representation of the RPN integration experience.

2. Methods

2.1. Setting. This study took place at an academic health science centre in Toronto, Canada. Our organization is a 450 bed centre which provides primary, tertiary, and quaternary care services. The clinical workforce is comprised of approximately 1914 nurses (1760 RNs and 154 RPNs) and 950 other health discipline clinicians.

2.2. Study Design. The study employed a mixed method approach utilizing both quantitative and qualitative methodologies. Quantitative data were collected using the

Assessment for Collaborative Environments (ACE-15) tool as well as a demographic survey to describe participants' work history. The demographic survey included clinical role, length of time on the unit, employment status, and the timing of typical shifts worked (i.e., weekday and weekend).

The ACE-15 is a 15-item measure with each item scored on a 4-point Likert scale ranging from 1 (strongly disagree) to 4 (strongly agree). Example items include "Team members appreciate each other's roles and expertise" and "All voices on the team are heard and valued" [10]. The total item scale runs from a reported low level of integration of 15 to a high level of integration of 60. The higher the score, the higher the perception of interprofessional integration, collaboration, and teamwork. An inductive qualitative approach using semi-structured interviews was utilized to explore RPN and NL perspectives on the integration of the RPN role at our organization. In particular, interpretative phenomenological analysis (IPA) was the framework used to analyze qualitative data. IPA employs a phenomenological, hermeneutic, and idiographic approach together within one methodology, thereby being the most suitable to approach the phenomenon of interest [11].

2.3. Participants. RPNs were eligible to participate in this study if at the time of the study they were employed as an RPN at our organization and had 3 months or more experience as an RPN at the study site. NLs were eligible to take part in the study if at the time of the study they were employed at the organization and responsible for the onboarding and nursing orientation of RPNs.

2.4. Procedures. Ethical approval of this study was received from the Research Ethics Board of the hospital. Eligible participants were recruited through an emailed study invitation letter from CLMs and CE-Ns who have RPNs on their units. The study was also advertised through the hospital's broader communication channels and biweekly newsletters as well as existing mailing lists. Potential participants were provided with the study team's contact information and were instructed to contact the study coordinator for additional information. The study coordinator reviewed the study with interested participants, obtained consent, and sent participants an online survey link which had both a demographic survey and the ACE-15 measure. Following completion of the survey and ACE-15, the research coordinator scheduled an in-depth interview with participants.

2.5. Interviews. All participants took part in semi-structured individual interviews which ran between 30 and 60 minutes. Interviews took place using Zoom, and audio recordings were extracted for transcription. At the start of all interviews, participants provided verbal consent to ensure willingness to continue taking part in the study. Interviews were scheduled at a time that was convenient to participants. A study team member (N.W.) with expertise in qualitative interviewing completed interviews with all participants.

Two separate semi-structured interview guides (RPN and NL versions) were developed (Appendix A). The RPN interview focused on onboarding and orientation to the

hospital and integration to particular units, preparedness for the RPN role, supports (people and resources) in daily work activities, and challenges in the RPN role. The NL participants were asked about the onboarding and orientation of RPNs, the impact of RPN introduction on teamwork dynamics, and the benefits and barriers to RPN integration. As the interviews were semi-structured, participants had the flexibility to discuss additional topics and experiences which they deemed significant to the study topic. Data collection ended when the research team collectively agreed that thematic saturation was reached.

2.6. Data Analysis. Descriptive statistical analysis was performed. Proportions were generated for categorical data. Means, standard deviations, medians, and range were generated for each item in the ACE-15 measure from all respondents. Means, standard deviations, medians, and the range were summed to create an overall score. A two-tailed unpaired *t*-test was used to determine if there was a significant difference in the overall score of teamness between RPNs and NLs.

All interviews were audio recorded using Zoom and transcribed verbatim. Two members (N.W. and M.D.) of the study team individually completed an inductive content analysis beginning with a line by line review of all the transcripts in order to develop a comprehensive understanding of the data and ensure the subsequent coding trees were created with fidelity to the data (Appendix B). RPN and NL interviews were treated as separate datasets. N.W. and M.D. together generated a set of preliminary codes through open coding [12]. To develop reliability and trustworthiness, the transcripts were coded individually by N.W. and M.D. and emerging codes were compared and reviewed until consensus was achieved. Following this, the initial coding tree was revised and previously coded transcripts were recoded as needed to incorporate newer codes. Finalized codes were discussed with all research team members in order to integrate RPN and NL themes in the final analysis.

3. Results and Discussion

3.1. Participant Demographics/Characteristics of Study Participants. 16 RPNs responded with interest to either a study invitation letter or hospital wide communications advertising the study. 4 did not reply to a response e-mail, outlining study participation requirements, 2 did not complete the interview due to scheduling difficulties, and 10 completed the interview. 10 NLs responded to the study invitation, and 10 completed interviews. In both groups, 70% of the participants ($N=20$, $\chi^2(1)=0.95$, and $p>0.05$) have been working on the unit for under a year. 65% of the participants ($N=20$, $\chi^2(1)=1.98$, and $p>0.05$) have been in the nursing profession for more than 5 years. Majority of the participants (80%, $N=16$, $\chi^2(1)=1.25$, and $p>0.05$) worked full time compared to part time. Majority of the RPNs (90%, $N=9$) worked rotating shifts, whereas majority of the NLs (80%, $N=8$) worked day shifts. A chi-square test of

independence showed that there was a significant relationship between day and rotating shifts ($\chi^2(1)=9.90$ and $p<0.05$).

3.2. ACE-15. The ACE-15 tool is an assessment of the quality of interprofessional teamwork in clinical sites. This measure is a 15-item, self-report survey appropriate for a broad array of health professionals working in a variety of clinical sites. Scores from the NLs' responses ranged from 37 to 60 with a mean of 48.6 and a standard deviation of 8.6, whereas the scores from the RPN responses ranged from 31 to 60 with a mean of 46.9 and a standard deviation of 11.1. A higher mean score and a lower standard deviation indicate more teamness and less internal disagreement. All of the RPNs and 9 of the NLs completed the ACE-15 (95% response rate). There was no significant difference in the level of teamness when comparing the NLs with the RPNs ($t(17)=0.37$ and $p=4.60$).

Figure 1 shows these results pictorially.

3.3. Qualitative Themes. Our inductive content analysis identified 5 themes. 4 themes ran across the two participant groups including preintegration process, nursing team dynamics, RPN role clarity, and challenges to RPN integration. One theme unique to the NLs was benefits to RPN integration.

3.3.1. Preintegration Process. RPNs and NLs both described the process of preparing individual teams and/or units for the integration of RPNs. The extent to which established teams were receptive to the introduction of RPNs onto their team was shaped by the education and preparation from NLs as well as the extent to which RNs had prior experience working with RPNs.

Both groups explained that there were RN concerns around workload, patient safety, job security, and general uncertainty about the new team model. Participants also discussed how pre-existing beliefs and assumptions about RPNs needed to be addressed and the addition of RPNs was framed as an opportunity to enhance the strengths of the existing team.

I think it was fortunate for me having worked with RPNs in the past, like helping the roll out of RPNs on the unit it came in handy for sure. Because I think like part of the stressful part about introducing RPNs is there are a lot of people who've never worked with RPNs before and they didn't know, you know, what it would look like? What does that mean to me and my workload, or to the patients and all that. So, having that experience, made it really helpful. (NL 019)

A lot of them [RNs] were very hesitant for us to be integrated even into the area that we were integrated into originally, because they had no knowledge about what our scope was, and instead of just educating themselves on what our scope is, made presumptions about what we could and couldn't do. (RPN 004)

FIGURE 1: ACE-15 scores.

Another NL suggests that nurses who have worked with RPNs in the past should speak about their collaboration experiences with their current team. This would be helpful to alleviate or address some of the concerns of existing team members and provide a sense of what the new team model will look like in terms of working with the patient population on the particular unit and how the new roles will inform one another.

I think first talking to the RN team, if they're not used to working with RPNs, and identifying any challenges that they foresee and then addressing those challenges before integrating the RPNs would help a lot, especially with the culture, if it's going to be a huge culture shift. You don't want to integrate RPNs when RNs are not being receptive. So addressing those barriers before integrating the RPNs into the unit, I think would be very beneficial. (NL 007)

Many participants addressed the culture of the unit as a salient aspect of the preintegration landscape. One of the NLs describes her unit as being fairly new and therefore lacking an established culture or history of a particular nursing model. As such, with the onboarding of RPNs, there was not a significant change to nursing practice as the unit was still building their processes and procedures.

One NL explained the need to educate the nursing team and build relationships when there is a change and a new blending of team members:

...you can't introduce a new role without someone else feeling like, who is this person? why are they here? what does this mean for me? And honestly, like, I had one nurse who actually said that, like, what does this mean, for me? So having people to talk to about that, and their biggest fears, their, you know, fantasies of what might happen, I think is critical to success when you're changing skill mix on a team. (NL 010)

NLs also noted that prior to the RPN integration, there was corporate communication, program level discussion, and unit specific education about the value of the RPN role, the RPN scope of practice, and how RPNs would fit into the existing team.

3.3.2. Nursing Team Dynamics. Nursing team dynamics emerged as a strong theme in the interviews as both RPNs and NL described the nature of the relationships between RPNs and RNs once RPNs were brought into the hospital. Some CENs and CLMs discussed tension early on as RPNs joined their teams. The RPNs also explained that there was initially some resistance when they joined their teams. As one RPN reflects,

There did seem to feel like a little bit of a divide, I don't know if that was just like me just overthinking things. But after a couple of weeks, in really getting to know the other staff, I could kind of tell that they didn't really care as long as the patients were kept safe. (RPN 009)

Another RPN describes that when they first came to the hospital, there were concerns about whether they could be trusted as capable members of the nursing team. An important component of integrating onto the team was patience as trust between RPNs and RNs was established.

I think when they when we [RPNs] first came in, they [RN]s felt like they couldn't trust us. I kept telling myself we are new to each other and it takes years. Just be patient. (RPN 003)

A NL describes the shift in RN feelings towards RPNs postintegration:

I believe that especially a couple of my naysayers, they've come around. I think it's because we had to prove it, they

had to live it, they had to see that, in fact, this [RPN integration] wasn't negatively impacting their assignments, and that these people [RPNs] were great team players, and that care being provided for patients remains the same. (NL 015)

Peer support between RPNs on a team was highlighted as a strategy to mitigate the tensions felt during the early days of integration. As one RPN explains, "a lot of the times, RPNs have to support RPNs as much as we can" (RPN 004).

Participants explained that over time there was a positive shift in the dynamics of the teams. The teams were described as being more cohesive and supportive. Many explained that they felt they were a nursing team as opposed to "RPN vs. RN." One RPN notes that she felt very supported by her team members and this gave her confidence to ask questions as she was learning the new role.

I was always supported when it came to my shadowing shifts. I always had somebody with me and anytime I had any type of questions, I would just full on ask them. I never felt afraid to ask any type of questions when it came to care. (RPN 008)

3.3.3. RPN Role Clarity. Participants explained that the role of the RPN as a unique designation with separate responsibilities from RNs was not always clear. One RPN explains, "RPN and RN care is not black and white, it depends on the care, patient, and staff who are on" (RPN 005). Another RPN states, "they limit what we can take on as RPNs. And sometimes it feels like there's a very blurred line" (RPN 009). The lack of role clarity was especially prevalent in units where there is less acuity in the patient population. As described in the interviews, RPNs are meant to take on patients who are more stable and predictable, while RNs accept patients who are less stable and less predictable. As such, more patient acuity in a unit suggests more differentiation between RPN and RN roles.

Generally, I do know that what is supposed to happen is that the patients who are more acutely ill, and whose status changes quicker, those patients are technically supposed to be given to the RNs and the more stable patients are supposed to be given to the RPNs. I don't believe in my personal opinion that is very true on this particular unit. I think that on this particular unit that all of the nurses are given equal assignments. (RPN 008)

So usually, they would like to assign patients with predictable outcomes to RPNs, anything that they're concerned where a patient may change, and it will require a lot more critical thinking, analysis work from an RPN, that's when you would choose to give the patient to an RN. But at the same time, it doesn't negate what an RPN can do, they could still have a more critical patient, but just making sure that there is an RN available for guidance in case of any kind of concerns. And then if it was just too beyond their scope, then you transition the care to the RN. So, I think on our unit, in general, since our patients are typically pretty

predictable outcomes, there isn't much difference in how we are assigning our patients for an RN versus an RPN. (NL 012)

Some NLS also described that because the tasks of RPNs and RNs are often very similar, there are scenarios in which healthcare professionals or patients and families will not know whether a nurse is an RPN or an RN.

You know, there's many things that the RPN can now do that they once couldn't do, but to actually see the tangible difference in regards to tasks it's very hard actually, to tell the difference between an RN and RPN. And if you ask a lot of our physicians, I don't think that they actually know the difference between the two. They see all of our nurses as quote un quote, nurses with different levels of experience. (NL 001)

One of the NLS predicts that "going forward for the future, I really see that the RPN and RN role is blending, like, I don't see the clarity between them" (NL 012). Another NL however cautions that blurring the line between various healthcare professional roles is not desirable and can compromise patient safety:

I think it's absolutely critical that there are clear identities and roles. You know, you have a special designation with a college of nurses, it should be clear to everyone, whether you're a nurse, an RPN, a social worker, an OT. Patients should be able to ask, family members should be able to ask, and I think just saying we're all just nurses, that just kind of minimizes it and from a safety perspective it's terrible. I don't like that idea that we're all one at all. (NL 010)

3.3.4. Challenges to RPN Integration. The challenges to the RPN integration were largely related to the setting being an RN only environment and a lack of understanding about what the RPN role would contribute to the established team composition.

And so it came with a lot of either positive or negative preconceived notions about what an RPN could bring to the table. I found that was probably one of the toughest challenges that we encountered was getting past people's, like myths, almost it was like it was things that people had heard, it's not that it was rooted in any sort of evidence. (NL 001)

One RPN explains how acceptance onto her unit was made difficult by team members who were not as open to the change in the nursing care delivery model:

If you were to ask me to give advice to someone that is onboarding, I would say, don't really take everything personally. Because it really depends on the personality of who you're dealing with. And that just could be who they are. And kind of just, they're adjusting to you joining their unit as much as you are adjusting to being

on the unit. Because it's like, that's their home. And that's what they're comfortable with. And some people don't like change. (RPN 009)

NLs also described structural challenges such as compensation discrepancies between nursing roles. Because RPN and RN tasks overlap in many respects, some NLs note that there is RPN dissatisfaction about pay inconsistency. Moreover, the lack of distinct nursing responsibilities between RPNs and RNs on some units raises questions about the distinct nature of the RN position:

The challenge I'm getting faced with now is, as I am rolling it out, I'm hearing two different things; what is the RN identity? What is our unique role in this hospital? And I guess, yeah, the use of the unique role of the RN has come up and then from an RPN point of view, I've heard such comments as why are we getting paid so much less and doing the exact same work? (NL 014)

Another NL elaborates that there is “tension amongst the team more so for the RPNs. Because the RPNs feel like, why am I getting paid like half your wage, when I'm doing literally the exact same job as you” (NL 017).

RPNs discussed the emotional impact of their integration as they highlighted feelings of being undervalued on their teams. As some RPNs were introduced to the organization during the early phases of the COVID-19 pandemic, some were first brought on as screeners in the emergency department. This was described as a source of frustration because RPNs felt they were not given an opportunity to utilize their nursing skill set.

3.3.5. Benefits of RPN Integration. NLs explained the benefits of integrating RPNs to the acute care setting from a staffing perspective. Some noted that RPNs delivered excellent patient care, they work as collaborative members of the team, and they are valued for their feedback about practice on the units. Moreover, RPNs were described as being experts in their particular fields who can support the nursing team as some RPNs came to the acute setting with decades of experience as internationally trained nurses or with experience from other settings such as complex care or long-term care.

Many interviews described the context of the COVID-19 pandemic which compounded prevailing staffing challenges. The addition of RPNs was beneficial as they were able to provide more hours of nursing services for patients.

They [RPNs] kind of provided us some flexibility in our staffing model. I think the pandemic too has been an interesting challenge. I guess in regards to that, like, I think the amount of registered nurses' vacancies that we've had on our particular unit, in the past, if you couldn't get a registered nurse that position would sit vacant. And so I guess too maybe it depends on the CLM but we were really able to increase our staffing capacity by hiring RPNs. (NL 001)

Whenever I brought in an RPN, there was a relief, yes, another full time [nurse] onboarded. I felt like people really welcomed, they wanted the expansion of the team. (NL 006)

The improvement of quality of patient care was also discussed as a benefit to RPN integration. By opening the workforce to RPNs, there is a wider pool of applicants from which nurses are hired. A NL states, “I think it's improved the quality of care in that we are getting the correct person and not someone based on a limited qualification. So we're getting more diversity in nursing and nursing knowledge” (NL 014).

3.4. Relationship between ACE-15 and Qualitative Themes. We aimed to assess whether self-reported levels of teamness on the unit were reflected in the respondent interviews. Accordingly, we re-explored the transcripts from RPN participants with the highest and lowest ACE-15 scores. The RPNs with the highest ACE-15 scores explained in their interviews that they felt very supported by their teams:

At first everyone was kind of touchy of like, what we can do and what can't we do? And now like we're more open, and we're more talkative with management and the unit leader and educator. (RPN 002)

I felt so supported my very first solo day, I think all of my buddy nurses, like, two nurses above me, when it came to the rooms and then two nurses behind me and the charge nurse, everybody knew that I was going solo and they kept checking in all the time. They're like, how are you doing? Do you need any help with this? I felt very, very supported. (RPN 008)

RPNs with the lowest ACE-15 scores noted feeling “underutilized” and distrusted by RNs on their teams:

Even to this day you can sometimes see where the RNs are hesitant to have RPNs, or just like that trust factor is very, like not, it's not automatic. Whereas a new grad student that just got out of an RN program, they have more trust than me, where I've been working as RPN for five years and on this floor for a year and a half now, but a new grad that just started last month is going to have more trust. (RPN 004)

Overall in this subanalysis, RPNs reporting a higher level of teamness described a more positive integration experience than those who reported a lower level of teamness.

4. Discussion

The integration of a new role to existing teams brings both benefits and challenges which are experienced uniquely by RPNs and NLs. Specifically, our in-depth study identified the following themes common to both groups: preintegration process, nursing team dynamics, RPN role clarity, and challenges to RPN integration. One theme unique to the NLs was benefits to RPN integration. Moreover, our secondary

analysis suggested that RPNs working on units with high levels of teamness generally had a more positive experience than those with low levels of teamness.

There are a variety of ways to enhance teamness and address gaps or challenges in team dynamics. Education or learning and development portfolios at healthcare organizations could develop and implement teamwork educational workshops and programs for fostering both inter- and intraprofessional collaboration [13]. Other examples include setting up charters for how teams will work together, protecting time in meetings for discussion about roles and scopes of practice, shadowing different professions to enhance role clarity and individual courses through learning centres. Teams might also employ validated tools such as the ACE-15 to assess levels of teamness on their units and address gaps either prior to or as part of the integration of new roles. Increasing teamwork among patient care teams is valuable as it can positively influence both job satisfaction and patient care [14].

Consensus among teams about roles and scopes of practice are also essential to a successful implementation of new nursing roles. Teams must have role clarity and understand how the various nursing positions fit into the wider team in order to have collaborative relationships among one another [15]. However, this is an ongoing process as factors such as evolving patient needs, interprofessional team models, and other healthcare system changes require constant monitoring and assessment of role clarity and scope of practice for all professions, including RPNs [16].

This study had both strengths and limitations. Our study examined two sets of nursing perspectives, utilized a mixed method approach, and was conducted at an organization that is early in its RPN integration process. Because RPNs are very new to the site, the findings are near real time. Finally, we included an RPN in the data coding process which allowed for a rich and nuanced analysis which was grounded in the RPN's clinical experiences. A limitation of the study is that NL participants may have been more supportive of RPNs than those who chose not to participate in the study. Conversely, RPNs who chose to take part in the study may have been those with more negative experiences and a self-selection bias may have been at play. A second limitation is that we did not include Registered Nurses (RNs) as participants other than those who are both RNs and NLs. The RN perspective would be valuable to an understanding of the nursing dynamics theme.

A strong theme that emerged from NLs was the necessity of preintegration activities that would help a unit succeed in the introduction of the RPN role. In particular, dedicating time to educating existing team members about the scope of RPNs' practice was explained as vital to the success of the integration process. In addition, a focus on the value RPNs bring to the team is important to highlight especially in circumstances in which team members are new to working with RPNs. Other NLs discussed having conversations with teams about RPN integration and the shifting dynamics of a new skill mix on the team. In this way, current team members would be educated and prepared for collaborating with RPNs.

The theme of role clarity suggests the value of developing unit-specific guidelines for tasks assigned to RNs and RPNs. Role clarity would allow for a common understanding of one another's roles for the entire interprofessional team. A shift assignment toolkit, for example, can enhance role clarity and collaboration with respect to patient assignments. A standardized resource on shift assignment can also help healthcare organizations diminish role ambiguity among newly introduced RPNs in acute care settings.

5. Conclusion

The integration of a new role to existing teams brings both benefits and challenges which are experienced uniquely by RPNs and NLs. NLs can utilize findings of this study to better prepare their staff and units for the integration of RPNs but also any shifts or changes in their models of care. Our findings could be used to improve RPNs' integration in acute care, optimize the professional nursing environment to allow RPNs to practice to their full scope, and enhance the quality of patient care. Future studies can explore other interprofessional team members' perspectives on RPN integration to provide a more fulsome picture of the integration process. For example, the RN perspective would be valuable in further exploring the nursing dynamics theme. Additional work could also evaluate strategies to help address some of the themes identified above by increasing levels of teamness to boost team dynamics. Finally, how these strategies affect long-term outcomes such as burnout and nursing retention remains to be explored.

Background: Negative leadership behaviour is very common and pervasive in nursing and healthcare, often leading to adverse effects such as nurses' silence, decreased job performance, and turnover. However, there is a lack of systematic reviews that summarize negative leadership types and nurses silencing behaviours. **Aim:** This systematic review examined the relationship between negative leadership behaviour and nurses' silence. **Evaluation:** We searched PubMed, Embase, the Cochrane Library, Web of Science, CNKI, VIP, and Wanfang databases from their inception until 30 April 2024 for articles examining the relationship between negative leadership and silent behaviour among nurses. The studies were reviewed in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. The risk of bias in the included studies was assessed using the Newcastle–Ottawa Scale. **Key Issues:** After full-text analysis, six papers were included in this systematic review. Four of the studies were conducted with nurses, and the remaining two were conducted with all medical staff including nurses. While most studies have shown that negative leadership causes nurses to become increasingly silent, others have shown that appropriate negative leadership behaviour instead reduces nurses' silence. **Conclusions:** Negative leadership behaviour can affect the silent behaviour of nurses. **Implications for Nursing Management:** Hospitals need to take the initiative to build a harmonious and safe working environment, correctly recognize and identify negative management behaviour, take appropriate and effective measures to enhance the positive leadership of nurse managers, and make an effort to prevent nursing staff's exposure to the negative management of direct leadership and mental health threats, which is a key point that hospital administrators and health policymakers tend to overlook. This is also effective for enhancing the leadership of hospital administrators.

1. Introduction

Leadership behaviour affects employees' work behaviour, organisational goals, and efficiency and has been a continual interest in management research. Most studies have focused on positive leadership behaviours and their positive effects, whereas little attention has been paid to the effects of negative leadership behaviours on employees and organisations [1]. Negative leadership behaviour refers to behaviour that leads to potential physical, psychological,

emotional, or economic damage to subordinates due to the abuse of power in the process of managing employees [1]. Abusive supervision, defined as “verbal and nonverbal behaviours perceived by subordinates as hostile by their superiors, excluding physical contact behaviours,” is the most common manifestation of negative leadership behaviour [2]. In addition, authoritative leadership and toxic leadership are also typically negative leadership behaviours. Authoritative leaders are those who emphasise that their power is absolute and unchallengeable [3]. Hoffman and Sergio described

disregarding employees' wellbeing and participating in actions and activities that demean, belittle, and discourage employees as characteristic traits of toxic leadership [4]. As nurses are the largest professional group in healthcare, currently, research on negative leadership behaviours such as abusive supervision within the healthcare sector has predominantly focussed on nurses [5–8].

Recent medical studies have reported various negative consequences of negative leadership behaviours, such as nurse's turnover and silence [5, 9]. Silence is defined as employees intentionally withholding vital information, concerns, suggestions, questions, and opinions about issues related to the job and the organisation [10]. Silence is prevalent in hospitals and has a negative impact on the human resources of healthcare organisations [11]. Previous studies have demonstrated that negative leadership is a significant factor in nurses' silence [10, 12–14]. Leaders' concepts used in the management process (e.g., they think they know more than their subordinates and deny the authenticity of information) can indirectly cause subordinates' silent behaviour [15]. Organizationally, nurses' silence poses a significant threat due to its pervasive detrimental effects, such as the loss of critical information and creative ideas, across all levels of the organization when compared to other passive responses to negative leadership behaviours [16].

Although previous study indicated that nurses' silence not only could have numerous negative impacts on both individuals and organisations but also could impede communication among nurses, obscure patient safety hazards, and hinder the prevention of adverse events individually [9, 16, 17]. There is a lack of systematic reviews on the relationship between negative leadership behaviours and silent behaviours of nurses. In addition, academic studies suggested that negative managerial behaviours of nursing leaders may lead to silencing of nurses, but the relationship is still unclear. This systematic review is conducted to clarify the relationship between negative leadership behaviours and silence among nurses.

2. Methods

2.1. Design. This systematic review was conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, and its protocol was registered in PROSPERO with the number CRD42023422847.

2.2. Search Methods. A comprehensive search was undertaken by two independent researchers (LZY and WQ) across the following databases: PubMed, Embase, the Cochrane Library, Web of Science, CNKI, Wanfang, and VIP databases, from inception until 30 April 2024, to identify studies that examined the relationship between negative leadership behaviours and nurses' silence. The search strategy involved a combination of relevant MeSH terms and other key terms such as “silence,” “speak out,” “speaking up,” “voice,” “work-related suggestions,” “abusive supervision,” “autocratic leadership,” “negative leadership,”

“toxic leadership,” “destructive leadership,” “passive leadership,” and “adverse leadership”. We conducted a manual search of the reference sections of the included publications to identify any articles that may have been overlooked during the initial search. The complete search strategy is outlined in Table 1.

2.3. Eligibility Criteria and Study Selection. We included studies with nurses or medical staff (including nurses). Studies assessing negative leadership and silence were included. Abusive supervision and authoritative or toxic leadership were considered negative leadership. The included studies were not limited to publications in languages. Qualitative reports, expert opinions, reviews (literature and systems), meta-analyses, and inaccessible articles are excluded.

First, two researchers (LZY and YYP) identified and removed duplicate records and then sifted through titles and abstracts to remove studies that were not relevant to the research question. Finally, the full-text articles were retrieved and reviewed for inclusion and exclusion, and any discrepancies in the above process were adjudicated by a third researcher (TTH).

2.4. Study Selection and Data Extraction. To prevent bias in the data extracted by individuals, two researchers (LZY and YYP) identified and removed duplicate records and then sifted through titles and abstracts to remove studies that were not relevant to the research question. Finally, the full-text articles were retrieved and reviewed for inclusion and exclusion. Any discrepancies in the abovementioned process were adjudicated by a third researcher (TTH) until a consensus was reached.

When appropriate studies were identified, a structured table was designed to obtain the following data from the included studies: authors, publication year, country, study design, hospital setting, sample size, participant characteristics, type of negative leadership, negative leadership measurement tool, silence measurement tool, and results of the correlation between negative leadership and silence among nursing staff.

2.5. Quality Appraisal. The selected studies were independently assessed for quality by two researchers (LZY and WQ) of this study. The Newcastle–Ottawa Scale (NOS) was utilised to evaluate the quality of the studies, and any discrepancies were reconciled through consultation with a third researcher (TTH) who received relevant training. The NOS assesses the quality of studies based on the following three domains: selection of study groups, comparability, and assessment of outcomes [18]. Studies that scored ≥ 7 stars were of high quality [19].

2.6. Synthesis of Results. The following three extensive outcomes were considered: (1) negative leadership behaviours, (2) silence, and (3) the relationship between negative leadership behaviours and silence among nurses. The

baseline and correlations for the outcome variables were evaluated. A meta-analysis could not be conducted due to the high heterogeneity of the included studies' designs and results reporting.

3. Results

3.1. Search Results and Quality Appraisal. A total of 7,077 studies were initially identified. After removing duplicate articles ($n = 1,629$), 5,448 articles remained for further evaluation regarding their potential inclusion in this systematic review. Of these, 5,168 articles were excluded after screening the titles and abstracts. A final total of 265 articles required full-text review. Following this rigorous process, only six studies were finally included in this systematic review (Figure 1). All six studies were assigned less than seven stars (Table 2).

3.2. Characteristics of the Included Studies. The characteristics of the selected studies are summarized in Table 3 [20]. All selected studies used cross-sectional study designs. Four of the included studies [9, 13, 14, 21] were from Asia and two [10, 12] were from Africa. Four of the studies [9, 11, 13, 14] were conducted with nurses and the remaining two [10, 21] were conducted with all medical staff including nurses.

3.3. Negative Leadership Behaviours. Table 4 shows that three studies [9, 10, 13] focus on abusive supervision; one [12] on toxic leadership and two [14, 21] on authoritative leadership. The mean scores for abusive supervision were from 1.5 to 2.5 [9, 10, 13]. The mean score of nurses' toxic leadership perception was 3.91 ± 0.51 . The mean score of nurses' authoritative leadership perception was 2.97 ± 1.06 [14]. In addition, one study using qualitative interview methods found that authoritative leadership was an important factor affecting the silent behaviour of medical staff [21].

3.4. Silence among Nurses. Three studies used identical scales, with mean scores ranging from 3 to 4, indicating that nurses' silence was at a moderate level [13, 14, 21]. In the three remaining studies, the nurses' silence scores were 4.90 ± 0.72 , 1.67 ± 0.63 , and 2.73 ± 0.77 , respectively [9, 10, 12].

3.5. Negative Leadership Behaviours and Silence among Nurses. The included articles showed a moderate positive correlation between negative leadership behaviours and nurse's silent behaviour in four out of six studies, with correlation coefficients of 0.40, 0.49, 0.35, and 0.64, respectively [9, 10, 13, 14]. Li et al. [13] and Zhang [14] also documented that negative leadership behaviour was not only

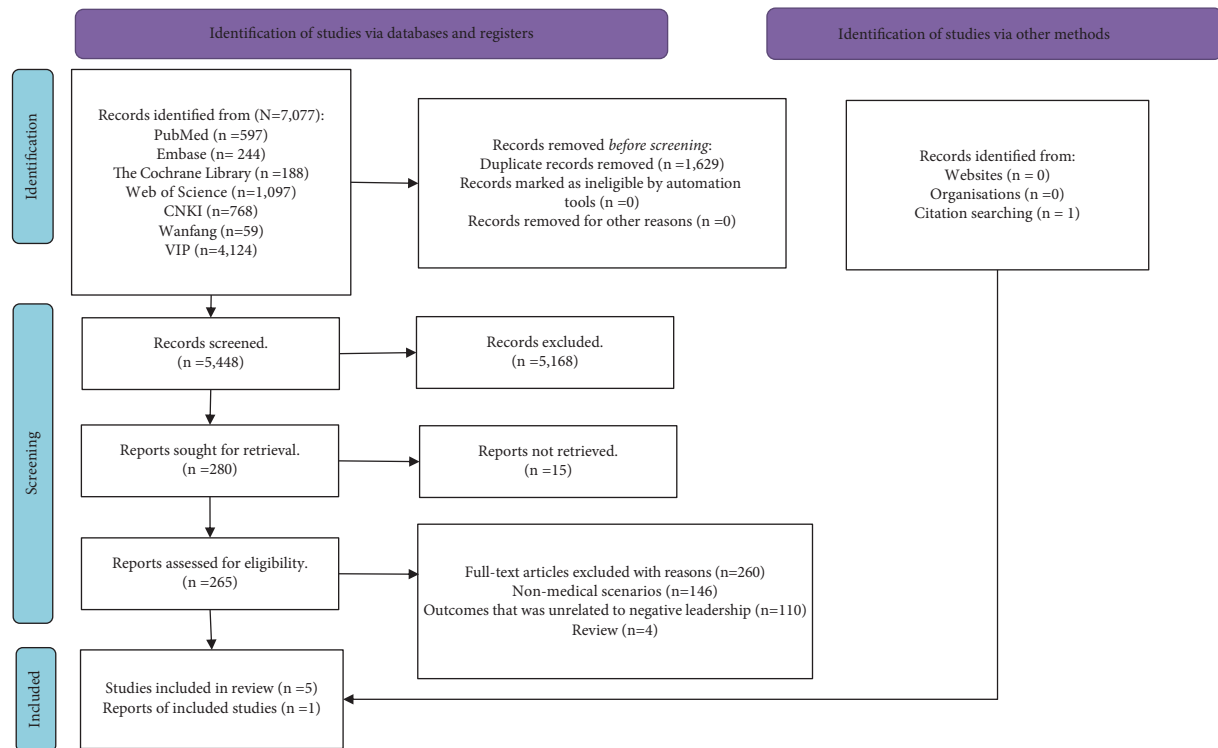

FIGURE 1: PRISMA flow diagram.

significantly and positively related to nurses' silent behaviour but also significantly and positively related to all three of its dimensions. Qualitative analysis concluded that negative leadership behaviours of hospital managers led to silent behaviours among medical staff [21]. All of the above-mentioned studies suggested that negative management behaviours exhibited by hospital leaders exacerbated the silent behaviour of nurses and retained relevant constructs about the organization or manager. However, not all studies have found a positive relationship between negative leadership behaviours and nurses' silence. Farghaly Abdelaliem et al. [12] found a significantly negative correlation between toxic leadership behaviours and nurses' silent behaviour, displaying negative correlation ($r = -0.77$).

Three of the selected articles found that there were other variables that played a role in the relationship between negative leadership behaviours and nurse's silence [9, 10, 14]. Li et al. [9] found that impression management motivation played a partially mediating role in negative leadership behaviours and nurse's silence. Osei et al. [10] showed that proactive personality positively moderated the effect of abusive supervision on medical staff silence. Zhang [14] showed that personality traits partially moderated the relationship between authoritative leadership and nurse's silence.

4. Discussion

4.1. Clinical Implications. To the best of our knowledge, this is the first systematic review on the relationship between negative leadership behaviours and nurses' silence. Many

studies on negative leadership behaviours and employee-silencing behaviours in companies or organizations outside of healthcare have drawn widespread recognition from academia and society, but few are based on healthcare scenarios. Among the six included studies, we found that most studies on negative leadership behaviour were conducted in Asia and Africa, and research was lacking on Western developed countries and regions. This may be related to the different cultural context, with Asian cultures being high power distance cultures, in which subordinates tend to accept and expect to maintain a subordinate relationship with their superiors [22]. A high power distance national culture may, therefore, disincentivize mutual respect and create conditions that are ideal for propagating unchallenged incivility throughout organizations [23, 24]. As for nurses' silence, Asian nurses were more silent, probably because in most Asian cultures, where hierarchies are more rigid and power differentials are greater, speaking up is more challenging than elsewhere and can be risky [25]. Furthermore, many nursing staff chose to remain silent to protect themselves when they perceive problems within their organizations [26].

Four studies [9, 10, 13, 14] showed a significant positive relationship between negative leadership behaviour and silent behaviour among nurses, which is consistent with most studies. Previous studies have showed that authoritative leadership is positively related to employee silence, and the stronger the authoritative leadership style, the more likely it is to lead to silent behaviour [27, 28]. Wang et al. [29] have established that employees' tendency to remain silent is a direct consequence of abusive supervision practices, and

this, in turn, influences their attitudes towards work, such as reduced work engagement. Furthermore, another experimental study found that when leaders showed cues that symbolized power, such as direct gaze and voice amplification (intentional or unintentional), subordinates were less vocal and remained silent [30]. Interestingly, for leaders with higher power and authority, the act of raising concerns or suggesting organizational changes can be perceived as a challenge to their management style. Consequently, nurses may choose to remain silent as a means of avoiding direct confrontation or contesting the leader's authority [9]. Moreover, Farghaly Abdelaliem et al. [12] found a significantly negative correlation between negative leadership behaviour and nurse's silence behaviour, reinforcing the previously raised research question of whether the relationship between negative outcomes observed in low-level negative leadership behaviours is appropriate for moderate and high-level negative leadership behaviours [31]. Currently, there is a research gap in the relationship between moderate-to high-level negative leadership behaviours and negative outcomes, and this study fills that gap in the existing literature.

Zhang [14] and Osei et al. [10] found that personality plays a mediating or moderating role in the relationship between negative leadership behaviour and medical staff silent behaviour and that different personalities influence silent behaviour in different ways and with diverse outcomes. Previous research found an association between neurotic personality and silent behaviour [32]. LePine et al. [33] showed that employees' introverted personalities can also impact silent behaviour, and employees with introverted personalities tend to use silence to reduce excessive communication with others. In addition to personality variables, the inclusion of the study showed that impression management motivation could also act as a mediating variable between negative leadership behaviours and nurses' silence [9].

Our findings contribute to the literature in several ways. First, our study extracted and condensed the research on the relationship between negative leadership behaviour and nurses' silence [34] in the medical field. Our findings reveal that negative leadership behaviour would lead nurses to withhold their suggestions and opinions from the organization and keep silent. This was consistent with most previous studies, as well as recent studies on the emergence of negative results such as increased stress [35], increased turnover intention [2], and decreased organizational performance [2, 36] due to leaders' abuse of power. Farghaly Abdelaliem et al. [12] found a negative relationship between negative leadership behaviour and nurse silence behaviour. Zhang et al. [37] also noted the positive impact of negative leadership behaviour in certain situations. Studies have confirmed that negative leadership behaviours do not always lead to negative consequences and can promote employee voice behaviour [38] and creativity [17] to a certain extent. This suggests that the negative behaviour of leaders and the silent behaviour of nursing staff may not just be a simple positive or negative linear relationship, but there may be a curvilinear relationship like a positive and then negative

influence. Fleishman et al. [39] pointed out that current research in the field of leadership focuses too much on a simple linear relationship and ignores the nonlinear relationship between the variables. Future research could focus more on whether there is a curvilinear relationship between the two. In addition, most previous studies [10, 12, 40] used nurses' silence as the mediating variable, but this study analysed nurses' silence as the dependent variable to understand the direct impact of negative leadership behaviour on nurses' silence. Second, most previous studies on negative leadership behaviour focused on the enterprise field, and few studies have examined the status quo of negative leadership behaviour and its impact on employee silence based on medical scenarios. The articles included in this study were all medical studies, which broadened the scope of our understanding of negative leadership behaviour. Finally, variables such as various personality traits played different roles in negative leadership behaviour and employee silence, which enriches the research literature on the relationship between negative leadership behaviour and employee silence [34].

4.2. Clinical Practice. Sweden, Canada, France, and South Korea have "workplace bullying laws" [40]. Therefore, from the perspective of leadership, hospitals, and other institutions can take various actions such as organizational culture guidance and regular management skills training for head nurses, department directors, and other leaders as a unit to improve leaders' awareness of negative management hazards, strengthen their self-control ability, and minimize the possibility of negative leadership behaviours [41]. Moreover, online and offline reporting centres can be set up in hospitals and other institutions to facilitate nurses or patients to report negative management at anytime and anywhere [40]. Managers in the medical field face greater pressure and challenges than other managers. Therefore, psychological counselling rooms can provide timely counselling when they encounter problems to prevent the occurrence of negative leadership behaviours. Organizations need to be highly attentive towards the psychological and physiological changes in nurses. This necessitates constant communication, understanding of nurse's psychological dynamics, and the establishment of a strong trust relationship. These efforts aim to effectively minimize silent behaviour among nurses. In addition, the implementation of diverse group-building activities can successfully alleviate work-related pressure, enabling nurses to effectively release negative emotions. In ordinary circumstances, fostering a peaceful and amicable atmosphere within the department becomes essential to encourage nurses' freedom of expression [41].

5. Limitations

This systematic review has several limitations. First, the number of selected studies was relatively small, which could lead to limited efficacy of our conclusions. Second, only four included studies focused on nursing staff; the bias estimated

may be inevitable. Third, the methodological quality of the included studies varied, potentially introducing a risk of bias. Fourth, using quantitative or statistically presented pooled evidence is preferable from a statistical perspective. However, performing a meta-analysis of the selected studies was challenging due to the inconsistent information provided. Fifth, the available limited, very low-quality evidence does not support an association between negative leadership behaviours and nurses' silence. Further studies are necessary to establish this connection. Finally, the lack of studies from developed Western regions in our inclusion criteria necessitates further exploration when extrapolating the study's results.

6. Conclusion

For the most part, it can be concluded that a significantly positive relationship exists between negative leadership behaviours and nurses' silence and that leaders' negative management behaviours lead nurses to choose silence for the sake of self-preservation. This phenomenon is detrimental to the physical and mental health of nurses. Hospitals and hospital leaders should increase their awareness of negative leadership and raise alarms or make improvements.

Background. Emotional responses and the ability to regulate emotions among nurses, especially first-line nurse managers, can influence various workplace dynamics. However, there is a knowledge gap regarding emotional intelligence, job satisfaction, and organizational commitment among nurses in Qatar, particularly first-line nurse managers. **Objectives.** The primary aim of this study is to determine if there is a significant relationship between emotional intelligence, job satisfaction, and organizational commitment among first-line nurse managers (FLNMs) in Qatar. **Design.** This is a descriptive cross-sectional correlational study. **Settings.** The research took place at Hamad Medical Corporation in Qatar. **Participants.** A total of 203 first-line nurse managers participated in the study. **Methods.** Participants were recruited using a convenience sample method. Data were collected using the Genos Emotional Intelligence Inventory—Concise, the three-component model Employee Commitment Survey, and the short-form Minnesota Satisfaction Questionnaire (MSQ). **Results.** The findings showed that participants had average levels of emotional intelligence, job satisfaction, and organizational commitment. Notably, a significant, moderately positive relationship was observed between emotional intelligence and organizational commitment, as well as between job satisfaction and organizational commitment. A weak positive relationship was identified between emotional intelligence and job satisfaction. Differences in emotional intelligence were observed based on variables such as gender, age, and unit specialty. Organizational commitment varied based on the current position and hospital type, while job satisfaction differed based on the current position and education level. **Conclusions.** The findings suggest that enhancing the emotional intelligence of first-line nurse managers can potentially improve organizational commitment, job satisfaction, and, subsequently, healthcare outcomes. There is a need for further research to delve deeper into these factors and devise strategies aiming to boost the emotional intelligence and job satisfaction of first-line nurse managers. **Implications for Nursing Management.** The study provides empirical data from Qatar's healthcare system, shedding light on FLNMs' emotional intelligence, job satisfaction, and organizational commitment.

1. Introduction

Leadership is a major challenge for healthcare organizations and nurse managers in the 21st century, as dynamic and rapid organizational and environmental changes require the availability of effective managers at all organizational levels. Nurses are a crucial component of the healthcare system, and nurse managers play an important role in ensuring quality patient care [1].

First-line nurse managers (FLNMs) are registered nurses with a license who work in a managerial position in a healthcare organization, typically at the operational level. They are in the position of managing and supervising a team of nurses, along with ensuring the seamless operation of the nursing unit [2]. FLNMs play a key role in nurse success and patient outcomes [1]. Therefore, it is important for them to focus on improving retention rates and meeting performance expectations [3]. FLNMs' performance has

a significant impact on job satisfaction and commitment [4]. Emotional intelligence (EI), on the other hand, has been shown to be an important factor in the workplace that affects job performance, job satisfaction, and organizational commitment [5]. The important role of EI in nursing comes from its impact on workplace harmony [6]. Also, EI involves controlling emotions, motivating others [7], fostering positive relationships, job satisfaction, and productivity as well [8, 9]. Healthcare managers along with FLNMs receive benefits from EI [9], FLNMs with EI influence quality of care, safety, staff nurse retention, and patient outcomes [10]. In contrast, a lack of EI in FLNMs leads to lower nurses' engagement, higher turnover, and lower staff nurse retention [11, 12]. As a result, EI fosters positive relationships and job satisfaction between nurses [5, 8].

Many FLNMs experience job-related stress due to insufficient knowledge and skills necessary for a challenging work setting [13]. Therefore, many FLNMs may not have been able to adapt to their position successfully.

FLNMs may lack knowledge and skills, causing stress and ineffective performance [13]. Incompetent FLNMs affects patient and staff nurses outcomes, so they required a competency-based and well-structured strategy for the development of FLNMs [2]. So, developing FLNMs with EI is crucial [2], but little study has been conducted on the EI of FLNMs [10]. EI can help retain and motivate FLNMs [14]. In general, it is believed that employees with more EI will perceive higher job satisfaction. This is due to the assumption that individuals with greater EI can develop strategies for dealing with potential stress-related consequences, while others with lower EI cannot. EI has been acknowledged as a crucial competency for healthcare professionals [4]. So, administrators and policymakers might use EI in healthcare as a strategy to develop organizational strategies for the retention and motivation of all FLNMs.

FLNMs play a vital role in nursing by bridging the gap between senior management and clinical nurses. The positive impact of enhancing EI and commitment among nurses and FLNMs leads to improved decision-making, care quality, and job satisfaction [15]. This will allow FLNMs to focus on building relationships and communicating well with nurses.

Job satisfaction, both intrinsic and extrinsic, refers to an employee's fulfillment with a particular job. The internal factors of an individual, such as personality and personal perspectives, as well as the exterior characteristics of the workplace, such as the work environment, can influence job satisfaction. Job characteristics can have an impact on an employee's wellbeing and affect job satisfaction and dissatisfaction [16]. Spector's definition of job satisfaction is one of the most common ones. It says job satisfaction depends on how a person feels about their job and all its parts [17].

An employee derives intrinsic satisfaction from the individual internal motivation when performing a certain task to achieve satisfaction, and as a result, satisfaction is derived from the staff member's active engagement in the assigned task [18–20]. On the other hand, extrinsic satisfaction derives from external elements such as money, promotion, and

the anticipation of receiving rewards [21]. Theories on human motivation, such as Maslow's needs hierarchy theory, Herzberg's motivator-hygiene theory, the job characteristics model, and the dispositional approach, are associated with theories on job satisfaction. This is due to the close relationship between the two sets of concepts [21].

On the other hand, organizational commitment is defined as a person's connection with and involvement in his or her current organization. This includes an individual's acceptance of the organization's objectives and values, along with a strong wish to continue working for that organization [22]. Job satisfaction and commitment are distinct concepts. Such a being emotionally attached to the organization indicates a deep loyalty to the organization.

Organizational commitment indicates that an employee cares about the organization's goals and values, whereas job satisfaction focuses on the employee's job [23]. John Meyer and Natalie Allen developed the organizational commitment theory [24].

Commitment in the workplace can be categorized into the following three dimensions: affective, normative, and continuous [24]. Affective commitment involves an employee's emotional attachment and involvement in their job. Normative commitment is when an employee feels obligated to stay loyal to the organization, often due to perceived investments made by the company or a desire to support colleagues. Continuous commitment is driven by concerns about the costs and benefits associated with leaving the organization, such as loss of compensation or potential gains from staying in the job. Job satisfaction and commitment have significant effects on the performance of FLNMs [25].

This study set the stage for future studies on the relationship between EI, job satisfaction, and organizational commitment among FLNMs in Qatar and other countries, along with factors that may affect that relationship.

This study aimed to examine the relationship between EI, job satisfaction, and organizational commitment among FLNMs in Qatar. This study intends to assess the emotional intelligence, organizational commitment, and job satisfaction levels among first-line nurse managers in Qatar and, in addition, examine differences based on demographic and organizational characteristics, as well as the relationships among these variables.

2. Methods

2.1. Design of the Study and Data Collection. A descriptive cross-sectional design examined the relationship between EI, job satisfaction, and organizational commitment. While this design provides a clear snapshot at a specific time, it has limitations, including the inability to establish causality [26]. The study involved ethical approval, online questionnaire use, and recruitment via email from the nursing corporation office and research nursing department to all target sample emails attached with a cover letter and questionnaire link. The survey was accessible on various devices, and invitations were sent through the research department to ensure equal opportunity. The data collection procedure took a total of four weeks. It involved sending an email two weeks after the

initial invitation and another reminder email three weeks later, and the survey took approximately 20 minutes to complete.

2.2. Participants and the Sampling Procedure. The target population for this study is FLNMs in Qatar. The accessible population was recruited from FLNMs among Hamad Medical Corporation (HMC) participants. HMC manages nine specialty hospitals and three community hospitals, and as well as being one of the largest employees in Qatar, HMC is the main healthcare provider in Qatar. Nonprobability convenience sampling was employed for those who met specific criteria, such as having managerial roles in the nurse and midwife career framework, holding a bachelor's degree, and working full time in selected hospitals for at least one year. The study used G*Power 3.1.9.7 software to calculate the required sample size, resulting in a minimum of 138 using a correlation test (power = 0.95, alpha = 0.05, two-tailed, and effect size = 0.3).

2.3. Instruments. The first section covers sociodemographic and professional characteristics such as age, gender, job position, educational level, years of experience as a nurse, years of experience as a first-line nurse manager, and nursing specialty unit. Then, three instruments were used to collect data in this study, reflecting each main variable in the study: the EI Genos Emotional Intelligence Inventory-Concise (self-assessment). For the Genos EI Inventory, one must use a 5-point Likert scale with 31 items. A 5-point Likert scale contains 31 items: 1 = almost never, 2 = seldom, 3 = sometimes, 4 = usually, and 5 = almost always. The questionnaire is specific to a workplace setting and takes 5–7 minutes to complete. Genos' instrument was selected because it has sufficient face validity, is clear and understandable, and is accessible. The scoring involves summing up the scores from different scales: Emotional Self-Awareness, Emotional Expression, Emotional Awareness of Others, Emotional Reasoning, Emotional Self-Management, Emotional Management of Others, and Emotional Self-Control. Each scale includes specific items, and the total Emotional Intelligence score is calculated by adding up the scores from all these scales. Percentile scores are used for interpretation, representing the percentage of individuals scoring below a particular raw score. The Genos EI Inventory provides percentile ranges, categorizations, and interpretive guidelines for scoring and interpretation [27]. The Genos EI Inventory (Concise) Scale's alpha reliability coefficient has been determined by previous research to be 0.86, and its subscale reliability is good enough [28].

The job satisfaction score was calculated using the short-form Minnesota Satisfaction Questionnaire (MSQ), developed by Weiss, Dawis, England, and Lofquist in 1967. The questionnaire consists of 20 items rated on a 5-Likert scale from 1 (dissatisfied) to 5 (very satisfied). Two factors, intrinsic and extrinsic satisfaction, are derived from the factor analysis of the 20 items. The general satisfaction score can be calculated by combining these two elements. The intrinsic

scale includes 12 items, while the extrinsic scale includes 6 items. Two items are part of the general satisfaction scale. Raw scores for each scale can be converted to percentile scores, with a score of 75 or higher indicating high satisfaction, a score of 25 or lower indicating low satisfaction, and a score between 26 and 74 indicating average satisfaction. The reliability coefficients for intrinsic satisfaction, extrinsic satisfaction, and general satisfaction are 0.86, 0.8, and 0.9, respectively [29].

The revised TCM Employee Commitment Survey by Meyer and Allen measures FLNM organizational commitment. It includes 18 items and six items measuring affective, continuance, and normative commitment [24]. The organizational commitment scores are calculated by computing averages for the Affective Commitment Scale (ACS), Normative Commitment Scale (NCS), and Continuance Commitment Scale (CCS) for each respondent. After reading each item, employees indicate the strength of their agreement by selecting a number from 1 (strongly disagree) to 7 (strongly agree). The implementation level of organizational commitment is determined by adding the range value to the level with the lowest mean score after obtaining the range value. Reports on reliability and validity show that this subscale has acceptable reliability ranging from 0.74 to 0.89 and construct validity via factor analysis confirming affective commitment as a distinct measure of organizational commitment [24]. This approach helps in effectively interpreting the data analysis and enhances the efficacy of data analysis and interpretation, which were computed using the subsequent formula [30]:

$$\text{Range Value} = \frac{\text{highest mean score} - \text{lowest mean score}}{\text{Number of level intended}} \quad (1)$$

A pilot study on 30 participants was conducted to assess survey clarity, filling time, analytic procedure, and participant response; the pilot subjects were not included in this study. Using Statistical Package for the Social Sciences (SPSS) Statistics version 26 software by IBM, the instrument's validity and reliability were evaluated using Cronbach's alpha coefficient, ensuring internal consistency and reliability. The instruments used for evaluation of Cronbach's alpha coefficient were the Genos Emotional Intelligence Inventory-Concise (self-assessment) (0.867), MSQ (0.939), and TCM Employee Commitment Survey (0.831). The study utilized English language instruments as the participants mainly spoke English.

2.4. Ethical Considerations. The study received ethical approval from Zarqa University and the Institutional Review Board (IRB) of the Medical Research Committee (MRC-01-23-058) at HMC. Email invitations were sent to participants with the assistance of the nursing corporate workforce. Participants were provided with an information sheet explaining the study, its risks and benefits, and their right to participate. Anonymity and privacy were maintained, and completed surveys were secured. Permission was obtained to use the research instruments.

2.5. Statistical Analysis. Statistical Package for the Social Sciences (SPSS) Statistics version 26 software by IBM was used for descriptive and inferential statistics. The data were coded, cleaned, and checked for normality assumptions. Data cleaning was performed to ensure the accuracy and reliability of the data. Frequencies and percentages describe sample characteristics. Independent *t*-tests and ANOVA tests examined differences in mean scores. Pearson's correlation explored relationships between variables.

3. Results

Out of 250 first-line nurse managers, 203 responded (81.2% response rate). As shown in Table 1, the majority were female (54.7%) and aged 35–44 years (61.6%). Most had a bachelor's degree (75.9%), while 24.1% had a master's degree. The majority had more than 10 years of nursing experience (83.2%) and more than 5 years as FLNMs (93.6%). Various positions, hospitals, and medical specialties are represented in Table 1.

The participants showed an average level of EI ($M = 49.87$ and $SD = 28.89$), with 42.4% above average and 41.4% below average, as shown in Table 2. The highest domain was emotional management of others ($M = 3.99$ and $SD = 0.62$), while the lowest was emotional expression ($M = 3.48$ and $SD = 0.54$), see Tables S1–S6 in the Supplementary Material for more details. As a result, as shown in Table 3, organizational commitment level averaged 4.55 ($SD \pm 0.83$); on the other hand, affective commitment scoring was the highest ($M = 4.72$ and $SD \pm 1.22$) and continuance commitment was the lowest ($M = 4.42$ and $SD \pm 1.05$), as shown in Table S2. The result represented in Table 4 shows that job satisfaction level had a mean score of 68.13 ($SD \pm 12.51$), with extrinsic satisfaction ($M = 3.90$ and $SD \pm 0.50$) higher than intrinsic satisfaction ($M = 3.47$ and $SD \pm 0.58$), as shown in Table S3.

On the other hand, the differences with sociodemographic and professional characteristics show that gender has a significant difference with EI ($t = 2.134$, $p < 0.05$), and age groups differ significantly ($F(3,199) = 3.25$, $p < 0.05$). Nursing unit specialties showed significant differences in EI ($F(12,190) = 2.58$, $p < 0.05$) also. On the other hand, current position, educational level, years of experience, and hospital type did not have a significant difference with EI, as shown in Table S4. While gender did not have a significant difference with organizational commitment ($t = 1.43$ and $p = 0.15$), the current position has a significant difference ($F(3,199) = 2.930$, $p < 0.05$), with head nurses reporting higher commitment. Hospital type influenced organizational commitment ($F(14,188) = 3.67$, $p < 0.05$), with primary hospitals having a significant difference in organizational commitment as shown in Table S5. Job satisfaction did not significantly differ based on gender ($t = 0.20$, $p = 0.84$), but educational level affected it ($t = 2.29$, $p < 0.05$), with bachelor's degree holders reporting higher satisfaction. The current position also affected job satisfaction ($F(3,196) = 3.70$, $p < 0.05$), with head nurses reporting higher satisfaction. Age group, years of experience, hospital type, and unit specialty did not have a significant difference with job satisfaction, as shown in Table S6. EI and organizational commitment had a moderate positive

OC r		0.599 *
p value		$p \leq 0.001$

Note. EI = emotional intelligence; OC = organizational commitment, *significant at the 0.01 level.

and job satisfaction among FLNMs in Qatar. Due to the dynamic nature of the healthcare sector and encountering new challenges, FLNMs' role in ensuring high-quality patient care and efficient operations has become increasingly crucial. The study revealed that FLNMs' EI level was average, which is consistent with findings from previous studies [15, 31–33]. However, some studies reported below-average levels of EI among FLNMs [34–36]. That may be because cultural and educational differences, workplace culture, job stress, and the workplace environment can influence EI. On other hand, according to the findings of this study, FLNMs exhibit a moderate to high level of organizational commitment [24, 37–40]. This may be attributable to their position within the organization, as they are linked to higher-level managers and administration, so they influence decision-making and have been perceived for their value in the organization. In addition, this may be attributable to the fact that they have been effective in the organization.

FLNMs' job satisfaction level was shown to be moderate to high [41–44]. In response to the study result, the instrument used in the instruction asked the participant to respond based on "how I feel about my current job." Since the level of job satisfaction corresponds with EI, EI is the ability to recognize, understand, and control one's own emotions as well as the emotions of others. In contrast, job satisfaction is a feeling of satisfaction or fulfillment that an individual gives to his or her job. It makes sense to think that people with higher EI are better able to control their feelings at work and, as a result, are more likely to be satisfied with their jobs. Since EI is closely related to how professionals exercise their

autonomy and manage their emotions, it makes sense that their EI would influence how they perceive and respond to these aspects of their job.

The study found that older FLNMs and those working in specialized units had higher EI scores than their peers. Also, research suggests that female tend to exhibit a higher level of EI in comparison to male. These findings are consistent with prior studies [45, 46]. EI is a skill that can be developed and enhanced through training and experience [47]. As FLNMs gain experience, they may develop greater EI skills that allow them to better understand and manage their own and others' emotions. A study conducted in Jordan to examine the relationship between emotional intelligence and nurse-nurse collaboration revealed that participants' gender, age, and years of experience were not significant factors in EI. Conversely, there were significant differences in EI based on nurse unit specialties and educational level [48]. Nursing personnel must be both curative and compassionate, especially during critical periods and end-of-life care, in line with the profession's core principles. This aspect of the work reinforces the performance-enhancing effects of EI on nurses. Gradually, this dependence on emotional intelligence may increase their awareness of their own emotional intelligence-related behaviors [36], allowing them to actively contribute to the provision of high-quality interdisciplinary care. Specifically, effective interactions between nurses and patients during end-of-life care could consistently foster a healing environment in the hospital. That is why you will see a difference in EI level based on age and nursing unit specialty.

The study found no significant association between emotional intelligence and level of education, current position, years of nursing experience, years of FLNM experience, or hospital type. These results are also consistent with previous studies [49, 50].

According to the results of this study, there was no significant difference in job satisfaction based on gender, age, hospital type, years of experience in the nursing field, years of experience as FLNM, or specialty. However, there were significant differences in job satisfaction based on current positions and levels of education.

A study examined job satisfaction among nurses in Egypt found no significant gender-based differences. These align with the study's findings [51]. The research also showed a significant difference in job satisfaction based on the educational level, with nurses holding a bachelor's degree reporting higher levels of job satisfaction than those with a master's degree, continuing to support the result.

In addition, a cross-sectional study on the job satisfaction of nurses in Saudi Arabia discovered that there were no significant differences based on gender, age, education level, or years of experience [52]. In another study, the authors investigated the relationship between organizational commitment and the job satisfaction of nurses in a Dubai hospital. They presented the results of their study and demonstrated the significance of different demographic factors, including age, education, years of experience, position, and specialization, on organizational

commitment and job satisfaction [53]. One more study found that those with postbasic nursing education reported significantly greater job satisfaction than those with only basic education ($p < 0.05$) [54].

A cross-sectional study conducted with a random sample of 5000 licensed nurses in the United States found that nurses' levels of job satisfaction did not vary by age, gender, educational level, or years of experience, except for hospital type, which had a significant difference in job satisfaction ($p = 0.02$), which also aligns with the study findings [55, 56]. According to the results of this study, there were significant differences in organizational commitment based on current position and hospital type. These findings are also consistent with prior studies.

A study investigated organizational commitment among nurses at a major public hospital in Saudi Arabia. Researchers revealed that participant gender, educational level, and years of nursing experience were not significant predictors of overall organizational commitment. Only age was a significant predictor of organizational commitment [57].

This research shows that the relative participation of males and females is not independent of other factors, given the issues in modern life, the equal gender combination in the workplace and organizations, and the social and cultural obligation for both males and females to participate in vocational activities. Therefore, other factors rather than gender affect FLNMs' organizational commitment.

Another study found that older nurses had higher level organizational commitment than younger nurses, nurses with higher education levels had higher organizational commitment than those with lower education levels, and nurse managers with more work experience had higher organizational commitment than those with less work experience [58].

Regarding hospital type, a multisite survey study was conducted and found no statistically significant differences in education level, current position, specialty, or hospital type [39]. One more study revealed a positive and significant association between organizational commitment and years of experience in the current position but no significant difference depending on age, gender, unit specialty, or educational level [59].

EI correlated positively with organizational commitment and job satisfaction [40, 56, 60–62]. FLNMs showed a positive relationship between organizational commitment and job satisfaction [53, 58, 63]. But it is important to remember that correlation does not necessarily indicate causation. However, it is possible that additional factors, such as salary, workload, or degree of job autonomy, may also influence their total satisfaction with their jobs.

The research findings have demonstrated that FLNM with high levels of emotional intelligence demonstrate an increased willingness to have positive attitudes towards their job and organization, leading to increased organizational commitment and job satisfaction. Furthermore, emotional intelligence can enhance FLNMs' understanding and control of their emotions, therefore promoting higher levels of job satisfaction and organizational commitment.

5. Limitations

There are a few limitations to this research. The current study's cross-sectional design is susceptible to usual biases, such as lower generalizability, including the inability to establish causality [26]. Furthermore, the implementation of self-assessment questionnaires could have generated self-report biases, such as "inflation" and "manipulation" biases. Indeed, the use of reliable and validated psychometric scales helped mitigate some of the self-report biases associated with self-assessment questionnaires. By employing established and well-tested instruments, researchers can enhance the credibility and accuracy of the data collected in the study. As an additional limitation, there could be other variables not included in the study that may influence the observed relationships. For instance, work-related stress, leadership style, or organizational support could have an impact on both emotional intelligence and job satisfaction. Furthermore, this limits the use of advanced methods of statistical analysis, such as linear regression.

6. Implications on Nursing Management

The study shows EI has a positive influence on job satisfaction and organizational commitment for FLNMs. Human resources should invest in EI training for FLNMs and consider it a core competency during recruitment. Nursing programs should invest in EI training programs and incorporate them into nursing curriculum content to prepare future nurses, while continuing education is essential. In addition, it is important to consider and incorporate these factors into nursing strategies and the policy-making process. Future research should prioritize conducting experimental studies to explore the potential impact of EI on job satisfaction and organizational commitment. It is important to consider a wide range of variables in these studies, including leadership, occupational stress, role stress, innovative behavior, social relations, and technology trends in the workplace.

Researchers should investigate the impact of emotional intelligence on the future of work and first-line nurse managers' perceptions of digital innovation in the workplace. By implementing these strategies, healthcare organizations can optimize their management practices and enhance workforce performance. Another variable that has been largely overlooked is the relationship between emotional intelligence and technology trends in the workplace.

7. Conclusion

This study highlights the importance of improving the emotional intelligence, job satisfaction, and organizational commitment of FLNMs in Qatar. Strategies include education, leadership development, and work culture. Implementing flexible work hours, recognition programs, and talent development can create a positive work environment, fostering job satisfaction and organizational commitment. Further research is needed to understand this relationship in different healthcare settings.

Data Availability

The data that support the findings of this study are available from the corresponding author upon reasonable request.

Ethical Approval

The Institutional Review Board at the Faculty of Nursing, Zarqa University (Zarqa, Jordan), approved the study with the number of (5/2022) and the Institutional Review Board (IRB) of the Medical Research Center (MRC-01-23-058) at HMC. All methods were carried out following relevant guidelines and regulations or the Declaration of Helsinki.

Consent

Informed consent was obtained from all participants.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

MIO conceptualized the study. MIO, AK, IO, and AJN contributed to research design, data collection, analysis, literature search, and manuscript preparation. All the authors have accepted responsibility for the entire content of this manuscript and approved its submission.

Acknowledgments

The Qatar National Library funded the publication of this article. This work was supported by the Medical Research Council at Hamad Medical Corporation (Doha, Qatar) (Grant number: MRC-01-23-058).

Aim. This study was conducted to determine the association between knowledge management and social value among nurses working in hospitals of Tehran University of Medical Sciences. **Background.** Knowledge management plays a significant role in healthcare systems. Healthcare providers require knowledge in every aspect of their work, and they must be able to rely on a knowledge management system to access the newest research and practice to ensure the highest quality of care. One of the evident goals of knowledge management is creating value in organizations. Creating value does not necessarily mean creating economic value, but creating social value is a category proposed as a prerequisite for knowledge management. **Methods.** This research is a descriptive-analytical study conducted in Tehran in 2021 on two groups of nurses ($N=228$) selected through a stratified random method. The data collection tools were Choi knowledge management questionnaire and a researcher-made questionnaire on social value validated in Iranian society. **Results.** There was a positive and significant correlation between the variables of knowledge management and social value in Bachelor of Science (BSc) nurses (P value ≤ 0.01 , $r=0.43$), and no significant correlation was observed in Master of Science (MSc) nurses (P value >0.05 , $r=0.14$). **Conclusions.** In the BSc nurses' group, a direct and significant association was found between knowledge management and social value of BSc nurses so that by increasing the score of knowledge management in the nursing community, individuals feel more self-worth, resulting in achieving a favorable level of customer satisfaction. **Implication for Nursing Management.** It is suggested that an accurate program should be designed for all academic levels of nurses in hospitals, the principal elements of creating knowledge and learning and its provision should be assessed, and the necessary measures should be taken.

1. Introduction

The necessity for rapid access to information in order to support decision-making in critical conditions in healthcare systems is inevitable. The world has undergone widespread changes during the recent decades culminating in new complications and challenges for all organizations, especially organizations that provide healthcare services. A new field called “knowledge management” has appeared to adapt to

these changes [1]. Knowledge management takes a great step towards efficient management by emphasizing learning, organizational thinking, a sense of cooperation, and approach orientation, encouraging individuals to express new ideas, forming an appropriate environment for expressing interests, and identifying individuals' abilities and capabilities and using them in executive affairs and decision-making and assigning them responsibility [2]. By using knowledge discovery in scientific and clinical research,

teaching, and other fields extensively to solve complicated problems and improve work efficiency, service provider systems are known as knowledge-based organizations that need skilled and knowledgeable staff [3]. Knowledge discovery, as the first step in the knowledge management process, turns information into knowledge and thereby helps healthcare service providers reduce information overload [4]. Knowledge, as an important resource, should also be managed effectively by the medical staff, particularly nurses, because organizations providing healthcare services need to collect, analyze, and turn data into information and knowledge for decision-making [5]. Having a clear understanding of the information required by nurses to design knowledge management systems is necessary [6]. Some of the positive consequences of knowledge management in the healthcare system are reduced medical errors, improved care quality, improved organizational learning, and increased collaboration, innovation, and reduced costs [7]. Nurses' knowledge management in different studies indicates different results. In Hassanian et al.'s study, knowledge management of the majority of nurses (60.4%) was reported at an average level [8], while in Lee et al.'s study, the mean score of nurses' knowledge management was 3.21 [9], requiring more examinations in the field of knowledge management among nurses. Also, considering the effect of educational levels on knowledge management, it is necessary to compare the knowledge management of nurses with different educational levels [10].

One of the evident goals of knowledge management is creating value in organizations. One of the most general ways to create value is to support efficient and effective decision-making. Creating value does not necessarily mean creating economic value, but creating social value is a category proposed as a prerequisite for knowledge management [11].

In the present organizational atmosphere, "social values" can make anything accessible, and without values, no action works [12]. These values are comprehensible, have an emotional burden, are shared among many individuals and groups, and are used as judgmental norms and a standard for discovering goals and ways to achieve them [13, 14]. Nursing is a profession manifesting its value in the relationship of the individual with the environment and colleagues. This profession provides precious services under challenging conditions to society, while every action contains a variety of values manifesting its actual meaning [15]. Social and moral values include new fields previously mentioned by Florence Nightingale [16]. Nursing social value is a fundamental value in this profession that can foster in the nurse simultaneously with providing nursing care, and this value can be promoted via training so that despite the crises experienced in society, promotes the individuals' perception of the field of nursing and its social value [15]. As a social action, nursing has a variety of values that give it meaning, i.e., these values reflect the practical principles of nursing and build nursing care based on them [15]. Among the most crucial values are social values. The results of a study conducted to determine the social values affecting patient-nurse interactions indicated that the most important social values influencing the patient-nurse relationship included affection or compassion,

honesty in words and actions of nurses, and justice and equality in benefitting from medical facilities and nursing services [17]. It is noteworthy that according to Gallup's annual report, nurses have been chosen for the 20th consecutive year by the population of the United States as the specialists who have gained the most trust due to their honesty and ethics, and with 81%, they ranked higher than doctors, teachers, and pharmacists [18]. Moreover, the findings of another study indicate that the value that society places on nursing is positive and is viewed as a profession necessary to improve individuals' health [19].

Despite the numerous advantages of knowledge management, not much research has been conducted on knowledge management and social value in nursing in hospitals, particularly among nurses facing with so much data in various situations. Socialization has not taken place in nursing. A notable point here is that despite the importance of recognizing the variables' positive effects, the resources still have not obtained accurate information regarding the interaction and relationship between these variables in nurses; therefore, by tracking information accurately and recognizing the variables and their role in the nurses' organizational performance exactly, the research team conducted the current research to determine the relationship between knowledge management and social value among nurses working in hospitals of Tehran University of Medical Sciences.

2. Methods

2.1. Study Design. This research is a descriptive-analytical study conducted in 2020 in all public hospitals of Tehran University of Medical Sciences.

2.2. Study Participants. The research population included all BSc ($N=4376$) and MSc ($N=213$) nurses working in public hospitals affiliated with Tehran University of Medical Sciences. The sample size was calculated using the pilot study's correlation coefficient (0.26) for type I statistical error to be 0.01 based on the formula ($n = (z/w)^2 + 3$) with ratios ($w = 1/2 \ln(1 + r/(1 - r))$) [20, 21], and finally, considering 15 probable drops, 112 people were determined as two separate research populations for each of the two groups of MSc and BSc nurses. Nurses were selected using a stratified random sampling method with allocation proportional to the size of the categories in the society so that 14 hospitals affiliated with Tehran University of Medical Sciences were regarded as categories. Based on the number of nurses working in each category, the number of nurses required in each category (hospital) was calculated using mathematical proportionality. After determining the number of nurses in each hospital, the number of nurses that should be placed in the research sample was specified using a table of random numbers. After going to each hospital and providing the random numbers to the nursing office, the researcher received the phone numbers of the sample individuals using the staff list and sent the research questionnaire to them. It should be mentioned that although the sample size was 112

people based on the formula, since the results of the proportionalities resulted in gaining decimal numbers, rounding off the numbers resulted in adding 2 units to the sample size. Thus, the final sample size was obtained at 114 in each group.

2.3. Study Tools. The data collection tools in this study consisted of three parts.

The first part was regarding demographic characteristics, including gender, age, marital status, education level, type of employment, service record, service department, and service record in the department.

The second part was Choi knowledge management questionnaire (2005) [22] designed specifically for nurses containing 23 items with a five-point Likert scale: five items regarding knowledge sharing culture, 6 items regarding nursing management system, 4 items regarding creative management leadership, 5 items regarding organizational learning, and 3 items regarding the performance outcomes-based reward system. The options of this scale are completely agree (5), agree (4), no idea (3), disagree (2), and completely disagree (1). The range of attainable scores in this questionnaire is 23–115. Higher scores denote higher levels of knowledge management. The questionnaire's validity and reliability were assessed and approved in Lee et al.'s [9] study, and Cronbach's alpha was reported as 93% [9]. Since Choi knowledge management questionnaire had not been ever translated into Persian, the translation-back-translation process was performed after asking for permission and consent to translate the mentioned questionnaire. After completing the translation process and performing face validity and content validity, the test-retest method was used to determine the knowledge management questionnaire's reliability. For this purpose, according to the opinion of the statistical consultant, the questionnaires were filled out by 20 nurses working in Imam Khomeini Hospital Complex and Shariati Hospital (10 nurses each) selected randomly. After two weeks, the questionnaires were provided to the same nurses again to respond, and the correlation coefficient was then calculated between the two groups of obtained data. The correlation coefficient for the knowledge management questionnaire was reported to be 0.8.

The third part of the social value questionnaire was researcher-made. Despite the existence of a number of tools in this field, none of them had been used specifically in nursing [23, 24]. According to the characteristics and conditions of the nursing profession, a researcher-made tool was designed from a combination of different tools [17, 23, 24]. It was provided to 10 faculty members of the Faculty of Nursing and Midwifery to assess and approve the qualitative and quantitative content validity and face validity. The primary number of questions was 45 questions, and after the faculty members' expert opinions and removing questions with the same concept, 29 questions remained. The content validity index (CVI) and content validity ratio (CVR) of the social value questionnaire in this study were calculated as 0.81 and 0.73, respectively. The test-retest method was used to determine the reliability of the social value questionnaire. For this purpose, according to the statistical

consultant's opinion, the questionnaires were completed by 20 nurses working in Imam Khomeini Hospital Complex and Shariati Hospital (10 nurses each) selected randomly. After two weeks, the questionnaires were provided to the same nurses again to respond, and the correlation coefficient was then calculated between the two groups of obtained data. The correlation coefficient for the social value questionnaire was reported to be 0.79. It should be mentioned that these 20 people were excluded from the research sample and the data obtained from them were not used.

2.4. Study Processes. Considering the coronavirus disease-2019 (COVID-19) epidemic and its resulting restrictions, data were collected as self-reports by the investigated units, and the questionnaires were sent online. Sampling was performed after confirming the questionnaires' validity and reliability. Because of the restrictions for the continuation of the COVID-19 epidemic, an in-person referral was not possible for the researcher; therefore, online sampling was performed by sending the questionnaire link to the cell phone and email of the selected research unit, which was designed by the researcher in Porsline software (<https://lilirezaei.digisurvey.net/40bmd>). After filling out and sending the questionnaire by the research units, the data were saved and retrieved in the researcher's email box. The questionnaire was designed in such a way that the research units were able to read, complete, and send the questionnaire as a self-report by spending approximately 10 minutes. They were supposed to answer all questions to submit successfully.

2.5. Study Analysis. After entering into SPSS software version 16, the data were statistically analyzed. First, given the participants' responses to the questionnaire questions, the scores obtained by them for the two main variables of the research, i.e., the knowledge management was calculated and classified into the following five scores: very few, few, neutral, high, and very high, and social value was calculated and classified into the following four scores: very low, low, neutral, high, and very high. In order to achieve particular goals and describe the research's main and background variables, descriptive statistics, including frequency distribution tables, central indices such as mean, dispersion indices such as standard deviation, were used for quantitative variables such as age, work experience, knowledge management, and social value, and inferential statistics including the independent *t*-tests, chi-square, analysis of variance (ANOVA), and the nonparametric Mann-Whitney *U* test were used for significant difference of variables between the two groups.

3. Results

Based on the research findings, the mean \pm SD age of BSc and MSc nurses is 35.89 ± 7.23 and 39.41 ± 7.50 , respectively. Furthermore, the mean work experience for BSc nurses was 11.86 ± 7.35 and for MSc nurses was 14.94 ± 7.05 . Other demographic information is presented in Table 1.

The research results indicated that the mean \pm SD score of knowledge management in BSc nurses was 78.12 ± 16.13 and in MSc nurses was 75.96 ± 19.47 . Over one third of the individuals in both investigated groups had a knowledge management score between 79 and 96, which is high. None of the BSc nurses gained a score under 42 and the mean score of this group was higher than that of the MSc group. Although according to the statistical test the existing difference was not significant, it can be said that the two groups had almost the same situation regarding the knowledge management score.

Moreover, the mean \pm SD score of social value and the score range in BSc and MSc nurses are 121.15 ± 11.82 (74–145) and 122.18 ± 10.88 (90–144), respectively. Over half of the investigated individuals have gained a very high score (122–145) in evaluating social value. Although given the lowest score and mean score the MSc nurses group is in a better situation regarding social value than the BSc group, the present difference is not to the extent that the statistical test shows it to be significant. Therefore, the two investigated groups are identical regarding the social value score (Table 2). Also, a positive and significant correlation was observed between knowledge management and social value in BSc nurses (P value ≤ 0.01 , $r = 0.43$), but there was no significant correlation in MSc nurses (P value > 0.05 , $r = 0.14$) (Table 3).

4. Discussion

The present research was carried out to assess the relationship between knowledge management and social value in nurses working in the hospitals of Tehran University of Medical Sciences.

4.1. Nurse's Knowledge Management. The results of this research indicated that over one-third of all participants in each group (BSc and MSc nurses) had high knowledge management in the range of 79–96; in other words, they are located in a range indicating that their level of knowledge management is high. In the BSc nurses' group, no nurse was placed in the very low range of knowledge management.

Moreover, no significant difference was reported regarding knowledge management between the two groups of BSc and MSc nurses. The high level of knowledge management in nurses causes them not to be anxious in administrating affairs in dealing with unpredicted events. Therefore, there is constantly an answer for each possible question and they solve the patients' problems with their knowledge. The high level of knowledge management in nurses necessitates their better perception of medical issues of the day, and this important issue directs them towards having higher social values. This study was consistent with Jahanbani et al.'s [25] study which reported the knowledge management state as desirable [25]. Despite the limited number of studies investigating the use of knowledge management technology in developing countries, particularly in Iran, studies indicate that the skills and awareness of the use of knowledge management technology are very low among healthcare service providers [26]. In supporting the abovementioned concept, Adane et al. showed in a report on the use of computers and the Internet by nurses in a Nigerian educational hospital that only 43% of the nurses could use knowledge management [27]. Similarly, only 33% of the health specialists in Ethiopia use knowledge management technology for various purposes [26]. In another study, Hosseini-Zahmatkesh et al. [28] evaluated the knowledge management level of nurses at an average level, which was inconsistent with the findings of the current research [29]. The difference between the mentioned study and the current research is that this study has merely investigated the community of BSc nurses and has used a different questionnaire [28]. Ahsan et al. [30] carried out another study to investigate the role of nursing care education based on knowledge management in infection prevention. In this study, the knowledge management level of nurses was assessed based on the pretest and post-test, indicating that after receiving training, the knowledge level of nurses was promoted by 38%. The mean score of knowledge management in the pretest was 56% and in the post-test was 85%. Their study and the current research are different in terms of different knowledge management questionnaires, the different number of samples, and different methods [30]. Since today's successful organizations are organizations that have

TABLE 2: Determining the score of knowledge management and social capital according to the level of education of nurses.

Variables	Bachelor nursing		Master sciences nursing		Test statistics	P value	
	N	%	N	%			
Knowledge management	23–41 (very few)	0	0	4	T = 0.91	0.36	
	42–59 (few)	17	14.9	22			19.3
	60–78 (moderate)	40	35.1	32			28.1
	79–96 (high)	45	39.5	39			34.2
	97–115 (very high)	12	10.5	17			14.9
	Total	114	100	114			100
Social value	29–52 (very low)	0	0	0	T = -0.68	0.49	
	53–75 (low)	1	0.9	0			0
	76–98 (moderate)	3	2.6	3			2.6
	99–121 (high)	48	42.1	42			36.9
	122–145 (very high)	62	54.4	69			60.5
	Total	114	100	114			100

Note. The knowledge management was calculated and classified into five scores as follows: very few, few, moderate, high, and very high. Social value was calculated and classified into five scores as follows: very low, low, moderate, high, and very high.

TABLE 3: Association between two variables in two separate groups.

Variables	Groups			
	Bachelor science group		Master science group	
	r	P value	r	P value
Knowledge management and social value	0.43	≤0.01	0.14	≤0.01

been able to induce or acquire new knowledge and use it practically in improving and promoting their activities, hospitals should also pay attention to this crucial matter, provide the required context, and encourage nurses to benefit from new and scientific methods to reform their performance.

4.2. Nurse's Social Value. The results of this study also indicated that over 50% of the nurses in both groups had a high level of social value. Zarei et al. (2011) reported in their research a high mean score of value perceived by inpatients. These findings reveal a high capacity to promote the value of services provided in hospitals. Guimaraes et al. [15] carried out a qualitative study to identify and perceive social value in the discourse of graduate nursing students and found that social value could be identified and perceived in the discourse of nursing students, being manifested in care pragmatism based on solidarity. As a result, the students acknowledged social value as the main trait in this profession. In the clinical setting, in contact with the patient and his/her family, the students were able to take the social value into consideration using sympathy and consider it necessary for nursing care, recognize patients as human beings, and value them. Students cared about patients not only from a physical-biological viewpoint but also due to their belief in humanity. It means they understood patients as individuals and tried to communicate with them through dialogue [15]. Yang et al. reported that nurses significantly influence the general population [31]. Glerean et al.'s study also displays an image of nursing that is precious to people and is definitely necessary for them [32]. In another study, Vega et al.

indicate high levels of trust in nurses and report that 97% of the users welcome nurses in their homes, 76% consider nurses reliable to apply new techniques, and 50% know nurses as reliable to prescribe medication [33], which the results of all these studies are the same as the findings of the current research. However, Pierrotti et al.'s study, although has considered nurses as important as doctors, reported that doctors have more credit than nurses [34]. According to the findings of Girvin et al.'s study, the nursing profession is sometimes not recommended by school vocational counselors or family members since it is not regarded as an ideal career [35]. On the contrary, in Vega et al.'s study, 73.4% of the respondents knew this profession as an acceptable career to be recommended to their loved ones [33]. Some studies indicate that nurses are generally depicted in the newspapers as professionals with a secondary role concerning another profession having low responsibility, independence, or decision-making capacity. It is also recognized as an uninteresting and challenging career, without creativity and responsibility, with few opportunities for growth or promotion, low scientific level, low salary, and low social position [35, 36]. On the contrary, the findings of Vega et al.'s study disagreed with the image of the nursing profession depicted by the media due to injustice regarding the profession's social position or prestige [33]. Some websites belonging to official institutions and healthcare centers suggest the superiority of medicine over other health professions [35]. The results of these studies differ from the findings of the present research, which may be due to different contexts of the nursing profession in different countries, the type of social value recommended in the study, the tools used, and the comparison of nursing with some other professions.

4.3. Relationship between Knowledge Management and Social Value. Finally, the results of this study indicated that the scores of knowledge management and social value in the BSc nurses' group had a statistically significant positive association in such a way that as the score of one of the variables increases, the score of another variable also increases, while no such association exists in the MSc nurses group. No study was found that has investigated the association between these variables. Perhaps one of the possible causes of the lack of association between the knowledge management and social value in the MSc nurses' group is that social value is fully formed in these nurses and is not related to other variables including knowledge management. However, Fulk and Yuan et al.'s study indicates that the clarity of individuals' interaction in the organizational social network value helps scholars acquire knowledge-related materials, leading to facilitating interaction with knowledge sources. Hence, the organizational social network value among social media programs is superior to traditional knowledge management systems in eliminating these challenges [37]. According to Ellison et al., organizational social network values culminate in improving knowledge sharing in multinational organizations via raising social capital, supporting relationships, and mutual effects. Organizational social network values make it possible to create knowledge management with various benefits according to the levels of control and interaction [38]. Furthermore, using organizational social network values is positively linked to staff performance [38]. It can be said that one of the obvious goals of knowledge management is to create value in organizations. Knowledge management can pave the way to promote the organization's performance and achieve the sublime goals correctly by integrating the organization's social value in different departments and directly affecting concepts such as customer orientation, organizational learning, leadership, and intelligent management and decision-making, generating new knowledge, turning implicit knowledge into explicit knowledge, and paying attention to individuals' and experts' knowledge. The abovementioned items are among the principal functions of knowledge management that organizations need to achieve their goals. The abovementioned items are among the knowledge management functions that organizations strongly need to achieve their goals.

4.4. Limitations. The statistical population of the present research consisted of BSc and MSc nurses working in the hospitals of Tehran University of Medical Sciences; therefore, the results of this study may be generalized to other societies and universities of medical sciences cautiously. Using the questionnaire is considered a limitation in such a way that a questionnaire assesses individuals' attitudes, not the reality, which can be viewed as a limitation. Moreover, when responding, nurses may think that the actual response harms them and respond conservatively, and consequently, the results may be doubted and threatened.

4.5. Implication for Nursing Management. It is suggested that an accurate program should be designed for all academic levels of nurses in hospitals, the principal elements of creating knowledge and learning and its provision should be assessed, and the necessary measures should be taken. Moreover, a platform should be formed for the acceptance of using knowledge management on behalf of each organization's staff by revealing the importance of this matter through participation, organizational commitment, extending staff's communication, and using virtual education platforms. In the meantime, simultaneously with creating and developing knowledge management and the affecting factors, the organization's managers should further emphasize the internalization and socialization of knowledge and focus less on its integration, which can promote clients' satisfaction and organizational productivity.

5. Conclusions

Based on the results of this study, knowledge management is directly and significantly related to social value in the BSc nurses' group so that by increasing the score of knowledge management in the nursing community, individuals feel more self-worth, resulting in achieving a favorable level of customer satisfaction. Due to large numbers of staff, professors, students, and beneficiaries at various levels, medical sciences and nursing require strong and coherent infrastructural dimensions regarding knowledge management.

Data Availability

The datasets used and analyzed during the current study are available from the corresponding author on reasonable request.

Ethical Approval

The current study was approved by the Ethics Committee of Tehran University of Medical Sciences and was registered under the registration number: IR.TUMS.FNM.-REC.1399.229. Before the commencement of the project, all required permissions were obtained. Moreover, the participants were assured of the confidentiality of the information and the possibility of withdrawing from the study at any stage.

Disclosure

The author(s) disclosed receipt of the following financial support for the research, authorship, and/or publication of this article: This project was article was extracted from an MSc thesis approved by Tehran University of Medical Sciences.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

F.H, L.R, and N.DN, were involved in designing the idea and preparing the proposal. Data collection was performed by L.R and H.A and data analysis was performed by R.JO and H.A All researchers have participated in data interpretation, preparation, and article preparation.

Acknowledgments

The authors wish to express their gratitude to the Tehran University of Medical Sciences research deputy, the faculty of nursing and midwifery, and all nurses who participated in this study.

Aim. We investigated the impact of empowering leadership on both perceived stress and salivary cortisol, a commonly utilized biological indicator for stress assessment. **Background.** Empowering leadership is gaining increasing interest in companies. However, the impact of empowering leadership on stress is still insufficiently explored, with conflicting findings within the literature on this topic. While certain studies indicate that empowering leadership reduces perceived stress, other studies have suggested that empowering leadership could be stressful. **Methods.** We conducted a cross-sectional study using a questionnaire among a sample of 397 participants working in a French hospital. Participants' salivary cortisol was assessed. All analyses exploring the relationships between empowering leadership, perceived stress, and salivary cortisol were performed using multiple imputation methods. **Results.** Empowering leadership could simultaneously increase and decrease perceived stress. Specifically, although the empowering leadership global factor showed a negative correlation with perceived stress, some specific empowering leadership behaviors were positively associated with perceived stress. However, salivary cortisol was positively related to perceived stress and strictly negatively related to empowering leadership. Furthermore, salivary cortisol could be explained by a significant interaction effect between perceived stress and empowering leadership, indicating that empowering leadership enables employees to cope with perceived stress. **Conclusions.** Although empowering leadership was an ambiguous antecedent of perceived stress, our findings suggested that empowering leadership was a protective factor against increased salivary cortisol. These results suggest that empowering leadership behaviors could prevent biological stress. **Implications for Nursing Management.** While empowering leadership showed a protective effect on salivary cortisol, it is essential for managers to adopt the full set of empowering leadership practices to guarantee protective effects on perceived stress. This trial is registered with NCT04010773.

1. Introduction

Managerial practices aiming to foster employees' autonomy, such as empowering leadership, are gaining interest in companies [1, 2]. Unlike traditional leadership behaviors that consist of motivating employees through rewards (e.g., promise of bonuses) or threats (e.g., threat of blame or sanction; [3]), empowering leadership aims to motivate employees by increasing their power over their professional role and settings [4]. Two main categories of behaviors can be distinguished within empowering leadership: behaviors of power sharing with the employees and behaviors of support of the employees' autonomy [4]. Under these managerial conditions, the employees can not only exercise autonomous control over their thoughts and behaviors (i.e., self-leadership) and thus make concrete experiences of self-determination and self-efficacy but also impact and meaningful experiences at work (i.e., psychological empowerment [5]). These psychological experiences are intrinsically satisfying [6], and they, in turn, promote the identification of employees with their work and their increased occupational commitment [7] and improve the company's performance [8].

While the benefit of this type of leadership for the efficiency of companies is well established [8], its impacts on health remain understudied, with conflicting findings within the literature on this topic [9]. On the one hand, empowering leadership was found to reduce stress by fostering resource development and thus enabling the employees to meet their work requirements [10, 11]. However, these effects were low [10, 11]. On the other hand, in contrasting investigations, empowering leadership was suspected to promote occupational stress [12]. More specifically, they have suggested that the autonomy resulting from empowering leadership may represent a cognitive demand that induces stress for employees [12, 13]. Hence, additional studies designed to clarify the impact of empowering leadership on stress are needed. Beyond the scientific interest, this would enable us to make recommendations for the implementation of empowering leadership, with the aim of preventing possible negative effects in terms of stress. By conducting this research, our aim is to further understand how empowering leadership influences stress. More specifically, by developing two original perspectives, we aim to clarify the valence of the association between empowering leadership and stress and to improve our comprehension of the mechanisms underlying this link.

First, we examined the effects of empowering leadership on perceived stress and on salivary cortisol, considered as a biological indicator of stress [14]. As a steroid hormone, cortisol is secreted, under the regulation of the hypothalamic-pituitary-adrenal axis, by the adrenal glands. It helps to regulate energy and cellular metabolism all along the day [15]. Cortisol secretion exhibits cyclic biological variations, increasing in the second part of the night leading to a peak following awakening and a decrease during the day, with the

lowest level at night [16, 17]. Upon exposure to a stressful situation, the activation of the hypothalamic-pituitary-adrenal axis intensifies, triggering an increase in secretion. This response aims to prepare the organism to effectively cope with stress [14]. The cortisol level, therefore, appears as a relevant marker of the activation of the biological mechanisms of the stress response [14, 16]. Salivary cortisol level is the most widely used parameter because it measures the free (and active) level of cortisol and because of the simplicity and the noninvasive side of its collection [17, 18]. Although perceived stress triggers the activation of these biological mechanisms [19], it does not capture the biological mechanisms of stress [14, 16]. Accordingly, completing perceived stress measurement with the assessment of salivary cortisol could provide stronger evidence of the effect of empowering leadership on stress. Two alternative models for assessing the association between empowering leadership and salivary cortisol were tested. First, given the precursor role of perceived stress in the activation of biological mechanisms [19], the mediating effect of perceived stress on the relationship between empowering leadership and salivary cortisol was studied.

Hypothesis 1. The effect of empowering leadership on cortisol will be mediated by perceived stress.

The moderating effect of empowering leadership on the relationship between perceived stress and salivary cortisol was then investigated. Indeed, empowering leadership promotes employees' behavioral engagement in the transformation of their environment in order to develop their resources and their ability to cope with job demands [20]. However, the literature indicates that the effect of perceived stress on health can be mitigated depending on the efficacy of the individuals' coping strategies [21, 22]. Consequently, it may be assumed that empowering leadership will decrease salivary cortisol by allowing employees to effectively cope with perceived stress.

Hypothesis 2. Empowering leadership will moderate the effect of perceived stress on cortisol, with a weaker effect of perceived stress on cortisol when empowering leadership increases.

In addition, we attempted to distinguish the overall effect of empowering leadership from that of each of its specific component behaviors, using bifactor models [23]. Bifactor analyses consist of specifying both a global factor defined by the entire set of items and the specific factors [23]. Once the global factor has been estimated (i.e., when the globality has been taken into account), the specific factors are estimated using the residual information [23]. As mentioned earlier, prior research has indicated that empowering leadership power-sharing behaviors could be a stressful demand [12]. Conversely, empowering leadership-related supportive behaviors could be an occupational resource, since they would allow employees to deal with the autonomy-related demands [4]. Briefly, empowering leadership might have contrasting

effects contingent on the empowering leadership behaviors considered. Such a method could allow highlighting in an original way the possible contrasting impacts of empowering leadership on stress that has been suggested [12]. Considering the lack of previous studies relying on bifactor models to reflect empowering leadership and its effect on stress, we consider the effect of empowering leadership-specific factors on perceived stress and cortisol as an open research question. However, assuming that the bifactor model will be validated, and given the generally positive effects associated with empowering leadership, we expect the empowering leadership global factor to be negatively associated with perceived stress and cortisol.

Hypothesis 3. The empowering leadership global factor will be negatively associated with perceived stress and cortisol.

2. Methods

2.1. Study Participants, Procedure, and Cortisol Level Measurement. Between January and May 2018, we conducted a cross-sectional study involving employees working in a French university hospital. Data were collected during the compulsory medical examination within the occupational health department. The participants were included by the physician, provided that they did not work at night and were not pregnant, after having given their written informed consent to participate. After completing the questionnaires, instructions for saliva self-sampling using a salivette (Sarstedt, Marnay, France) were given by a nurse to all participants. They were asked to (a) collect the sample between two working days, to ensure that the salivary cortisol level could reflect both recent occupational exposure and occupational exposure anticipation [24]; (b) avoid collecting the sample after an intense stressful event, to ensure that the salivary cortisol level reflected chronic occupational exposure and not an isolated event [24]; (c) in participants treated with corticosteroids, not to take treatment within 24 hours prior to sample collection [17, 18]; and finally (d) collect the sample in the morning, after awakening, and without toothbrushing, while fasting and without tobacco [17, 18]. Sampling was scheduled after awakening to accommodate the circadian rhythm of cortisol [16, 25].

Salivary cortisol levels were analysed by the physician of the occupational health department for medical control. Among all the participants with an elevated salivary cortisol level, none was diagnosed with Cushing's syndrome [26].

This study was ancillary to the Chrysalide research project [27], so there was no sample size determined specifically for this study. The sample collected ($n = 397$) was deemed sufficient to conduct structural equation modelling for the measurement model [28].

2.2. Salivary Cortisol Analyses. Free salivary cortisol level was assessed through a previously described "liquid chromatography-tandem mass spectrometry" (LC-MSMS) in-house method [29]. This method was chosen because of the specificity of its measurement [18]. Briefly, free salivary

cortisol was determined from 500 μL of the salivary sample, using a liquid-liquid extraction (LLE) with dichloromethane. High-performance liquid chromatography (HPLC) systems were from Agilent Technology (Agilent Technologies, Les Ulis, France) coupled with 3200 Qtrap spectrometers (Sciex, Les Ulis, France). The quantification transition used was $363 > 121$. The deuterium internal standard contained cortisol-d4. Cortisol standards for establishing calibration curves were diluted in methanol.

2.3. Psychometric Measures. Empowering leadership was measured using the Leader Empowering Behaviour Questionnaire (LEBQ; Supplementary Table S1) created by Konczak et al. [30]. The questionnaire consists of 17 items helping to measure six behaviors: accountability, delegation of authority, information sharing, self-directed decision-making, coaching for innovative performance, and finally skills development. The level of agreement with each statement was indicated on a seven-point scale, ranging from "strongly disagree" to "strongly agree." The LEBQ has been found to exhibit satisfactory criterion validity and reliability [30, 31].

Perceived stress was measured using the Perceived Stress Scale in its four-item version [32]. Participants were asked how often they had been faced with each situation during the last four weeks, on a five-point scale ranging from (1) "never" to (5) "often." The four-item version of the PSS has been previously found to exhibit satisfactory criterion validity and reliability [33].

2.4. Ethical Approval Statement. This work belongs to the Chrysalide research project [27]. The Nantes University Hospital Ethics Committee (i.e., GNEDS, Groupe Nantais d'Éthique dans le Domaine de la Santé) approved the research protocol (reference number GNEDS02122018). The entire methodology was conducted in line with the Declaration of Helsinki guidelines. The protocol is registered online under the reference number NCT04010773 (ClinicalTrials.gov).

2.5. Statistics

2.5.1. Test of the Bifactor Configuration of Empowering Leadership. We first tested the bifactor structure of empowering leadership using Mplus software, version 8.3. The models were assessed with the maximum likelihood of robust standard errors (MLR). The analysis strategy recommended by Morin et al. [23] was used. More precisely, four competing empowering leadership measurement models were estimated (Supplementary Figure S1 online): (1) the original six correlated factors model is proposed by Konczak et al. [30] using confirmatory factor analysis (CFA), in which the factors are strictly defined by their corresponding items; (2) the same six correlated factors configuration using exploratory structural equation model (ESEM), in which the items can contribute to multiple dimensions simultaneously as cross-loadings are considered

[23]; (3) a configuration using a bifactor CFA model (BCFA) with one global factor defined by the entire set of empowering leadership items and six specific factors defined by their respective items [23] (Factors were specified as independent (i.e., orthogonal) without cross-loadings, considering that the global factor accounts for the covariance between the dimensions [23]); and (4) the same configuration using a bifactor-ESEM model (BESEM), in which the items are allowed to contribute to the other specific factors, as well as to the global factor and their dedicated specific factor. The best factor configuration for measuring empowering leadership was then used to assess the complete measurement model integrating empowering leadership and perceived stress (defined based on a CFA model).

We then compared the models with each other, assessing the parameters and fit indices estimated within the models. The model fit was evaluated by utilizing the root mean square error of approximation (RMSEA), comparative fit index (CFI), and Tucker–Lewis index (TLI). A CFI (or a TLI) equal to or exceeding 0.90 indicates an acceptable fit, while a value of 0.95 or higher indicates an excellent fit to the data [34]. Similarly, a RMSEA less than 0.08 is considered acceptable, and a value below 0.06 indicates an excellent fit [34]. The comparison begins with ESEM and CFA models. The ESEM model could be selected based on three criteria: (a) exhibiting the best-fit indices, (b) a decrease in interfactor correlations when accounting for cross-loadings, and (c) a correct definition of factors [34]. Second, a comparison was made between the chosen ESEM or CFA model and its respective bifactor model. One could select the bifactor model based on three criteria: (a) a correct definition of the global factor by the entire set of items, (b) a correct definition of the specific factors, and (c) the best-fit indices [23]. The composite reliability coefficient omega (ω) was also calculated for each factor.

2.5.2. Multiple Imputation Strategy. Of the 397 study participants, 110 did not provide their saliva sample (i.e., 28%). To take into account missing data, all the analyses exploring the relationships between empowering leadership, perceived stress, and salivary cortisol were performed using the multiple imputation method [35] using the factor scores (in their standardized form: mean = 0 and standard deviation = 1) extracted from the complete measurement model integrating empowering leadership and perceived stress. The 4.1.0 version of the R software was used to perform analyses with the “mice” package [35]. More precisely, 20 datasets were created by imputing the salivary cortisol level each time using a stochastic regression [35]. Then, the graphical appearance of the 20 imputed distributions of the salivary cortisol level was compared with that of the observed distribution of the salivary cortisol level to verify their similarity and the absence of aberrant imputations (e.g., negative values [35]). Finally, combined regression analyses were performed on the imputed 20 datasets according to the strategy described below.

2.5.3. Relationship between Empowering Leadership, Perceived Stress, and Salivary Cortisol Level. We assessed a series of models to investigate the effect of empowering leadership (a) on perceived stress and (b) on salivary cortisol, (c) the mediating effect of perceived stress on the relationship between empowering leadership and salivary cortisol, and (d) the moderating effect of empowering leadership on the relationship between perceived stress and salivary cortisol. First, two explanatory perceived stress models were assessed: Mps0, with the control variables only, and Mps1, with the addition of the six specific factors and the global factor for empowering leadership as explanatory variables. Mps1 allowed investigation of the effect of empowering leadership on perceived stress. The comparison of the R^2 of Mps1 and Mps0 showed the share of perceived stress variance explained by empowering leadership, independently of the control variables. Then, we assessed a series of explanatory models for salivary cortisol: Mc0 with the control variables only, Mc1 with perceived stress, Mc2 with the specific factors and the global factor for empowering leadership, Mc3 with perceived stress, the six specific factors and the global factor for empowering leadership, and Mc4, using the same specifications as for Mc3, with the interaction between perceived stress and the specific factors, as well as the global factor for empowering leadership. Mc1 showed the effect of perceived stress on salivary cortisol. Mc2 showed the effect of empowering leadership on salivary cortisol. Mc3 showed the relative contribution of perceived stress and empowering leadership in explaining salivary cortisol. Finally, Mc4 showed the interaction between empowering leadership and perceived stress to explain salivary cortisol. The comparison of the R^2 of Mc1 and Mc2 with the R^2 of Mc0 showed the share of salivary cortisol variance explained, respectively, by perceived stress and empowering leadership, independently of the control variables.

All models assessed with multiple imputations were adjusted for the controlled variables (i.e., gender, age, occupation, working time, and length of service in the organization). Fourteen participants reported being treated with corticosteroids (3 oral, 6 dermal, and 5 nasal). Therefore, the explanatory models for salivary cortisol were also adjusted for the intake of corticosteroids. A significance threshold of 5% for the risk of error α was applied when testing the hypotheses.

Considering recent developments in statistics, the mediating effect of perceived stress was directly tested using the bootstrapping method [36] combined with multiple imputation analyses [37]. These analyses were performed using *bememLavaan* package with R [38]. The method involves drawing B bootstrap samples from the original data and then generating K multiple imputations nested within each of the B bootstrap samples. The mediation effect is estimated in each of the $K * B$ subsamples, giving the distribution of the mediation effect and allowing 95% confidence intervals to be constructed (for details, refer to [37]). According to the recommendations, we performed 1000 bootstrap samples with 20 multiple imputations each [35, 37].

3. Results

3.1. Participants. The sociodemographic variables and salivary cortisol, perceived stress, and empowering leadership before modelling are described in Supplementary Table S2 online. A sample of 397 participants was included. The mean age was 40.37 ± 10.57 years (range: 19–69 years), and the mean service length in the organization was 13.71 ± 9.81 years. About 80% of participants were women. The most represented occupations were nurses, nurse assistants, and physicians, accounting for 36.3%, 22.2%, and 21.9% of the sample, respectively. Most participants worked full time (71.5%). The mean total empowering leadership score was 4.61 ± 0.95 (range: 1–7), indicating that overall, the participants perceived that their manager was engaged in empowering leadership behaviors. The mean perceived stress score was 6.16 ± 3.25 (range: 0–16), close to that observed in the broader French workforce [39]. The mean salivary cortisol level was 2.84 ± 1.60 ng/mL (range: 0.24–13.50 ng/mL).

3.2. Fit of the Measurement Models for Empowering Leadership. Table 1 displays the fit indices of the measurement models. The residual item variance (δ), the standardized item factor loadings (λ), and the dimension reliability are shown in Supplementary Table S3 online. Supplementary Table S4, available online, presents the correlations between the factors within both the ESEM and CFA models. There was an overall satisfactory fitting for the four empowering leadership measurement models, except for the CFA configuration, with a TLI of 0.889. The best fit to the data for all the indices was obtained with the BESEM model.

3.3. ESEM versus CFA Models. The ESEM model exhibited a better fit compared to the CFA one. Both in the ESEM and CFA models, the dimensions for empowering leadership were well-defined by their devoted items ($\lambda = 0.289$ – 0.949 and $\lambda = 0.360$ – 0.902 , respectively). Regarding the ESEM configuration, many cross-loadings could be observed and were found to remain lower than the loading coefficients observed for the devoted items ($\lambda = 0.003$ – 0.287). Finally, relative to the CFA model, the ESEM model exhibited a decrease in the interfactor correlations. In sum, the ESEM configuration could be considered the best model.

3.4. ESEM versus BESEM Models. The BESEM model was overall well-defined. Except for item 6 relating to accountability ($\lambda = 0.053$), all empowering leadership items showed high and significant loading coefficients for the global factor ($\lambda = 0.357$ – 0.735). The specific factors were found to be correctly defined by their devoted items ($\lambda = 0.073$ – 0.708). However, item 7 showed a non-significant and very low loading coefficient in defining its specific factor (i.e., self-directed decision-making). Nonetheless, the other dedicated items correctly defined the self-directed decision-making dimension ($\lambda = 0.592$ – 0.595).

The other specific factors for empowering leadership were also well-defined. In summary, the BESEM model exhibited the best fit, with the global and specific factors being correctly defined. Therefore, the BESEM model was retained as the best model for measuring empowering leadership in further analyses.

3.5. Perceived Stress and Empowering Leadership Measurement Model. The final measurement model, combining the BESEM model for measuring empowering leadership and perceived stress, was well-defined (Table 2) and showed an excellent fit for all the indices (Table 1).

3.6. SC Level Imputation. The distributions of the salivary cortisol level in the 20 imputed databases, as well as the observed distribution of the salivary cortisol level, are shown in Supplementary Figure S2 online. The appearance of the imputed distributions was similar to that of the observed distribution, without outliers.

3.7. Empowering Leadership and Perceived Stress. Table 3 presents the Msp0 and Msp1 models for perceived stress. As expected, the global factor for empowering leadership is negatively correlated with perceived stress, thereby confirming Hypothesis 3. However, the specific factors for coaching for innovative performance, information sharing, and self-directed decision-making were surprisingly positively associated with perceived stress. Empowering leadership accounted for 13.3% of perceived stress. Further analyses revealed a percentage of perceived stress equivalents for the global factor and the specific factors for empowering leadership grouped together, ranging between 5.7% and 7.1% (Supplementary Table S5).

3.8. Empowering Leadership, Perceived Stress, and Salivary Cortisol. The models for salivary cortisol are presented in Table 4. A positive correlation was observed between salivary cortisol and perceived stress. Conversely, the global factor for empowering leadership is negatively correlated with salivary cortisol, thereby confirming Hypothesis 3. Unexpectedly, there was also a negative correlation between the specific factor for accountability and salivary cortisol. The comparison of Mc2 with Mc0 revealed that empowering leadership significantly explained 9.8% of the change in salivary cortisol, an explained variance level significantly higher by 8.3% compared to that of perceived stress (comparison of the R^2 of the Mc1 and Mc2 models). Therefore, at this stage, empowering leadership could be considered a stronger predictor of salivary cortisol level after awakening than perceived stress.

Bootstrapping analyses combined with multiple imputations for the test of the mediating effect of perceived stress were not significant (Supplementary Table S6). Therefore, we could not conclude that perceived stress mediated the relationship between empowering leadership and salivary cortisol. Consequently, Hypothesis 1 is rejected.

TABLE 1: Results of the fit analysis of the measurement models.

	χ^2 (df)	CFI	TLI	RMSEA	90% CI
Alternative models of empowering leadership					
CFA	316.244 (104)*	0.915	0.889	0.072	[0.063; 0.081]

stress and salivary cortisol decreased as the specific factor for accountability and the global factor for empowering leadership increased, to the extent that when the levels of the specific factor for accountability and global factor for empowering leadership were the highest, perceived stress was no longer related to high salivary cortisol levels.

4. Discussion

4.1. Bifactor Model for Measuring Empowering Leadership. These findings unequivocally highlighted the superiority of the bifactor model in capturing empowering leadership, thus supporting the simultaneous manifestation of global and specific phenomena within empowering leadership. On the one hand, the identification of the specific factors supported the specific phenomenon, which involves the independent implementation of the behaviors of coaching for innovative performance, skills development, information sharing, self-directed decision-making, accountability, and delegation of authority. On the other hand, the identification of the global factor supported the global phenomenon, which involves the implementation of a set of empowering leadership behaviors. By extension, these findings suggest that managers can selectively exhibit each of the specific empowering leadership behaviors and adopt all empowering leadership behaviors.

Finding a global factor aligns with existing literature. In fact, the most recent scales for measuring empowering leadership propose the combination of various behaviors into overarching factors (e.g., the two-dimensional scale proposed by Amundsen and Martinsen [4]). Nevertheless, the identification of the specific factors along with the global factor raised questions about the limits of the parsimonious operationalization of empowering leadership. Indeed, it could be assumed that they did not allow to take into account the specific nature of certain practices and their outcomes.

4.2. Empowering Leadership and Perceived Stress. As expected, the bifactor analysis confirms the contrasting effects of empowering leadership on perceived stress suggested in the literature [12]. We showed that all the empowering leadership behaviors (i.e., the global factor) contributed to decrease perceived stress. This result suggests that empowering leadership functions as an occupational resource that can enhance employees' perceived ability to cope with job demands [40]. This aligns with recent studies on the topic, including those conducted by Kim and Beehr [20] as well as Tripathi and Bharadwaja [11]. However, when the effect of the global factor was taken into account, some specific factors were positively associated with perceived stress. This result confirmed that some empowering

leadership behaviors might also pose a stress-inducing demand for employees [40], as proposed by Cheong et al. [12].

First, the positive effect of the specific factor for self-directed decision-making indicated that fostering autonomy and the expectation of autonomy expressed by the manager in the decision-making could be a factor for perceived stress. This finding is aligned with the assumption of Cheong et al. [12], according to which empowering leadership-induced autonomy could be a stressing demand. Furthermore, it is consistent with the mixed effect of autonomy reported in the literature. While it is predominantly viewed as a resource

[40], job autonomy is also demanding for employees, as they are required to independently make decisions with regard, for instance, to the work procedure or method [13].

Similarly, the specific factor for coaching for innovative performance was positively related to perceived stress. This could be explained by the fact that encouraging innovation could be demanding [40] for the employees. Indeed, the manager's incentive to propose new ideas implies an effort by the employees to identify problems, to search and encode information, to generate new ideas, and to express them publicly [7]. Therefore, it seems reasonable to consider that the manager's encouragement to innovate in empowering

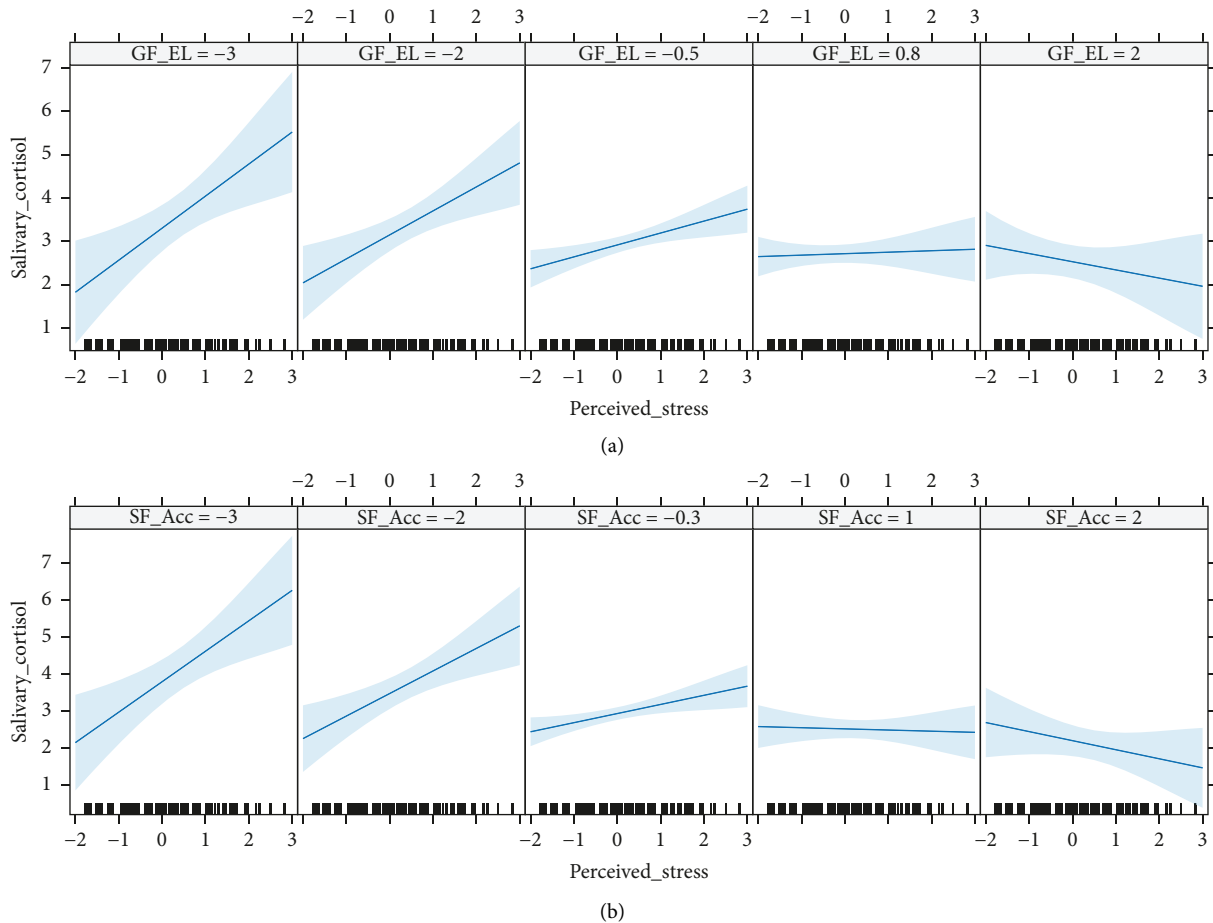

FIGURE 1: Moderating effect of empowering leadership in the analysis of the relationship between perceived stress and salivary cortisol. (a) Moderating effect of the global factor for empowering leadership. (b) Moderating effect of the specific factor for accountability. Note. GF EL = empowering leadership global factor; SF Acc = accountability specific factor.

leadership could be demanding for the employees and could, therefore, reduce their resources and generate perceived stress [40].

Finally, the positive association between the specific factor for information sharing and perceived stress indicated that access to information could also be a job demand. In this sense, some studies have shown that the increase in available information may exceed the processing capacities of individuals and lead to a relative experience of information overload and perceived stress [41]. The overload would be observed in particular when the information available is useful [41]. The perceived usefulness would push individuals to consider the information with a potential risk of exceeding their cognitive abilities and experiencing stress [41]. This mechanism could explain the contrasting effect we observed. Once the positive effect of information sharing is taken into account through the effect of the global factor, the sharing of “additional” information could be a factor leading to information overload and thus to perceived stress, characterized by the positive effect of the specific factor for information sharing on perceived stress.

More generally, we could assume that an imbalance mechanism in the implementation of empowering leadership behaviors could also be considered to understand the

negative effect of the specific factors [42]. Indeed, it should be noted that the specific factors should be considered as deviations from the global factor for empowering leadership [23]. In other words, we could assume that the global factor reflects the combined implementation of the entire set of empowering leadership behaviors, while the specific factors reflect the isolated implementation of these behaviors. Following this reasoning, the negative effect of the global factor on perceived stress could indicate the protective effect of the combination of the whole set of empowering leadership behaviors, while the positive effect of the specific factors on perceived stress could reflect the demanding effect associated with the isolated implementation of these behaviors. In this sense, the literature widely indicates that the effect of job demands on stress is likely to be moderated by job resources [40]. Using this reasoning, we could assume that the combined implementation of all the empowering leadership behaviors (i.e., the global factor) is likely to moderate the negative effects of information sharing and incentives for autonomy and innovation. Indeed, we can suppose that combining information sharing and incentives for autonomous decision-making and innovation on the one hand, with power sharing, accountability, and skill development on the other hand, could give employees the power

and skills they need to cope effectively with the demands of autonomous decision-making, innovation, and information processing and thus reduce perceived stress. Conversely, the selective implementation of these behaviors could induce perceived stress through the mechanisms suggested in the previous paragraphs. Nevertheless, further person-centered research (e.g., latent profile analyses) is needed to confirm this assumption [42].

4.3. Empowering Leadership and Salivary Cortisol. Nevertheless, the contrasting effect of empowering leadership seemed limited to the field of perception. Indeed, our results clearly indicated a negative effect of empowering leadership on salivary cortisol. Therefore, our study confirmed the protective effect of empowering leadership against employees' stress. Moreover, with almost 10% of variance explained, empowering leadership was a better predictor of salivary cortisol than perceived stress (1.5%). Thus, the measurement of the employees' resources, and in particular empowering leadership, could be preferred to estimate the impact of the psychosocial environment on their biological health [43, 44].

To understand this effect on salivary cortisol, we tested two alternative models: a perceived stress-mediated empowering leadership model, and a perceived stress-empowering leadership interaction model. Only the interaction model was validated. To put it differently, the protective effect of empowering leadership against elevated salivary cortisol could be better explained by the improved capability of employees to manage perceived stress, rather than by the reduction in perceived stress. In this sense, the transactional model of stress that measures perceived stress at a time t could not affect health at a time $t+2$ if the strategies implemented in the meantime (i.e., at $t+1$) have allowed regulating the environmental threat and reducing perceived stress [21]. To this end, strategies centered on stress factor regulation generally show a significant efficiency [45]. However, implementing these strategies assumes that the individuals have a sufficient level of resources [43], particularly in terms of control over their environment [22]. Considering the effect of empowering leadership on empowerment and the development of new resources, we could assume that empowering leadership gives employees the resources necessary for their behavioral commitment in the regulation of environmental demands to cope with perceived stress and thus contributes to reduce salivary cortisol.

Besides the effect of the global factor for empowering leadership, we observed that the specific factor for accountability was negatively associated with salivary cortisol. This result is particularly original since the literature suggests on the contrary that accountability could have the effect of a stressful occupational demand [12]. Moreover, the explanatory power of the specific factor for accountability ($b = -0.405$) was significantly higher than that of the global factor for empowering leadership ($b = -0.246$), suggesting that the employees' accountability could be the most protective aspect of empowering leadership against biological stress.

Laboratory studies have shown that the threats of social esteem or identity loss would be a powerful predictor of the activation of the biological response to stress [19]. To address these situations, individuals with high self-esteem tend to lack self-esteem less when faced with a threat to their social identity (e.g., social rejection) and, in turn, to experience a lesser increase in cortisol level [46]. According to us, accountability promoted by the manager could increase self-esteem, by encouraging employees to personally appropriate the results of their work. In this sense, the literature indicates that some forms of support, consisting of indicating to the employees their skills and value for the organization, could have a direct positive effect on self-esteem [47]. This positive effect of accountability on self-esteem could, in turn, reduce the employees' propensity to lack self-esteem, especially when faced with situations likely to threaten their social identity (e.g., observation of their work by others [19]), and thus decrease the activation level of the biological mechanisms of the stress response [46]. Moreover, as a personal resource [40], the self-esteem induced by accountability could also promote the employees' commitment to the regulation of perceived stress [43] and thus reduce the impact of perceived stress on biological stress.

4.4. Limitations. Considering that the cultural and organizational contexts can modify the effect of empowering leadership [1], these findings should be replicated in other samples. Furthermore, the cross-sectional design of the study might be biased. An experimental study assessing the effect of different empowering leadership behaviors on several measurements of salivary cortisol upon awakening could provide a stronger level of evidence of the effect of empowering leadership on biological stress [16].

5. Conclusions

We can conclude that empowering leadership is an ambiguous predictor of perceived stress, likely to both decrease it but also increase it if specific factors are taken into account. In this regard, these findings underscore the importance of embracing all empowering leadership behaviors to yield positive impacts on stress perception. On the other hand, empowering leadership shows clear protective effect against the increase in salivary cortisol. Although these results need to be confirmed, they suggest that empowering leadership behaviors could prevent biological stress [16].

6. Implications for Nursing Management

This study supports the need to implement empowering leadership in organizations and to prevent employee's stress. However, it invites to combine all empowering leadership behaviors to favor protective effects on perceived stress. Specifically, before sharing information and inviting employees to be innovative and autonomous, managers should be willing to recognize responsibility, provide support, and share power. On the flip side, managing through incentives for autonomy and innovation or information sharing, without recognizing employees' responsibility, supporting,

and sharing power, might contribute to perceived stress. Therefore, this study calls for future interventions designed to encourage the implementation of the full set of empowering leadership behaviors.

Data Availability

The dataset collected in the study will be available from the corresponding author upon reasonable request three years after the end of the study.

Disclosure

This study was conducted as part of the Chrysalide research project [27]. The ministry of health and the Nantes University Hospital have no role in the definition of the protocol, the conduct of the study, the data collection, the processing and interpretation of the data, nor in the choice of the results to present or the modes of valorization chosen.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

The study was designed by BC and JG. BC and JG assumed the roles of principal investigator and study coordinator, respectively. BC, under the supervision of NG (psychology coordinator), formulated the psychometric indicators and outlined the psychosocial objectives of the research. Under the supervision of KB (biology coordinator) and DT (medicine coordinator), JL articulated the biological indicator and formulated the biological objectives. The design of the study methodology was coordinated by DT, KB, GFB, and LM. Under the supervision of PC and NG, the statistical analysis was performed by BC. All authors, including IG, EF, AP, AA, FO, KB, PC, NG, and DT, proposed changes and contributed to the drafting of the present manuscript produced by BC. The manuscript was read and approved by all authors.

Acknowledgments

The authors would like to thank the contribution of psychology students (Lola Garcia Dupuis, Kiliane Chabonnel, Annaël Joubert, Hugo Normand, Mélanie Gendron, Antoine Tastayre, and Lucille Boulery), psycho-sociologists (Thomas Sterchi, Marine Robert, and Arnaud Lecun), physicians (Mickaël Humilier, Guéric Fourneau, Pierre-Alban Pioch, Amélie Mear, François Léger, Loïc Louisy, Stéphanie Grégoire, and Claire Gordeeff), and nurses (Annaïs Thureau, Jeremy Thureau, and Solenn Renault). Finally, the execution of this research would not have been possible without the support of Christophe Collignon and Alexandre Gérard, the CEOs of the innovating businesses involved, and Jean-Claude Vallée and Luc-Olivier Machon, directors of the hospital. This study was funded for 498 180 € (grant number: PREPS-16-681) from a scientific call for tender by the French Ministry of Health (Direction Générale de l'Offre de Soins),

within a PREPS (Programme de Recherche sur la Performance du Système de Soins). The authors acknowledge the peer review for the grant attribution conducted by an independent scientific jury.

Aim. To explore potential resilience and psychological flexibility patterns in nurses and analyze the effects of related factors such as growth mindset and professional recognition of categories. **Background.** Resilience and psychological flexibility can help nurses resist occupational pressure and play essential roles in promoting personal growth and professional development. **Methods.** A latent category approach was used to examine the patterns of heterogeneity in resilience and flexibility among 805 nurses. Differences in the influences related to resilience and flexibility were analyzed using univariate and multivariate logistic regressions, with demographic information, growth mindset, and career recognition as covariates. **Results.** Participants were divided into three potential categories: toughness-flexible (32.8%), power-deficit-emotional (23.1%), and toughness-rigid (44.1%). The results of multivariate logistic regression analysis showed that monthly income, mode of employment, growth mindset, and professional identity were influential factors in the potential categories of nurse resilience and flexibility. **Conclusion.** One cohort of nurses had high resilience and low flexibility, and psychological rigidity was related to the fact that the monthly income was less than RMB 5,000 and the contractual mode of employment. An excellent growth mindset and a high professional identity indicate that nurses are resilient and flexible. **Implications for Nursing Management.** Hospitals and nursing managers should pay attention to nurses' different career development needs and implement appropriate safeguards.

1. Introduction

There is no single definition of resilience or mental flexibility. An extensive review of the empirical literature summarizes resilience into five themes: overcoming adversity, adaptation and adjustment, prevalence, good mental health, and positive personal responses to challenges [1]. Psychological flexibility is the management of actions in a way that facilitates the pursuit of one's goals or values as

appropriate to the situation's needs [2]. In resilient shield theory [3], several indicators are interwoven to form a protective shield to help people withstand adversity. This clearly explains the theoretical system developed by many factors and flexibilities, in which the flexibility of the thinking layer allows for the transformation of cognition. Overall, resilience positively correlated with coping. Psychological flexibility, in contrast, is accompanied by goal orientation and action management. Both resilience and

flexibility in terms of favorable outcomes mean beating the odds, but there may be differences in the process involved and the result of the choices made.

The nursing community is a high-pressure occupational group, and nurses' mental health in China and other countries has received particular attention [4]. Work pressure, burnout, moral dilemmas, and vicarious trauma often lead to anxiety, depression, and other negative psychological aspects of this group [5–7], thus, laying hidden dangers to the quality of nursing services and even casting doubt on the value of the nursing profession [8]. When nurses face stress and challenges over time, better resilience helps them cope and adapt to adversity. However, psychological flexibility serves as a guiding light, telling the nurse the direction or goal for which they should strive. Better resilience and flexibility with greater adaptability positively impacted nurses' psychological, physical, and occupational functioning.

Resilience is dynamically variable and multifactorial from resource-, outcome-, and process-based perspectives [9]. The process of coping with stress and challenges reflects the underlying characteristics of individuals. Although many studies have demonstrated a significant positive correlation between resilience and psychological flexibility, it is unknown whether more resilient individuals possess better psychological flexibility. Latent class analysis can categorize the study population based on probability, significantly differentiating between groups and allowing heterogeneous individuals to exhibit characteristics that differ from other categories [10]. This is an excellent approach for exploring differences in resilience and flexibility within the same group of nurses. Compared to clustering algorithms, latent class analysis reduces human-induced errors and can be used to test more complex variable relationships. Therefore, this study aimed to explore resilience and psychological flexibility patterns among clinical nurses.

The second aim was to elucidate the factors influencing nurses' resilience and psychological flexibility. The growth mindset theory hypothesizes that belief in changing our intellect and mindset can influence how we handle challenges and define goals [11]. The motivation involved involves a complex interaction between goal orientation and mindset and has a wide range of applications in education. Michael reviewed 27 medical professional education articles on growth mindset. He noted that one of its potential benefits is that it provides people with emotional and psychological support, increased resilience, improved mental health, and self-confidence [12]. Professional identity is a positive perception and evaluation of the occupation in which you work [13]. Affirmation of the profession likewise affects the psychological state of the nurses themselves, their personal career development, quality nursing care, and the advancement of the professional discipline [14]. Nurses' resilience is significantly associated with their professional identity [15]. Higher resilience corresponds to a more positive career perception [16]. Figure 1 illustrates this study's portfolio framework.

Therefore, we propose the following hypotheses: (a) there is heterogeneity in patterns of resilience and psychological flexibility among clinical nurses, (b) a growth

mindset can influence nurses' patterns of resilience and psychological flexibility, and (c) professional identity can influence nurses' patterns of resilience and psychological flexibility. Exploring models of nurse resilience, psychological flexibility, and related influences can provide hospitals and nursing administrators with new perspectives and evidence for nurses' mental health management and career development.

2. Method

2.1. Study Participants. In August 2023, nurses from five public hospitals at level II and above in Anhui Province were selected as survey respondents using convenience sampling. Inclusion criteria encompassed the following: (1) possessing a nursing license; (2) working as a nurse for more than one year; and (3) informed consent to this study; exclusion criteria included the following: leave of absence such as vacation and further training.

2.2. Measurement

2.2.1. General Information Questionnaire. General information included age, sex, education, marital status, number of children, title, position, duration of employment, education, mode of employment, monthly income, and hospital grade status.

2.2.2. Simplified Version of the Psychological Resilience Scale. The original scale was the Connor–Davidson Resilience Scale [17]. The study was tested using the Chinese version of Laura Campbell-Sills [18], simplifying the 10-item entry [19]. The scale is based on a 5-point Likert scale with a positive scoring principle. It has shown good reliability and validity for testing mental health in the Chinese population. The Cronbach's alpha coefficient for this scale in this study was 0.933.

2.2.3. Acceptance and Action Questionnaire Second Edition. The second version of the Acceptance and Action Questionnaire (AAQ II) was developed by Hayes et al. and later adapted by Bond et al. [20]. The study used the Chinese version of Cao et al. [21], with 7 entries. Currently, there are more satisfactory applications for different Chinese populations. The scale measures acceptance and action on a 7-point Likert scale (from 1 = "never" to 7 = "always"), with higher total scores resulting in lower levels of psychological flexibility. The Cronbach's alpha coefficient for this scale in the present study was 0.973.

2.2.4. Growth Mindset Scale. This study uses the Growth Mindset Scale revised by Zhu et al. [22] in the context of Chinese culture, developed by Dweck et al., comprising three items. The scale is based on a 6-point Likert scale, with scores of 1–6 indicating complete agreement with complete disagreement; the higher the score, the better the level of growth mindset. The Cronbach's α for this study was 0.957.

FIGURE 1: Combined framework of resilience and psychological flexibility models. In the face of stressful events, resilience and psychological flexibility comprise different psychological characteristics of a positive coping model with goal orientation. Resilience and psychological flexibility interact in the model and form a heterogeneous pattern by their different demographic characteristics. A growth mindset and professional identity had an influential role in the model. In summary, the resilience and psychological flexibility model influences mental health and professional development.

2.2.5. Nurses' Professional Identity Rating Scale. The original scale was obtained from the University of Tokyo, Japan, and a version translated by Fangli Deng from China was used in this study [23]. The scale was merged into five dimensions based on Chinese cultural conventions: sense of self-efficacy and grasp, sense of congruence, sense of self-determination, sense of patient and organizational influence, and sense of meaningfulness. The entries totaled 21 items and were rated on a 5-point Likert scale, with 1 to 5 indicating strongly disagree~strongly Agree, respectively. The scores were positively related to professional identity. This scale is widely used in the Chinese population. The Cronbach's alpha coefficient for the scale in this study was 0.969.

2.3. Data Collection. This involved explaining the purpose and method of questionnaire distribution to the heads of the nursing management in each hospital. After obtaining consent, you can fill out the questionnaire using the Internet, and you will be limited to one response per IP address. The questionnaire included an omission prompt to ensure the completeness of the information. Data in the web backend were exported if they were not updated for one consecutive week. The two researchers jointly verified and excluded invalid questionnaires; 805 valid questionnaires were returned, with a valid recovery rate of 94.15%. The study used a rough estimation of the sample size, and with the addition of approximately 20% meaningless questionnaires, the maximum number was 252, which was sufficient for this study.

2.4. Ethical Considerations. The study was approved by the Ethics Committee of Bengbu Medical University, and all participants provided informed consent before the investigation. The ethical approval number was Grant no. 2023369.

2.5. Statistical Analysis. The CD-RISC-10 is scored on a 5-point scale. In particular, with a value < 3 as the lower responder. The low responder group was estimated to be 0. Furthermore, a value ≥ 3 was the higher responder group, estimated as 1. AAQ II was scored on a 7-point scale, with ≥ 4 categorized as a low responder group and estimated as 0. In addition, a value < 4 was categorized as a higher responder group and estimated as 1. After the scores were standardized to dichotomous categories, potential category analysis was conducted using the Mplus 7.4 software. We used a range of test values to explore the most superior classification [24]. Akaike's information criterion (AIC), Bayesian information criterion (BIC), and corrected Bayesian information criterion (aBIC) with lower values indicated a better fit. When the likelihood ratio (LMR) and bootstrap-based likelihood ratio test (BLRT) are significant ($p < 0.05$), the classification of the k -class model is better than that of the $k-1$ class. Regarding the classification accuracy, the closer the entropy value is to 1, the better. More importantly, the final choice of the model must be fully observed for its practical implications [25].

Data were statistically analyzed using the SPSS software (version 26.0). Frequencies and percentages indicate qualitative data, while quantitative data obeying normal

distribution are expressed as mean \pm standard deviation ($\bar{x} \pm s$). Comparisons of scores between scales and modalities were performed using analysis of variance (ANOVA), and unordered categorical comparisons were performed using chi-square tests. The Fisher–Freeman–Halton test was used to measure the underfrequency of a particular cell, and the Kruskal–Wallis test was used to measure differences in continuous variables. Finally, multivariate logistic regression was used to analyze the factors influencing nurses' resilience and flexibility categories, which were statistically significant at $p < 0.05$.

3. Results

3.1. General Demographic Characteristics. A total of 805 nurses participated in this study. The results are summarized in Table 1. More than one-third were 30 years of age or younger (34.2%), primarily female (92.2%), and married (71.4%). 359 nurses (44.6%) had only one child, 412 nurses (51.0%) were mid-level, only 74 nurses (9.2%) were care managers, 205 nurses (25.5%) had been working for one to five years, 609 nurses (75.7%) had a bachelor's degree, 402 nurses (49.9%) were contracted employees, 383 nurses (47.6%) earned between \$5001–7000 per month, and 640 nurses (79.5%) worked in a tertiary care hospital as shown in Table 2.

3.2. Scale Scores. Resilience (37.96 ± 7.34); psychological flexibility (26.91 ± 10.75); growth mindset (11.35 ± 3.83); and nurses' professional recognition dimensions and total scores were 35.07 ± 6.34 , 16.57 ± 3.73 , 15.54 ± 4.12 , 25.62 ± 6.12 , 22.1 ± 4.54 , and 114.9 ± 22.32 points.

3.3. Latent Classes of Resilience and Psychological Flexibility. Exploratory latent class analyses were based on nurses' resilience and flexibility dichotomous scores. First, 1–5 models were established. The values of AIC, BIC, and aBIC in the model tended to be minor, and the LMR of the five classifications was >0.05 . Therefore, they were not considered. For the four categorical models, when both LMR and BLRT were significant, the curves of the four classifications were more complex, somewhat ambiguous, and challenging to interpret in terms of their theoretical and practical significance. By observing the three-category model with an entropy of >0.8 and both LMR and BLRT of <0.05 , the categorization is concise, and its functional relevance is more apparent. The results are summarized in Table 1. Ultimately, the best latent class was determined to be three.

3.4. Characterization and Naming of Different Models. Of the three classification schemes identified, the first group was named the "toughness-flexible group," which accounted for 32.8% of the total. In this group, the probability of scoring most items for resilience and mental flexibility was above 0.8, indicating that nurses in this group were more resilient and flexible. The second group was categorized as the "power-deficit-emotional group," which accounted for

23.1%. The perceived sense of strength against adversity was low, and the low-scoring entries in flexibility were emotional concerns and worries that led to stumbling. The third group was categorized as the "toughness-rigid group," which accounted for 44.1% of the total. This group is characterized by a degree of resilience but generally poor mental flexibility as shown in Figure 2.

3.5. Results of One-Way Analysis of Latent Classes of Resilience and Psychological Flexibility. Comparisons of nurses in the different resilience and psychological flexibility categories regarding monthly income, job title, and mode of employment revealed significant differences. The results are summarized in Table 3.

3.6. Comparison of Growth Mindset and Professional Identity Scores for Nurses in Three Latent Classes. A comparison of nurses in the three potential categories of resilience and psychological flexibility in terms of growth mindset and total professional identity scores revealed statistically significant differences ($p < 0.05$), as shown in Table 4.

3.7. Multiple Logistic Regression Analysis of Factors Influencing Latent Classes of Nurses' Resilience and Psychological Flexibility. Unsorted multicategorical logistic regression analyses were conducted using the potential categories of nurse resilience and psychological flexibility as dependent variables (with the toughness-flexible group as the reference) and variables statistically significant in the univariate analyses as independent variables and covariates. The results indicated that contract employment style was a predictor of the strength-deficit-emotional group; monthly income $< \text{RMB}5,000$, staffing agency, contract employment style, and growth mindset were predictors of the toughness-rigid group; and higher occupational identity and growth mindset together predicted the toughness-flexible group, as shown in Table 5.

4. Discussion

4.1. Monthly Income Mode of Employment can Affect Nurses' Resilience and Psychological Flexibility. Nurses earning less than RMB 5,000 per month were more likely to be in the rigid toughness group than in the flexible toughness group. In this group, nurses with families and children accounted for more than 2/3, and for their family consumption, a monthly income of less than 5,000 yuan was slightly constrained. An Australian study [26] states that low-income families may be more likely to adopt a child-focused spending plan that allocates less to the adult budget and often requires careful budgeting to meet the family's needs. The dual pressures generated by work and life lead to looking ahead and empirical avoidance when addressing other challenges. Psychological flexibility mediates perceived stress and negative emotions [27]. Based on the family systems' theory, poorer parental psychological flexibility leads to poorer family functioning [28].

TABLE 1: Potential category model fit indices for nurse resilience and psychological flexibility ($n = 805$).

Model	Log (L)	AIC	BIC	aBIC	Entropy	LMR (P)	BLRT (P)	Probability
1	-5454.491	10942.982	11022.726	10968.742	—	—	—	1
2	-3827.287	7724.575	7888.754	7777.609	0.955	<0.001	<0.001	60.4/39.6
3	-3607.693	7321.386	7570.001	7401.696	0.902	0.0191	<0.001	32.8/23.1/44.1

5	-3324.538	6827.077	7244.562	6961.936	0.923	0.1165	<0.001	7.8/44.2/3.6/19.2/25.2

TABLE 2: Demographic characteristics of participants.

	Projects	Number	%
Age	<30	276	34.3
	<35	236	29.3
	<41	131	16.3
	≥41	162	20.1
Sex	Female	745	92.5
	Male	60	7.5
Education level	Junior college and below	193	24.0
	Undergraduate	609	75.7
	Postgraduate or above	3	0.4
Marital status	Unmarried	213	26.5
	Married	577	71.7
	Others	15	1.9
Number of children	0	261	32.4
	1	359	44.6
	≥2	185	23.0
Monthly income	<5000 RMB	260	32.3
	<7000 RMB	383	47.6
	≥7000 RMB	162	20.1
Working years	1~5	205	25.5
	6~10	178	22.1
	11~15	204	25.3
	16~20	82	10.2
	≥21	136	16.9
Position	Nurse	731	90.8
	Nursing managers	74	9.2
Professional title	Junior title	364	45.0
	Intermediate title	412	51.0
	Senior title	29	3.6
Employment relationship	Staffing of government-affiliated institutions	161	20.0
	Personnel agent	242	30.1
	Contractual employment	402	49.9
Hospital level	Contractual employment	640	79.5
	Tertiary hospitals and others	165	20.5

For nurses with families and children, the more negative emotions generated, the less family functioning and psychological flexibility.

Contractual hiring practices were an influential factor in the strength-deficit-emotional group compared to the toughness-flexibility group. Contractual employment is one of the most common methods of recruiting nurses. However, this may make nurses feel more apprehensive. In

certain cities in China, other modes of employment represent different jobs, hospital benefits, and professional statuses. In contrast, nurses employed on a contractual basis have relatively low educational qualifications, monthly incomes, and retirement benefits. Dr Kate interviewed nurses working temporarily in the UK, who reported feelings of isolation, fewer training opportunities, and difficulties in maintaining permanent jobs [29]. According to the job

FIGURE 2: Conditional probability distributions for latent classes of resilience and mental flexibility.

demand resource model [30], when job resources are limited, demand fulfillment frustration occurs, and personal commitment to work decreases, which may ultimately lead to burnout or separation from service [31].

Personnel agencies and contractual hiring practices affected the toughness-rigidity group. This may have had a different influence on the two outcomes of toughness and mental rigidity in this group. The better flexibility in this group may have resulted from the personnel agency method of employment. A personnel agency is a new type of personnel management in which the Chinese government provides social services for talent. [32]. Compared with other forms of employment, staffing agencies consider the advantages of legal protection, flexible employment, and reasonable distribution of performance pay, among others. Most contractors are highly educated and qualified [33]. This implies favorable future career development and confirms the protective role of the professional dimension in the shield layer of resilient shield theory.

4.2. Growth Mindset as an Influence on Resilience and Flexibility of Nurses' Mindset. A growth mindset is a factor influencing the "tough-flexible" group and the "tough-rigid" group. A similar characteristic of both groups was a high level of resilience. After several major public health events, the nursing community underwent significant changes in professionalism and psychological adaptation [34]. Mental health and occupational psychology have received worldwide attention [35]. To prevent and recover emotional resilience from burnout, Jay encourages cultivating a growth mindset that can be used to enhance emotional resilience through the lens of positive psychology [36]. Raquel demonstrated significant correlations and predictions between psychological flexibility and resilience to minimize burnout and trauma among Spanish nurses during major public health events [37]. Growth mindset and mental flexibility, while not practical in prediction, showed statistically significant differences in

growth mindset in at least two groups in one-way outcome analyses. In short, the predictive effect of a growth mindset in this study appears to be related to nurses' resilience, and its relationship with psychological flexibility needs to be further demonstrated.

4.3. Professional Identity Affects Nurses' Psychological Resilience and Flexibility. Professional identity predicts toughness and flexibility. Zhou et al. concluded that nursing students with a high level of professional identity had positive perceptions and evaluations of the nursing profession, and their capacity for self-directed learning was higher [38]. Research has also demonstrated that people with higher levels of self-directed learning also tend to be more personally resilient [39]. Conversely, Chen further elucidated the critical role of resilience in work-family conflict and career development in his study, explaining why occupational identity is a high resilience predictor [40]. Chong et al. [41] conducted an online survey of 514 Hong Kong citizens whose sequential equation modeling showed that psychological flexibility directly affected prosocial behavior. Occupational identity includes how the wider society recognizes the work an individual does and is a way of demonstrating the individual's relationship with society [42]. Professional identity includes a great deal of prosocial identity.

4.4. Limitations. Our study had some limitations. First, our sample comes from only one province in Central China, and economic development and humanistic literacy differ across regions, which may result in a certain degree of bias. Second, there were more female nurses in the sample, which may have prevented comparisons from considering gender differences. Third, the sample size of tertiary care hospitals was large, and differences between different hospital levels may not have been available. Future studies should expand the sample to a national or multinational scale to extrapolate the results.

Professional identity	-0.027	0.005	35.493	<0.001	0.973	0.964 0.982

The toughness-flexibility group is taken as a reference category.

5. Conclusions

This is the first study to simultaneously examine the relationship between nurses' resilience and psychological flexibility. Moreover, this study empirically demonstrates the effects of a growth mindset and professional identity on psychological resilience and flexibility. According to our study, higher career identity predicted the toughness-flexibility group, a better growth mindset predicted high flexibility, and the relationship with psychological flexibility needs further validation. Different modes of employment and income levels are equally important factors affecting the resilience and flexibility of nurses. With the current significant nursing shortage, fair and varied career development for the nursing community is a must for healthcare providers.

5.1. Implications for Nursing Management. The percentage of poorly adapted groups in the different models explored in this study was 67.2%, indicating that more resilient nurses may experience poor psychological flexibility. By examining variables related to nurses' career development, we found that improving professional identity and a growth mindset contribute to the psychological resilience and flexibility of the nurse population. This also reflects the fact that good personal growth and professional development are beneficial for nurses' adaptive mindsets. By synthesizing work-related characteristics, nursing administrators and related leaders can make the following attempts: first, enhancing nurses' sense of professional identity and social recognition. Examples include education about the significance of the profession, a sense of respect, and the exploration of multiple channels to build career development paths and display platforms. Second, nurses need to develop a growth mindset, such as teaching practices and learning experiences that support personal development, competency-based medical education, matching vocational assessment programs to nurses' professional needs and purposes, and managers practicing encouraging language and building supportive interactions. Third, employment mechanisms should be reformed, job security implemented, and equal pay for equal work.

Data Availability

The data that support the findings of this study are available from the corresponding author upon reasonable request.

Ethical Approval

This study was approved by the Ethics Committee of Bengbu Medical College (approval number: Grant no. 2023369).

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

Xiumu Yang, Changjiang Yuan, Shuang Zhao, Zeyu Zhang, Xiaocui Duan, and Yujiao Shao contributed to the conception and/or design of the study. All authors contributed to data collection and analysis. Shuang Zhao drafted the manuscript and all authors contributed to refining and/or critically reviewing the manuscript. All authors are in agreement with the manuscript. All authors agree to be responsible for all aspects of the work. Shuang Zhao, Zeyu Zhang, Xiaocui Duan, Yujiao Shao, Fuzhi Wang, Yongxia Chen, Congyan Yang, Lingling Chen, Fei Wang, Jiaoping Zhang, Hailing Zhang, Xiumu Yang and Changjiang Yuan contributed equally to the study.

Acknowledgments

This study was supported by the Climbing Plan of Humanities and Social Sciences of Bengbu Medical College (2020bypd206SK), the 2021 Anhui Quality Engineering Project (2021xqhzsjd051, 2021xsxxkc168, and 2022msgzs034), the Medical Education Branch of the Chinese Medical Association and the National Center for the Development of Medical Education 2023 Medical Education Research Standing Project (2023B014), the Bengbu Medical University Research Project (2023byfy142sk and 2023byzd166sk), and the Graduate Student Research and Innovation Program of Bengbu Medical College in 2022 (Byycx22082). The authors thank the participants who took part in our study.

Background. Nurse protection is a multifaceted concept that has become increasingly relevant in recent years. Despite its importance in effectively managing pandemics, there is still a gap in knowledge about how nurses achieve protection in hospitals. **Objective.** To describe the process of seeking protection among nurses during the COVID-19 pandemic. **Methods.** A grounded theory approach from 2020 to 2022, employing purposive and theoretical sampling. Face-to-face and online interviews were conducted with 25 participants, resulting in 29 interviews. Data analysis was carried out using Corbin and Strauss's method (2015). **Results.** The analysis revealed that nurses encountered numerous obstacles related to patients, nurses themselves, organizations, and the passage of time during the COVID-19 pandemic. These challenges were intertwined with three key concepts: transformations, inequalities, and emotional challenges, highlighting the multifaceted nature of nurses' protection concerns. In response, nurses employed a protective strategy bolstered by catalysts to address these challenges. This strategy encompassed both optimistic outlooks ("Bright horizon") and somber reflections ("Unpleasant reflection"). Ultimately, seeking protection in the heart of the storm emerged as the core concept, representing the multifaceted process through which nurses navigate and seek protection amidst the unique challenges posed by the pandemic. **Conclusions.** This study presents a comprehensive theory that explicitly explains the multifaceted process of seeking protection among hospital-employed nurses during a pandemic. The theory captures the interconnectedness of challenges faced by nurses and the protective strategies they employ while acknowledging the nuanced balance between hopeful prospects and sobering reflections. **Implications for Nursing Management.** Policymakers, managers, and educators can utilize the findings to improve nursing management and support systems. By increasing awareness, addressing challenges, and providing robust support, they can enhance the well-being and effectiveness of nurses during healthcare crises, ultimately improving patient care quality.

1. Introduction

The COVID-19 pandemic presented significant challenges to healthcare systems globally, especially affecting nurses who were at the forefront of patient care [1]. Nurses faced

extreme working conditions and threats to their protection and safety while caring for COVID-19 patients [2, 3]. They were exposed to both physical and psychological risks, resulting in infections up to deaths among healthcare workers [2–4].

Ensuring the protection and safety of nurses during a pandemic is crucial due to their vital role in managing infectious diseases and protecting public health [3]. In this study, the focus is on the protection and safety of nurses themselves, distinct from the concept of patient safety, which is also of paramount importance. The term “protection” refers to the measures and strategies nurses employ to defend themselves against the various threats and hazards they face, such as exposure to the virus, inadequate personal protective equipment (PPE), and high-stress levels.

Various theoretical perspectives, such as needs theory, managerialism, and motivational theory, have recognized the importance of different types of safety, including physical, psychological, professional, and social safety. These theories provide valuable insights into the multifaceted nature of safety. For example, Maslow’s hierarchy of needs positions physical safety as the second fundamental requirement, emphasizing its significance [5]. Herzberg’s theory distinguishes between hygiene factors and motivators about professional safety, encompassing elements like job security, adequate staffing, and growth opportunities [6]. The Job Demands-Resources (JD-R) model highlights the balance between demands and resources to ensure psychological safety, taking into account factors like heavy workloads and emotional stress [7]. Theoretical frameworks like social support theory or the JD-R model shed light on how social interactions impact the overall sense of safety and well-being [8]. By incorporating these theories, we can develop a comprehensive understanding of the importance of safety and its diverse dimensions for nurses during the COVID-19 pandemic. According to these theories, we can also better understand what happens when safety is threatened: nurses compromised safety can adversely affect their health, work quality, and performances, leading to dissatisfaction, increased absenteeism, and intentions to leave the profession [1, 3]. These factors ultimately result in poorer patient care and increased pressure on hospitals and healthcare costs [3, 4].

Given the unprecedented nature of the pandemic, prioritizing healthcare worker protection and safety was paramount to ensure effective patient care management [9]; in this context, learning from the experience lived by deepening nurses’ perceptions, behaviors, and interactions related to staff protection and safety is crucial [10]. Therefore, this study aims to shed new light on the concept of “seeking protection” as perceived by nurses. Nurses seek protection and safety not only as part of their responsibility of caring for patients affected by the COVID-19 infection but also from the various risks associated with their frontline duties, including exposure to the virus, PPE, and high-stress levels. Operationalizing this concept may inform how to mitigate these risks to protect nurses’ well-being while they fulfill their critical role during a pandemic. Consequently, qualitative research can uncover nurses’ experiences, feelings, and deeper perspectives, providing valuable insights to support and prepare healthcare professionals and improve organizational actions in future pandemics.

Available evidence suggests that seeking protection and safety among nurses is an interactive process rooted in

a specific natural context and reflects the group’s nursing-related and social interactions within a real work environment [11, 12]. This process can be influenced by the culture, norms, routines, and habits of each context. In particular, the unique characteristics of the context in Iran, such as the low nurse-to-patient ratio [13], lack of experience in dealing with a widespread pandemic, challenging economic conditions, and insufficient resources to combat COVID-19 [14], make it even more crucial to provide comprehensive information and gain a deep understanding of the process. Despite numerous research studies, the literature still indicates a knowledge gap in this area [15].

Therefore, this study aims to elucidate the multifaceted process of seeking protection among hospital nurses amidst the unique challenges posed by the COVID-19 pandemic, particularly in contexts with specific socioeconomic and healthcare system characteristics, such as the Iranian country.

2. Methods

2.1. Study Design and Setting. A qualitative study was conducted using the grounded theory [16–18]. Grounded theory aims to explore, understand, and describe psychological and social processes within natural social settings. By adopting this approach, the researchers immersed themselves in the participants’ world to gain insights and contribute to acquiring their experiential knowledge [19, 20]. Therefore, grounded theory was chosen to develop a theory from experiential data [20]. The methodology version proposed by Corbin and Strauss in 2015 was followed for its structured data analysis system, which is especially suitable for novice researchers [20, 21]. The study adhered to the Standards for Reporting Qualitative Research (SRQR) [22] (see Table 1 in the Supplementary file) and involved academic medical centers in two Iranian cities with populations of 13,267,637 and 1,270,420, respectively, between 2020 and 2022.

2.2. Study Participants. Researchers identified participants among nurses working in academic medical centers designated to care for COVID-19-positive patients using purposive sampling. The inclusion criteria included nurses educated at the level of Bachelor of Science in Nursing (BSN), which is the minimum nursing qualification in Iran. Additionally, participants needed to demonstrate an interest in communication and expressing their views and experiences, as this was considered essential for providing valuable insights. Furthermore, participants were selected based on their experience in caring for COVID-19 patients or working in facilities designated to receive such patients, ensuring firsthand knowledge and experiences, and thus helping in understanding the challenges faced in this context. These criteria were crucial in achieving the maximum theoretical richness and in-depth understanding of the experience lived by nurses [20]. Moreover, to achieve maximum theoretical variations, richness, and diversity, the researchers identified participants with diverse personal and professional

characteristics to obtain comprehensive data and develop findings with higher transferability. After the first interview, additional interviews were conducted based on the analysis of previous interviews and using a theoretical sampling [20]. For example, when the topic of “unsafety of non-COVID-19 wards” was developed, the first researcher felt the need to interview nurses who did not work in COVID-19 wards as the next step, which was agreed upon by a second researcher. Theoretical sampling continued until saturation was reached, as judged by the research team [20]. No friendship was established between the interviewer and the participants before the interview. A total of 27 nurses were contacted consecutively, and all agreed to be interviewed except for two who refused. The demographic characteristics of the participants are provided in Table 1.

2.3. Data Collection. A female researcher (MSh), educated at the doctoral level and holding a faculty position, conducted audio-recorded interviews with participants’ consent and collected field notes when necessary. The interviews started with an open-ended question: “Given your experience caring for COVID-19 patients (or during the pandemic for those not in COVID-19 wards, see Table 1), how did you protect yourself?” As data collection progressed, interviews followed a semistructured format, with questions like: “What influenced your actions?” After theoretical sampling, when some issues emerged as “inadequate support, discrimination, and dissatisfaction with PPE rationing,” interviews were then conducted with a head nurse and a supervisor responsible for coordinating shifts and PPE in COVID-19 wards. They were asked about challenges faced during the pandemic and strategies used to ensure nurses’ safety and protection. Subsequent interviews were guided by participant responses, with exploratory questions, such as: “Can you explain further?” and “Why?” Participants were given the chance to add to their comments at the end of each interview. Of the 29 interviews with 25 participants, 22 were conducted in person while adhering to protective protocols and seven were conducted by online video call via WhatsApp at the request of the participants. In these cases, four supplemental interviews were conducted to ensure the richness and depth of the interviews and to confirm the findings. The average, minimum, and maximum duration of the interviews were 50, 45, and 90 minutes, respectively, reflecting variations in the duration spent with each participant.

2.4. Data Analysis. The data analysis in the grounded theory method is a dynamic and circular process carried out through continuous and simultaneous comparison, data collection, and analysis, leading to the extraction of deep and reliable information about the phenomenon of interest [20]. In our study, the researchers used the method of Corbin and Strauss (2015) [16] to discover the basic theory, employing open coding to identify concepts, developing concepts in terms of their properties and dimensions, analyzing data for context, bringing the process into the analysis, and integrating categories to identify the core category [20].

The MAXQDA10 software was used to manage the large dataset, which consisted of about 580 verbatim-transcribed pages. Initially, one of the researchers (MSh) listened to the interviews, transcribed them, and reread the text and notes multiple times. The data were then segmented into manageable chunks, and semantic units were created.

Initial categories were formed through brainstorming and comparing concepts, with constant comparisons to classify codes based on similarities and differences. The researchers carefully considered both micro- and macro-conditions affecting nurses’ safety. Memos and diagrams were used from the beginning of the analysis to aid in this process. By analyzing data and reviewing narratives repeatedly, the researchers identified the interactions, feelings, strategies, and behaviors of participants. “Seeking protection in the heart of the storm” emerged as the core category, encompassing the experiences of all participants. Finally, the researchers examined the relationship between concepts and categories, developing a theory to explain the phenomenon under study. An example of the process of forming a main category is shown in Table 2 in the Supplementary file.

2.5. Trustworthiness and Rigor. To ensure the quality of our study, we applied the criteria proposed by Corbin and Strauss (2015), which include checkpoints for assessing the methodological consistency and the quality and applicability of a grounded theory-based study [20]. Additionally, we incorporated the criteria of credibility, dependability, confirmability, transferability, and authenticity as suggested by Guba and Lincoln [23]. Specifically, data were collected simultaneously in an iterative process, and actions and processes were analyzed and conceptualized rather than focusing on themes and structures. Comparative methods, such as constant comparison, were used to confirm or reject codes and categories, determine relationships between categories, and uncover hidden processes in the data. Inductive categories were developed through a constructive approach, and theoretical sampling was employed to identify variations in categories. We ensured prolonged interactions with participants, allocated sufficient time for data collection, maintained trustworthy communication, and involved member reviews. The research team reviewed extracted codes, compared themes, conducted discussions to reach consensus on issues, peer-reviewed the data, and preserved preliminary study documents. We also provided a detailed description of the research process, participant characteristics, and research context and selected diverse participants to ensure the applicability of the data to other similarly structured communities.

2.6. Ethical Considerations. The Ethics Committee of Tehran University of Medical Sciences (TUMS) granted ethical approval (IR.TUMS.FNM.REC.1399.193). All participants provided consent after receiving explanations about the study’s objectives, their voluntary participation, and their freedom to withdraw at any point. They were also given the option to choose the interview time and location. Permission was secured for audio-recording the interviews. Participants

TABLE 1: Participants' main characteristics.

were ensured regarding data confidentiality, including the deletion of audio files after the study and anonymization of all participants and working units in documents (e.g., Participant 1, P1). Subsequently, the audio files underwent verbatim transcription and anonymization.

3. Findings

3.1. Emerging Categories and Subcategories. The analysis of data gathered from participants uncovered a range of challenges that hospital nurses encountered during the COVID-19 pandemic. These obstacles encompassed various aspects, such as patient-related issues (e.g., increased patient load, poor patient compliance), challenges faced by nurses themselves (e.g., working conditions), organizational factors (e.g., human resource difficulties, inadequate protective measures), and the passage of time (e.g., from extreme reactions to normalization).

These conditions were found to be interconnected and gave rise to three key concepts: transformations, inequalities, and emotional challenges. These concepts reflected the complex and multifaceted nature of the issues faced by nurses in their efforts to ensure their protection and safety. In response to these challenges, nurses adopted a strategy of seeking protection, which was fueled by catalysts that propelled them in this pursuit.

The strategy of seeking protection exhibited both optimistic prospects, symbolized by a “Bright horizon,” and somber reflections, represented by an “Unpleasant reflection.” These contrasting elements shaped nurses’ approach to safeguarding themselves during the pandemic. Consequently, the core concept that emerged from this analysis was termed “seeking protection in the heart of the storm” as depicted in Figure 1 and elaborated upon in detail in Table 2.

3.1.1. Contextual Conditions. Participants emphasized the paramount importance of understanding the dynamics of safety pathways, including obstacles and catalysts, in shaping the journey toward safety and protection for hospital nurses during the COVID-19 pandemic. These contextual conditions consist of two main categories and six subcategories (refer to Table 2 and Figure 1), which have been identified as crucial in influencing the seeking protection process among frontline nurses. This in turn contributes significantly to their well-being and the effectiveness of patient care.

(1) Safety Pathway Obstacles. Participants indicated that they encountered a spectrum of impediments along the safety pathway categorized into four main challenges: organizational, patient/relative-related, time-related, and nurse-related challenges.

Organizational Challenges. The challenges faced by organizations have triggered several issues for nurses: staffing problems, difficulties in information gathering, in providing training; unfavorable infrastructure factors, time-consuming documentation for accreditation, and inadequate supervision, support, and organizational assistance were all

reported. Additionally, varying ward-related safety conditions were shared.

“In the first few days, we were suddenly sent to the COVID-19 intensive care unit without any training or preparation; we were confused. We did not know what was going to happen. It scared us, and many of my colleagues caught the virus.” (P 7)

Nurses shared their personal experiences with safety hazards related to the shortage and poor quality of PPE.

“The protective equipment was scarce and of poor quality. In the first few months, they gave us two N95 masks and told us to wash and reuse them.” (P 17)

Participants disclosed that organizational challenges led to various physical, psychological, and professional issues.

Patient/Relative-Related Challenges. According to participants, another factor impacting nurses’ safety and protection was dealing with patients and their relatives. This included ensuring patient care in challenging conditions, inadequate patient compliance, noncompliance among relatives/visitors, and high expectations from patients’ relatives regarding nursing care.

“In intubated patients, the stress is even greater, especially during resuscitation or suctioning. The cardiopulmonary resuscitation team, which is more directly involved, told us that the risk of infection increases when a bag valve mask is administered manually.” (P 10)

Regarding safety risks related to noncompliant visitors, one nurse reported:

“Companions and visitors are fully or partially non-compliant on the ward. For example, they don’t use masks or just put them over their mouths. No matter how strictly we follow the rules, their non-compliant behavior puts us at risk and increases our fear and anxiety.” (P 21)

Another nurse emphasized the safety threat posed by relatives in response to unexpected outcomes.

“We often faced situations where patients arrived late, worsening their condition. For instance, they were brought in when their lungs were already inflamed. If such patients were then connected to life support machines and unfortunately passed away, their relatives would direct aggression towards us, blaming us for the outcome.” (P 16)

Time-Related Challenges. The passage of time has had a significant impact on working conditions, the availability of PPE, and the responses of caregivers during the early and later phases of the pandemic. Time has played a role in how nurses achieve safety, with changes in their psychological reactions influencing their adherence to safety protocols. Initially, nurses experienced intense anxiety and fear, leading

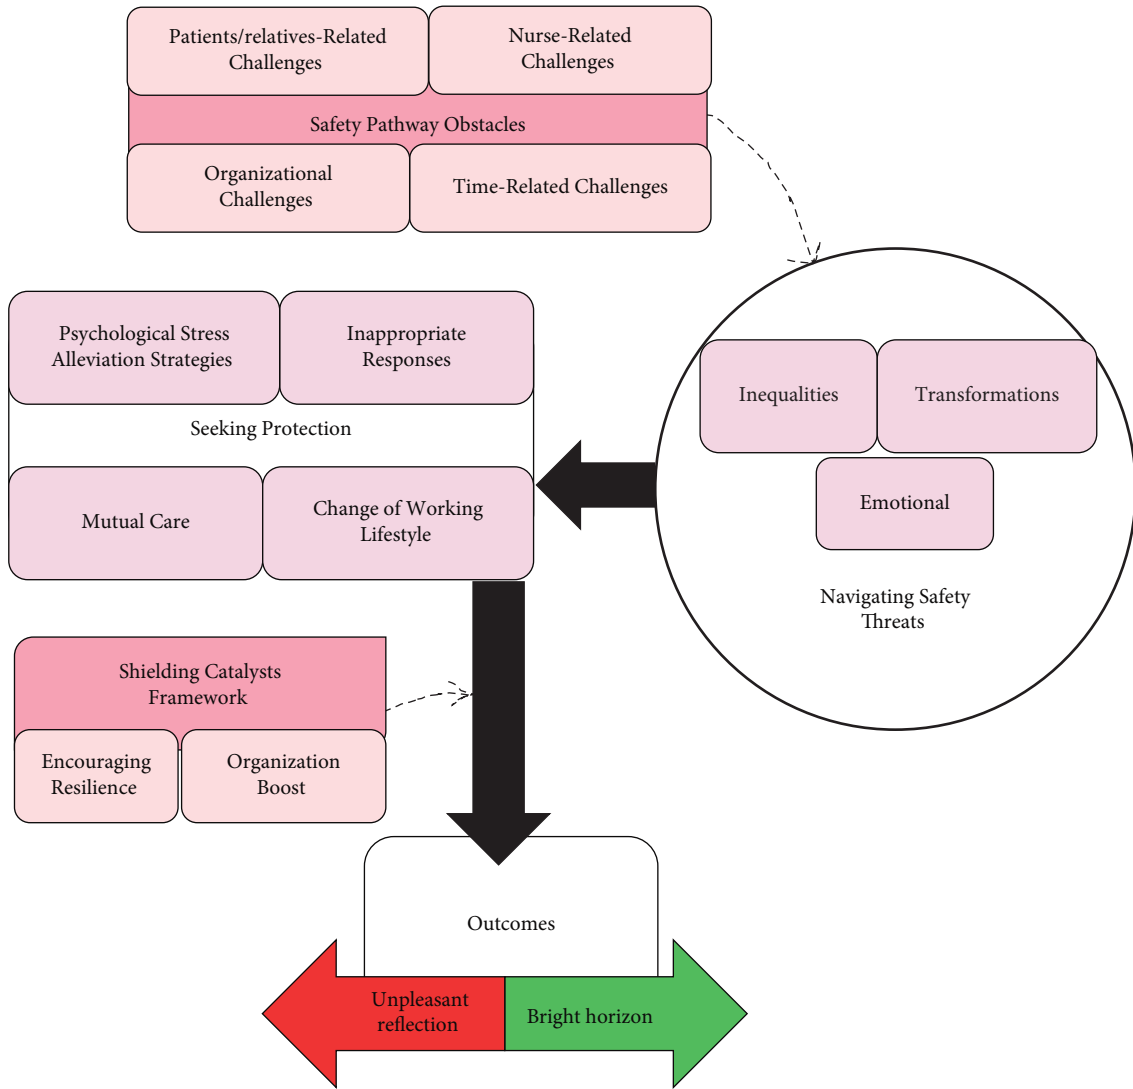

FIGURE 1: The structure and the process of the “seeking protection in the heart of the storm” theory.

TABLE 2: The process of “seeking protection in the heart of the storm” among hospital nurses during the COVID-19 pandemic.

TABLE 2: Continued.

Paradigm components	Categories	Subcategories
Outcomes	Bright horizon	Satisfaction Physical protection Individual stress
	Unpleasant reflection	Organizational vulnerability Patient injury

to strict adherence to protocols. However, as time passed, they began to return to a sense of normalcy.

“In the beginning, we had difficulties with the lack of protective equipment or inferior masks. In the first few months, they gave us a single N95 mask for a week and told us to wash and reuse it, but in the beginning, we adhered more strictly to protocols out of deep fear and anxiety. Over time, however, our sensitivity weakened, and some colleagues no longer took the disease seriously.” (P 21)

Nurse-Related Challenges. According to participants, nurse-related factors directly affect them as microconditions influencing their access to safety. These factors include the nurses’ response to immunizations, which ranged from opposition to acceptance of vaccination. Other factors include the nurses’ living conditions, how they commute to work, their personal-social characteristics, personality traits, underlying disease status, and their willingness to work in the COVID-19 unit.

“I’m married and have two children. I also take care of the housework. I cooked for my family even when I was sick. With the heavy equipment we use, I’m constantly on my feet even while I’m working; from the time I arrive to the time I return home. I mean, I’m completely worn out and my body has become weak. I’m exhausted. This is the case with most of my colleagues who have children. On the other hand, we’re more anxious and worried that our children might catch it.” (P 8)

On the contrary, a nurse living alone shared a contrasting experience:

“I reside alone, so I didn’t notice many changes at home compared to my colleagues who live with family. However, when I fell ill, I faced significant challenges. Being alone, there was no one to provide care or assistance. I had to manage everything on my own, which made the situation extremely challenging. I felt a profound sense of isolation and lack of support during this difficult time.” (P 21)

(2) **Shielding Catalysts Framework.** Participants’ experiences revealed that alongside various hindering factors, certain enabling elements played a role in enhancing nurses’ safety, albeit with a lesser impact. These elements collectively form the “Shielding Catalysts Framework,” encompassing two subcategories: “Encouraging Resilience” and “Organization Boost.”

Encouraging Resilience. Supportive feedback and positive reinforcement were vital in bolstering nurses’ resilience and well-being. Participants highlighted the significance of receiving encouragement amid challenging circumstances, including support from family members showing empathy. Positive feedback from peers, friends, and the community served as a source of hope and motivation, fostering their ability to withstand stressors and maintain psychological safety.

“My father used to say, “You must work under such circumstances.” He said, “For the education you have, you have to serve the people.” That added to my peace of mind, and I could bear the difficult situation better, but my husband was a little upset that I was working in the COVID ward.” (P 19)

Organization Boost. The proactive stance of health authorities in implementing supportive measures reflects a commitment to fostering conducive work environments. Participants emphasized the significance of these initiatives, such as facilitating transfers for staff facing unique challenges, prioritizing vaccination for healthcare workers, and implementing motivational strategies. These efforts were instrumental in mitigating nurses’ psychological stress and enhancing overall well-being.

“Breastfeeding and pregnant nurses and those with health problems were isolated, and they didn’t allow this group to stay in the COVID ward. That alone made my colleagues and me feel like they cared about our health and our children’s health, which was a factor in nurse satisfaction.” (P 16)

3.1.2. **Navigating Safety Threats.** The contextual conditions identified as obstacles and catalysts shaped the nurses’ perceptions of safety threats and challenges. These were represented by three categories and seven subcategories (refer to Table 2 and Figure 1). The categories, named “Transformations,” “Inequalities,” and “Emotional,” reflect the multifaceted nature of the issues faced by nurses in ensuring their safety.

(1) **Transformations.** Transformations refer to significant changes in the personal and professional lives of nurses due to the challenging working conditions brought on by the COVID-19 pandemic. The circumstances of nurses’ personal and family lives have been dramatically altered.

“There is no way to plan anything. Our education is interrupted. Our work and personal lives are in limbo. My whole life is on hold.” (P 13)

In addition, there were both positive and negative changes at the professional level that impacted nurses' access to safety. The "Transformations" category encompasses changes in both personal life and professional transitions.

Changes in Personal Life. Participants stated that they had made changes in their daily lives since the beginning of the COVID-19 pandemic to ensure the highest level of safety. However, some of these changes led to excessive fatigue and vulnerability of their immune systems.

"I change my clothes in the parking lot and hang them in the storage room. Then I go straight to the bathroom and sometimes shower twice a day. I was really scared when I contracted the virus, especially after the second infection." (P 9)

Some nurses mentioned that their attitude toward life has changed compared to before the pandemic triggering the capacity to see more meaning in their lives and a more positive outlook. They decided not to be overwhelmed by details, to value time with loved ones, and to seize the moment. This new attitude provided them with inner peace, reduced their fear of the virus, and possibly increased their psychological safety.

"My attitude toward life has changed compared to the time before the pandemic. I owe this change to the coronavirus. Now I enjoy every moment I spend with my loved ones. I have decided to ignore trivial things because I have seen death up close. Trivial things should not destroy the value of being together. This change in my perspective has brought me peace." (P 16)

In many cases, the mentioned changes caused disruptions in the normal flow of personal and family life, also delaying or interrupting daily plans. At the family level, these changes were evident in restricted emotions, families' worries about the nurses' health, disapproval of the nurses' work in the COVID-19 ward, concerns about inadequate supply of PPE, and fear of getting infected and coming to the hospital. These factors, in turn, increased the psychological pressure on nurses.

"In the first few months, I was going straight to my room when I was coming home from the hospital because I was afraid of infecting my family. Even my mother would put my food behind the door so I could pick it up later. I did not talk to my family at all, which was very worrying for both my family and me." (P 1)

Professional Transitions. Participants experienced difficult transitions at the professional level, including changes in performance and professional wellness triggering burnout. They also rediscovered their passion for the nursing

profession. Nursing care was delivered with extreme caution, but poor nursing care caused by factors such as fear of being close to patients resulted in changes in nurses' performance. These changes posed threats to nurses' psychological safety, leading to psychological exhaustion and discomfort.

"The workload was so heavy that there was no coordination among the staff, and most of them were rookies. The crowding and extreme pressure were exhausting. Sometimes I completely forgot when I had visited my patients, and my duties were limited to administering medications and I was not able to attend to the other needs of the patients, which put a lot of stress on me." (P 17)

The unfavorable working conditions, the heavy workloads, long and busy shifts, limited support, witnessing patients' pain, suffering, and death, and other issues caused nurses to experience severe fatigue, physical and mental trauma, sleep disturbances, nightmares, and a sense of helplessness.

"The working conditions here are extremely difficult. You care for one patient, only to discover that another one requires your attention. Despite only being assigned two patients, the workload seems never-ending. Occasionally, due to staffing shortages, we are forced to care for three patients at once. This has drained our energy and left us lacking the motivation to carry on." (P 19)

In contrast, the media and public attention given to the nursing profession and nurses fostered a sense of worth and altruism, and ultimately rediscovered love for the profession among nurses.

"The COVID-19 pandemic raised some awareness in society about nurses, the nursing profession, and its values and risks. It made us happy, motivated us, and eased the psychological burden for me and my colleagues. Therefore, I think the nursing community should be grateful for the COVID-19 pandemic, although it has suffered a lot." (P 24)

(2) *Inequalities.* During the pandemic, nurses experienced a variety of unfair treatments and discrimination within and between professions, negatively affecting their psychological, physical, and professional safety.

Intraprofessional Inequalities. Intraprofessional inequalities refer to the disparities between nurses within the same center or between nurses in different centers. Some participants pointed out that there was inequity in the allocation of sick leave among nurses with varying employment statuses. Additionally, there reported perceived inequities among nurses based on their years of experience working on the COVID-19 ward and being assigned to critically ill patients.

“There was a difference between agency staff and permanent or contract nurses. For example, we weren’t entitled to sick leave if we got infected. And they wouldn’t pay for it if we left work. This made us frustrated and unmotivated.” (P 8)

One participant described the impact of employment status on nurses’ safety as follows:

“After a few months, they refused to pay us because we were contract workers. Some of my friends and I had to work in two places to make ends meet. Now, this arrangement of working in two places exhausted us and weakened our immune systems. On the other hand, job insecurity was getting to us.” (P 22)

Participants also mentioned that there were differences between nurses at different centers in various areas regarding PPE allocation and financial compensation, which caused psychological distress.

“Well, I heard that the nurses in hospital X receive financial allowances in addition to full PPE kits, while we barely manage to ration our PPE. Why does it have to be this way? It added to the psychological burden for us.” (P 12)

Interprofessional Inequalities. There were various forms of inequality among physicians and nurses in terms of PPE allocation, patient visitation protocols, and compensation, including the “COVID-19 bonus.” There were also disparities between nurses and administrative staff, as well as external organizational inequalities.

“There was a difference between us and the physicians in terms of getting equipment. They easily got as many pieces as they requested, but for us, it was rationed. Even now, we get our N95 masks under our doctor’s name in our station. This kind of treatment by the authorities was hurtful to us.” (P 10)

The other level of inequity was between nurses and administrative staff in the form of diagnostic laboratory test accessibility.

“Well, despite the protocol to do the PCR test for us, the nurses would compulsorily do the tests only in the case of presenting severe clinical symptoms in the almost-dying phase! But the administrators could easily test themselves once in a while. Well, that kind of thing puts psychological stress on you.” (P 11)

Some nurses expressed feeling discriminated against when they observed administrators in other organizations readily approving sick leave and providing free PPE for their

administrative colleagues. These factors worsened the psychological distress experienced by the nurses.

“You know, compared to hospitals, other organizations care much more about the health of their employees. For example, I have a relative who works somewhere else. They get sick leave for even the mildest symptoms and get PPE not only for themselves but also for their family members. . . .” (P 17)

(3) *Emotional Challenges.* Emotional challenges included unpleasant emotional repercussions, the experience of reason-emotion dichotomy that arose from confronting phenomena that contradict professional values, and the experience of stigma associated with COVID-19.

Unpleasant Emotional Repercussions. Most participants experienced various unpleasant psychological effects, such as fear, terror, intense anxiety, and dread of an unknown future. As the pandemic lasted for a long time, they also underwent changes in psychological effects, such as experiencing a depressive and sad phase, weakening nurses’ immune systems, and jeopardizing their safety.

“For example, my colleagues used to talk about another year [of the pandemic crisis]. Then they would say to me, “Given how things are going, do you think you’ll survive another year? I doubt it very much. . . . there’s a kind of depressed mood.” (P 15)

Reason-Emotion Dichotomy. Moral dilemmas arose from confronting double-sided phenomena that contradict professional values. The lack of facilities forced them to prioritize care, leading to anguish and problems for the nurses in the form of guilt.

“We had a shortage of ventilators This was very stressful psychologically and led to additional fatigue.” (P 4)

Sadness of Stigma. Sadness of stigma included negative behaviors and attitudes, labeling, avoidance, and rejection related to nurses, especially those in direct contact with COVID-19 patients. Nurses experienced various stigmas, from their families to their neighbors, colleagues, and the public. The perceived stigma posed a threat to the safety of the nurses.

“The avoidance behavior of others was hurtful. But what did we do? We were taking care of patients in terrible conditions. At the same time, others, including some family members, friends, and people, annoyed us by giving us strange looks, avoiding us, and even saying nurses were sources of infection.” (P 21)

3.1.3. Strategies. Several strategies have been implemented by participant nurses represented by the “seeking protection” category, as articulated in four subcategories (Table 2 and Figure 1). These strategies implied changes in working lifestyle, inappropriate responses, efforts to reduce psychological stress, and providing mutual care. All of these strategies have been enacted to help nurses stay on track despite the challenges they face.

(1) Change of Working Lifestyle. Nurses employed several strategies to improve their work lifestyle. These strategies included taking preventive measures, regulating the arrival and departure of companions/visitors, issuing safety alerts, educating patients and their caregivers, conducting peer training, seeking help, obtaining information from credible sources, practicing self-care due to a lack of PPE, managing physical trauma, and lodging complaints to authorities regarding their workplace protection.

“I would try to get information from clinical supervisors, doctors, or university professors about COVID, such as how to protect myself and control the disease.” (P 2)

Inappropriate Responses. According to participants’ experiences, the onset of the pandemic led to increased work pressure and fatigue, which resulted in the adoption of inappropriate responses. Some nurses displayed maladaptive responses to the COVID-19 crisis, such as aggression toward patients and companions, avoidance of certain situations, negative coping mechanisms, contact avoidance, obsessive protection, and secrecy. These responses were linked to negative outcomes, such as increased personal tension, strain within the organization, and potential harm to patients.

“Some people’s avoidance behavior made me conceal my work in the COVID ward. Whenever someone asked, I would deny that our center had cases of coronavirus. However, my conscience kept bothering me, reminding me that I was in close contact with patients and needed to ensure their immune systems were not compromised to get severe illness.” (P 17)

Psychological Stress Alleviation Strategies. One strategy that significantly helped in reducing psychological stress and improving well-being was filtering incoming information, spending time with family and friends, turning to spirituality, engaging in recreational activities, fostering hope, creating a positive environment, desensitizing, seeking medical assistance, and trying to combat stigma.

“When I take breaks, I listen to one of my favorite songs on my phone to lift my spirits.” (P 9)

These strategies decreased psychological pressure, enhanced relationships, physical well-being and immunity, improved sleep quality, and better management of physical issues.

“Since I started exercising and focusing more on spirituality, like reading the Quran before bed, my nightmares have ceased. I also experience less stress and fewer heart palpitations.” (P 21)

Mutual Care. Mutual care, expressed in the form of asking for and giving family support, limiting interactions, being stricter about personal hygiene than ever before, practicing self-care, using alternative treatments, and supporting colleagues, was a strategy used by most participants due to their sense of responsibility for others. These strategies played an important role in restoring calm to the family and improving relationships. However, during the ongoing pandemic, the strategy of self-quarantine, which prevented the opportunity to give and receive mutual support, induced feelings of sadness.

“During this time, we canceled all gatherings, funerals, and weddings, even visits to our parents, because I was afraid of being a carrier and infecting others. We haven’t taken a trip in two years.” (P 20)

3.1.4. Outcomes. Outcomes of using the strategies mentioned above to protect oneself and others varied between two categories (Figure 1 and Table 2) as

- (1) “Bright horizon” indicates satisfaction (reduction of psychological stress, improvement of relationships, and restoration of family peace) and physical protection (immunity, reduction of sleep problems, and management of physical problems)
- (2) “Unpleasant reflection” indicates individual stress (increased likelihood of infection, physical complications, regret, feelings of neglect, and sadness), weakening of the organization (exacerbation of the lack of power, greater spread of disease, and a decrease in trust), and the risk of harm to patients (delivering poor quality of care, compromising patient safety, and being dissatisfied with patients and their relatives). However, with the increased scientific understanding of the COVID-19 disease nurses continued to seek protection in the heart of the storm but the contextual factors changed:

“As time goes on, I feel that everyone has gotten over the shock, that scientific information is increasing, that training groups are being formed in the hospital, and that there is some comfort in hearing that the disease can be controlled if you increase your knowledge and follow the protocols.” (P 6)

4. Discussion

The theory “seeking safety in the heart of the storm” explains how nurses navigate safety challenges during pandemics, incorporating concepts, such as transformations, inequalities, and emotional challenges. It highlights the balance between hopeful outlooks and sobering reflections,

ultimately leading to the core concept of seeking protection in the heart of the storm. By drawing on established theories like coping, resilience, and social support, a comprehensive framework emerges to understand nurses' safety-seeking behaviors [24, 25]. Additionally, it aligns with Kang and colleagues' model (2023) of "seeking to protect the safety of oneself and the patient" to describe the experiences of nursing students facing safety-threatening conditions and their adaptation process [26]. Our theory compares well with that of Kang et al., addressing obstacles, positive and negative influencing factors, effective and ineffective strategies used by nurses to maintain protection, and resulting outcomes. As a result, it stands as a comprehensive theory for understanding the adaptive strategies of nurses during crises.

First, contextual factors emerged as influencing the protection of hospital nurses during the COVID-19 pandemic, shedding light on the obstacles and catalysts that shape their journey toward safety and protection. Among the organizational challenges, staffing, information gathering, and training [27], protection issues and unfavorable infrastructure factors emerged, as in previous studies [3, 28]. Additionally, inappropriate monitoring and supervision, lack of organizational support [29], and varying ward-related protection conditions [30] also emerged as already well-documented, indicating that nurses worldwide have faced similar organizational conditions. However, the time-consuming documentation appears to have played a significant role in Iran, suggesting that digital transformation may ease this burden in the future.

In terms of patient/relative-related challenges, they appear to be similar to those reported in previous studies [31]. The presence of patients and their families has been highlighted as crucial for nurses in alleviating distress [32]. Consequently, harassment, frequent calls and follow-ups, unreasonable expectations, and misconceptions among patients and relatives pose a serious threat to nurses' safety and health [33, 34]. Also, these findings are in line with those reported in previous studies. However, noncompliance with restrictions or preventive measures was also reported, possibly due to the emotional bonding in Iranian culture between family members and patients' relatives demanding the lifting of visiting restrictions. Moreover, nursing-related factors have also been documented in previous studies, such as reactions to vaccination [35], living conditions [36], transportation to work [37], personality [38], underlying disease [39], and willingness to visit the COVID ward.

The experiences of nurses during the pandemic showed a spectrum of psychological reactions. Initially, nurses were confronted with negative feelings, such as anxiety, fear, shock, and stress. Over time, they adapted to the new working conditions, but also showed symptoms of depression, a sense of hopelessness in the face of the never-ending situation, and occupational burnout due to the ongoing challenges of the pandemic [28, 36].

The shielding catalysts framework acted as a guiding light for nurses navigating the path to protection during the COVID-19 pandemic, incorporating elements, such as fostering resilience and enhancing organizational support.

Societal and family support played a crucial role in enduring difficult conditions and enhancing self-esteem, and readiness for work [36, 40]. Various forms of support, such as providing information, extending work shift intervals, offering childcare facilities for nurses' children, and mental support, greatly contributed to nurses feeling secure [36].

Nurses' perceptions of safety and protection threats and challenges were influenced by contextual conditions. These influences gave rise to three main lived experiences, each closely tied to concerns about safety and protection: "transformations," "inequalities," and "emotional challenges." The first refers to forced and deliberate changes in personal life [31, 41] requiring modifications to achieve peace of mind, such as showing more appreciation for life and spending time with family as a form of "psychological growth" [36]. Moreover, changes at the professional level were also reported: a different mode of care was delivered in terms of human interaction and physical contact with patients [42] requiring professional changes in the performance and limiting the nurses' presence in the patient room, i.e., due to the fear of contracting the virus, the need to reduce physical contact with patients [43], and PPE deficiencies [36]. Occupational burnout and the negative experience in these transformations seem to be contrasted by the nurses' sense of competence, accomplishment [40], and pride [31], which may have increased the professional commitment, satisfaction, and intention to continue to work as a nurse [44].

Inequalities are another emerged core category: discrimination has been reported as increasing during the COVID-19 pandemic [45], leading to different reactions that negatively affect both professional engagement and performance. Nurses' moral dilemmas have also increased, as reported elsewhere [46]. Despite their efforts to save lives, nurses have often been considered a source of viral transmission during the COVID-19 pandemic [40]. A lack of adequate awareness in society is one of the main reasons for occupational stigma [47], and providing sufficient information may help to reduce it [48]. Overall, the emotional challenges that result may have triggered the intention to leave the profession [49], a phenomenon largely documented in the postpandemic era.

"Seeking protection" was the term used to describe the strategies employed by nurses to protect themselves and others. "Changing the working lifestyle" involved adhering to preventive measures in the wards, managing lockdowns, and safety alerts; seeking help and training; obtaining information from credible sources; self-managing PPE shortages; and complaining to authorities about the need for protection in the workplace, as documented in previous studies [28, 40]. However, in their efforts to safeguard themselves, nurses resorted to inappropriate strategies, such as avoidance (of situations or contacts), aggression (toward patients or relatives), or obsession (such as excessive searching for protection). Avoidant behavior was reported in studies involving nurses during the Ebola outbreak [50], while compulsive behavior in following protocols was reported by nurses in Turkey and Qatar [40, 51]. This ineffective behavior may further escalate feelings of being

unsafe and negatively impact the work environment climate and personal well-being of nurses.

In applying “Psychological Stress Alleviation Strategies,” several actions undertaken have already been documented. Examples include filtering incoming information, interacting with family and friends, resorting to spirituality and leisure activities, fostering a sense of hope, creating a joyful atmosphere, seeking medical help [52], and attempting to combat stigma by concealing facts, limiting relationships, and following protocols more strictly [40, 51, 53]. Providing “mutual care” to protect themselves and others, self-impairing intense isolation [31, 36, 43], strictly adhering to protective protocols, and the fear of losing relatives have also been documented [54]. The support and help that colleagues provide to each other using compassion and collaboration techniques in the workplace ease the workloads and enhance nurses’ sense of safety [36, 40]. Discussions with colleagues and receiving updates and information from managers who listened and responded to feedback have been highlighted as being more helpful than external support mechanisms [55].

The perceived outcome varied between “Bright horizon” and “Unpleasant reflections.” The former was reported in other studies, such as in a protective feeling among caregivers after vaccination [56], and increased resilience and peace of mind due to trust in God and the use of self-care strategies [52, 57]. On the other hand, the latter can result in overlooking the role of family members in the care process [29, 53] or further compromising the safety and quality of care [30, 58].

4.1. Limitations. Our study has several limitations. First, due to the qualitative nature of the study, our findings may not be generalizable to other communities or contexts. Second, some interviews were conducted via video calls based on participant preferences, potentially limiting the depth of shared experiences. Third, while the extended study period (2020 to 2022) allowed for the development of a theory encompassing all pandemic stages, its validity requires confirmation across different cultures, countries, and pandemic waves. Fourth, the study focused solely on hospital nurses; therefore, the theory should be validated in various settings, disciplines, and professions to achieve a more comprehensive understanding of the phenomenon, which could impact all healthcare professionals.

5. Conclusions

To the best of our knowledge, despite numerous studies on nurses’ perceived safety during the recent pandemic, a comprehensive grounded theory describing the process of seeking protection by frontline nurses has not been formulated to date. With this qualitative inquiry, we attempted to address this gap by delving into how hospital nurses sought protection during COVID-19.

At an overall level, the study developed the “seeking protection in the heart of the storm” theory, illustrating nurses’ efforts during the pandemic. Available literature has

already produced evidence; however, the fragmented evidence has not been included in a comprehensive picture. Nurses faced various challenges, termed “Safety Pathway Obstacles,” including organizational, patient-related, temporal, and nurse-specific issues. These challenges coalesced into three themes: Transformations, Inequalities, and Emotional Challenges, emphasizing the complexities of safety in nursing care. Despite these obstacles, nurses adopted protective measures, implying lifestyle adjustments and coping strategies, resulting in both positive outcomes (satisfaction, well-being) and negative outcomes (stress, patient harm). Taken together, the results highlight the intricate interplay of adversity, resilience, and practices adopted by nurses during difficult times. Findings provide a composite picture depicting nurses striving to achieve safety to shield themselves and their families from the relentless impact of the disease. This imperative accentuated their awareness and dedication to navigating toward safety, prompting the adoption of diverse strategies, some effective and others not, propelled by the urgent need to secure safety. These choices significantly influenced outcomes, leading to either positive or negative consequences. In essence, the research sheds light on the intricate nature of nurses’ experiences and underscores the crucial role of nurturing supportive work environments and policies to enable effective coping mechanisms. By acknowledging the challenges confronted and the strategies employed by nurses, healthcare institutions can offer better support to frontline workers, thereby improving overall patient care outcomes. These elements can inform informative, educational, and organizational strategies at the local, regional, and national levels, aiming to capitalize on the lived experience of nurses in a proactive strategy to protect them during difficult times.

6. Implications for Nursing Management

Developing a theory can enhance our understanding of phenomena informing customized preventive measures and evaluating their effectiveness. First and foremost, there is an urgent need for a cohesive strategy to protect nurses, acknowledging their safety as a public health priority. Additionally, investments in cultural, educational, and organizational resources should prioritize nursing roles at both macro- and microlevels. Third, promoting individual preparedness is crucial. It is important to acknowledge that not all strategies employed by nurses yield positive outcomes, emphasizing the importance of effective coping strategies.

Moreover, researchers should evaluate the theory’s applicability across different contexts and cultures to ensure its empirical validity. Policymakers, managers, and educators can use the emerged insights to inform decision-making and educational initiatives according to nurses’ concerns and coping mechanisms. In clinical settings, healthcare professionals, especially nurses, can learn from successful strategies to enhance care provision during crises. Embedding process of seeking protection into nursing education and healthcare provider training programs can further enhance preparedness.

Data Availability

The data supporting the findings are available from the corresponding author. The data are not publicly available due to privacy or ethical restrictions.

Conflicts of Interest

The authors declare that there are no conflicts of interest regarding the publication of this article.

Authors' Contributions

Mehraban Shahmari, Arpi Manookian, and Nahid Dehghan Nayeri designed the study, investigated, curated the data, conducted the analysis, and wrote the original draft. Seemin Dashti investigated the study, curated the data, and wrote, reviewed, and edited the study. Alvisa Palese collaborated on the data analysis, theory development, manuscript writing, and revision. All authors read and approved the final version for submission.

Acknowledgments

Researchers hereby express their gratitude to all the nurses participating in the study and the Vice-Chancellor for Research and Technology of TUMS.

Supplementary Materials

Standards for Reporting Qualitative Research (SRQR) and an example of the process of forming a main category as a supplementary material file will be submitted with our manuscript. (*Supplementary Materials*)

Aim. To determine Senior Nurse Managers' perceptions of integration of Nurse Practitioner roles in Healthcare Organisations across Ireland and Australia. **Background.** Introduction of the Nurse Practitioner role in both countries is well established with national policies aimed at developing a critical mass in the health workforce. Current policy requires Senior Nurse Managers to be actively involved in the introduction of and oversight of the integration of Nurse Practitioners across healthcare settings. This is integral in the context of the success and sustainability of the services provided by the Nurse Practitioner. **Methods.** A quantitative, cross-sectional cloud-based survey of senior nurse managers across Ireland and Australia from April to September 2022. **Results.** Of 300 responses received, 122 were eligible for analysis. Of these, 77% expressed that there should be a specific role to support the integration of Nurse Practitioner roles at local level, and 61% recommended that this should occur at a national level, whilst 48% reported the absence of a standardised governance structure. Three reporting structures were identified: professional, clinical, and operational. Autonomous clinical decision making and prescribing were two Nurse Practitioner functions most identified. Fifty-five percent reported having performance indicators for Nurse Practitioner roles, with 24% agreeing that performance indicators captured the quality of care provided. Thirty-five percent of senior nurse managers indicated that there were agreed reporting timelines for performance indicators and a requirement for the provision of an annual report. **Conclusion.** Whilst some participants reported structure to guide and evaluate the work and value of Nurse Practitioners, the approach was inconsistent across organisations and countries. This paper demonstrates that integration is not broadly established across both countries. **Implications for the Profession.** The main findings were that Nurse Practitioners were misunderstood and the development of a structured framework to support the integration of Nurse Practitioners would provide long-term benefits.

1. Introduction

Nurse Practitioners (NPs) are clinical nurse leaders and a key component in healthcare transformation and healthcare reform [1]. In response to the current global workforce challenges and increased demands on health services, NPs have been shown to reduce fragmentation of care and improve the patient journey whilst improving efficiency of service provision [2] and to be cost-effective [3].

NPs practice autonomously and independently within agreed caseloads in the Irish context and scopes of practice in the Australian context [4]. They undertake care across broad contexts and settings—wide-ranging both geographically and clinically—and are capable of reducing health service gaps and increase services where wait times for treatment are excessive [5, 6]. Further, evidence supports a reduction in hospital transfers when NPs are involved in care [7], that hospital readmissions reduced and safe

prescribing increased with the inclusion of NPs in service delivery [6, 8].

Integration of NPs for the purposes of this research is referred to as a process of embedding the roles into the healthcare teams through organisation change at the micro and macrolevels [9]. The integration of NP roles depends on a structured, multilevel support system to ensure they are embedded within the service rather than remain as an “add-on” [2, 10]. The complex multilevel support required involves clinical support to facilitate clinical practice, team support whilst team dynamics are being redesigned, system-wide support in the form of strategic direction from nurse managers, and financial support from the organisation [10]. This framework by Contandriopoulos et al. [10] was previously used to explore NP perceptions of integration in the Irish context [11].

Previous research has identified that the sustainability of NP roles requires planning and support to ensure the role is adequately integrated into service provision [2]. Despite this, recent research identified that a structured approach was lacking in relation to the integration of NP roles into acute healthcare organisations, potentially leading to missed opportunities to demonstrate the true value of NPs in healthcare and long-term sustainability of roles [11]. These factors support further research in the area on NP integration.

Whilst there are a number of NP integration frameworks emerging, there is no international collaboration to date on this issue. Previous research has affirmed that the NP regulatory framework and roles are comparable [4]. The research team concluded this was an opportunity to explore NP integration from an international perspective between countries with similar regulatory frameworks.

2. Background

Previous work has highlighted the need for effective leadership to drive changes necessary for NP integration and to overcome the barriers presented by existing organisational structures and professional cultures [2]. Leadership, specifically through challenging current structures and facilitating and enabling change of healthcare service delivery, is supportive of NP integration [2]. Integration of NP roles is reported as problematic globally, with inconsistent utilisation of NPs, and ineffective policy and governance issues [12, 13]. Porat-Dahlerbruch et al. [13] identified macrolevel NP integration factors at national policy level, such as pay scales and focused healthcare policies related to healthcare delivery. Organisational factors and institutional policies supporting streamlined governance structures are known as mesolevel factors, and microlevel factors relate to inter and intraprofessional relationships and clear understanding of roles and responsibilities within healthcare teams [13]. Chouinard et al. [14] identified that Directors of Nursing were the key stakeholders enabling NPs to enact their role to its full potential and that nurse managers are the most useful source of support to define and develop NP roles in a primary healthcare setting.

Current Department of Health policy in Ireland supports the increase of Registered Advanced Nurse Practitioner (RANP) roles to achieve a critical mass target of 2% of the

workforce [15] in targeted areas. This target has been achieved (Nursing and Midwifery Board of Ireland [16]). An evaluation of this policy implementation in Ireland by Brady et al. [6] referred to the key barrier to successful implementation of the Department of Health policy was the requirement for organisational governance. There is no standardised governance structure for NP integration in Ireland [11].

In the current Australian context, the Nurse Practitioner Workforce Plan (called The Plan) aims to increase the number of NP roles nationally and ensure they are working to their full scope of practice [15]. The Plan [15] acknowledges that the integration of NPs into workforce planning assists in a whole of workforce planning framework, achieved through better understanding of roles by health workforce planners, healthcare teams, and consumers of health.

Despite the varying national policies, previous research comparing the NP roles across Ireland and Australia has determined that there is no significant difference in the work of both roles [17]. The same research reported that the leadership activities were validated by NPs in both Ireland and Australia, supporting the similarities in both roles [4, 17].

A NP integration framework was proposed by Contandriopoulos et al. [10]. The framework identified five factors for the successful integration of NPs in a primary care setting. The original factors included planning, role definition, practice model, collaboration, and team support. The framework was previously modified to explore NP perceptions of integration in one healthcare region in Ireland. The modification resulted in the identification of four distinct categories in a NP integration framework which included planning, governance and support, role definition and consensus, collaboration and referral, and outcome and performance measurement. This modification is reported in detail by Ryder and Gallagher [11].

3. The Study

3.1. Aim. The study’s aim was to determine senior nurse managers’ perceptions about the integration of Nurse Practitioner roles in Healthcare Organisations across Ireland and Australia.

3.2. Objectives. The research questions were generated under four distinct categories for NP integration, defined by Ryder and Gallagher [11]. The survey questions were rephrased from Ryder and Gallagher [11] for the purpose of this study: (1) planning, governance, and support; (2) role definition and consensus; (3) collaboration and referral; and (4) outcome and performance measurement. The objectives of this research are to

- (1) Identify the perceptions of governance and support necessary by nurse managers to integrate NP roles
- (2) Ascertain senior nurse managers’ perceptions of role definition and whether consensus exists
- (3) Determine senior nurse manager perceptions of specific outcome and/or performance measures used to evaluate NP practice

4. Methods

4.1. Design. The study was a quantitative, cross-sectional cloud-based survey. Participants of interest were senior nurse managers across Ireland and Australia.

4.2. Setting, Sampling, and Recruitment. The population for the current study included senior nurse managers in Australia and Ireland. Primary recruitment was via social media and targeting professional nurse management associations in Ireland and Australia. Convenience and snowball sampling was used to enable participants to share the study information with colleagues and others within their organisations and networks. It is not possible to know the exact figures of the population as there was no database to describe this figure.

A snowballing technique was used to disseminate (1) a flyer and (2) a plain language information sheet (PLIS) providing details of the study aims, which also included a link or QR code to enable direct access to the online survey. The research team included managers, clinicians, and academics. The team disseminated the invitation to the survey among their own networks with a request to forward to other potentially suitable participants. The invitation included the flyer and/or the PLIS so the link could be accessed directly. The survey remained open online between June and September 2022. For the purposes of this study, senior nurse manager roles include

- (1) Director of Nursing
- (2) Assistant Director of Nursing
- (3) Directorate Nurse Manager
- (4) Director of Midwifery
- (5) Clinical Manager
- (6) Director of Education
- (7) NP/RANP (Australian and Irish terminology, respectively)

4.3. Sample Size. Convenience and snowball sampling was used to identify and recruit Senior Nurse Managers across Ireland and Australia. A power analysis was not undertaken for this study as it is not possible to determine the number of senior nurse managers working in Ireland or Australia.

4.4. Instrument. An online survey instrument was designed by the research team to survey senior nurse managers. The concept for the instrument was based on previous research by Lowe et al. [2]. The instrument was modified following an exploration of existing literature on the topic from Contandriopoulos et al. [10] who developed a framework for nurse practitioner integration in primary care. Development of the online survey instrument modified from Contandriopoulos et al. [10] framework is described in detail by Ryder and Gallagher [11]. There are four sections in the instrument of Ryder

and Gallagher [11]. Questions in the instrument were adapted for senior nurse managers for the purpose of this research using Qualtrics® software.

The final instrument for this study was composed of four sections, namely, planning/governance and support (9 items); role definition and consensus (9 items); collaboration and referral (2 items); and outcome/performance measurement (9 items). In addition, the questionnaire included demographic items (5), questions exploring previous experience working with NPs (6 items), and two open-ended questions. There were a total of 42 items in the final survey instrument (available upon request). The survey was tested for face validity among five senior nurse managers working in healthcare regions in Ireland and Australia. The senior nurse managers were randomly selected by members of the research team. No modifications to the survey were recommended following review. Reliability was tested during analysis. The survey was hosted on the Qualtrics platform and accessed via a direct link or QR code.

4.5. Quality Appraisal. The first appraisal sought to identify incomplete responses. All responses with less than 70% completion were removed to ensure the quality of data collected was optimal [18]. Secondly, where responses indicated the role title was inconsistent with our inclusions (see Section 4.3) the responses were removed.

4.6. Data Abstraction. Data were exported directly from the cloud-based survey platform Qualtrics® to SPSS® for analysis.

4.7. Data Analysis. Data collected from the closed questions were analysed using IBM SPSS Statistics (Version 27). Descriptive statistics were used to summarise and describe the data. Content analysis was used for the open questions to determine themes, concepts, and relationships in the data, using a technique described in [19]. This process involved descriptions and interpretations of various levels of abstraction and interpretation [20].

4.8. Ethical Considerations. Submissions were made to the relevant ethics committees with approval numbers LS-E-22-23-Ryder and B22-022 provided as evidence of approval for the study. A participant information document was embedded into the survey which required selection of “I consent to participate” to access the cloud-based questionnaire. A flyer was prepared for social media recruitment with survey access links embedded. All responses were anonymous.

5. Results

A total of 300 responses were recorded in the cloud platform. Of those, 122 responses were identified as suitable for analysis. The results will be presented using subheadings consistent with those in the survey.

TABLE 1: Demographics.

	Ireland N (%)	Australia N (%)	Total N (%)
<i>Age</i>			
25–44 years old	29 (24)	5 (4)	34 (28)
45–64 years old	77 (63)	26 (21)	103 (84)
<i>NPs in organisation</i>			
Previous experience working with NP/candidate NP (NP in preparation)	96 (79)	26 (21)	122 (100)
Currently working with NP/candidate NP (NP in preparation)	90 (74)	26 (21)	116 (95)

*Participants were permitted to select more than one option for work location.

FIGURE 1: Key stakeholders required in healthcare organisation to integrate NP role. *Other: nurse practitioners/health service managers/patient representatives/administrative and financial personnel/departmental staff.

FIGURE 2: Senior nurse manager perception of NP autonomous functions.

FIGURE 3: Senior nurse manager perceptions of how NPs can improve patient care in organisations. *Other: Continuity of care/educating staff/integration across acute and community/role modelling.

5.1. Demographics. The majority ($n = 91$; 75%) were in the 45–64-year-old age category. The mean years in nursing was 28 (SD 8) and mean years in the current role was 10 (SD 7). The majority were from Ireland ($n = 106$; 87%) and identified working in a metropolitan area ($n = 52$; 43%), Table 1.

All participants reported having previously worked with NPs or NPs in preparation, and 95% ($n = 116$) currently have NPs or NPs in preparation working in their organisation. The average number of NPs (whole time equivalent (WTE)) per organisation was 10 (SD 13; range 0–92) NPs in preparation $M = 6$; $SD = 8$; range 0–36.

Participants were asked to identify the top 3 gaps in service delivery that could be addressed by NPs to improve patient care. The most common areas identified were chronic disease management ($n = 12$), cardiology ($n = 11$), and mental health ($n = 10$), followed by diabetes and cancer ($n = 8$) and then respiratory and outpatient services ($n = 6$). Other clinical areas included dermatology ($n = 5$), women's health ($n = 4$), endocrinology and endoscopy ($n = 2$), and wound care ($n = 1$).

5.2. Planning, Governance, and Support. The second category in the survey related to items that identified opportunities for NP roles, support for integration into organisations, and advocates for the role. A majority expressed an opinion that there should be one specific role (single person) to fulfil this remit within an organisation ($n = 94$; 77%) and a single person responsible for identifying opportunities nationally ($n = 75$; 61%). The open text response indicated that this should be a senior nurse manager position at the level of Assistant Director of Nursing or above.

Participants identified the Director of Nursing position and the consultant (medical) in the specialist area as the two key stakeholders required when integrating the NP role into a healthcare service (Figure 1).

A higher proportion of participants ($n = 59$; 48%) reported that there was no standardised governance structure for the development/expansion and integration of the NP role in organisations. These participants selected that a standardised governance structure was required. The key stakeholders identified by participants for inclusion were senior

nurse manager roles, consultants, allied health professionals, hospital governance, and service user representation to ensure roles are properly integrated into healthcare organisations.

Ninety-three percent of participants ($n = 113$) indicated a requirement for a three-dimensional reporting structure for NPs. This included professional reporting to the Director of Nursing ($n = 95$; 78%), clinical reporting to the medical consultant in specialist area ($n = 89$; 73%), and operational reporting with less clear responses to a Directorate Nurse Manager/Assistant Director of Nursing/Business Manager for the specialist area ($n = 59$; 48%). Additional reporting structures included regional and national nurse leaders and the regulator.

5.3. Role Definition and Consensus. Participants were asked to identify the autonomous functions of NPs from a list provided. The two functions identified most commonly were (1) autonomous clinical decision making to inform care management and (2) prescribing (Figure 2). The open text comments were related to (1) a lack of understanding by colleagues and other healthcare professionals of the NP role, (2) the need for additional time and support for NPs to engage with research outputs related to their service, and (3) concerns related to admission rights and referral for investigative procedures.

Participants were also asked to identify how they believed NPs could improve patient care within their organisation (Figure 3).

The majority ($n = 102$; 84%) indicated the presence of a specific job description for NPs within their organisation. Preparation of the job description was the role of the consultant in the relevant specialist area ($n = 103$; 84%) and the Director of Nursing ($n = 98$; 80%). Sixty-five participants (53%) reported that there was no agreed process to review NP roles and job descriptions ($n = 53$; 43%).

5.4. Outcome and Performance Measurement. Fifty-five participants (43%) reported that NPs in their organisation had agreed performance indicators (KPI). It was the opinion of some participants ($n = 58$; 47.5%) that the agreed KPI did not capture the quality of care provided by NPs. Forty-three

participants (35%) reported that there were agreed KPI reporting timelines, with the same number (35%) reporting that NPs provide annual reports of activities. One question was related to the sustainability of NP roles. Participants were provided with a drop down option box and the ability to choose “all that apply.” The top three factors identified by senior nurse managers were (1) support from nursing management ($n=87$), (2) organisational culture ($n=86$), and (3) medical management support ($n=80$).

Participants were provided with an opportunity to make any further comments to the researchers related to NP role integration through open text comment options in each category. Content analysis on the responses concluded that (1) work is required on the development of governance procedures to safeguard the future sustainability of the roles, for example, “annual report should be mandatory” and “national job description for specialties”; (2) integrating the role with interprofessional colleagues, for example, “a multidisciplinary committee so that stakeholders are engaged from the outset” and “multidisciplinary forums to present achievements”; and (3) that NP voices must be heard, for example, “NP/ANPs need to be more proactive and find a voice” and “NP/ANPs need a national voice.”

6. Discussion

There was a paucity of literature exploring senior nurse manager perceptions of NP roles internationally and this was the first time they had an opportunity to report their understanding of the roles against clear components of NP practice. A number of key findings were evident from the results of this study. First, whilst there was overall support for NP roles, a lack of understanding of the autonomous function of the role and scope of practice was evident. Further, governance of NP roles once implemented was reported as ad hoc and evaluation was unclear. Third, there was inconsistency between reporting research as an activity to improve patient care and understanding of NPs' engagement with research.

Consistent with previous literature, the first key finding of this study was that senior nurse managers in Australia and Ireland perceived that NPs were capable of autonomous practice and that their roles could have a positive impact on patient outcomes. Senior nurse managers reported a range of areas within their organisations where patient outcomes could improve with the addition of NP roles, particularly chronic disease management, cardiology, and mental health—areas identified as priorities by governments in both countries.

Whilst the majority of senior nurse managers (80%) reported their perceived understanding of the autonomous function of NPs included prescribing medicine and treatment, the majority of participants did not perceive that the autonomous role included admitting and discharging patients by NPs (41% and 52%, respectively). Despite national standards outlining admission and discharge of patients within the scope of NP roles [16, 21, 22], there is a discrepancy between the reported perception of these autonomous functions indicating a lack of understanding of these

clinical responsibilities. This finding suggests that the role and function of NPs lacks clarity for some senior nurse managers and could result in missed opportunities for working to full scope of practice. The International Council of Nurses (ICN) definition of NP scope of practice is:

A Nurse Practitioner is an Advanced Practice Nurse who integrates clinical skills associated with nursing and medicine in order to assess, diagnose, and manage patients in primary healthcare (PHC) settings and acute care populations as well as ongoing care for populations with chronic illness [23].

This finding was consistent with recent evidence that NPs report a lack of understanding of their role across a variety of healthcare settings [4, 24]. It is also widely acknowledged by NPs themselves that their role is largely misunderstood, despite role clarity being essential to successful integration [25, 26]. With senior nurse managers identified as playing an important role in NP role integration [14], it is crucial that a full understanding of the current roles and future potential can be harnessed. The process of introducing and incorporating the NP role into any healthcare organisation is a key integration attribute to the successful outcome and sustainability of the role in the long term [13].

The second key finding was that senior nurse managers indicated very high expectations of NPs' ability to improve service delivery and patient care outcomes. There was a clear indication that NPs improve healthcare service delivery within organisations, which was consistent with previous literature [1]. However, a concern identified in this research indicated that there was a lack of agreed process to review or evaluate the NP roles, the NP patient population/eligible patients, and job descriptions. Almost half (44%) of senior nurse managers reported that NPs have outcome/performance measures, yet they reported that (1) the performance measures did not accurately capture the quality of care (24%); and (2) that outcome/performance measures were not a priority for role sustainability (46%)—again possibly due to the lack of clarity and/or understanding. Whilst Chouinard et al. [14] reported that Directors of Nursing were the key stakeholders enabling NPs to enact their role to its full potential and that nursing managers are the most useful source of support to define and develop NP roles in a primary healthcare setting, managers seldom reported meeting with NPs to clarify their roles. There are several reasons why it is vital to evaluate all NP services. There are several reasons why it is vital to evaluate all NP services, including; 1) planning for future workforce, 2) understanding patient sensitive outcomes, 3) identify the effects on organisational goals and 4) demonstrate and showcase the outcomes associated with NP roles on patient care [27].

The third key finding was the incongruity in senior managers' perceptions of NP engagement in research activities. Most participants reported that engaging in research activities would improve patient care; however, understanding of this activity as a function of the NP role was rated much lower. This finding is consistent with previous literature, with results that (1) 3% of

NP work related to research, (2) all NPs indicated it was not supported by nurse managers, and (3) most NPs completed research in their own time, suggesting a misunderstanding of what constitutes research engagement [4, 17]. A translational research framework for NPs has been proposed in the literature which identifies the range of NP activities aligned to research engagement within the framework [11]. Examples of the activities included are implementing evidence-based practice (EBP) through guideline development and evaluation of the NP services provided. Smigorowsky et al. [28] propose that little is known about the outcome of NP work due to the poor quality of research produced. Failure to understand the value and importance of research engagement and supported time dedicated to research activities within the role inhibits the development and enhancement of research skills.

6.1. Strengths and Limitations. One of the key strengths of this research is that it is the first time there have been clear variables provided for senior nurse managers to report their understanding of the NP roles.

Limitations of the research include factors associated with the response rate which made it difficult to stratify the results by role of employment. The sample population was consistent across both countries; however, there were more responses from Ireland than Australia and legislative differences may have impacted responses. The role of individual participants may also have influenced their responses.

6.2. Recommendations for Further Research. The first recommendation for further research is the development of a framework to support the structured approach to NP integration across health services. The framework should include the three multilevel factors described by Chouinard et al. [14] but further incorporate the horizontal layers necessary for NP clinician and nurse manager support across systems [14]. The second recommendation is for NP job descriptions to be established as live documents, regularly reviewed by the NP and senior nurse manager. This third recommendation is to support the accurate evaluation of the value NPs add to service and therefore patient outcomes including the value of research engagement.

7. Conclusion

The study has highlighted that there continues to be positive perceptions of the ability for NPs to improve service delivery and patient care. However, understanding of the full scope of practice of NPs and therefore the potential benefits to health services is yet to be identified and fully appreciated. This work is aimed at the mesolevel described by Porat-Dahlerbruch et al. [13] with findings supporting the need for a structured approach to NP integration in healthcare organisations [29].

7.1. Implications for the Profession. The main findings indicate that NPs were misunderstood and that the development of a structured framework to support the integration of Nurse Practitioners would provide long-term benefits.

Data Availability

The survey data used to support the findings of this study are available from the corresponding author upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Nursing and midwifery education in Malawi entails theoretical learning and clinical practice, essential for developing competent professionals. However, challenges such as staff shortages and limited resources hinder effective clinical teaching. Simulation-based education (SBE) offers a promising solution. This study aims to explore how SBE can enhance clinical teaching in Malawian nursing and midwifery education. Data were collected through in-depth interviews with lecturers, clinical instructors, and focus group discussion (FGD) with the final-year students. Thematic analysis revealed several key findings: SBE serves as a valuable gap-filler in clinical education, addressing complex needs while offering diverse learning opportunities. It also provides a platform for enhanced supervision and assessment strategies. The results indicate that SBE enables students to master various clinical skills without direct patient contact, reducing congestion at clinical sites while ensuring credit acquisition. Moreover, it proves effective as both a supervision and assessment tool for evaluating students' clinical performance. In conclusion, the study advocates for the integration of SBE into Malawian nursing and midwifery education to alleviate the challenges associated with traditional clinical teaching. By leveraging SBE, institutions can mitigate overcrowding at clinical sites and provide students with diverse learning experiences. However, successful implementation requires adequate infrastructure, resources, and skilled lecturers. Ultimately, SBE holds the potential to significantly enhance the quality and outcomes of nursing and midwifery education in Malawi.

1. Introduction

Nursing and midwifery are complex professions that require knowledge, affective attitudes, and psychomotor skills for safe professional practices and optimal patient outcomes [1]. The training of nurses and midwives in Malawi is organised in such a way that students are taught theoretical modules before they are exposed to aspects in clinical settings [2].

Students can choose to do a program that combines nursing and midwifery, or they can train as midwives or nurses separately. The transfer of theoretical knowledge into practice is a crucial part of preparing students for nursing and midwifery practice. This process is facilitated by clinical placement in various health facilities where students undergo clinical teaching and supervision [3]. The clinical aspects of nursing and midwifery training enable student

nurses and midwives to grow professionally by allowing them to put their theoretical knowledge into practice, thus applying theory to real-world situations [4]. The literature recommends that clinical instructors in health facilities teach or guide students during their clinical placement to achieve the necessary competencies [5].

During clinical placements, nurse/midwifery lecturers and clinical instructors are expected to collaborate to facilitate students' clinical learning experiences and development of clinical skills. According to the Nurses and Midwives Council of Malawi clinical guidelines, ten students are supposed to be supervised by one clinical instructor during clinical placement. However, with a large student population coupled with staff shortages, limited clinical sites, and material resources, it is not possible to effectively provide quality clinical support, as stipulated by the professional regulatory body. This compromises the quality and quantity of clinical teaching in Malawi [4]. Therefore, the clinical support and teaching of students by both academic and clinical staff is reported to be unsatisfactory [4].

Bø et al. [6] indicate that SBE is useful in the acquisition of nursing and midwifery skills in resource-limited countries. Other scholars have described SBE as an evidence-based pedagogical tool that is effective in the acquisition of clinical skills and thoroughly prepares students to train in a safe environment that is not hazardous to patient safety [7].

The Nurses and Midwives Council of Malawi developed SBE guidelines to improve the acquisition of skills by students in training institutions and health facilities. However, apart from the guidelines, there is limited literature on innovative teaching strategies in Malawi that can mitigate the challenges encountered in clinical teaching. Therefore, this study was conducted to explore how SBE can improve clinical teaching in nursing and midwifery education in Malawi.

2. Methodology

2.1. Design. This study used an exploratory descriptive qualitative design to explore how SBE can improve clinical teaching in nursing and midwifery education in Malawi. According to [8], an exploratory descriptive qualitative design is used when not much has been done in the area under study. In the current study, the design was considered appropriate because there is a paucity of literature on the use of SBE in relation to the clinical teaching of nurses and midwives in Malawi.

2.2. Study Population. The study population was comprised of the following:

- (i) Fourth-year nursing and midwifery students
- (ii) Lecturers in nursing and midwifery training institutions
- (iii) Clinical instructors in health facilities

2.3. Inclusion Criteria. The inclusion criteria include the following:

- (i) Nursing and midwifery students in the final year of their program and aged 18 years and above

- (ii) Clinical instructors and lecturers with more than six months of work experience in selected hospitals and training institutions, respectively

2.4. Exclusion Criteria. The exclusion criteria include the following:

- (i) Nursing and midwifery students aged below 18 years in years 2–4 of their programs
- (ii) Clinical instructors and lecturers with less than six months of work experience in selected hospitals and training institutions, respectively

2.5. Sampling Strategy. Purposive sampling was used to identify lecturers, clinical instructors, and final-year nursing and midwifery students who participated in this study. Purposive sampling is a method in which the researcher deliberately selects participants based on specific criteria [9]. Clinical instructors were approached by nursing officers responsible for different health facilities to meet the research team and provide consent for their participation in the study. Lecturers and students were recruited through the heads of the department and the office of the students' dean, respectively.

2.6. Data Collection. Data were collected through in-depth interviews and focus group discussion (FGD) which were audio-recorded with permission from the participants. FGD and in-depth interviews were conducted at the participants' institutions by appointment. The main focus of the FGD and in-depth interviews were the participants' knowledge about SBE problems being experienced in clinical teaching and how SBE can help to deal with some of the problems. Each FGD and in-depth interview lasted approximately 60 min and 45 min, respectively. Thirty-five in-depth interviews were conducted with 24 lecturers and 11 clinical instructors, using the same semistructured interview guide. A total of 90 final-year nursing and midwifery students participated in ten FGDs, with each group having between 8 and 10 participants (Table 1). All participants in the FGD thoroughly discussed each issue before moving to another issue to give all participants an opportunity to make their contributions.

This study was part of a larger study which focused on challenges encountered in clinical teaching in Malawi and gaps in the nursing and midwifery curricula in Malawi that could be filled using simulation. However, the focus of the current study was to explore feasible solutions to mitigate the challenges in clinical teaching and provide suggestions on how simulation could improve clinical teaching in Malawi.

2.7. Data Management. All audiotaped data were stored in soft copies on multiple computers before transcription to prevent data loss. The audiotaped raw data were then transcribed verbatim to prepare the information for analysis. Member checking was performed on ten conveniently selected study participants after transcription. This was done

TABLE 1: Proportion of study participants in relation to the population for each participant group.

Participant group	Total population	Sampled participants	Percentage
Students	639	90	14
Clinical instructors in health facilities	702	11	1.5
Lecturers	136	24	18
Total	1477	125	8

in order for the participants to verify the information that was collected from them.

2.8. Data Analysis. Data analysis was based on Clarke and Braun's [10] thematic analysis framework which has six steps. It was conducted by the principal investigator (PI) and a research assistant, who was a nurse midwife with vast experience in qualitative research methods. The PI and research assistant independently analysed the data from in-depth interviews and FGD. They began by familiarising themselves with the data by reading the transcripts to obtain a clear understanding of the data. In the process, the two identified words and phrases which appeared frequently in the transcripts and coded them as they were deemed to represent specific ideas. Coded words and phrases were later scrutinised and grouped according to their commonalities. Each group was given a heading which was considered as a tentative theme. The tentative themes were reviewed by two researchers, the principal investigator and research assistant, to identify the final themes, as indicated in Table 2.

2.9. Ethical Considerations. Ethical approval for this study was obtained from the College of Medicine Research and Ethics Committee (P.07/21/3362). In addition to ethical approval, permission to access the participants was obtained from responsible officials in the participating health facilities and training institutions. Verbal and written informed consent were obtained from each participant before the interview. To maintain the privacy of the participants, data were collected in designated institutional rooms. The researchers also ensured that the names of participants were not written in any research document and were not associated with any information that was collected from the respective participants. Participants had the right to withdraw from the study without any negative consequences.

3. Results

3.1. Participant Demographic Characteristics. Results show that 52 (57.7%) of the participants who took part in FGD were aged between 21 and 25 years, and 76.6% (69) were female. On the other hand, 40% (14) of the participants in the in-depth interviews were aged between 36 and 40 years, and 65.7% (23) of them were female (Table 2). In terms of qualifications, 48% (17) were holders of a bachelor of science, while in terms of work experience, 34.3% (12) of the participants had between 11 and 14 years of work experience and with some kind of previous experience with SBE at the time of the interviews.

TABLE 2: Participant demographic characteristics.

Age	Number of participants	Relative frequency (%)
<i>Participants for FGDs</i>		
18 years to 20 years	0	0
21 years to 25 years	52	57.7
26 years to 30 years	25	27.7
Above 30 years	13	14.3
Total	90	100
<i>Gender</i>		
Male	21	23.3
Female	69	76.6
Total	90	100
<i>Participants for in-depth interviews</i>		
<i>Age</i>		
25 years to 30 years	1	2.9
31 years to 35 years	3	8.6
36 years to 40 years	14	40.0
41 years to 45 years	10	28.6
46 years to 50 years	6	17.0
Above 50 years	1	2.9
Total	35	100
<i>Gender</i>		
Male	12	34.3
Female	23	65.7
Total	35	100
<i>Qualifications</i>		
BSc level	17	48.0
MSc level	14	40.0
PhD level	4	11.4

<i>Work experience</i>		
6 months to 5 years	7	20.0
6 years to 10 years	8	22.9
11 years to 14 years	12	34.3
15 years to 19 years	6	17.1
Above 20 years	2	5.7
Total	35	100

3.2. Themes. Following a comprehensive analysis, which involved amalgamating data from individual interviews with those from FGD to establish unified descriptors, four primary themes and their corresponding subthemes emerged, as delineated in Table 3 and explained below. These themes and subthemes were elucidated through quotations extracted from FGD and in-depth interviews. Table 3 lists the themes that emerged from these data.

3.3. SBE as a "Gap-Filler". Participants indicated that SBE can help fill the gaps in clinical teaching. This theme emerged from the four subthemes listed in Table 2. Lecturers and clinical instructors explicitly elaborated that with SBE, an

overloaded curriculum would no longer be a challenge. They indicated that using scenarios and objectives in an SBE provides an opportunity to effectively cover several topics in one scenario. In addition, participants indicated that hospitals and other clinical sites would be relieved of the burden of high student numbers, as some of the activities would be performed at simulation sites.

“Simulation could be ideal in lightening the pressure of our overloaded curricula because we can cover so many topics with just one scenario. The good thing is that so many students can learn so many topics through one scenario; even if they are withdrawn from the clinical sites to work in the simulation centres or skills laboratory to ease the clinical congestion, the hours would still be counted by Nurses and Midwives Council of Malawi.” Senior Lecturer 5.

Clinical instructors indicated that working in teams with real patients is not always possible in a real clinical environment, where some trainee health professionals may decide to work independently of others. Therefore, they felt that SBE would help students from different professions and training institutions work in teams.

“The more students simulate, the more they develop multi-disciplinary skills, how to communicate and relate with other professionals, which is currently missing in our nursing and midwifery education. Simulation provides a more practical—hands-on experience of more skills in one scenario involving other professionals such as medical officers, dietitians, physiotherapists, radiologists even laboratory staff which is not possible with other teaching methods.” Clinical instructor 3.

Clinical instructors and lecturers acknowledge that there are knowledge and skill gaps, particularly for some clinical emergencies, conditions, and skills in clinical settings. This was confirmed by qualified nurses and midwives, who felt that SBE can significantly help expose students to conditions and emergencies that are rare in the clinical setting.

“Some qualified nurses/midwives have gone into practice without experiencing some conditions/skills in the college or clinical settings. Like some of us, we spent our entire college life without coming across procedures/skills like managing shoulder dystocia. With simulation, nurses and midwives can have a chance to practice and get oriented to these rare conditions or skills in teams or with a friend (mentorship) in the skills labs or simulation rooms.” Clinical instructor 6.

Several clinical instructors have noted that simulated patient-based education could potentially mitigate the language barrier they confront while engaging in teaching sessions with students or healthcare professionals from non-English-speaking countries. The role-playing that is done during simulation makes it easier for those who are not

proficient in English to understand what is happening through action.

“There are times when international students or health professionals from other French-speaking countries like Burundi, Congo come for clinical orientation in our health facilities through NCMC (the regulatory body) before being licensed to practice in Malawi; they do not fluently speak English, use of simulation could reduce language barrier if it is only reinforced...” Clinical instructor 3.

3.4. Needs in Clinical Teaching. The participants, mostly students, felt that there were some needs in clinical teaching which could be addressed by SBE. They highlighted the need to adopt innovative teaching strategies, lecturers, and clinical instructors to properly master nursing and midwifery skills. They suggested the adoption of innovative teaching strategies to improve students' acquisition of skills during clinical placement. They believed that SBE was an innovative strategy that could effectively assist students in integrating theory and practice.

“Clinical teaching remains a challenge in Malawi as it demands mastery of skills apart from having knowledge. Most lecturers as they grow professionally, they shun away from bedside care to office work because they may be deficient in some nursing and midwifery skills depending on how they were taught the skills; so they are good at knowledge not skills but with simulation that challenge can be reduced because it exposes nursing and midwifery students to a lot of practical activities which have the potential to greatly improve their nursing and midwifery skills.” Student 13.

Most students felt that frequent use of SBE would help lecturers and clinical instructors be fully equipped with theoretical knowledge that would help them properly guide students during SBE sessions. It would also help them master nursing and midwifery skills which could be an advantage for the students.

“They say practice makes things perfect and I think this can also be applied to teaching clinical skills by our lecturers. The more they teach using simulation, the more skills and knowledge they gain because they will be doing it now and again. So, I feel that in addition to us, as students gain the required skills using simulation, it is also time for our teachers to further sharpen their clinical skills and knowledge” Student 31.

3.5. Opportunities for SBE. Both lecturers and students felt that, during theory sessions in training institutions, students did not have adequate opportunities to practice in skills laboratories because of limited time and space. Therefore, participants suggested the establishment of SBE centres that could be accessible to students at any time in all training institutions.

TABLE 3: Themes and subthemes on how SBE can be used to improve clinical teaching in Malawi.

Themes	Subthemes
SBE—a gap-filler	(1) Lightening the pressure of an overloaded curriculum through the use of scenarios (2) Students working in teams using a multidisciplinary approach (3) Training rare clinical skills (4) Mitigating language barriers in teaching international students
Needs in clinical teaching	(1) Innovative teaching strategies (2) Mastery of nursing and midwifery skills for lecturers and clinical instructors
Opportunities for SBE	(1) Establishment of simulation corners in health facilities (2) Establishment of simulation centres in training institutions
Strengthened supervision and assessment strategy	(1) SBE for clinical supervision (2) SBE for clinical assessment

“In the case of our institution, we have over 1,500 students who would want to practice some skills in the skills laboratory which can only hold about 20 students at a time. . . makes it somehow difficult for all the students to use the laboratory. The time required for laboratory testing is also limited. If I was given an opportunity to advise management, I would say we need a purposefully built simulation centre which is well equipped and where students can practice skills at any time they want.” Lecturer 7.

According to the study participants, most health facilities do not have rooms where skills can be practiced before students start practising with real patients. The participants indicated that such rooms would help gauge students’ skills before they started dealing with patients. Therefore, they suggested that health facilities should provide special rooms for skill acquisition through SBE.

“During training, time for skills labs is not adequate. . . Simulation corners in health facilities can significantly help in skill acquisition. I have provided evidence through the two training sessions I attended on the SBE. Students in South Africa and Tanzania benefit from simulation corners situated within health facilities. Our students lack simulation corners for skills acquisition after theory block. . .it is a matter of liaising with hospital management to create space for skills acquisition within health facilities.” Senior Lecturer 2.

3.6. Strengthened Supervision and Assessment Strategy. This study found that SBE can be used as a strategy for the supervision and assessment of students’ clinical learning. The participants indicated that simulation can provide students with an opportunity to rehearse skills and recognise their weaknesses and strengths through feedback from colleagues. They further indicated that in all these, the clinical instructor or lecturer would be there to supervise a clinical activity and provide assistance where needed.

“With simulation, lecturers can supervise and assess our competencies concurrently as they provide feedback, while we evaluate ourselves on how we have performed to perfect our skills, current teaching methods miss on this.” Student 9.

This study found that SBE can be used to assess students’ knowledge and skills. The participants reported that a simulation session can give the clinical instructor or lecturer an idea about the students’ level of knowledge and skills, depending on their performance in a simulation session. Such an assessment would help make proper decisions about students to attain the expected clinical learning outcomes.

“Simulation is very effective in assessing and evaluating knowledge and skill acquisition. If students grasp the desired outcomes of a particular topic or skill, they will act in accordance with the given instructions and demonstrate their acquired knowledge or skills. In this way, lecturers can assess students. Students will also be able to self-assess their learning” Clinical instructor 1.

4. Discussion

The aim of this study was to explore how SBE can be used to improve clinical teaching in Malawi and to discuss the major findings of the study in relation to the available literature.

4.1. SBE and Gaps in Clinical Teaching in Malawi. The findings indicate that SBE helps fill the gaps in clinical teaching in Malawi. According to this study, such gaps are related to overloaded curricula, overcrowded clinical sites, working in teams, clinical teaching of rare skills and conditions, and language barriers. Pivač et al. [11] highlight that the use of scenarios in SBE helps teachers to cover more clinical skills and topics in a given time as opposed to the traditional ways of teaching skills. Similarly, a quasi-experimental study conducted in Tanzania asserted that a well-facilitated simulation provides learners with a wide range of high-quality experiences through a single scenario and promotes critical thinking, reasoning, and decision-making while also strengthening hands-on skills [12]. In addition, inadequate clinical sites, such as hospitals, make them overcrowded with students from various training institutions. Jacob et al. [13] conducted a study in Tanzania to gauge the perceptions of students about their clinical environment where it was found that among others, students had negative perceptions about their clinical environment because of congestion. Similar findings were reported in

South Africa by Fadana and Vember [14], who indicated that overcrowding reduces students' opportunities to practice with patients. On the other hand, Mbakaya et al. [15] argued that student overcrowding at clinical sites limits their acquisition of skills and competencies. In such situations, SBE would be an alternative to relieve such clinical sites of the pressure of having too many students.

In modern times, working in multidisciplinary or interprofessional teams is advocated [16, 17]. It is believed that simulations which involve trainees from different professions help students learn from one another, understand the roles of other professions, and perfect their skills in patient care [18]. Multidisciplinary teams would also help students improve their communication skills, interpersonal relationships, and leadership skills [19]. These skills can be transferred to the workplace, thereby enhancing patient care. Therefore, the use of SBE would help to bridge the interprofessional gap in the Malawian clinical setting where teamwork of students from different disciplines is lacking, according to the current study.

This study has shown that it is not always possible for students in a clinical setting to find certain clinical conditions on which they can practice [20]. In addition, a lack of knowledge and skills regarding uncommon conditions among students and healthcare workers could be a recipe for poor medical care [21]. Therefore, SBE fills the gap by providing students with scenarios which can mimic rare or uncommon conditions, situations, or unusual complications in the clinical setting. Such scenarios require students to make proper diagnoses and provide the right healthcare plan. Sanges et al. [22] developed an innovative approach which was successful in teaching rare diseases to medical students using role-play simulations.

The study findings have shown that SBE can fill a gap related to language and culture in clinical teaching in Malawi. While clinical teaching may focus on students' acquisition of critical skills and competencies related to their profession, it is very easy to ignore some skills which on the surface may not seem to be crucial on the surface. Nurses, midwives, and other healthcare providers may come into contact with clients from diverse language and cultural backgrounds which can present a problem in the provision of care due to the inability to understand clients [23]. As such, students in healthcare professions are supposed to be equipped with proper skills that would help them deal with clients who may have a different language and cultural background from their own. Therefore, SBE can be used to train healthcare students on how they can provide quality healthcare to culturally diverse groups of clients or clients with whom they do not share a common language [24].

4.2. Mastery of Both Knowledge and Skills. The study participants felt that the use of innovative teaching strategies, such as simulation, in nursing and midwifery education can help improve clinical teaching. This is in line with research conducted on obstetric neonatal emergency simulations in rural India by Zhong et al. [25], who recommended the use of simulation in the training of healthcare workers. Simulation is

an effective pedagogical approach that provides students with hands-on linkages between theory and practice [26], and thus helps them develop competency in nursing and midwifery. Studies have highlighted the value of simulations in the training of healthcare workers [27–29]. In a study that evaluated a simulation-based education program with final-year undergraduate nursing and midwifery students Plummer et al. [30] reported that the use of SBE improves students' decision-making skills, critical thinking skills, motivation, confidence, and experience in real-life practice. Similarly, a meta-synthesis about the appropriateness of SBE in the training of radiologists in South Africa, by Hazell et al. [31] found that simulation increased students' confidence.

The findings of this study highlight the significance of lecturers' and clinical instructors' mastery of knowledge and skills in improving clinical teaching. For clinical teaching to achieve the intended outcomes, lecturers and clinical instructors should have the appropriate knowledge and skills which should be imparted to students. Hill [32] attests that role-playing in an obstetric emergency can be challenging for both lecturers and students, because of the complexity and urgency of the situation. Such challenging situations require professionals who are knowledgeable and skilled. Several studies have reported that SBE is a good strategy for teaching and fostering the development and acquisition of knowledge and skills [6, 33, 34]. This implies that formal SBE training for all lecturers and clinical instructors in all training institutions and settings should be emphasised.

4.3. SBE Infrastructure. Both lecturers and students in the current study felt that, during theory, students did not have adequate time to practice skills in training institutions, and even during clinical allocation, the students did not adequately assist in sharpening their skills and improving their nursing and midwifery competencies before they started assisting patients. Most health facilities and training institutions do not have infrastructure in which skills can be practiced before and during clinical placements. These findings resonate with Toale et al. [35], who further opine that one way in which SBE can facilitate clinical teaching is through the establishment of simulation corners within health facilities which can provide students with ample time to master their clinical skills. Studies have shown that SBE can be conducted in actual clinical settings in designated rooms to provide students with the opportunity to practice clinical skills and increase their proficiency in both technical and nontechnical skills [36, 37].

4.4. SBE as a Supervision and Clinical Assessment Strategy. The study participants alluded to the fact that SBE is a good strategy for supervising students' clinical activities and assessing how well they are performing in the activities. The purpose of clinical supervision in the training of nurses, midwives, and other health professionals is to help students develop as professionals in their respective training fields [38]. According to Bifarin and Stonehouse [39], clinical supervision is a process in which students who are doing clinical work are properly supported by teachers and other

clinical instructors to attain and improve the skills necessary for their profession. The use of SBE in student supervision helps students gain a deeper understanding of issues and concepts and improves their problem-solving and decision-making skills through scaffolding [20].

Supervision and assessment in education go hand in hand, although their aims differ [40]. While supervision mostly focuses on supporting, coaching, and facilitating student learning, assessment is mainly concerned with making judgments about student learning and achievement of certain milestones or objectives. Ryall et al. [41] conducted a systematic review to examine the use of simulation for assessment of technical skills in health professional education where it was found that simulation-based clinical assessments can be used to evaluate students' performance and skills acquisition. In addition, Koster and Soffler [42] highlighted that because of other assessment barriers in the real clinical environment, simulations are becoming a valuable means for assessing students' competences and skills. In the case of Malawi, one of the barriers that could reduce students' opportunities to be assessed in an authentic clinical situation, as highlighted elsewhere, could be the congestion of students at clinical sites. In a study conducted in Canada to investigate simulation utilisation and evaluation practices and approaches among undergraduate nursing educational programs, Zitzelsberger et al. [43] indicated that participants reported that simulation was a valuable strategy for the evaluation of students' learning and performance. Therefore, with careful planning, clinical assessment using simulations in Malawi can become a reliable way of making judgments about students' clinical learning.

In conclusion, SBE is a possible solution to some of the challenges encountered in clinical teaching in Malawi. Despite the many challenges posed by clinical teaching, SBE is consistently believed to mitigate these challenges and add value to clinical teaching through improvements in knowledge and skill acquisition. This study suggests that simulation centres and corners should be established in all training institutions and health facilities to provide lecturers and students with ample time to bolster their clinical skills, thereby improving the quality of patient care.

4.5. Study Limitations. This study was mostly conducted in training institutions and health facilities where researchers constantly interacted with the study participants. To some extent, some of the collected data may have been influenced by this prior interaction. However, the involvement of other training institutions not affiliated with researchers' institutions has remedied this limitation. Furthermore, some data collectors had no prior interaction with the participants. Second, this study presents the perspectives of the lecturers, clinical instructors, and students. This was a limitation in terms of adequately and properly amalgamating the themes from all three groups of participants. However, analysis of the data by experienced people ensured that the analysis was performed with great care to capture views from all groups of participants.

Data Availability

The data used to support the findings of this study are included within the article.

Disclosure

The views and opinions expressed in this article are those of the authors and do not necessarily reflect the official policies or positions of any affiliated agency. This article expands on the research presented at the 15th International Conference on Education and New Learning Technologies held on 3–5 July, 2023, in Palma, Spain.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

G.M., P.M., A.M., and M.M. contributed to the conceptualisation and design of the work, data collection, data analysis and interpretation, drafting of the article, and critical revision of the article. E.C.F., K.H., IT, and B.B. critically revised the article. All authors have contributed to the final version of the manuscript.

Acknowledgments

The authors would like to thank all nursing and midwifery students and health workers who gave up their time to participate in this study. The authors also thank the management and staff of all training institutions and health facilities for their participation in this study. The authors acknowledge all local participants for sacrificing their time. This work was supported by NORHED II, the Norwegian Program for Capacity Development in Higher Education, and Research for Development (Grant no. 70722).

Purpose. Healthcare organisations need to define the role of the nurse manager in light of recent global health developments. For this purpose, several core competencies essential for each hierarchical management level need to be assessed. Different measurement instruments have been developed to assess nurse managers' competencies. This systematic review summarises the characteristics and psychometric properties of existing instruments measuring first-, middle-, and top-level nurse managers' competencies. **Methods.** Following PRISMA guidelines for reporting and Consensus-based Standards for the selection of health Measurement INstruments (COSMIN) guidelines, 789 articles were retrieved from PubMed, Scopus, CINAHL, and APA PsycINFO databases with no time limitation. The review protocol was registered on PROSPERO (CRD42023425854). **Results.** Ten tools were identified, assessing one or more competencies among nurse managers: Competency Elements for Nurse Managers of Tertiary General Hospitals, NICA-NL, HCCI, I-FLNMMCS, NMCI, Chase Nurse Manager Competency Questionnaire, CASHN, Questionnaire for Head Nurses' Managerial Competencies, Nurse Manager EBP Competency Scale, and the Home Healthcare Nurse Manager Assessment Tool. **Conclusion.** Following the COSMIN assessment, the Chase Nurse Manager Competency Instrument was the most comprehensive among the included instruments, and the CASHN questionnaire scored highest on methodological quality and level of evidence. These instruments can be used in clinical practice to evaluate competencies and as a basis for developing managerial training courses.

1. Introduction

The literature extensively discusses the concept of competence, but notable discrepancies in its definition hinder consensus. This lack of clarity often arises from using specific frameworks across diverse contexts and disciplines, revealing significant disparities in the interpretation and application of key terms related to competence and

understanding of their interrelation. European Directive 2006/962/EC suggested exploring competencies linked to specific disciplines for a better understanding. One of the earliest and widely used definitions by Hamel and Prahalad [1] characterizes competence as the intersection of knowledge, skills, attitudes, and values, mobilized to address diverse situations. This perspective recognizes the intricate interplay between competence and other aspects that

contribute to performance. Clinical psychologist Robert White defines competence as a fundamental human effort motivating individuals, asserting that competence and activities fostering it lead to inspirational pathways to success [2].

Several interpretative approaches view competence as a function of the context in which it is applied, where “worker and work form one entity through the lived experience of work” [3]. Within this framework, competencies go beyond learned contents/concepts, imposing a profound reorganisation of acquired knowledge and relative transfer in the labour market. Moreover, it is essential to consider that discipline-specific competencies represented only 30% of the entire cluster of competencies, while the remaining 70% were expected to have a wide range of specialisations [4].

In healthcare management, certain competencies, such as planning and managing resources or supporting teamwork and communication, are common to other specialisations. In contrast, nursing-specific competencies have become the subject of study in more recent research over the last ten years and were approached from various perspectives. For example, Chase [5] identified competencies such as technical, human, conceptual, and leadership and organised quality care services. On the other hand, the American Organization of Nurse Leaders has identified competencies such as the ability to create and maintain good relationships, communication, leadership, knowledge of the healthcare environment and clinical principles, professionalism, business skills, and strategic leadership as key areas in developing competencies [6, 7].

Effective management competencies constitute the cornerstone of success and efficiency in healthcare organisations. Competent nurse management fosters the quality of patient care and contributes to favourable employee morale and engagement, reducing turnover rates and cultivating a positive workplace culture [8, 9]. According to a systematic review, competencies such as planning, communication, and leadership are associated with enhanced patient satisfaction, increased nurses’ job satisfaction, and reduced occurrences of patient mortality, prescription mistakes, restraint usage, and hospital-acquired infections [8].

Different levels of healthcare organisational management and governance require distinct competencies for effective role application in this scenario. Top-level nurse managers (NMs) engage in higher-level planning, such as mission and strategy, which require more excellent conceptual skills [10]. Middle-level NMs deal with specific processes to deliver value, necessitating technical skills to manage their area of specialisation [11, 12].

First-level NMs are leaders of units in hospitals or other medical settings. Their role does not include regular interaction with patients. Instead, they influence the quality of healthcare by leading the work and helping to ensure that the medical facility operates smoothly [13, 14].

Competence-related conceptual models combine skills, abilities, and knowledge encompassing specific behaviours that an individual exhibits. Competencies are typically categorised into three main types, as described by Robert L. Katz, who developed a framework to explain managerial

competencies [15]. In his 3 Skills Taxonomy, he set out the following categories:

- (i) Conceptual, as the formulation of ideas. Managers understand the importance of relationships, developing ideas, and problem-solving.
- (ii) Human involves the ability to interact with people. Managers interact and cooperate with employees, patients, and superiors.
- (iii) Technical involves knowledge and proficiency in managing processes. Managers use specific tools for one particular area.

Dreyfus [16] identified five stages of progress in competencies: novice, advanced beginner, competent, proficient, and expert. Their model assumes that the longer one practices, the more competent one becomes at a job or task. Acquisition of competencies is a matter of experience; each stage requires time and practice.

Regarding more nursing-specific concept models, a scoping review conducted by González-García et al. [17] identified 22 competencies grouped into six dimensions: management, communication and technology, leadership and teamwork, knowledge of the health system, nursing knowledge, and personality. Based on that, the same authors created a nurse executive competency model (MCGE-executive level) to define the executive nurse’s position, expected level of performance, and development required. It is composed of 51 competencies, tracking progress in each from “competent” to “expert” [10].

The current research in nursing and management endeavours to delineate essential competencies required for nurse managers, stratifying them based on the level of management. The absence of a comprehensive description of competencies and how they manifest at different managerial levels poses a challenge in effectively measuring the enrolment and evaluation of nurse managers. There is a pressing need for an instrument capable of measuring nurse manager competencies across various hierarchical levels, facilitating our understanding of the nuanced application of these competencies in real-world healthcare settings. In order to identify appropriate instruments to measure NMs’ competencies, this study summarises existing instruments for assessing and evaluating core competencies of first-, middle-, and top-level nurse managers.

2. Methods

A systematic review was carried out to examine existing instruments assessing the core competencies of nurse managers according to CONsensus-based Standards for the selection of health Measurement INSTRUMENTS (COSMIN) guidelines [18]. The Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) checklist was used to describe the study selection process [19]. The COSMIN guidelines were used for the quality assessment of the included articles.

The review protocol was registered on PROSPERO with ID record no. CRD42023425854.

2.1. Search Strategy. A search was performed on the following four online bibliographic databases: PubMed, CINAHL, Scopus, and APA PsycINFO. Search terms were based on a COSMIN search filter to identify studies of psychometric properties, combined with terms relevant to nurse manager competencies. Table 1 summarises the search strategy used and the main terms included. We also hand-searched the reference lists of articles identified for inclusion in the review to uncover additional relevant studies.

To guide the synthesis of selected articles, Robert L. Katz's framework [15] was used as a methodological approach to organise the results and discover patterns and commonalities. The research team chose this specific framework because, to date, it is the most referred to from studies conducted in this area of interest.

The selection of studies was carried out from database inception to March 30th, 2023.

The PICO (population, instruments, construct, and outcomes) was formulated as follows:

- (i) P: nurse managers at every hierarchical level
- (ii) I: instruments assessing core competencies through validation studies and psychometric measurements testing
- (iii) C: instruments' constructing the building process
- (iv) O: to establish a level of recommendation based on measurement properties

2.2. Inclusion and Exclusion Criteria. The inclusion criteria were as follows: (i) development and validation studies of instruments assessing NMs competencies (at every level: first, middle, and top management and in different settings); (ii) grey literature such as dissertations (only doctoral); (iii) published peer-reviewed studies; and (iv) articles written in English and Italian. No time limitation was applied.

The exclusion criteria were as follows: (i) qualitative and quantitative studies that did not have as their main goal the development, psychometric testing, and validation of a new scale for managerial competencies (e.g., surveys, cross-sectional or phenomenological design, protocols, or reviews); (ii) studies that tested the developed instrument on core competencies of managers in nursing samples; (iii) studies that did not publish the instrument in the paper; or whose instruments were not in English. The researchers contacted the authors of such scales to ask for the instrument and/or its availability in English. The study was excluded if no answers were received or if the instrument was not available in English.

To provide a comprehensive and up-to-date overview, we decided to report in this study only the most recent version or modification of an instrument that has been validated. However, when evaluating quality, we also considered previous validation publications. Of these, cross-cultural validation studies and those that presented limited and/or insufficient validation data (e.g., only Cronbach's alpha and no exploratory factor analysis) were excluded.

2.3. Data Extraction and Synthesis. Two researchers (LF and DI) independently screened the titles and abstracts of the articles identified by the search strategy. Disagreements about inclusion or exclusion were resolved by consulting a third researcher (EDS), who is a supervisor or senior member of the team who has major knowledge and experience on the topic. Articles that potentially met our inclusion criteria but whose supporting information was insufficient for inclusion were retrieved.

In the final phase, interresearcher agreement on inclusion and exclusion was calculated as Cohen's kappa. The scores of the two independent researchers were compiled and compared. The agreement coefficient was $\kappa=0.67$ (86.7%), indicating a substantial agreement [20].

In accordance with the COSMIN manual for systematic reviews of PROMs [21], data were synthesised reporting the following:

- (i) The characteristics of the included PROMs, such as the name of the PROMs, reference to the article in which the development of the PROM is described, constructs being measured, language and study population for which the PROM was developed, the intended context of use, the available language version of the PROM, number of scales or subscales, number of items, response options, recall period, interpretability aspects, and feasibility aspects;
- (ii) The characteristics of the included study population;
- (iii) The methodological quality ratings of each study per measurement property;
- (iv) A Summary of Findings' (SoF) table per measurement property.

2.4. Quality Appraisal. Three independent researchers (LF, DI, EDS, and ML) assessed included studies' methodological quality and psychometric properties under the Consensus-based Standards for the Selection of Health Measurement Instruments (COSMIN) checklists [21].

First, the researchers evaluated each instrument development study and content validity against ten quality criteria defined in the COSMIN checklist. An overall rating for instrument development and content validity was determined based on the quality and results of the available studies. For each instrument, the researchers summarised the results as sufficient (+), insufficient (-), inconsistent (\pm), or indeterminate (?) and classified the quality of the evidence as high, moderate, low, or very low, using a modified GRADE approach based on the risk of bias (quality of the studies), inconsistency (of the results of the studies), and indirectness (evidence comes from different populations, interventions, or outcomes from those of interest in the review) [18].

Second, researchers evaluated the instruments' construct validity, reliability, and responsiveness. The COSMIN checklist assesses whether a study meets the standards for good methodological quality on a four-point rating scale (very good, adequate, doubtful, inadequate), classifying the

TABLE 1: Literature search terms.

Database	Search terms	Number of articles ($n = 789$)
PubMed CINAHL	("assess*" [all fields] OR ("evalua*" [all fields])) AND "competenc*" [all fields] AND "nurse administrator" [MeSH terms] OR "nurse" [all fields] AND "nurse administrator*" [all fields] OR ("nurs*" [all fields] AND "manager" [all fields]) OR "nurse manage*" [all fields] OR ("nurse lead*" [Journal] AND ("coordinat*" [all fields] OR ("nurse administrat*" [MeSH terms] AND "executive*" [all fields]) OR "nurse executive" [all fields])) AND "tool" [all fields] OR "instrument*" [all fields] OR ("scale*" [all fields] AND "measure*" [all fields]) OR "inventor*" [all fields] OR "questionnaire*" [all fields] OR ("survey" [all fields])	351 249
Scopus	TITLE-ABS-KEY ((assessment OR evaluation OR monitoring) AND (competenc* AND (nurse AND manager OR nurse AND leader OR nurse AND coordinator OR nurse AND executive OR nurse AND administrator) AND (tool OR instrument OR scale OR inventory OR questionnaire))	81
APA PsycINFO	((any field: assessment OR any field: evaluation OR any field: monitoring) AND (any field: competenc*) AND (any field: nurse AND any field: manager OR any field: nurse AND any field: leader OR any field: nurse AND any field: coordinator OR any field: nurse AND any field: executive OR any field: nurse AND any field: administrator) AND (any field: tool OR any field: instrument OR any field: scale OR any field: inventory OR any field: questionnaire))	108

psychometric properties as sufficient (+), insufficient (-), or indeterminate (?) and assigning a quality of evidence as high, moderate, low, and very low.

Finally, an overall recommendation is made using the grading of recommendations assessment, development, and evaluation (GRADE) approach, assigning level A of recommendation for use in higher-quality studies, level B for studies potentially recommended but in need of further testing, and level C for studies not recommended for use. Level B is assigned when the scale cannot be classified as level A or C.

3. Results and Discussions

Overall, 789 publications were retrieved from the electronic databases. After removing duplicates and studies that did not fulfil the inclusion criteria, the authors were left with 10 studies included in the review that were eligible for methodological quality assessment.

The PRISMA flow chart of study selection is presented in Figure 1.

3.1. Characteristics of Included Studies and Instruments. Overall, 10 studies were included in the review. The studies were conducted in different countries: USA (6), Iran (1), China (1), Thailand (1), and Indonesia (1). A detailed information on studies is summarised in Table 2.

The studies targeted competencies of different nurse managerial categories such as *supervisors*, *directors*, *head nurses*, *chief nurses*, and others. In some studies, a clear division of managers into first-level, middle-level, and top-level categories was presented, specifying the sample size for each category [22–26], whereas in other studies, the sample was described in an aggregated form [5, 27–29].

All reviewed studies were conducted in main hospital settings except for two that were conducted in a tertiary general hospital [22] and in a home healthcare nursing agency [26]. The instruments were self-reporting with

structured response options of 3- to 5-point Likert scales. The number of items ranged from 16 [25] to 93 items [29], and the instruments were tested on samples of managers ranging from 30 to 614 persons.

3.2. Psychometric Properties and Methodological Quality of Instruments. The quality of evidence and the psychometric properties of the development and validation studies of the instruments are presented in Table 3.

Overall, one study was of high quality [28], 8 instruments [5, 22, 23, 25–30] presented moderate quality of evidence in the content validity, and one was of low quality [24].

The most common areas of bias were instrument development procedures (doubtful qualitative methodology for finding relevant items; doubt over the presence of any trained moderator/interviewer; lack of interview guidance in the article; a doubtful process of recording/transcribing participant's responses; doubt over the independence of the data decoding process; and doubt whether data saturation was reached).

In pilot tests, bias was assigned to doubtful relevance, completeness, or clarity of items to the respondent and to the low numbers of participants enrolled in the pilot test/expert panel.

Regarding the construct's psychometric properties, one study [28] presented high quality on internal consistency and structural validity, 4 studies [5, 22, 29, 30] presented moderate quality, 4 studies [24–27] were of low quality, and 1 study [26] was of very low quality. Low scores for structural validity were given when the sample size used in the analysis was inadequate (adequate rating = at least 5x and ≥ 100 , or 6x and < 100).

Overall, five instruments were given a GRADE A rating [25, 27–30], and five instruments a GRADE B rating [5, 22–24, 26] because, in most of them, the sample size did not satisfy the requirement of at least 5 times the number of items and ≥ 100 or at least 6 times the number of items but < 100 .

FIGURE 1: PRISMA 2020 flow diagram [19].

3.3. *Instruments Descriptions According to Quality Level and Managerial Domains Explored.* The instruments included in this review varied in the complexity of the competencies explored. Some scales included 17 domains of competencies, whereas others included only 4. The details are presented in Table 4. Four scales [5, 27, 28, 30] explored the greatest number of competencies.

Some competencies were commonly included in more than 6 instruments, including staff advocacy and development, team communication and collaboration, time management, quality improvement, leadership, problem-solving, and evidence-based practice. However, other competencies, such as organisational and policy overview or negotiation, were mentioned only by single instruments [5, 27].

(i) Nurse Manager Competency Inventory (NMCI).

The NMCI measures competencies in building cohesive teams by fostering a collaborative and supportive environment [25]. This scale explored the following job competency domains: staff retention, staff recruitment, staff development, performing supervisory responsibilities, quality care, conducting daily unit operations, fiscal planning, communication, quality improvement, promoting a professional practice model, and developing self.

Cronbach's α was calculated and reported only for item-total correlations, giving a "moderate" quality of evidence (QoE) in content validity and "low" QoE in structural and construct validity and internal consistency. Only this study measured responsiveness data before and after intervention with effect size. The respondent's role by itself accounted for only 2-3% of the total overall variance. The measurement properties quality (MPQ) was "sufficient." This resulted in a GRADE A level of recommendation.

(ii) The Human Capital Competencies Inventory (HCCI) for nurse managers.

The HCCI is a self-assessment instrument for measuring NMs' competencies in managing human capital [24]. Content validity testing ($N=3$ and $CVI=1.0$, for all retained items) and internal consistency reliability ($N=99$; Cronbach's $\alpha=0.84-0.89$) yielded 58 activities in five subscales: developing self, recruiting, developing others, utilising, and retaining.

This development study was not performed in a sample representing the target population, resulting in a "low" QoE in every psychometric property measured. Moreover, reviewers evaluated

how the items were worded and whether the response options matched the question as “undetermined.” Therefore, the MPQ for content validity was “insufficient,” as was the structural validity. Internal consistency and construct validity were rated as “sufficient” because Cronbach’s alpha was calculated for each unidimensional subscale separately, and an adequate description of the important characteristics of the subgroups was provided. The inventory was finally given a GRADE B.

- (iii) Chase Nurse Manager Competency Instrument.
- The authors used the five domains of Katz’s conceptual framework (technical, human, conceptual, financial, and leadership), confirmed by a PCA. Test-retest reliability was conducted by administering the same test twice, at a two-week interval, to a group of 23 NMs ($r=0.88$). With regard to comparing tools, Chase [5] was the only researcher who could compare his latest scale version with the first one developed in 1994.
- The Chase Nurse Manager Competency Instrument was the only one validated in other languages (Hebrew and Slovenian) by other authors [31, 32]. Experts produced the translations independently and performed multiple forward and backward translations. Still, no numerous group factor analysis or differential item functioning (DIF) analysis was reported as COSMIN guidelines recommend.
- These results allowed the reviewers to rate all properties as “moderate.” A “sufficient” QoE was given to all measurements except for structural validity (inadequate sample size). The instrument was finally assigned a GRADE B.
- (iv) Home Healthcare Nurse Manager Assessment Tool.
- The tool developed by Rosenfeld et al. [26] focused on home healthcare nurse managers’ competencies, comprised of five domains: leadership, problem-solving, planning and organisation, coaching, and aligning performance for success, tested with a PCA with varimax rotation explaining 66.9% of the variance. Cronbach’s alpha for each subscale ranged from 0.866 to 0.948 and weighted kappa from 0.58 to 0.86.
- The tool scored “moderate” QoE except for structural validity, internal consistency, and reliability, where it scored “very low.” Reviewers gave these scores because of inadequate sample size, the absence of any clear description of the construct, and the lack of a qualitative method to assess comprehensibility. This tool was allotted a GRADE B recommendation.
- (v) Competency Assessment Scale for Head Nurses (CASHN).

The CASHN tool was developed by Tongmuang-tunyatep et al. [28] to evaluate head nurses’ competencies in community hospitals. The final version comprised five factors: leadership, healthcare environment management, policy implementation and communication, management, and professional ethics.

The CASHN presented an I-CVI ranging from 0.83 to 1.00, and the S-CVI was 0.94. The internal consistency reliability ranged from 0.93 to 0.96.

This scale was the only one that scored “high” and “sufficient” in every measurement property, reaching a GRADE A. Therefore, we highly recommend this instrument for future cultural validation studies.

- (vi) Nursing Informatics Competency Assessment for the Nurse Leader (NICA-NL).
- The NICA-NL instrument was specifically developed to assess a set of informatics competencies relevant to NMs [26].
- The scale comprised 26 items and six domains: strategic implementation, advanced information and education, executive planning, ethical and legal concepts, information systems concepts, and requirements and system selection.
- Cronbach’s alpha ranged from 0.81 to 0.96.
- This scale scored “low” for structural validity and internal consistency. Only EFA was performed, and the sample size included in the analysis was inadequate. Neither qualitative nor quantitative methods to assess comprehensibility were described. The final GRADE was B.
- (vii) Nurse Manager EBP Competency Scale.
- Shuman et al. [29] developed an entire instrument focused on measuring NMs competencies regarding EBP consisting of 16 items and two domains: EBP knowledge and EBP activity. The subscales demonstrated reliabilities of 0.90 (95% CI = 0.87 and 0.93) and 0.94 (95% CI = 0.92 and 0.96), respectively. Cronbach’s alpha for the entire scale was 0.95.
- This scale was rated “moderate” and “sufficient” in all the psychometric properties except for “indeterminate” in structural validity due to inconsistent sample size. The scale has a GRADE A of recommendation.
- (viii) Questionnaire for Head Nurses’ Managerial Competencies.
- Moghaddam et al. [27] initially developed a competency model to provide a valid tool for assessing the managerial competencies of hospital department head nurses. This tool measured 27 competencies categorised by four main managerial tasks: planning, organising, leadership, and control (Cronbach’s alpha = 0.93; ICC = 0.89).

Results revealed that the study population gave the highest priority to strategic thinking (0.122) and the lowest to evidence-based decision-making (0.007).

The questionnaire scored “sufficient” for the methodological quality of each assessed property. Internal consistency and reliability were rated as “low” because statistics were not calculated for each unidimensional subscale separately, and the time interval (recall period) for face validity was not clearly stated. The scale reached a GRADE A level of recommendation.

(ix) Indonesian First-Line Nurse Managers’ Managerial Competence Scale-I (FLNMMCS).

This study developed a practical, 43-item instrument (I-FLNMMCS) with 7 domains: leadership, facilitating spiritual nursing care, self-management, staffing and professional development, informatics, financial management, and applying quality care improvement to evaluate the managerial competence of Indonesian FLNMs (Cronbach’s $\alpha = 0.955$; CVI = 0.859; $r = 0.321-0.687$) [30].

The scale underwent a forward-backward translation method from Indonesian to English (CVI from 0.83 to 1).

The scale achieved “moderate” QoE and adequate methodological quality for the measured properties, resulting in GRADE A.

(x) Competency Elements for Nurse Managers of Tertiary General Hospitals.

This study examined the NM competency model of tertiary general hospitals in China [22]. The instrument consists of 22 competencies and four dimensions: leadership and management ability, personal traits, professional quality, and professional ability, and includes elements of proper staffing/scheduling, hiring/recruiting, developing staff competencies, role-modelling, retaining staff, and coaching/mentoring professionals (Cronbach’s $\alpha = 0.745-0.885$; KMO = 0.928).

The reviewers rated all the psychometric properties as “moderate,” with some differences for the QoE. Relevance and comprehensiveness were rated as “insufficient” because the origin of the construct was not clear (a theory, conceptual framework, disease model, or clear rationale provided to define the construct to be measured), and it was doubtful whether skilled interviewers were used for concept elicitation. Structural validity was also “insufficient” because only EFA was performed. The final GRADE was B.

3.4. Discussions. This systematic review aimed to summarise the characteristics and psychometric properties of existing instruments measuring first-, middle-, and top-level nurse managers’ competencies. The review evidenced that some instruments explored a broad range of competencies,

addressing core competencies and major themes such as change and resource issues, leadership and management, teamwork and communication, finance, informatics, and technology. Other instruments explored at a deeper level single competencies such as the EBP competency scale [29] and the NICA-NL tool for informatics [23]. Furthermore, among the included instruments, only the Chase Nurse Manager Competency Instrument was validated in other languages, delineating the need for further testing of the other instruments explored in this review.

The first instrument that measured the competencies of nurse managers was developed in 2006; most of them were developed during the last 17 years. This suggests that the study of competencies among NMs is still in its infancy and needs further exploration.

Scales developed more recently showed better quality in psychometric properties than previous ones due to the continuous updating of statistical techniques and the broader range of support literature compared to past years.

Management competencies are context-sensitive and influenced by the complexity of the sector, teams, and organisations in which these competencies must be demonstrated. Hence, most of the domains encountered in this review regarding this specific sector can also be commonly found in different nonhealthcare realities such as commercial banks [33], marketing [34], and the military [35]. As also demonstrated in the studies that consider a generic population of middle managers, not strictly related to the healthcare sector, communication, organisation, information searching, analytical thinking, and planning skills are typical yet required for good public middle managers. Achievement orientation, leadership, directiveness, persuasiveness, and creativity are qualities that separate good public middle managers from mediocre performance. Furthermore, some other new competencies obtained inductively through a thematic analysis are important for effective public managers: adherence to laws and regulations, multistakeholder collaboration, and technical competencies [36, 37].

Some domains overlapped across scales, while others with the same terminology included different skills. The number of domains (factors) varied between scales, from a minimum of 2 to a maximum of 11.

Learning from previous studies, the individual’s educational and work background significantly impact developing competencies, representing a possible bias during the assessment [38]. However, having been a nurse manager does not adequately equip them for the vast range of abilities required, necessitating specialised training and practical work experience [39].

Regarding the COSMIN evaluation of the instrument quality, various critical aspects were identified that could potentially lead to ambiguous or unclear outcomes. For example, in 7 out of 10 studies, the sample size was below the recommended level based on the number of items included in the instrument. Also, insufficient attention was given to formulating an appropriate hypothesis regarding the expected correlations between competencies and the identified comparators, or the correlations needed proper

confirmation [40, 41]. While exploratory factor analysis (EFA) was conducted to test scale dimensionality, confirmatory factor analysis (CFA) was performed in only a few studies before using the measurement instrument for research [42]. In two studies, Cronbach's alpha was calculated for the full scale instead of being calculated for each dimension in multidimensional instruments [43]. Addressing these methodological gaps is crucial for enhancing the validity and reliability of future studies employing these instruments. By summarizing the findings of this review, we can say that the study of competencies among NMs is still in its infancy and needs further exploration.

3.4.1. Recommendation GRADE A. Despite criticism regarding weak structural validity, five instruments received a GRADE A recommendation. The studies of DeOnna [25], Tongmuangtunyatep et al. [28], Shuman et al. [29], Gunawan et al. [30], and Moghaddam et al. [27] exhibited satisfactory methodological quality in most of the measurement properties, and the quality of evidence ranged from low to high. In accordance with the COSMIN guidelines, these instruments are recommended for clinical practice use.

The NMCI questionnaire [25] received a positive assessment, but it exhibited deficiencies in some properties due to the lack of clarity in the stated method for data analysis. Nevertheless, it could serve as a foundation for sequencing competencies to develop an Middle Nurse Manager (MNM) orientation and career path program. The CASHN instrument scored highest in most of the measurement properties evaluated, with satisfactory methodological quality and high evidence level. Nurse executives can use this scale to plan the development of integrity and awareness of regulatory requirements for head nurses and to develop effective educational programs [28].

The Nurse Manager EBP Competency scale [29] can be used in complex and dynamic practice settings, explaining variations in implementing and sustaining EBP. An MNM's full competency in evidence-based management (EBM) may contribute to effectiveness in promoting good quality care. More research is needed on the reasons for and barriers to EBP implementation.

The I-FLNMMCS tool [30] can be used as a basis for FLNMs to improve their competence levels and as a vehicle for feedback mechanism; however, despite all psychometric properties being rated as sufficient and of moderate quality, structural validity was deemed insufficient due to an inadequate sample size.

Finally, the Questionnaire for Head Nurses' Managerial Competencies [27] was designed based on a proposed framework that included four main managerial tasks: planning, organising, leadership, and control. It showed limited evidence of structural validity: the sample size included in the analysis was inadequate [44]. Consistent with the findings of this study, a previous study conducted by Pillay [45] affirmed that head nurses should have strategic planning skills to set the vision, mission, goals, objectives, and strategies.

3.4.2. Recommendation GRADE B. None of the included instruments received a GRADE C recommendation; however, five of them were categorised as GRADE B. The HCCI tool by Donaher et al. [24], the Home Healthcare Nurse Manager Assessment Tool [26], the Competency Elements for Nurse Managers of Tertiary General Hospitals by Wang et al. [22], the NICA-NL instrument developed by Yen et al. [42], and the Chase Nurse Manager Competency Instrument [5] received a GRADE B, primarily due to insufficient structural validity resulting from a small sample size. Notably, the NICA-NL instrument [42] distinguished itself as the sole tool specifically addressing informatics competencies. Validating these competencies equips nurse managers to personally contribute, rather than delegate, digital competencies to interprofessional initiatives, thereby fostering optimal and supportive care environments [23]. The Chase Nurse Manager Competency Instrument [5] holds the distinction of being the most widely used tool. The identified methodological gaps in these instruments underscore the necessity for additional testing to strengthen the validity and reliability of future studies employing these tools.

Thus, this systematic review of instruments measuring competencies among nurse managers confirms that management competencies can be broadly categorised as generic or specific to a particular profession [4]. Many competency domains encountered in the instruments included in the review are also commonly found in nonhealthcare sectors such as commercial banks [33], marketing [34], and the military [35], emphasizing the versatility of these competencies. Commonalities exist in competence domains such as communication, organisation, information searching, analytical thinking, and planning competencies [40]. Moreover, specific competencies such as adherence to laws and regulations, multistakeholder collaboration, and technical skills are important for managers in the healthcare sector [36, 37]. In addition, distinct levels of healthcare organisational management require varying competencies, including achievement orientation, leadership, directiveness, persuasiveness, and creativity [40]. These qualities are crucial for effective performance among top-middle managers in the healthcare sector, differentiating between good and mediocre performance in this context [40]. The interplay of educational and professional background further influences the development of competence and performance levels [38, 39]. Therefore, this comprehensive review lightens the multifaceted nature of management competencies among nurse managers, highlighting their relevance to the healthcare sector and underscoring the crucial need for specialised training in developing competencies for effective healthcare organisational management.

When designing new instruments, efforts should be made to standardize the instrument development process. Scale development and measurement property validation can be carried out by utilising standardized development techniques or the COSMIN guidelines. When developing scale items, the expert consultation approach should be supplemented with additional qualitative research methods, such as in-depth interviews and focus group discussions, to extensively investigate patients' viewpoints from different

perspectives. Scale creation and measurement property evaluation should be guided by item response theory, classical measurement theory, and other relevant theories. In addition, a recall period should be established during scale creation to offer a useful reference for measuring scale responsiveness and to assure consistency and accuracy in the assessment.

3.5. Strengths and Limitations. The strength of this study lies in the methodological rigor applied to instrument evaluation and the resulting recommendation for the use of instruments with high quality. Researchers selected the COSMIN checklist, known for its rigorous assessment of methodological quality in reviewed studies, to fortify the methodology of this systematic review on measurement properties. Adhering to the PRISMA guidelines, two researchers independently ensured a standardized and coherent data selection process. The methodological quality of the included studies was individually assessed by reviewers, and a consensus was reached on the rating scores. A notable strength of this study lies in its objective to encompass available instruments measuring the competencies of nurse managers across various levels and the inclusion of diverse settings for evaluating the phenomena on a broad scale. All ten reviewed studies were conducted in heterogeneous public and private settings such as hospitals, primary care, home-based care, and acute and chronic care. This comprehensive approach spanned countries across four continents, enhancing the study's global relevance and applicability.

However, certain limitations need to be taken into account.

The search was limited to four databases, including English and Italian language studies. This may have excluded relevant studies written in other languages and indexed in other databases.

In addition, as measurement properties were extracted from published articles, the limited space available in journals could have restricted the reporting of instrument validation, affecting methodological quality assessment.

Since the COSMIN criteria for assessing the methodological quality of instrument measurement properties are highly detailed and rigorous, an instrument rated as poor or indeterminate could still be valid or reliable. The quality of reporting and the design of the validation studies should be improved by using, for example, COSMIN quality criteria as guidelines.

3.6. Implications and Recommendations. As already known, high-level nurse management competencies influence healthcare quality and relative outcomes. The results of this study could be significant for shaping the design of competency-based academic and training programs for nurse managers as well as for the development of competency assessment tools, performance appraisal tools, and staff recruitment strategies.

The results of this study may be used to design the professional roles of nurse managers, and to improve the leadership and management skills. Another remark is that

nurse managers' research and development competencies still need to be improved since they have a crucial role in developing nursing care, despite the fact that their roles have evolved and become less clinical in some nations. Therefore, nursing personnel consider this role to be one of their most important contacts for communicating concerns and patient care requirements.

Although existing instruments may comprehend some of the fundamental domains, they do not set out to capture all elements of nurse management competence that may be important to consider. Indeed, a significant degree of heterogeneity was found in the definition of competency, and different synonyms were used for the domains studied and the competencies included in each of them, making it challenging to compare scales and their assessment methods. Therefore, future studies should try to unify competency descriptions and interpretations to achieve consistency and a common language between countries.

We recommend advancing the study of the aforementioned instruments by contextualising them in other settings and countries. In addition, defining a cut-off point on the scales to assess the level of achievement and comparing it over repeated intervals can further enhance our understanding of specific knowledge and competence in nursing management.

4. Conclusions

This review aims to provide a meaningful understanding of existing instruments for measuring and evaluating the core competencies of first-, middle-, and top-level nurse managers.

Due to limited or unknown evidence about some measurement properties, the identified instruments should be used cautiously in clinical practice because of their variations.

Exactly half of the selected instruments were divided between GRADE A (Nurse Manager EBP Competency Scale, NMCI, CASHN, I-FLNMMCS, and Questionnaire for Head Nurses' Managerial Competencies) and B (HCCI, Chase Nurse Manager Competency Instrument, and Home Healthcare Nurse Manager Assessment Tool, NICA-NL, and Competency Elements for Nurse Managers of Tertiary General Hospitals) recommendations.

The difference between one level and the other lay in the accuracy and depth of the methodology chosen to validate the instrument, especially due to the inadequacy of the sample size.

Some competencies were commonly explored among instruments, including staff advocacy and development, team communication and cooperation, time management, quality improvement, leadership, problem resolution, and evidence-based practice. Other competencies, such as organisational and policy overview or negotiation, were less addressed.

The CASHN tool was the one with the highest score in both methodological quality and GRADE of evidence. The Chase Nurse Manager Competency Instrument was the one that included the most competencies.

Future research should focus on developing scales by using a more rigorous methodology, considering well-accepted theories to assess the different dimensions of management-related competencies and creating an inclusive definition for managerial competencies.

We also suggest completing the validation procedures started for both newly constructed and previously developed instruments but with higher-quality techniques and estimation of all psychometric features.

Data Availability

No data were used to support the study.

Additional Points

What is Already Known? High-level nurse management competencies influence healthcare quality and help achieve organisational goals. Existing instruments do not include all elements of competence that may be important to measure. *What This Paper Adds?* The CASHN tool (Competency Assessment Scale for Head Nurses) is the most recommended and effective methodological instrument for evaluating the competencies of nurse managers. A more rigorous methodology should be employed to conduct psychometric validation for both newly constructed and previously developed nurse manager competence instruments.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

The study was funded by the Centre of Excellence for Nursing Scholarship (CECRI), Order of Nurses of Rome, Italy (Grant reference 3.23.3).

Background. The misallocation of scarce healthcare resources globally raises concerns regarding the underuse of high-value care and the overuse of low-value care. Economic evaluations can help policy makers determine whether an intervention presents a better value for money and desirable clinical benefits, thus realizing value-based care. **Aim.** We aimed to conduct a systematic review of the economic evaluations of clinical nursing practices to advance knowledge on value-based care. **Methods.** A systematic review was conducted using MEDLINE, Embase, Web of Science, Cochrane Central Register of Controlled Trials, CINAHL, NHS Economic Evaluation Database, Health Technology Assessment, and Tufts CEA Registry for full economic evaluations of clinical nursing practices from January 2013 to January 2023. Outcomes were incremental cost-effectiveness ratios, incremental cost-utility ratios, incremental cost-benefit ratios, incremental net benefit, and the differences in costs for cost-minimization studies. Methodological quality was evaluated using the Consensus Health Economic Criteria-extended checklist. Results were synthesized using permutation matrices for all studies. The protocol was registered with PROSPERO (CRD42023415918). **Results.** Thirty-five studies were included in this review, with 27 studies categorized as good methodological quality and 8 as moderate quality. Clinical nursing practices were dominant (i.e., more effective and less costly) in 19 studies, potentially cost-effective depending on willingness-to-pay thresholds in 15 studies, and were dominated (i.e., less effective and more costly) in 1 study. **Conclusion.** Our study advanced knowledge on value-based care for clinical nursing practices. Results suggest that most clinical nursing practices studied may be clearly economically favourable or potentially favourable. **Implications for Nursing Management.** The results of this review provide valuable insights into value-based care in nursing and facilitate the decision-making of healthcare policymakers regarding health resource allocation to achieve value-based care.

1. Introduction

Since nursing care represents a significant proportion of healthcare expenditures, there are substantial opportunities for nurses to contribute to and lead efforts in cost reduction and healthcare improvement [1, 2]. Compared to the economic value of clinical practices provided by medical specialists, less attention is paid to the economic value of clinical nursing practices [2]. Clinical nursing practices were defined as clinical interventions, programs, or approaches to care that were delivered by or ordered by nurses, or led by nurses, within the scopes of registered nurse practice or advanced practice nursing [1]. The research that examines the

economic value of clinical nursing practices can inform nurse decision-makers, seeking to allocate limited financial resources efficiently and effectively, thus eventually contributing to the realization of value-based care.

Value-based care is defined as a framework for optimizing health and well-being per unit of expenditure [3]. When patients do not receive care that is highly likely to improve the quality or quantity of life, which represents good value for money, the phenomenon is commonly referred to as underuse of high-value clinical practice. Conversely, when patients receive care in which evidence suggests its potential harm exceeds the potential benefit or the additional costs do not provide proportional added

benefits, it is commonly referred to as overuse of low-value clinical practice [3, 4]. It has been estimated that approximately 30% of healthcare spending is on low-value clinical practice, which wastes limited resources and may threaten the sustainability of the healthcare system [2, 5].

To achieve value-based care, both the underuse of high-value clinical practice and the overuse of low-value clinical practice should be focused on, with supportive evidence from economic evaluations [6]. Economic evaluation is the comparative analysis of alternative courses of action in terms of both their costs and consequences, which can help determine whether clinical practices present a better value for money and desirable use of healthcare [7, 8]. There are four types of full economic evaluations: cost-effectiveness analysis (CEA), cost-utility analysis (CUA), cost-benefit analysis (CBA), and cost-minimization analysis (CMA), which differ in the way consequences are measured. CEA measures consequences in natural (health) units, such as life years gained, whereas CUA measures outcomes in a single unit of measurement, such as quality-adjusted life year (QALY). CBA measures consequences in monetary terms, which can directly express whether the benefits outweigh the costs. CMA is a method of comparing different alternatives that use comparisons of costs when benefits have shown to be equivalent [8].

Earlier efforts to summarize the evidence on economic evaluations of clinical nursing practices are limited. One previous review evaluated and described the quantity and quality of economic evaluations in nursing-relevant research conducted in the United States (USA) between 1997 and 2015 [1]. However, to the best of the authors' knowledge, no comprehensive systematic review of economic evaluations in the field of nursing has been conducted to identify both low- and high-value clinical nursing practices. Our study aimed to conduct a systematic review of the economic value of clinical nursing practices to advance knowledge of value-based care. The results of this review can facilitate the decision-making of healthcare policymakers regarding health resource allocation to achieve value-based care.

2. Methods

2.1. Design. We followed the guideline recommendations for conducting systematic reviews of economic evaluations for informing evidence-based healthcare decisions [9–11], and all findings were reported according to the updated version of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA 2020) guidelines [12]. The protocol was registered with the International Prospective Register of Systematic Reviews (PROSPERO CRD42023415918).

2.2. Inclusion and Exclusion Criteria. We included full economic evaluations (cost-effectiveness, cost-utility, cost-benefit, and cost-minimization analyses) of clinical nursing practices. Both trial-based and model-based economic evaluations were included. Clinical nursing practices were defined as clinical interventions, programs, or approaches to

care that were delivered by or ordered by nurses, or included nurses, within the scopes of registered nurse practice or advanced practice nursing [1]. We restricted the review to studies published in English from January 2013 to January 2023 to ensure its feasibility and timeliness of the results. In addition, we considered studies identifying the economic evaluation results wherein one clinical practice being dominant or dominated by the alternative.

We excluded studies of practices provided by other healthcare professionals or nursing procedures that require an order from other healthcare professionals such as medication prescribing or requests for lab testing by physicians. We also excluded research protocols, conference abstracts, editorials, letters to editor, and narrative reviews.

2.3. Search Strategy and Study Selection. An extensive literature search was conducted in MEDLINE (via Ovid), Embase, National Health Services Economic Evaluation Database (NHS EED), Health Technology Assessment (HTA) Database, Cochrane Central Register of Controlled Trials (via Ovid), Cumulative Index to Nursing and Allied Health Literature (CINAHL), Web of Science, and the Tufts Cost-Effectiveness Analysis Registry (<https://www.cearegistry.org>). The full search strategies for each database are presented in Appendix 1. Furthermore, reference lists of included studies and studies cited in previous reviews were also screened to identify additional studies.

All citations were exported to EndNote (version X8) in which the duplications were eliminated. A screening web tool system, RAYYAN (<https://rayyan.ai/>), was then used for the screening process. To ensure reliability, sets of 200 citations were independently evaluated and then discussed by the reviewers until acceptable agreement was achieved during study selection. Two reviewers (YSG and RFK) then independently screened all identified records using titles and abstracts. All abstracts that could potentially apply to the inclusion criteria were forwarded to full-text review. Any disagreement was resolved through discussion between reviewers and, if necessary, consultation with a third reviewer (ZLM).

2.4. Data Extraction. An electronic data extraction form was developed, with a detailed instruction manual and piloted on a representative sample of 10 publications. Pairs of reviewers (YSG and ZLM) independently extracted the following information from eligible studies: country, intervention and comparator, study design (single study-based and model-based), type of economic evaluation, population, perspective, threshold, cost categories, outcomes, and cost-effectiveness results (incremental cost-effectiveness ratio (ICER), incremental cost-utility ratio (ICUR), incremental cost-benefit ratio, incremental net benefit, and the difference in costs for cost-minimization studies). Any conflict was resolved through consensus. In cases of disagreement, a third reviewer (TTX) with content expertise in economic evaluation was consulted. The corresponding authors were contacted by emails to obtain additional information when necessary.

2.5. Quality of Methodology Assessment. Two reviewers independently assessed the methodological quality for each included study using the recommended approach, the Consensus Health Economic Criteria (CHEC)–extended checklist (Appendix 2) [13, 14]. This 20-item checklist can appraise model-based or trial-based studies, with positive responses scored 1 and negative responses scored 0 [10]. The total score for each item was summed and converted to a percentage with the final scores ranging from zero to 100 (final score = (total score/20) × 100%). The total CHEC score for each study was categorized into four grades based on cutoff values: low (≤ 50), moderate (51–75), good (76–95), and excellent (>95) [15]. Higher scores indicate higher quality. We also presented the results in a graph using RevMan 5.3 software.

2.6. Data Synthesis and Analysis. Meta-analyses were not performed due to the heterogeneity of the costing methods and the interventions, in line with Cochrane guidelines [16]. Instead, a narrative synthesis of the findings from included studies was presented. We used a permutation matrix summarizing results according to nine possible outcomes of cost (higher, same, and lower) and effectiveness (higher, same, and lower), which was adapted from the systematic review of economic evaluation guidelines developed by Joanna Briggs Institute [17]. Costs were converted to 2024 international dollars (Int.\$) using a web-based tool [18]. For studies that did not report the reference year, an assumption of base year prior to the publication date was made as the base year. For cost-utility studies, we used a willingness-to-pay threshold of \$50 000 per QALY gained to assist in interpreting the results [19]. Our goal was to be as broad as possible to assist the readership with the interpretation of results in line with their settings so we did not consider applicability or transferability to specific settings in the synthesis methods.

3. Results

3.1. Results of the Search. The initial search identified 10,313 studies. After excluding duplicate studies, 6,534 records remained for title and abstract screening. Of these, 96 were eligible for full-text assessment. After the full-text screening, 35 studies were included in the systematic review. The study selection process is summarized in Figure 1. Sixty-one full-text articles were excluded because they did not meet the “full economic evaluation” criteria ($n = 13$), were not primary studies reporting results of an economic evaluation (e.g., protocols) ($n = 7$), or did not target clinical nursing practices ($n = 41$) (see Appendix 3).

3.2. Characteristics of Included Studies. The characteristics of included studies are shown in Table 1. Among the 35 included articles, 28 studies were conducted in high-income countries: the United Kingdom ($n = 6$), Australia ($n = 5$), the United States ($n = 5$), Canada ($n = 2$), Germany ($n = 2$), Sweden ($n = 1$), Denmark ($n = 1$), the Netherlands ($n = 1$), Italy ($n = 1$), Ireland ($n = 1$), Japan ($n = 1$), Korea ($n = 1$),

and multicountry ($n = 1$). Seven studies were conducted in low- and middle-income countries (LMICs): China ($n = 3$), Brazil ($n = 3$), and Turkey ($n = 1$). Eighteen studies were published between 2018 and 2022 and 17 studies between 2013 and 2017. A total of 16 studies were single study-based economic evaluations and 19 were model-based economic evaluations. Most studies ($n = 23$) performed a cost-effectiveness analysis, 15 performed a cost-utility analysis, and four performed a cost-benefit analysis (five of these performed both a cost-effectiveness and a cost-utility analysis; two of these performed both a cost-effectiveness and a cost-benefit analysis). The majority of studies were conducted in hospital settings ($n = 29$), while six studies were conducted in primary care settings. Sixteen economic evaluations were conducted from a healthcare system perspective, eight from a societal perspective, and five from a payer perspective (two of which were conducted from both a healthcare system and societal perspective). The perspective was not reported in eight studies. A total of 18 economic evaluation studies assessed the cost-effectiveness of treatment practices, and 17 studies assessed prevention practices. Targeted economic evaluations of treatment practices included wound care ($n = 4$) [20–23], urinary catheterisation care ($n = 1$) [24], intravenous therapy ($n = 3$) [25–27], medication administration ($n = 1$) [28], pressure ulcer management ($n = 1$) [29], peristomal skin care ($n = 1$) [30], oxygen therapy ($n = 1$) [31], pulse oximetry monitoring ($n = 1$) [32], nutrition management ($n = 1$) [33], nasogastric tube placement ($n = 1$) [34], immobile patient care ($n = 1$) [35], respiratory rate monitoring ($n = 1$) [36], and doula care ($n = 1$) [37]. Targeted economic evaluations of prevention practices included pressure ulcer prevention ($n = 9$) [38–46], catheter-associated urinary tract infection prevention ($n = 2$) [47, 48], central venous catheter-related infection prevention ($n = 1$) [49], medication error prevention ($n = 1$) [50], fall prevention ($n = 2$) [51, 52], delirium prevention ($n = 1$) [53], and aspiration prevention ($n = 1$) [54].

3.3. Methodological Quality of Included Studies. Table 2 and Appendix 4 summarize the results of the risk of bias assessment of the included studies, as indicated by the percentage score. Each item was scored as 1 if the study met the requirement or 0 if it did not meet or only partially met the requirement. Moreover, “not applicable” (NA) was noted and was scored as 1 if the assessed item was not relevant to the study. The quality of all studies ranged from 60% to 95%. A total of 27 studies [20, 21, 23, 25–32, 34–38, 41, 42, 44–49, 51, 52, 54] were categorized as good quality, eight [22, 24, 33, 39, 40, 43, 50, 53] as moderate quality, and no study as low quality. Two items, model description (item 5) and generalizability (item 18), had the lowest scores. Of the 19 model-based studies, 13 (68.4%) did not report the structural assumptions and the validation methods of the model. Regarding generalizability, 21 studies (60.0%) did not discuss the generalizability of their results to other settings and populations. Other methodological shortcomings included the following: 12 studies (34.2%) did not state the ethical issue (item 20), nine studies (25.7%) did not identify all relevant costs (item 8), nine studies (25.7%) did not describe

the population characteristics in detail (item 1), eight studies (22.9%) did not state the study perspective (item 7), and seven studies (20.0%) did not perform uncertainty analyses (item 16).

3.4. Results of Economic Evaluations. The results of the economic evaluations are presented in Table 3, Figure 2, and Appendix 5. Out of 35 economic evaluations, the intervention group was dominant (more effective and less costly when compared with the control) in 19 studies (Table 3, Figure 2, and Appendix 5). Five dominant interventions were identified from randomized controlled trials (RCTs) (see Appendix 6).

The intervention group was more effective and more costly in 11 studies, and the intervention was less effective and less costly in four studies (Table 3 and Figure 2). These interventions were likely to be cost-effective, at specified willingness-to-pay thresholds (Appendix 5). Among the six cost-utility studies that reported ICUR, the interventions were favoured in five of these [27, 34, 37, 44, 45] at a willingness-to-pay threshold of \$50 000 per QALY gained.

Note. NA: not applicable. The items 1–20 assessed in the Consensus Health Economic Criteria (CHEC)–extended checklist are shown in Appendix 2.

As shown in Table 3, Figure 2, and Appendix 5, the intervention group was dominated (i.e., less effective and more costly) by the control in an economic evaluation alongside an RCT: a pressure ulcer prevention care bundle consisting of information and education resources targeted to patients (DVD, poster, brochure, and face-to-face education) and nurse training package was dominated by standard care which was aligned with regional guidelines [42].

4. Discussion

To the best of our knowledge, this is the first study to systematically review the scientific literature to summarize evidence on the economic value of clinical nursing practices. We identified 35 full economic evaluations published between January 2013 and January 2023. The clinical nursing practices were clearly economically favourable (more effective with lower costs) in 19 out of 35 economic evaluations (54.3%), potentially favourable (more effective with higher costs or less effective with

lower costs) in 15 (42.9%), and unfavourable (less effective and more costly) in 1 (2.9%).

It was noteworthy that most interventions were clearly economically favourable or potentially favourable, while only one intervention about pressure ulcer prevention care bundle might represent low-value care (less effective and more costly). Of the economic evaluations included, the number of cost-effective interventions was significantly greater than that of the non-cost-effective. While multifactorial, part of the reason may be that the lack of standardization of the types of costs included and the lack of evaluations from the societal perspective, which may result in misestimating the value of the intervention. In most of the economic evaluation studies included, which were conducted from a healthcare system perspective, only direct costs of the interventions were considered, without including other indirect costs such as productivity costs. Moreover, there may be a risk of publication bias, representing a small fraction of the nursing interventions evaluated for effectiveness, even among those found to be effective [55]. This probably led to misestimates of the

Cost-effectiveness	Higher cost	Same cost	Lower cost
Higher effectiveness	Avşar et al., 2018 [43] Greiner et al., 2019 [37] Hälleberg et al., 2013 [24] Heinrich et al., 2013 [51] Lee et al., 2014 [53] Neil et al., 2016 [30] Padula et al., 2019 [44] Padula et al., 2019 [45] Panneman et al., 2021 [52] Silva et al., 2019 [50] Tan et al., 2016 [26]		Arora et al., 2022 [28] Ashby et al., 2014 [20] Balegar et al., 2013 [33] Forni et al., 2020 [46] Huang et al., 2021 [31] Hutton et al., 2018 [47] Inoue et al., 2015 [40] Javanbakht et al., 2022 [36] Kaitani et al., 2015 [29] Liu et al., 2020 [35] Lobmann et al., 2019 [23] Mak et al., 2015 [21] Mantravadi, 2017 [54] Mathiesen et al., 2013 [38] Mitchell et al., 2019 [48] Moore et al., 2013 [39] Moretti et al., 2022 [32] Pedrolo et al., 2018 [49] Walzer et al., 2018 [22]
Same effectiveness			
Lower effectiveness	Whitty et al., 2017 [42]		Marsden et al., 2015 [41] McFarland, 2017 [34] Tuffaha et al., 2014 [25] Wu et al., 2021 [27]

FIGURE 2: Permutation matrix. Note: areas highlighted in green indicate that interventions were dominant (i.e., at least as effective as lower cost). Areas highlighted in yellow indicate that interventions were potentially cost-effective at specified willingness-to-pay thresholds (i.e., more effective and more costly, or less effective and less costly). Areas highlighted in red indicate that interventions were dominated (i.e., the same or less effective and higher costs).

economic benefit of the interventions. The findings suggest the importance of emphasizing the publication of negative studies as much as the positive studies, as the absence of either may lead to publication bias.

It was also of interest to note that five interventions were clearly dominant compared to their comparators, supported by evidence from RCTs. In the hierarchy of research designs, the results of RCTs are considered the highest level of evidence, whereas observational studies are susceptible to potential confounding biases [56]. Therefore, these comparators, with a high level of evidence (RCTs), may present opportunities to reduce low-value care through deimplementation. For instance, “do not recommend routinely repositioning 6 h, using the 90° lateral rotation as the first repositioning choice for most patients to prevent the pressure ulcers” [39], “do not recommend four-layer bandage for healing of venous leg ulcers as the first choice” [20], “do not recommend routinely continuous pulse oximetry monitoring for the supportive care of hospitalized infants with

bronchiolitis” [32], “do not recommend nasal high-flow oxygen for treating respiratory distress in newborns as sole primary support” [31], and “do not recommend swabbing methods in cleansing wounds healed by secondary intention as the first choice, instead, pressurized irrigation” [21].

It should also be considered that although this review included all international articles meeting the inclusion criteria, only 35 full economic evaluations of clinical nursing practices were identified. Moreover, the majority of the economic evaluation studies were conducted in high-income countries, mostly in the UK, the USA, or Australia, with limited evidence from LMICs. In LMICs, where healthcare resources are scarce, more attention should be paid to the evidence from economic evaluation studies to aid in decision-making regarding the allocation of limited healthcare resources. Moreover, studies conducted in LMICs examining the economic evaluations of clinical nursing practices would increase the generalizability of the findings.

In terms of methodological quality, all the included studies demonstrated moderate to good quality, but some methodological limitations were observed. For example, a significant portion of model-based studies (68.4%) failed to specify the structural assumptions or the validation methods of the model. Also, many studies (60.0%) [20, 22–24, 27, 29, 30, 34–36, 38–43, 48, 49, 51, 53, 54] did not discuss the generalizability of the results. In addition, some studies (22.9%) [21, 24, 26, 33, 39, 40, 50, 53] did not specify the perspective adopted in the study, which is critical for the identification of cost components. Moreover, some studies (20%) [24–26, 33, 39, 40, 43] did not incorporate uncertainty analyses. Ideally, both deterministic and probabilistic uncertainty analyses should be conducted within a single economic evaluation to reflect the uncertainty of parameters [57]. These analyses are helpful for assessing the reliability of cost-effectiveness inferences and informing the direction of further research [57]. These findings implied that more attention should be paid to the methodological rigor in these items of economic evaluations of clinical nursing practices in the future.

4.1. Strengths and Limitations. To our knowledge, this is the first systematic review on full economic evaluations of clinical nursing practices, addressing a major knowledge gap on the economic value of clinical nursing practices in both developing and developed countries. We used a comprehensive search strategy that encompassed multiple electronic databases to identify relevant economic evaluations. In addition, two independent reviewers conducted a rigorous quality assessment of the included studies using the CHEC-extended list.

However, our review has several limitations. Although we used a comprehensive search strategy and searched specialised databases, we only searched electronic databases, potentially overlooking economic evaluations of clinical nursing practices that were not available in these databases. Moreover, we restricted the review to studies published in English since January 2013 to ensure its feasibility and relevance to current practices in value-based care. In addition, as cost-effectiveness measures cannot generally be compared across studies, quantitative synthesis was not advisable. Instead, we synthesized results qualitatively using a permutation matrix. We attempted to facilitate comparison between cost-utility studies by applying a unique willingness-to-pay threshold, while the results obtained will be dependent on the chosen threshold. In our study, the cost-utility studies indicating potentially favourable interventions based on willingness-to-pay thresholds were all conducted in high-income countries, where the threshold (\$50 000 per QALY gained) used in our study is widely applied in the literature. Furthermore, the heterogeneity in cost estimates, which may not be generalizable across different regions or countries, is another limitation of our study.

5. Conclusions

Despite these limitations, our study systematically reviewed the evidence regarding the economic value of clinical nursing

practices to advance knowledge on value-based care. We found that interventions were dominant in 19 studies, likely cost-effective in 15 studies, and dominated by comparators in 1 study. Results of this review can help nurses and decision-makers to assess the value of clinical nursing practices. However, caution is needed in extrapolating the results of our study, given the potential for publication bias and certain methodological limitations in the reviewed studies. More high-quality economic evaluations in clinical nursing practices are warranted to provide evidence of their value, particularly in LMICs, improving the cost-effectiveness of healthcare delivery and facilitating the realization of value-based care.

Data Availability

Data sharing is not applicable to this article as no new data were created or analyzed in this study.

Disclosure

The funder had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; and decision to submit the manuscript for publication.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

Meng and Guan conceptualized and designed the study. Guan, Meng, Ru, and Kang were involved in data acquisition. Guan, Meng, Ru, and Jia were involved in data analysis and interpretation. Guan, Meng, and Ru drafted the manuscript. Guan, Meng, and Xu critically revised the paper for important intellectual content. Meng obtained funding. Guan and Meng supervised the study.

Acknowledgments

This study was funded by the National Natural Science Foundation of China (Grant no. 72104154).

Background. Emergency departments suffer from authoritarian and manipulative leadership styles that affect team dynamics, emotional exhaustion, and quality patient care. However, little research specifically explores these toxic leadership effects on conflict management and nurses' organizational commitment. **Objectives.** This cross-sectional study aimed to assess the correlations between perceived toxic leadership, conflict resolution strategies, and commitment dimensions among emergency nurses while evaluating conflict tendencies as a mediating mechanism. **Methods.** A cross-sectional design that included multiple regression and mediation analyses was utilized. The sample consisted of 387 emergency nurses from five major Saudi hospitals surveyed using validated scales that measure perceived toxic leadership, conflict styles, and organizational commitment. **Results.** High prevalence rates for perceived authoritarian (77%), narcissistic (75%), and unpredictable (63%) leadership were reported. Increased toxicity was positively related to dominating and avoiding conflict styles but negatively related to integrating and compromising strategies. Toxic leadership is also associated with lower affective/normative commitment but higher continuance commitment. Conflict management partially mediated the leadership-commitment relationship, which explained 29% of the total effect. Finally, higher experience and education predicted greater perceived toxicity. **Conclusions.** The significant correlations between destructive leadership, adverse conflict, and reduced commitment in emergency nurses underscore the need for context-specific leadership training. Fostering supportive environments through multifaceted interventions can counteract toxicity impacts, impart constructive communication techniques, improve nurse well-being, and ensure high-quality patient care. As conflict tendencies and nurse characteristics influence susceptibility to detrimental leadership, tailored programs addressing experience levels are vital.

1. Introduction

Emergency departments (EDs) are critical high-stake environments within the healthcare system [1], where the pace is relentless and the margin for error is minimal [2, 3]. These units serve as the central hub for acute treatment, where decisions must be rapid and precise [4–6], with the potential to significantly alter patient outcomes [3]. The intensity and pressure inherent in emergency departments require a leadership style that not only facilitates rapid decision-making but also nurtures

a supportive and cohesive team environment [7, 8]. However, the prevalence of authoritarian and manipulative leadership styles in such settings often undermines these objectives, introducing a toxic dynamic that can severely affect team functionality, staff well-being, and, ultimately, patient care quality [9–11].

Toxic leadership in emergency nursing is characterized by a spectrum of harmful behaviors [12, 13], including but not limited to abusive supervision, rigid top-down control [14], exploitation, self-serving actions, and emotional manipulation [15–17]. These behaviors collectively contribute

to an environment where nursing staff can experience decreased well-being, reduced morale [18, 19], and a general sense of job dissatisfaction [20–23]. The extreme stress and urgency that define emergency care exacerbate the negative repercussions of such leadership, amplifying the challenges faced by nursing teams and compromising the quality of care provided to patients [24–26].

The literature extensively documents the adverse effects of toxic leadership in various organizational contexts, highlighting increased workplace stress, burnout, and emotional exhaustion among employees [27–29]. In the emergency nursing field, these effects are particularly pronounced due to the specialized nature of the work [30], which demands tight coordination among different specialists under intense pressure [31, 32]. Therefore, the vulnerability of emergency nursing teams to toxic leadership is markedly higher, given the critical reliance on effective communication, collaboration, and team cohesion to ensure optimal patient outcomes [33–35].

Despite the well-documented negative impacts of toxic leadership on organizational well-being and performance, there is still a significant gap in understanding how such leadership influences conflict confrontation strategies and organizational commitment among emergency nurses [36, 37]. This gap is particularly concerning given the critical importance of effective leadership in fostering team cohesion, maintaining high-performance standards [38–41], and ensuring the delivery of quality care in high-risk emergency settings [27–31]. Effective communication and the management of interpersonal tensions are crucial for maintaining constructive team dynamics [42, 43]. Yet, there is a dearth of research focusing on how emergency nurses, who are at the frontline of care delivery and coordination, navigate conflicts and maintain commitment in the face of toxic leadership [44–46].

Emergency nursing, with its unique challenges related to coordination, decision-making, and high-stakes outcomes, requires a leadership approach that supports rather than undermines team efforts [47, 48]. The distinct context of emergency care, where patient lives are frequently in the balance, underscores the nonnegotiable need for leadership that promotes rather than detracts from team cohesion, performance, and care standards [42, 49]. Therefore, there is a pressing need for research that specifically examines the repercussions of toxic leadership on emergency nurses [50, 51], particularly in terms of their strategies for confronting conflicts and their perceptions of organizational commitment [45, 52–56].

This study aims to address these critical gaps by providing an in-depth analysis of the impacts of toxic leadership on conflict resolution and organizational commitment among emergency nursing staff. By focusing on the unique challenges and dynamics of emergency nursing, the research seeks to uncover the specific ways in which toxic leadership behaviors manifest in this context and their implications for team dynamics, nurse well-being, and patient care. The ultimate goal is to inform targeted interventions and reforms that promote constructive communication and ethical

leadership practices and support the well-being of nursing staff, thus improving the overall quality of emergency care delivery.

In doing so, this study not only aims to contribute to the existing body of knowledge on leadership in healthcare but also to provide practical insights that can guide the development of policies and practices to mitigate the negative effects of toxic leadership in emergency departments. By elucidating the mechanisms through which toxic leadership impacts emergency nursing teams, this research underscores the urgent need for systemic changes that foster healthier team dynamics, improve nurse welfare, and, most importantly, improve patient outcomes in these high-pressure settings.

2. Materials and Methods

2.1. Objective

- (1) Assess the prevalence of the perceived impact of toxic leadership behaviours experienced by emergency department nurses.
- (2) Investigate the relationship among the perceived impact of toxic leadership, organizational commitment, and conflict management strategies used by emergency department nurses.

2.2. Design. A cross-sectional design was used that included a survey of emergency nurses in a single dimension and commitment dimensions [57]. The ability to collect substantial descriptive numerical data from a relatively large sample to support quantitative statistical analysis was also an asset for investigating complex phenomena within emergency nursing environments [58]. Additionally, cross-sectional designs enable accessing samples with diverse perspectives, compared to case studies or longitudinal approaches, which tend to involve fewer subjects. Therefore, the methodology facilitated the evaluation of the impacts of perceived toxic leadership that can be generalizable in five major emergency departments [59]. Overall, the cross-sectional approach offered feasibility and generalizability advantages that aligned well with the study's objectives.

2.3. Settings. This study was completed in emergency care units of five large public hospitals in the northern province of Saudi Arabia. These hospitals provide emergency services to residents in major metropolitan areas, as well as smaller rural communities in the region. Emergency departments treat a high volume of patients annually and are staffed by nurses, physicians, specialists, and support personnel. The units operate 24/7 to provide critical and trauma care.

2.4. Sample. A systematic multistage sampling approach was adopted to select participants from large public emergency departments in a northern province. Initially, five hospitals were chosen according to predefined inclusion criteria. The target population was emergency department nurses who worked full-time and met inclusion criteria in five major

public hospitals with emergency medicine departments in the Hail region of northern Saudi Arabia. These hospitals provide emergency and trauma services to urban and rural catchment areas. The parameters defining this population include their employment status (full-time registered nurses), primary workplace setting (emergency departments), and direct participation in patient care activities.

Power analysis was performed using RaoSoft software to determine the recommended sample size. The input included a 95% confidence level, a 5% error margin, an estimated population of nurses of 580 across sites, and a 50% response distribution. These parameters detected medium effect sizes between study variables with 80% power. The minimum adequate sample size calculated was 387 subjects. This aligned with the recommendations that nursing research should have sufficient power [60, 61].

The RaoSoft tool was chosen for its user-friendly interface and its ability to provide accurate sample size estimates based on essential criteria such as confidence level, margin of error, and expected distribution of responses [62]. Its application in our study was based on a methodological approach that values precision and adherence to the statistical norms recognized by the academic community. This approach ensures that our findings are robust and that the sample size adequately supports the study objectives and anticipated analyses.

A purposive, multistage sampling technique was utilized during recruitment at departmental meetings, through informational flyer distribution, and researcher visits. Of approximately 580 eligible nurses, 580 were invited to participate over a 15-day period [63]. Emphasizing voluntary participation and confidentiality during recruitment aimed to minimize sampling bias by encouraging representative enrollment across specialty experience levels.

Purposive sampling was utilized to recruit participants with substantial emergency department experience who could intentionally provide meaningful perspectives on the leadership dynamics central to this research. Although probability methods have advantages with respect to representativeness and generalizability, accessing informed participants was an efficient way to obtain rich insights into this complex phenomenon. During the multistage recruitment process, concerted efforts were made to emphasize voluntary participation and transparency around the purposes of the study to mitigate biases and approximate a representative enrollment of providers. However, the input to assess alternative probability sampling methods is valuable advice should subsequent follow-up studies be conducted to generalize findings further.

Finally, 387 nurses completed the survey packet, representing a response rate of 67%. This purposive approach supported accessing informed perspectives on a complex phenomenon from an adequately powered sample of experienced emergency department nurses. The sampled nurses reflected a diversity of ages, experience levels, genders, and education levels. Limitations include regional specificity since nurses were recruited from within a single Saudi Arabian province rather than nationally.

2.5. Eligibility Criteria

(i) Inclusion criteria:

- (1) Registered nurses employed full-time in emergency departments.
- (2) At least one year of experience in emergency care settings.
- (3) Currently working in selected public hospitals in the northern province of Saudi Arabia.
- (4) Provided informed consent to participate in the study.

(ii) Exclusion criteria:

- (1) Nurses who took extended leave (e.g., maternity) in the last 6 months.

2.6. Data Collection Tools. Rigorously developed, psychometrically sound instruments were used to ensure a valid and reliable measurement of key variables, including perceived toxic behaviors, conflict tendencies, and organizational commitment. Extensive prior research provides confirmation of strong validity and reliability for the selected tools in various settings [64–68]. Reevaluation among the target nursing population during piloting further upholds these measurement properties. The following descriptions provide an overview of each established data collection tool, including interpretations.

(1) Toxic Leadership Assessment [69]:

This 30-item scale developed by Schmidt (2008) measures perceived toxicity that spans five dimensions: abusive supervision, authoritarian leadership, narcissism, self-promotion, and unpredictability. Items use a scale of agreement of 1–6, with higher scores indicating greater perceived destructive behaviors. Previous studies in all fields produced Cronbach's alpha scores of 0.82–0.96 [65, 70], suggesting excellent internal reliability. The analysis of confirmation factors during the pilot test supported the multidimensional structure and validity of the construction among the target nurse population.

(2) Rahim Organizational Conflict Inventory-II (ROCI-II) [67]:

Developed by Rahim in 1983, this validated inventory identifies the tendencies of conflict management style on five subscales: dominating, avoiding, obliging, compromising, and integrating. The 28 items reflect varying concerns for self-versus others when facing conflicts using a 5-point Likert scale. Extensive research reports that Cronbach's alpha reliability coefficients exceed 0.70 on subscales, indicating solid internal consistency and the ability to discriminate styles [71]. Pilot testing among nurses confirmed the reliability and stability of the factor structure.

(3) Organizational commitment scale [72].

This instrument, conceptualized by Meyer and Allen (1991), assesses employee attachment across three commitment dimensions: affective, normative, and continuance. Using a 7-point Likert agreement format, higher scores reflect stronger feelings of emotional connection, perceived obligation, and necessity-driven commitment, respectively [72, 73]. Confirmatory research supports predictive validity regarding outcomes like turnover and performance [73]. Reliability analysis during piloting maintains internal consistency with an alpha of 0.88.

2.7. Ethical Approval. Ethical approval for this study was obtained from the Research Ethics Committee for Health Affairs in the Hail region, KSA (IRB: KACS, KSA: H-08-L-074). Permission to access the study sites and participants was granted by the nursing directors of the five participating emergency departments. Participants were provided with information sheets detailing the purpose of the study, voluntary participation, potential risks/benefits, and confidentiality measures. Written informed consent was obtained from each participant before the distribution of the surveys, and they had the option to withdraw at any time. The study followed ethical guidelines for nursing research according to the Declaration of Helsinki and the Code of Ethics of the International Council of Nurses, and the Ethics Committee reviewed all procedures and protocols to protect the rights and welfare of participants.

2.8. Procedure. A systematic procedure was developed, validated, and implemented to obtain quantitative measurements that aligned with the study objectives on perceived toxic leadership and the consequent outcomes among emergency nurses.

Following approval from the institutional ethics review board, the data collection process began across the 5 major hospital sites based on a multistage cluster sampling technique detailed in the dedicated Sample and Sampling section. The directors of the nursing department also provided site access approvals prior to recruitment.

The initial participation of the participants involved raising awareness through announcements at staff meetings and informational flyers on the importance of leadership dynamics research to evoke interest among emergency nurses. For nurses expressing interest and meeting the experience inclusion criteria, the principal investigator obtained written informed consent to participate after discussing:

- (i) The purpose is to investigate perceived leadership behaviors and impacts.
- (ii) Survey response process and types of deidentified data collected
- (iii) Minimal risk and direct benefits associated with voluntary participation
- (iv) Right to withdraw participation anytime despite initial agreement

- (v) Storage of completed surveys in an access-restricted locked cabinet

Consenting participants received numbered survey packets, including validated Likert-type scale instruments on perceived leadership toxicity (30 items), conflict confrontation tendencies (28 items), and organizational commitment (24 items), along with a basic demographic questionnaire. The packets had an estimated completion time of 15–20 minutes during work hours without disrupting the operation of the emergency department.

The sealed envelope collection boxes were placed in accessible common staff areas within each unit for returned packets over 2 consecutive weeks. Daily secured recovery, storage protocols, and tracking of response rates enabled midpoint reminders to optimize participation and motivational prompts during meetings to underscore the importance and encourage collaboration.

At the conclusion of the study, a participation rate of 67% was achieved, providing 387 fully completed nurse surveys for sufficient statistical power in the planned quantitative analyses. Encrypted data sets excluded any identifying details to uphold respondent rights and confidentiality standards governing ethical research. Restricted access and data aggregation protected anonymity prior to controlled analyses. This rigorous procedure allowed significant quantitative measurements aligned directly with the specific research questions on perceived toxic leadership outcomes.

2.9. Statistical Analysis. All data were analyzed using SPSS version 22.0 (IBM Corp, Armonk, NY). Descriptive statistics, such as means and standard deviations, summarized sample demographics and scale measurement scores. Pearson's correlation analysis quantified the bivariate relationships among perceived toxicity, conflict management styles, and organizational commitment types. Multiple linear regression examined predictors of affective commitment. The mediation analysis evaluated whether conflict management tendencies mediated the effect of destructive leadership on reduced commitment. For all tests, a p value <0.05 was considered statistically significant. Reliability analysis confirmed the internal consistency of measurement instruments. The assumptions of parametric testing were checked, including normality and homoscedasticity evaluation to meet the application criteria. The effect sizes were calculated to quantify the strengths of the observed relationship.

3. Results and Discussion

3.1. Results. The results of this cross-sectional study provide important insights into the complex relationships between perceived toxic leadership, conflict management approaches, and organizational commitment among emergency department nurses. Key findings demonstrate the high prevalence of destructive leadership behaviours reported by participants, with authoritarian, narcissistic, and unpredictable actions notably prevalent. Significant

TABLE 1: Demographic characteristics of emergency care nurses ($n = 387$).

Variable	Category	<i>N</i>	%
<i>Age</i>	25–30 years	152	39
	31–40 years	170	44
	41–50 years	53	14
	>50 years	12	3
	<i>Gender</i>	Male	162
	Female	225	58
<i>Marital status</i>	Single	127	33
	Married	152	39
	Divorced	75	19
	Widowed	33	9
<i>Education level</i>	Diploma	75	19.4
	Bachelor's degree	250	64.6
	Master's degree	62	16
<i>Years of experience</i>	1–5 years	180	47
	6–10 years	152	39
	11–15 years	37	10
	>15 years	18	4

correlations emerged between perceived toxicity and conflict management styles, with passive and aggressive approaches positively associated but constructive strategies negatively related. Toxic leadership also related to lower affective/normative commitment but higher continuance commitment. Furthermore, conflict tendencies were found to partially mediate the link between destructive leadership and reduced commitment. Finally, higher nurse experience and education predicted higher perceived toxicity. The following sections delve deeper into these results, underscoring the need for supportive leadership and conflict training tailored to the intense emergency context. Elucidating these dynamics is the first step toward fostering healthy environments where nurses can thrive and provide optimal patient care even in high-stake situations.

Table 1 presents key demographic characteristics of the 387 emergency care nurses sampled in this study. The table shows a relatively young sample, with 83% under 40 years of age. Most were women (58%), typical for the nursing field. A range of education levels were represented, from diplomas to master's degrees, with most holding a bachelor's degree (65%). In terms of experience, most nurses had 1–10 years of tenure (72%), while few were new nurses or very experienced.

Table 2 effectively highlights the prevalence and characteristics of perceived toxic leadership behaviours among emergency nurse leaders. Inclusion of both the percentage of respondents reporting each behaviour and the mean score with standard deviations offers a nuanced understanding of the problem. The table shows that authoritarian leadership and narcissism are the most commonly perceived toxic behaviours, with 77% and 75% of nurses reporting these experiences, respectively, and correspondingly high mean scores (4.0 and 3.9). This suggests a significant impact of

TABLE 2: Prevalence of perceived toxic leadership behaviours among emergency nurse leaders.

Toxic leadership behaviour	<i>N</i>	%	Overall toxic leadership ($M \pm SD$)
Self-promotion	212	55	2.8 \pm 0.6
Abusive supervision	167	43	2.3 \pm 0.7
Unpredictability	245	63	3.3 \pm 0.5
Narcissism	289	75	3.9 \pm 0.4
Authoritarian leadership	298	77	4.0 \pm 0.3

these behaviours on the workplace. In contrast, abusive supervision, although serious, is reported less frequently (43%), with a lower mean score of 2.3. The range of standard deviations (0.3 to 0.7) indicates the variability in how these behaviours are experienced among the respondents. The high prevalence rates, combined with notable mean scores, underscore the critical nature of addressing toxic leadership in emergency nursing settings to improve workplace dynamics and overall quality of care.

Table 3 of the study presents insightful findings on the relationship between various toxic leadership behaviours and organizational commitment, mediated by conflict management styles. The table reveals a negative correlation between all forms of toxic leadership and organizational commitment, indicating that higher levels of toxic behaviour's correspond to lower levels of commitment among emergency care nurses. In particular, authoritarian leadership shows the strongest negative correlation (-0.45), suggesting that it has the most detrimental impact on organizational commitment. The sizes of the mediation effect, ranging from 0.15 for self-promotion to 0.22 for authoritarian leadership, indicate that conflict management styles play a significant role in mediating these relationships. The statistical significance of these relationships is further underscored by the p values, with most falling below 0.001. These data imply that the way nurses manage conflict can significantly buffer or amplify the negative effects of toxic leadership on their commitment to the organization.

Table 4 presents the results of a mediation analysis that examined whether the conflict management style of nurses mediated the relationship between perceived toxic leadership and organizational commitment. The significant indirect effect ($B = -0.33$) suggests that conflict management partially mediates the association between perceived toxic leadership and commitment. This lends preliminary support to the hypothesis that leadership toxicity may influence nurses' conflict approaches, which in turn impacts their organizational commitment. However, the cross-sectional design prevents determining directionality or causality. The results should also be interpreted with caution given the reliance on subjective assessments of leadership toxicity. However, the table succinctly conveys that conflict management appears to play a mediating role in the link between perceived toxic leadership and organizational commitment among these emergency care nurses. The results provide initial evidence that the modification of conflict approaches could potentially counteract some negative impacts of toxic leadership on nurses' commitment.

TABLE 3: Relationship between toxic leadership and organizational commitment mediated by conflict management.

Toxic leadership behaviour	Correlation with organizational commitment	Mediation effect size	<i>p</i>
Self-promotion	-0.31	0.15	<0.01
Abusive supervision	-0.35	0.18	<0.01
Unpredictability	-0.40	0.20	<0.001
Narcissism	-0.42	0.21	<0.001
Authoritarian leadership	-0.45	0.22	<0.001

TABLE 4: Mediation analysis of the conflict management style on the relationship between toxic leadership and organizational commitment.

Path	<i>B</i>	SE	<i>p</i>
Toxic leadership in conflict management	0.57	0.08	<0.001
Toxic leadership to organizational commitment	-0.42	0.09	<0.001
Conflict management to organizational commitment	-0.33	0.07	<0.001

Table 5 presents the results of a multiple linear regression model that predicts the affective organizational commitment of nurses to perceive toxic leadership, avoidant conflict style, integration of conflict style, age, and education level. The model was significant, which explained 28% of the variance in affective commitment. Higher perceived toxicity and avoidant conflict are independently related to lower affective commitment, while integrating style and age are associated with higher commitment. The large sample size lends confidence in the findings. However, limitations include the cross-sectional design and the reliance on subjective assessments. The variation of the common method can also inflate the relationships between the measured variables. However, the table succinctly summarizes key predictors of nurses' affective commitment, highlighting the negative impacts of destructive leadership and conflict avoidance, as well as the positive effects of collaborative conflict management.

Table 6 shows the results of a hierarchical linear regression mediation analysis. The significant indirect effect indicates that conflict management partially mediated the relationship between perceived toxic leadership and organizational commitment. Approximately 29% of the total effect of leadership on commitment operated indirectly through conflict management styles. This supports the hypothesis that toxic leadership may influence nurses' conflict approaches, which then affects their commitment. However, the cross-sectional design prevents determining causation or directionality. The subjective nature of leadership and conflict measures should also be considered. However, the table succinctly summarizes evidence that conflict management plays a mediating role in the association between perceived toxic leadership and commitment among these nurses. It points to the conflict style as a potential mechanism through which destructive leadership relates to reduced organizational commitment.

TABLE 5: Multiple linear regression analysis that predicts affective organizational commitment.

Variable	<i>B</i>	SE <i>B</i>	β	<i>p</i>
(Constant)	2.83	0.23		<0.001
Toxic leadership	-0.41	0.07	-0.32	<0.001
Avoidant conflict style	-0.38	0.09	-0.28	<0.001
Integrating conflict style	0.26	0.08	0.21	0.002
Age	0.02	0.01	0.14	0.012
Education level	-0.18	0.09	-0.11	0.048

Table 7 presents the results of a logistic regression model that predicts the likelihood that nurses will perceive high levels of toxic leadership based on their demographics. Nurses with higher education levels and more years of experience showed significantly greater odds of reporting high toxicity. The model provides initial evidence that personal factors can affect perceptions and experiences of destructive leadership behaviours. However, the cross-sectional design prevents determining causality. Response biases are also a concern with self-reported leadership ratings. However, the table succinctly summarizes the exploratory findings suggesting that nurse education and tenure may predict perceived leadership toxicity, warranting further investigation. Although preliminary, the results point to potential vulnerabilities based on nursing background that could inform prevention efforts.

3.2. Discussion. This cross-sectional study aimed to address gaps regarding perceived toxic leadership impacts on conflict and commitment specifically in emergency nursing. The objectives were to assess the prevalence of the perceived impact of toxic leadership behaviors experienced by emergency department nurses and investigate the relationship between the perceived impact of toxic leadership, organizational commitment, and conflict management strategies used by emergency department nurses. By elucidating these complex dynamics, the intent was to inform interventions tailored to intense emergency contexts where leadership failures could profoundly impact nurse and patient outcomes. The following discussion interprets results regarding the stated objectives of delineating relationships among perceived toxic leadership, conflict management, and commitment in this understudied yet high-stake specialty setting.

Leadership behaviors have far-reaching impacts in healthcare settings, yet toxic leadership remains an understudied phenomenon among nurses [23, 74]. This concern is

TABLE 6: Mediation analysis using hierarchical linear regression.

Effect	<i>B</i>	SE <i>B</i>	<i>t</i>	<i>p</i>
Total effect				
Toxic leadership → commitment	-0.53	0.08	-6.98	<0.001
Direct effect				
Toxic leadership → commitment	-0.24	0.09	-2.73	0.007
Indirect effect				
Toxic leadership → conflict → commitment	-0.29	0.07	-4.25	<0.001

TABLE 7: Logistic regression predicts the likelihood of high toxic leadership based on nurse demographics.

Years of experience	0.18	0.09	3.92	0.048	1.20
Education level	0.67	0.28	5.73	0.017	1.95
Marital status	-0.34	0.20	2.88	0.090	0.71

due to evidence linking detrimental leadership with poorer clinical outcomes, staff well-being, and quality care [75]. Emergency departments represent a high-stake context where leadership failures could have dire consequences [76]. However, little research has examined toxic leadership among emergency nurses specifically [23, 39, 77, 78]. This study helps address this gap by elucidating the impacts of perceived toxicity on the management of nurses' conflicts and organizational commitment. The findings promise to inform interventions to foster healthy leadership and optimal team functioning in this fast-paced environment where lives are on the line.

Our sample of 387 nurses from five emergency departments in Saudi Arabia reported high perceived toxicity, especially authoritarian, narcissistic, and unpredictable behaviours. Leadership toxicity was positively correlated with passive and aggressive conflict styles but negatively associated with constructive conflict approaches. Additionally, the increased perceived toxicity is related to a lower affective/normative commitment but a greater commitment to continued commitment. A salient finding was the mediating effect of conflict management, which explained nearly a third of the relationship between leadership and commitment. Finally, nurses with more experience and education showed a greater likelihood of perceiving toxic leadership.

3.2.1. Prevalence of Toxic Leadership Behaviours. The high prevalence of perceived authoritarian (77%), narcissistic (75%), and unpredictable (63%) leadership behaviours confirm toxic leadership as an issue in emergency care settings. These rates exceed estimates from a recent meta-analysis that aggregates toxicity prevalence between industries (10–15%) [23]. The extreme stress and urgency of emergency departments can partially explain this elevated toxicity [7, 41]. However, the authors in [79] found lower perceived toxicity among Indian emergency nurses (14–23% for different behaviours). This discrepancy highlights the need for comparative data from multiple sites, as the

organizational and cultural context can influence the prevalence. Furthermore, the reliance of this study on self-reports could bias the results, as nurses' attitudes, expectations, and attributions shape their perceptions of leaders [80, 81]. Integrating peer, supervisor, and patient assessments would provide a more balanced perspective.

3.2.2. Conflict Management as a Mechanism. A significant finding was the mediating effect of conflict management, which explained almost a third of the total leadership-commitment relationship. This proposes conflict tendencies as a key mechanism that converts toxic leadership into attitudinal outcomes. Longitudinal and experimental studies could further validate this mediation model and directionality [82–84]. However, the results suggest that strengthening nurses' conflict management skills could potentially neutralize some detrimental impacts of poor leadership.

3.2.3. Individual Susceptibility Factors. Finally, higher education and experience predicted greater perceived toxicity compared to some research in which novice nurses reported worse leadership [85]. It implies that standards for acceptable leader conduct increase with experience. Alternatively, toxic leaders can target underconfident junior nurses. In either case, the results underscore the need to cultivate leadership skills at all levels and protect those most vulnerable.

3.2.4. Relationships among Toxic Leadership, Conflict Management, and Commitment. Significant positive correlations emerged between perceived toxic leadership and dominating/avoiding conflict styles, while negative associations with integrating and compromising approaches were observed. This is consistent with meta-analytic findings linking abusive supervision to more passive and aggressive conflict tendencies [86, 87]. However, contrasting reports show toxic leadership that specifically relates to avoiding rather than dominating conflict [23, 88]. This discrepancy could reflect situational factors, as the emergency context may require more dominant behaviors to match the urgency. Additionally, higher perceived leadership toxicity is related to lower affective/normative commitment but higher continuance commitment. These results support conclusions from a nursing review that identified leadership as an important determinant of organizational commitment [32, 89, 90]. However, the authors in [91] found no

association between perceived toxicity and overall commitment among nurses. This discrepancy highlights potential cross-cultural variations in leadership-commitment dynamics.

3.2.5. Mediating Role of Conflict Management. A significant finding was the mediating effect of conflict management on the toxic leadership-commitment relationship, which explained 29% of the total effect. This suggests that leadership behaviors can alter nurses' conflict approaches in a way that reduces commitment. Although scarce research has directly tested this mechanism, the authors in [92] similarly implicated conflict management as a mediator in the leadership-engagement relationship. However, the cross-sectional design prevents causal inferences. Longitudinal designs could help establish directionality.

3.2.6. Practical Implications and Future Directions. The findings of this study underscore the critical need for the development of conflict management training programs specifically tailored for emergency department nursing staff. Such initiatives could potentially serve as a buffer against the detrimental effects of toxic leadership, potentially improving organizational commitment and workplace morale. Future research should extend these findings through longitudinal studies to determine the long-term impact of conflict management training, examine individual nurse characteristics that affect perceptions of leadership, and assess implications for patient care outcomes. Expanding the scope of research to include diverse cultural and organizational settings would enrich the understanding of toxic leadership dynamics in the emergency care environment.

4. Conclusions

This cross-sectional study provides valuable insights into the concerning prevalence of perceived toxic leadership behaviors among emergency department nurse leaders and the implications for nurses' conflict management approaches and organizational commitment. Key findings demonstrate high rates of authoritarian, narcissistic, and unpredictable leadership, which are positively associated with destructive conflict tendencies like domination and avoidance. In turn, these connect to lower affective/normative commitment. A salient finding is that conflict management explains almost a third of the total effect of toxic leadership on reduced commitment. The significant correlations found among toxic leader behaviours, adverse conflict strategies, and diminished commitment highlight the vital need to cultivate supportive leadership that fosters constructive communication and healthy team dynamics in intense, high-stake emergency departments. Doing so promises to improve nurses' well-being, performance, and patient care quality. The mediating effect of conflict management also suggests that this could be leveraged to mitigate detrimental leadership impacts.

However, there are limitations given the single-source design and reliance on subjective measurement. The cross-

sectional methodology also prevents determining causality. Follow-up longitudinal and experimental studies validating the directionality and causal pathways are warranted. Additionally, the sample is regionally limited so that generalizability may be restricted. Nonetheless, by elucidating the prevalence and outcomes associated with destructive leadership in understudied emergency care contexts, this study meaningfully informs policies, training programs, and interventions to counteract toxicity.

Data Availability

The data will be available on request.

Ethical Approval

This study was carried out with the approval of the Health Affairs, Hail Region, KSA with IRB: KACS, KSA: H-08-L-074.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Aim. To explore the mediating effect of psychological empowerment in the association between transformational leadership and organizational citizenship behaviors in nursing context. **Background.** Healthcare organizations worldwide are facing unprecedented challenges, necessitating effective leadership strategies to ensure quality patient care and organizational success. Transformational leadership has emerged as a tool to promote positive workplace behaviors, including organizational citizenship behaviors, among nursing staff. However, the mediating role of psychological empowerment in this relationship remains underexplored. **Methods.** A cross-sectional survey was conducted from March 2023 until August 2023 involving 305 registered nurses at King Khalid Hospital to investigate the relationship among transformational leadership, psychological empowerment, and organizational citizenship behaviors. Validated scales were used to assess these variables. A single mediation analysis was conducted through processing macro version 3.5 model 4. **Results.** This study found a strong positive association between transformational leadership and both psychological empowerment ($r = 0.507$, $p < 0.001$) and organizational citizenship behaviors ($r = 0.445$, $p < 0.001$) among nursing staff. Additionally, psychological empowerment partially mediated the relationship between transformational leadership and organizational citizenship behaviors, with a significant indirect effect ($B = 0.110$, $CI: 0.058-0.166$). **Conclusions.** Transformational leadership positively impacted nurses' feelings of empowerment, which then led to higher exhibition of organizational citizenship behaviors. **Implications for Nursing Management.** Leadership development programs should prioritize the cultivation of transformational leadership qualities and support the psychological empowerment of nursing staff. This approach can enhance organizational effectiveness, foster positive workplace environments, and improve patient outcomes.

1. Introduction

Healthcare is currently experiencing substantial transformation due to the prevailing economic challenges worldwide. At the same time, demographic patterns are evolving, with a notable increase in the aging population in the most affluent nations of the industrialized world,

combined with a growing global population. In this dynamic healthcare landscape, the ability to meet rigorous standards is paramount and this necessitates the implementation of effective leadership styles [1, 2].

Nurse leadership emerges as a particularly crucial element in this unpredictable and occasionally tumultuous world of healthcare. Nurse leaders play a vital role in

ensuring the delivery of safe, evidence-based treatment that enhances the overall patient experience. Their guidance and expertise contribute to maintaining high standards of care and promoting positive patient outcomes [3]. Throughout history, nurse leaders have consistently demonstrated strong management abilities. However, to truly excel as a leader, one must possess transformational leadership skills. This entails the ability to inspire and motivate individuals on a personal level, encouraging them to take innovative actions that lead to the attainment of optimal outcomes. By embodying transformational leadership qualities, nurse leaders can foster a culture of innovation, collaboration, and continuous improvement, ultimately enhancing the quality of care and patient outcomes [4].

Transformational leaders exhibit effective communication, inspire others, demonstrate enthusiasm, foster positive change, and guide individuals towards shared objectives that enhance nurses' wellbeing [5]. Transformational leadership is crucial for achieving exceptional organizational performance and efficiency. Additionally, transformational leaders can significantly improve staff satisfaction by providing support and motivation, empowering employees, encouraging constructive feedback, fostering open communication, and demonstrating respect [6]. Transformational leadership inspires people to surpass their usual duties, promoting flexibility and dedication to a shared goal or mission. These additional efforts, referred to as organizational citizenship behaviors (OCBs), help strengthen the workplace environment by exceeding expectations and have been associated with enhanced organizational performance [7].

Moreover, transformational leaders recognize the importance of empowering their staff by delegating authority, fostering accountability, and involving employees in decision-making processes. This acknowledges the increasing need to promote OCBs to maximize the efficient use of limited resources [7, 8].

Concurrently, OCBs have been observed as a significant predictor of employees' productive work [9]. To foster these kinds of behaviors, organizations must provide additional consideration. For instance, when employees lack sufficient information and control over their job duties, have limited involvement in decision-making, experience communication issues, or feel dissatisfied with leadership, it can exacerbate negative behaviors such as turnover. These factors directly oppose the principles of psychological empowerment [10].

In this study, we aim to investigate the influence of transformational leadership on OCBs through psychological empowerment. Specifically, we argue that transformational leaders can enhance nurses' psychological empowerment by elevating the significance they attribute to their work, equipping them with the necessary skills for task completion, and fostering a sense of control over their environment. This assumption builds on the theoretical idea of social exchange theory [11]. According to social exchange theory, employees engage in discretionary behaviors, such as OCBs, when they perceive that their efforts are valued and rewarded by their leaders or the organization. Transformational leadership, which emphasizes inspiring and empowering followers, can

foster a supportive work environment where employees feel psychologically empowered to engage in OCBs as a form of reciprocal exchange for the positive leadership they receive.

Previous studies have investigated the distinct associations among transformational leadership, psychological empowerment, and OCBs [12, 13]. Nevertheless, there exists a lack of research concerning the manner in which psychological empowerment serves as a mediator in the relationship between transformational leadership and OCBs, particularly within the nursing workforce. This study will contribute to the existing literature by providing insights into the mediating role of psychological empowerment in the relationship between transformational leadership and OCBs within the nursing context. By examining the mediating pathways, this research will enhance our understanding of the mechanisms underlying these relationships, offering valuable implications for healthcare management and leadership development.

1.1. Literature Review and Hypotheses Development

1.1.1. Transformational Leadership and OCBs. The hallmark of a transformational leader is their capacity to uplift and encourage subordinates to reach greater heights of achievement and personal development [5]. A multitude of studies have been conducted on the transformational leadership style, consistently demonstrating its significant impact on employee commitment, satisfaction, and overall organizational performance. The findings consistently highlight the positive association between transformational leadership and employee outcomes, such as increased job satisfaction, higher levels of organizational commitment, and improved performance [14, 15].

A prior research has demonstrated that positive outcomes in nursing organizations depend on the adoption of a transformational leadership approach. This style effectively leads nursing staff, addresses staffing concerns, and improves nurse retention [16]. The encouragement and promotion of reasoned thought as a leadership quality have a significant impact on employees' creative behavior and foster collaboration [17]. Empirical data derived from a study encompassing a total of 219 nurses demonstrate that transformational leadership possesses a significant impact on the advancement of OCBs within the nursing profession [18]. Correspondingly, Zurañmi et al. [19] emphasize the intricate connection between transformational leadership and the occurrence of OCBs among nursing staff at the Tapan Regional General Hospital. Moreover, transformational leadership plays a substantial role in fostering the emergence of employee OCBs [20]. As a result, we have formulated the following hypothesis:

H1: Transformational leadership will have a positive effect on OCBs among nurses

1.1.2. Transformational Leadership and Psychological Empowerment. Transformational leaders in nursing play a vital role in supporting change processes that advance

various goals, including enabling high-quality care, ensuring patient safety, and improving the overall quality of life for nurses in the workplace. To achieve these outcomes, managers must provide nurses with the autonomy and freedom to perform their duties in alignment with best practices. This involves empowering nurses to make decisions, take ownership of their work, and contribute to the organization's mission. Psychological empowerment for nurses is not only necessary but also has a significant influence on work performance. When nurses feel empowered, they are more likely to be engaged, motivated, and committed to delivering exceptional care, thereby positively impacting their overall work performance [21]. Given its profound positive effects on both organizations and their personnel, psychological empowerment has emerged as a compelling subject for practical application and scholarly inquiry, driving further exploration and examination in the field [22]. In 1995, Spreitzer was proposed four components to conceptualize psychological empowerment, namely, meaning, competence, self-determination, and impact. Additionally, a resilient and dependable survey was formulated to expedite the economic evaluation of psychological empowerment [23].

The study conducted by Aydogmus et al. [24] sheds light on the relationship between transformational leadership and psychological empowerment, highlighting the significant influence leaders have on employees' perceptions and experiences. Additionally, the research conducted by Cheng et al. [25] further emphasizes the role of transformational leadership as an influential factor in shaping employees' psychological empowerment. These findings contribute to our understanding of how transformational leadership behaviors can foster a sense of empowerment among employees, ultimately influencing their attitudes, behaviors, and overall well-being in the workplace.

Transformational leaders have the remarkable ability to instill faith in their team members' abilities to achieve objectives, thereby strengthening followers' sense of competence. This sense of competence fosters a strong personal dedication towards their objectives and propels individuals with an inner drive, making them less reliant on external oversight to carry out their duties. As a result, the accomplishment of individual goals amplifies one's impact and enhances their sense of autonomy [22]. Furthermore, as transformational leaders, they empower their followers to realize their full potential and instill confidence in their ability to make a positive impact on the organization. Consequently, it is suggested that followers guided by such leaders experience psychological empowerment [26]. Therefore, building on the previous discussion, we developed the following hypothesis:

H2: Transformational leadership and psychological empowerment are positively correlated.

1.1.3. Psychological Empowerment and OCBs. In accordance with the principles of social exchange theory, individuals operating within environments that foster empowerment are inclined to exhibit OCBs [27]. Numerous studies have identified psychological empowerment as a pivotal pathway

leading to the manifestation of OCBs [28, 29]. These studies have found that when individuals perceive themselves as empowered within their organization, they are more likely to engage in behaviors that go beyond their formal job requirements and contribute to the overall well-being of the organization. Furthermore, Singh and Singh [30] conducted a study that revealed organizations fostering a sense of empowerment among their staff members experience positive outcomes, which are manifested in the form of OCBs. This suggests that psychological empowerment plays a crucial role in cultivating an organizational climate that encourages and motivates employees to engage in discretionary behaviors that benefit the organization and its members. Employees' OCBs are positively impacted by psychological empowerment because it creates a favorable work environment that improves their performance outside of their roles [8].

In conclusion, organizations that implement psychological empowerment programs are well-positioned to enhance OCBs and reduce intentions of employee turnover and retention [31]. Empowerment serves as a catalyst for motivating employees to exert their optimal efforts and signifies a heightened organizational commitment to goal achievement [32]. Building on the insights obtained from the aforementioned literature, we propose the following hypothesis:

H3: Psychological empowerment has a positive and significant impact on OCBs among nurses.

1.1.4. Psychological Empowerment as a Mediating Role. Earlier research findings have suggested that the skillful utilization of transformational leadership behaviors, such as idealized influence, intellectual stimulation, and individualized consideration, during organizational tasks can stimulate a sense of psychological empowerment among followers. This, in turn, has the potential to contribute to a higher level of organizational commitment [33, 34]. Empirical studies align with the principles of leadership theory. For instance, transformational leadership theory posits that the manner in which leaders and followers interact during the management of organizational activities can motivate followers to prioritize the interests of the organization over their own [35].

Moreover, in accordance with the psychological empowerment model, intrinsic task motivation has the potential to enhance employees' engagement and satisfaction with their work, irrespective of external rewards. The psychological empowerment model suggests that when employees feel a sense of autonomy, competence, meaningfulness, and impact in their work, they experience intrinsic motivation, which arises from the inherent satisfaction and enjoyment derived from the work itself. This intrinsic motivation is driven by the individual's internal desire to engage in the task and is not contingent on external rewards or incentives [36]. In line with this perspective, we propose that psychological empowerment, which has been found to have a positive correlation with OCBs, is closely linked to transformational leadership.

Transformational leaders, by exhibiting behaviors that inspire and empower their followers, create an environment conducive to psychological empowerment [26]. Furthermore, as job satisfaction arises from the fit between employees' jobs and their job values, fewer satisfied employees tend to perceive their jobs less matched with them and obtain less support (both extrinsic and intrinsic) when performing jobs [37].

Based on these insights, we propose the following mediating hypothesis:

H4: Psychological empowerment mediates the relationship between transformational leadership and OCBs among nurses.

Based on the previous literature review and hypothesis development, the conceptual framework of the present study was developed as shown in Figure 1.

2. Materials and Methods

2.1. Study Design and Participants. This cross-sectional study was conducted at King Khalid Hospital in El-kharij Governorate. This hospital is equipped with high-quality health and medical departments that deliver efficient services to patients across various specialties. These departments include medical, surgical, operating room, radiology, dental, and intensive care units. Additionally, the hospital offers a dedicated section for psychological consultations, staffed by top doctors and psychologists. Furthermore, the hospital has a specialized department for medical endoscopy. The study utilized a convenience sampling method to recruit registered nurses from different age groups and departments within the hospital. The inclusion criteria required participants to be actively engaged in providing direct patient care on a full-time basis. To maintain consistency in the participant group, nursing interns and managers were excluded from the study. Out of the initial 357 nurses approached to participate in the study, a total of 305 nurses completed the self-reported questionnaires, resulting in a response rate of 85.4%.

2.2. Sample Size. The sample size was computed using the formula $n = (Z^2 * \sigma^2) / d^2$, where "n" represents the required sample size, "Z" is the standardized normal deviation corresponding to a 95% confidence level and $\alpha = 0.05$ ($Z = 1.96$ for a two-tailed test), " σ " denotes the expected standard deviation in the population ($\sigma = 0.4$) based on the study by Taghinezhad et al. [38], and "d" signifies the acceptable margin of error for the mean ($d = 0.05$). This calculation initially yielded a minimum sample size of 246, with provision for an anticipated 15% attrition rate. Subsequently, the final sample size was adjusted to 283 nurses.

2.3. Instrumentations. Data for the study were collected using three scales, all of which utilized a five-point Likert scale ranging from "1" representing "strongly disagree" to "5" representing "strongly agree."

FIGURE 1: Conceptual framework developed for this study.

2.3.1. Global Transformational Leadership Scale. The researchers employed the Global Transformational Leadership Scale developed by Carless in 2000 [38], to measure nurses' perceptions of transformational leadership demonstrated by their immediate leaders or managers. This scale contains seven items that assess four dimensions: idealistic impact, inspirational motivation, individual consideration, and intellectual stimulation and critical thinking. The reliability of the scale in this study was evaluated using Cronbach's alpha, which yielded a value of 0.74, indicating acceptable internal consistency.

2.3.2. Psychological Empowerment Scale. The researchers utilized the Psychological Empowerment Scale developed by Spreitzer [23] to measure the various dimensions of psychological empowerment. This scale consists of twelve items, equally distributed across four dimensions: competence, meaning, self-determination, and impact. The internal consistency of the scale was assessed using Cronbach's alpha, which yielded a value of 0.89 for the total items, indicating high reliability. Furthermore, the subscales of the psychological empowerment scale demonstrated good internal consistency, with Cronbach's alpha values ranging from 0.71 to 0.90.

2.3.3. OCBs Scale. The OCBs scale utilized in this study was developed by Podsakoff and his colleagues [39]. It consists of 12 items that are categorized into three dimensions: helping (6 items), civic virtue (3 items), and compliance (3 items). The internal consistency of the scale was assessed using Cronbach's alpha, which yielded a value of 0.70 for the total items. The subscales of the OCBs scale demonstrated satisfactory internal consistency, with Cronbach's alpha values ranging from 0.71 to 0.75. The utilized English scales demonstrated good reliability and validity in previous studies [40, 41].

The researchers opted to employ the English versions of the measurement scales in light of the fact that the registered nurses participating in the study routinely use English in their clinical practice and research was being conducted in English. Utilizing scales in English helped ensure the validity and reliability of responses by nurses sufficiently proficient in the language both professionally and academically. This approach reinforced the integrity of data collection and subsequent analysis within the study's methodological framework.

2.4. Data Collection. The data collection for this study occurred between March 2023 and August 2023, utilizing self-administered handwritten questionnaires. Participants were recruited through in-person meetings, during which they were provided with comprehensive information about the study, including its objectives, procedures, and their right to withdraw without facing any repercussions. Informed written consent was obtained from all participants before they proceeded to complete the questionnaire. To ensure confidentiality, participants were instructed to submit the completed questionnaires anonymously. Prior to the full implementation of the data collection, a pilot study was conducted with a sample of 29 registered nurses. The purpose of this pilot study was to identify any areas of the survey that required clarification or refinement. This iterative process allowed the researchers to enhance the clarity and user-friendliness of the survey items, thereby promoting the reliability of the data collection process. The estimated time for participants to complete the questionnaire ranged from 15 to 20 minutes. To ensure the accuracy and integrity of the collected data, the researchers conducted a thorough review of each received questionnaire. This rigorous review process was promptly undertaken to address any potential data omissions, inconsistencies, or missing information. By following these meticulous procedures, the researchers aimed to maintain the quality and reliability of the collected data.

The researchers carefully distributed the questionnaires to registered nurses, ensuring coverage across different shifts and working hours. By doing so, they aimed to capture a diverse range of perspectives. To discourage participants from providing hasty and careless responses, the researchers made a deliberate effort to collect the completed questionnaires at the end of the nurses' shifts. This approach allowed participants the autonomy to choose a suitable moment during their working hours to fill out the survey, promoting a conducive environment for thoughtful and thorough responses. The researchers believed that by providing participants with sufficient time and attention to complete the questionnaire, the quality and reliability of the collected data would be enhanced.

2.5. Ethical Considerations. This study obtained ethical approval from the institutional review board at Prince Sattam bin Abdulaziz University, identified by reference number SCBR-042-2023. Participation in the study was voluntary, and informed consent was secured with a guarantee of anonymity. Staff nurses were reassured that their responses would not impact performance evaluations, work status, or salaries. Completed questionnaires were submitted anonymously, and the data were treated confidentially, exclusively for research purposes.

2.6. Statistical Analysis. Data were meticulously organized, categorized, and presented in tables. Descriptive statistics, comprising numbers and percentages, were employed to delineate participants' demographic characteristics. The independent sample *t*-test and ANOVA test were utilized to

compare means across diverse categories pertaining to personal characteristics and various study variables. The reliability of study variables was assessed using the Cronbach alpha test (α). Pearson correlation analysis explored the correlation matrix among different variables and subscales, with the strength of the correlation categorized according to Pearson's correlation coefficient. The process macro version 3.5 model 4 was employed for analyzing one independent variable (transformational leadership), one dependent variable (OCBs), and one mediator (psychological empowerment). The researchers utilized a biased bootstrap 95% confidence interval (CI) to assess the significance of total, direct, and indirect effects. The analysis was conducted using IBM SPSS Statistics 23, with the significance level set at $P < 0.001$.

3. Results

As shown in Table 1, most of the nursing staff were female (69.2%), less than half of them aged between 31 and 40 years, more than half were married (54.8%), two thirds had a bachelor's degree (66.2%), approximately two thirds of them have more than ten years of experience in nursing, while less than half of them usually worked in the morning shift (44.9%). 25.6% of the nursing staff worked in medical units. Finally, there were no statistically significant differences among transformational leadership, OCBs, and psychological empowerment with personal characteristics.

Table 2 demonstrates nurses who recorded mean scores of 3.38, 3.40, and 3.54 for transformational leadership, psychological empowerment, and OCBs, respectively. Among the dimensions of psychological empowerment, the highest mean was observed in the meaning dimension (3.53 ± 0.83). Similarly, the compliance dimension recorded the highest mean for OCBs (3.69 ± 0.60).

The findings in Table 3 reveal a positive correlation between staff nurse's transformational leadership and psychological empowerment ($r = 0.507$, $P < 0.001$), as well as with OCBs ($r = 0.445$, $P < 0.001$). Additionally, a positive correlation was observed between psychological empowerment and OCBs ($r = 0.451$, $P < 0.001$).

Table 4 further illustrates that transformational leadership has a positive impact on psychological empowerment ($B = 0.433$, $p < 0.001$) and OCBs ($B = 0.208$, $p < 0.001$) among the studied nurses. Furthermore, psychological empowerment positively influences OCBs among the participants ($B = 0.254$, $p < 0.001$). Notably, psychological empowerment was identified as a partial mediator in the relationship between transformational leadership and OCBs among the studied nurses ($B = 0.110$, CI: 0.058–0.166).

4. Discussion

The present research study aimed to investigate the relationship between transformational leadership and OCBs in the nursing context, with psychological empowerment acting as a mediating factor.

Our findings demonstrated a positive impact of transformational leadership on OCBs among nursing staff,

TABLE 1: Personal characteristics of the studied nurses and differences in the study variables.

Characteristics	N	%	Transformational leadership	Psychological empowerment	Organizational citizenship behavior
			Mean \pm SD	Mean \pm SD	Mean \pm SD
<i>Age (years)</i>					
20–30	73	23.9	3.25 \pm 0.75	3.30 \pm 0.64	3.48 \pm 0.53

supported H1. This is attributable to the development of a supportive work environment characterized by open communication, collaboration, and mutual respect. In such environments, employees are more likely to engage in OCBs, as they experience a stronger sense of belonging and commitment to the organization's goals. This, in turn, leads to improved job satisfaction and overall organizational performance [7, 16, 32].

Our study aligns with the findings of Qiu et al. [42], who conducted research across eight hospitals in China and revealed that a leadership style characterized by role modeling, integrity, and ethics had a direct impact on OCBs among nursing staff. Similarly, a study conducted by

Aloustani et al. [43] among nurses from twelve teaching hospitals in Tehran demonstrated that a leadership style that promotes an ethical climate has the ability to enhance OCBs. This indicates that when nurses perceive their leaders as ethical and morally upright, they are more likely to exhibit behaviors that benefit the organization as a whole.

Furthermore, the study by López-Ibort et al. [44] in Spain, which included nurses and supervisors from nine public hospitals in the autonomous community of Aragon, revealed that a leadership style that fosters quality nurse-supervisor relationships encourages OCBs among participants. Rimatanti et al. [45] also found a positive and significant effect of transformational leadership on OCBs

TABLE 2: Descriptive statistics of the study variables.

The study variables	Min-max	Mean \pm SD
Transformational leadership	1.14–4.86	3.38 \pm 0.74
Psychological empowerment	1.42–4.67	3.40 \pm 0.64
Meaning	1.00–5.00	3.53 \pm 0.83
Competence	1.00–5.00	3.37 \pm 0.84
Self-determination	1.00–5.00	3.40 \pm 0.87
Impact	1.00–5.00	3.32 \pm 0.84
OCBs	1.67–4.92	3.54 \pm 0.53

OCBs: organizational citizenship behaviors/*** $p < 0.001$.

among a purposive sample of nurses in Indonesia. Similarly, Hall [46] conducted a study among registered nurses in the United States and found that leadership skills play a crucial role in promoting OCBs. Moreover, transformational leadership in nursing unit managers improves nurses' empowerment, performance, job satisfaction, and organizational commitment [47]. However, it is important to note that the study by Kim [48] in South Korea found no significant influence of transformational leadership on OCBs among employees of the Gwangju Metropolitan City government. This discrepancy may be attributed to cultural or contextual differences between the nursing context and the government setting.

The study findings revealed that transformational leadership had a significant and positive relationship with psychological empowerment, supporting H2. This implies that transformational leaders foster supportive and inclusive environments that prioritize the growth and development of

employees. In such environments, individuals feel valued, acknowledged, and supported in their personal and professional journeys. These elements significantly contribute to the enhancement of employees' sense of competence, autonomy, and self-determination, which are fundamental aspects of psychological empowerment [49]. Moreover, transformational leaders actively engage in coaching and mentoring behaviors, offering valuable guidance and feedback that aid in the skill-building and confidence-boosting processes of employees. This, in turn, further strengthens their overall sense of empowerment [50].

These findings are consistent with the meta-analysis study conducted by Schermuly et al. [22], which investigated the effects of various leadership styles on psychological empowerment. Their study found that transformational leadership contributes to psychological empowerment. Additionally, the Chinese study by Hua et al. [51] revealed that nurse managers who adopt

a transformational leadership style enhance psychological empowerment among nurses. The mediation study of Zhang et al. [52] found that transformational leadership had a positive and significant impact on psychological empowerment.

The findings of the present study showed that psychological empowerment has a positive and significant impact on OCBs among nurses, supporting H3. This may be due to psychological empowerment is associated with higher levels of job satisfaction and organizational commitment among nurses, which further encourages them to exhibit OCBs as a form of positive citizenship behavior that enhances the overall effectiveness and success of the organization [53, 54]. Our findings are supported by the study of Turnipseed and VandeWaa [55] that was carried out among nurses in a medium-size urban general hospital and revealed that there are differential relationships between the dimensions of psychological empowerment and the dimensions of OCBs. Also, the meditation study of AlHammadi and Elanain [12] revealed that psychological empowerment had positive and direct impact on OCBs. Moreover, Jafari et al. [29] found that psychological empowerment associated positively with positive organizational behavior among nurses working in university hospitals affiliated to the Kermanshah University of Medical Sciences in Iran.

Our findings revealed that psychological empowerment mediates the relationship between transformational leadership and OCBs among nurses, supporting H4 and indicating that transformational leaders may foster a work environment where nurses feel empowered to contribute positively to the organization, leading to increased OCBs. These findings in the same line with the study of Saira et al. [8] revealed that transformational leadership positively impacts employee outcomes like OCBs and turnover intention through increased psychological empowerment. Similarly, in north-eastern United States, Dust et al. [56] found that psychological empowerment mediated relationships between transformational leadership and employee task performance and OCBs. Moreover, Cheng et al. [25] showed that transformational leadership shows positive and negative effects on deep acting and surface acting, respectively. The positive effect on deep acting is partially mediated by psychological empowerment, while the negative effect on surface acting is fully mediated by psychological empowerment. The study of Shapira-Lishchinsky and Benoliel [57] found that nurses' psychological empowerment and their head nurses' authentic leadership positively impact their OCBs, tardiness, absenteeism, and intent to leave the hospital. The study of Han et al. [58] indicates a significant direct effect of transformational leadership on psychological empowerment, organizational commitment, and OCBs. Moreover, transformational leadership also shows an indirect effect on employees' OCBs, which, in turn, is identified as the primary factor that influences knowledge sharing among employees of five large companies in South Korea. Huang et al. [59] found that psychological empowerment positively mediated the relationships between both transformational and contingent reward leaderships and organizational commitment among university members in China.

Moreover, psychological empowerment plays a crucial role in the relationship between transformational leadership and positive consequences in nursing context. For instance, the investigation of Masood and Afsar [60] found that transformational leadership fosters innovative work behavior among nursing staff by increasing psychological empowerment, intrinsic motivation, and knowledge sharing behavior. Also, the study of Zhang et al. [52] found that transformational leadership and psychological empowerment significantly improve nurses' innovative behavior during the COVID-19 pandemic.

5. Conclusion

In conclusion, his study emphasizes the role of psychological empowerment as a mediating factor in the relationship between transformational leadership and OCBs among nurses. It underscores how leadership styles shape organizational culture and employee behaviors. Organizations that prioritize and nurture transformational leadership are positioned to witness increased levels of voluntary, positive behaviors, which ultimately enhance the overall success and well-being of the organization.

5.1. Limitations of the Study. This study is limited in its scope to a specific setting and a distinct group of nurses, which may restrict the generalizability of the findings to other healthcare contexts, nursing professions, or diverse healthcare professionals. Therefore, future research should aim to replicate the current study in diverse healthcare settings and among different healthcare professionals to assess the generalizability of the observed relationships. The utilization of a cross-sectional design captures only a snapshot of the relationships at a specific moment, cautioning against drawing causal conclusions. To gain more insight into the causal dynamics over time, longitudinal studies could be employed. Additionally, supplementing self-reported data with objective performance measures or supervisor ratings would enhance the validity of the study. The reliance on self-reported data through questionnaires introduces the potential for response bias, as participants may provide socially desirable answers or not fully reflect their actual behaviors. To address this limitation, incorporating a mixed-methods approach that includes qualitative insights could provide a more comprehensive understanding of the subjective experiences of nurses and leaders. Lastly, conducting intervention studies focused on leadership training programs may offer practical insights into enhancing transformational leadership behaviors and their subsequent impact on psychological empowerment and OCBs.

5.2. Implications of the Study. Nurse managers should cultivate and strengthen their transformational leadership behaviors to empower nurses psychologically, thereby fostering a positive workplace culture and promoting OCBs. To achieve this, the development of training programs focused on enhancing psychological empowerment among nurses is

recommended. These programs should emphasize the significance of nurses' roles, provide opportunities for skill development, and promote autonomy.

Data Availability

The data that support the findings of this study are available on reasonable request from the corresponding author.

Conflicts of Interest

The authors declare that they have no conflicts of interest regarding the research, authorship, and/or publication of this article.

Acknowledgments

The authors would like to thank the Deanship of Scientific Research at Shaqra University for supporting this work.

Background and Purpose. Nursing theory can provide a framework for analyzing and solving problems in nursing research, nursing management, nursing education, and clinical nursing. The development of nursing theory has been more than one hundred years and has gradually developed mature. However, no bibliometric analysis has been conducted on nursing theory. *Methods.* This study adopted bibliometric approaches and analyzed the nursing theory research literature included in the Web of Science database during the 33 years between 1990 and 2022 using VOSviewer software. The source countries and regions, subject categories and distributions of institutions/units, journals, and highly productive authors of 23,180 nursing theory publications from the past 33 years were analyzed. The top ten funding agencies of nursing theory literature were also analyzed. Cluster and topic evolution analyses were performed on high-frequency keywords in nursing theory literature. *Results.* Historical trends in nursing theory were explored based on the number of articles published each year. The authoritative academic journals of nursing theory were identified based on the number of articles published, and the leaders of nursing theory and their academic research teams were identified based on the authors and their institutions. Moreover, the research hotspots and development trends in nursing theory were explored based on keyword clustering and topic evolution analysis. Thus, it is helpful to guide nursing practice and effectively solve nursing problems in nursing management. *Conclusion.* Research on nursing theory has been increasingly applied in clinical practice and tested or verified through clinical interventions in treating diseases. Theoretical research is inseparable from the development of nursing education. Moreover, research methods should be specific and diverse. Further improvement of theories depends on patient-centered clinical practice. Therefore, this study plays an important role in the continuous enrichment and development of nursing theory, which is conducive to further promoting the progress of nursing management and nursing discipline.

1. Introduction

Nursing theory can function as a description, an explanation, guidance, or a prediction. Specifically, it can describe situations in nursing disciplines, explain relationships between phenomena, guide nursing practice, and predict nursing outcomes. Moreover, it may also provide a framework for analyzing and solving problems in nursing research, nursing management, nursing education, and clinical nursing [1]. Nursing theory has been developed for over a century, and relatively mature nursing theories, construction ideas, and methods have been established [2].

Bibliometrics visualize research results through literature analysis and bibliometric mapping to identify major trends in research development. As an effective tool for Big Data processing, bibliometrics has been widely applied in qualitative assessments of the development status and academic influence of a specific field [3]. However, no systematic bibliometric analysis of literature related to nursing theory has been conducted.

The Web of Science (WoS) database has adopted a set of strict selection procedures and an objective evaluation process. It includes the most authoritative and influential scholars, journals, and literature in various disciplines.

Moreover, it clearly demonstrates a division of disciplines. Therefore, this study analyzed relevant literature on nursing theory research from the past 33 years, using the WoS database and the visualization analysis software VOSviewer, to understand the growth patterns, research hotspots, and development trends of nursing theory research publications worldwide, which can serve as a reference to promote clinical nursing theory research.

2. Data and Methods

2.1. Data Source. WoS is the largest academic literature database covering the largest number of disciplines in the international academic community [4]. The journals included in the Science Citation Index Expanded (SCI-E) and Social Science Citation Index (SSCI) are mainly based on their impact factor (IF), which reflects the average citation frequency of journal articles. However, the journals included in the Arts and Humanities Citation Index (A&HCI) are based on the peer review results of major scholars in related disciplines worldwide. Therefore, the WoS core collection (SCI-E, SSCI, and A&HCI) database was selected, and an advanced search was performed. The search formula was set as TS=(nursing OR nurse OR nurses OR care OR caring) and TS=(theory OR theories); language type: English; document type: article & review; and time range: January 1, 1990–December 31, 2022 (retrieval date was January 6, 2022). In total, 44465 pieces of bibliographic information were downloaded. The downloaded bibliography was imported using NoteExpress software, and the duplicate content-checking function was used to remove duplicate documents. Incomplete bibliographies, character profiles, hospital or institution introductions, manuscript appointments, and documents with irrelevant research topics were eliminated after two investigators read the titles, abstracts, keywords, and other information, resulting in a final total of 23,180 documents. Data collection flow chart is shown in Figure 1.

2.2. Analysis Methods. The bibliometric analysis approach is based on bibliometrics theory and uses the literature information in the research field for analysis and investigation. This approach is currently widely applied in scientific research that uses existing literature as the research object. VOSviewer is a visualization tool for creating network diagrams that can perform quantitative analysis of literature and draw visual diagrams to reveal research hotspots and trends in a certain field. Each node in the visualization map represents a cited keyword, and the size of the node indicates the citation frequency. Connections between two nodes indicate the cocitation of a keyword, and the connection's thickness reflects the strength of that link. The distance between two nodes indicates a correlation in the co-occurrence network.

3. Results

3.1. Number of Publications and Cumulative Publications on Nursing Theory. In the past 33 years, 23,180 articles related to nursing theory have been published and included in the WoS database. Figure 2 shows the general trend. In 1990, the

database included only two publications, which increased to 154 articles by 1995, while the number of publications declined in 1996 and 1997. Compared with the number of publications in 1997, the number was higher from 1998 to 2011. During this period, the number of publications increased yearly until it reached 849 in 2011 and then fell again in 2012. In 2013, the number of publications gradually increased again, reaching its highest point in 2021, with an annual publication volume of 2177 articles and 1880 articles in 2022, which, despite being slightly lower than 2021, was still over twice the volume of ten years prior.

3.2. Distribution of Country (Region) of Nursing Theory Literature. A total of 130 countries (regions) had publications on nursing theory, with relatively concentrated distribution (Table 1), mainly in North America and Europe, such as the United States, the United Kingdom, Canada, and the Netherlands, as well as Australia. The United States provided 8,745 published articles, far exceeding other countries and accounting for 37.73% of the total publications. The United Kingdom, Canada, Australia, and the Netherlands accounted for approximately 13.95%, 8.81%, 7.56%, and 3.59% of the published articles, respectively. Regarding the number of published articles, the top five countries accounted for 71.64% of the total number of publications in nursing theory. A total of 808 articles on nursing theory were published in China (ranking sixth overall).

3.3. Subject Categories in Nursing Theory Publications. The published literature related to nursing theory included a total of 141 disciplines, with 12730 publications involving one discipline, 7983 publications involving two disciplines, 1710 publications involving three disciplines, and 99 publications involving four disciplines (Table 2). Among all the included disciplines, the top five were nursing, health care sciences and services, public, environmental, occupational health, psychology, and medicine general internal, as shown in Table 3.

3.4. Distribution of Institutions (Units) of Nursing Theory Publications. A total of 753 institutions (units) have published literature on nursing theory, and the top 30 institutions (units) and their cumulative number of publications are shown in Table 4. Most of the top 20 institutions in terms of publication volume were from the United States, the United Kingdom, Canada, and Australia. The University of Toronto and University of Alberta in Canada ranked highest, with 128 and 109 articles, respectively, followed by the University of Washington, University of North Carolina, University of California, San Francisco, and University of Michigan.

3.5. Journal Distribution of Nursing Theory Publications. The 23,180 research articles on nursing theory were published across 204 journals. The top 30 journals are listed in Table 5. The *Journal of Advanced Nursing* (IF 3.057) had the largest collection of nursing theory-related articles, with 985

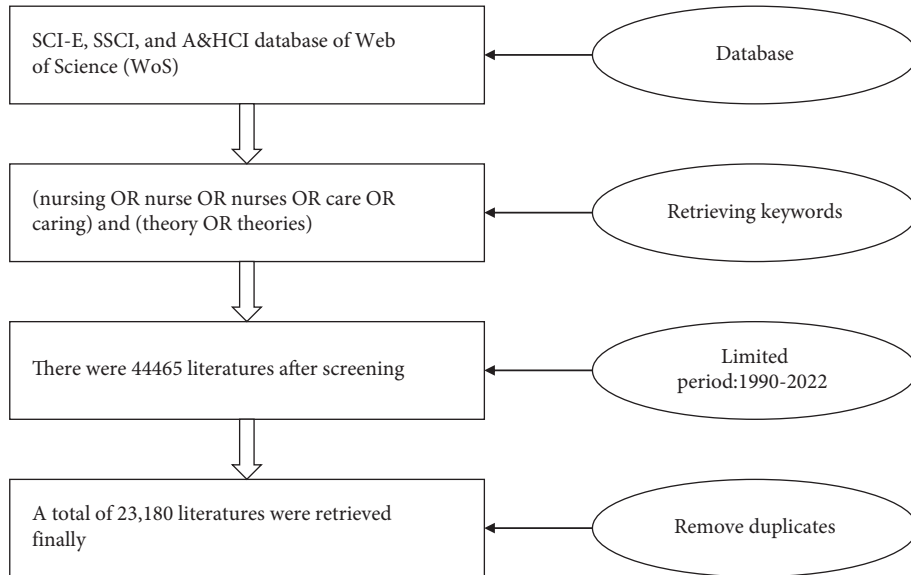

FIGURE 1: Flow chart of data collection.

FIGURE 2: Number of publications and cumulative number of publications on nursing theory in the WoS database from 1990 to 2022.

articles published in 33 years. This was followed by the *Journal of Clinical Nursing*, *Nurse Education Today*, and *BMC Health Services Research*, each with collections of over 450 relevant publications, with IFs of 4.423, 3.906, and 2.908, respectively. According to Bradford’s law [5] (i.e., if the journals are divided into three levels based on the number of publications on a certain subject within a certain period of time to make the number of relevant papers contained in each level equal, that is, exactly equal to one-third of the total number of articles on this subject published in all journals), it can be seen that the articles at the first level (core level) came from n1 journals, which are small in number but with

the highest efficiency. After calculation, the core journals publishing articles on nursing theory were the top 30 journals, which included 7,766 related articles, accounting for approximately 33.50% of the total number of articles.

3.6. *Distribution of Highly Productive Authors in Nursing Theory Publications.* A total of 57,853 authors were included in the publications on nursing theory, and Table 6 lists the top 20 most active authors. The most productive author of research articles on nursing theory was France Légaré from the Department of Family Medicine and Emergency Medicine, Laval University, Canada, who has published 31

related articles, followed by Jeremy M. Grimshaw from the Faculty of Medicine, University of Ottawa, Canada, who has published 28 articles, and Susan Michie from the Department of Clinical, Educational, and Health Psychology at the University College London; Marie Johnston from the Health Psychology Group at the University of Aberdeen; and Barbara Riegel from the School of Nursing at the University of Pennsylvania, who have all published more than 20 related articles. An analysis of cooperative research of the top 80 authors is shown in Figure 3. Most authors shared connections, indicating the establishment of cooperative relationships with a small number of noncollaborators around the cooperative network [6]. The closeness of the cooperative relationships between authors can be seen from the network density. The top ten most highly productive authors all had collaborators, indicating the vital importance of cooperation between researchers.

3.7. *Top 10 Funding Organizations for Publications on Nursing Theory.* Scientific research funds may significantly promote the development of health care, and the funded research articles may reflect the latest scientific research level to a certain extent and are highly informative documents. The science funding system has become a strong driving force for the rapid development of nursing research, has produced excellent output, and has contributed greatly to scientific research articles [7]. Among the 23,180 publications related to nursing theory, 18,966 were funded, involving 197 funding categories in total. Table 7 shows the top ten funding agencies. The US Department of Health and Human Services funded the largest number of nursing theory publications, followed by the US National Institutes of Health, Canadian Institutes of Health Research, National Natural Science Foundation of China, and UK National Institute for Health and Care Research.

3.8. *Co-Occurrence Analysis and Coword Clustering Analysis of High-Frequency Keywords in Nursing Theory Publications.* Coword clustering is a multivariate statistical method that measures the relationships between data and provides classifications based on similarities between index data. According to bibliometrics principles, no uniform standards are placed on the number of high-frequency words in coword clustering analysis. Should the number of high-

frequency words be too small, it would be unable to reflect the structure of the subject. Conversely, a selection range that is too large would interfere with the analysis. At present, words with a cumulative frequency reaching approximately 40% of the total frequency are generally selected as high-frequency words [8]. In this study, 23,180 nursing theory-related publications in 33 years included a total of 47,365 keywords. After thorough consideration of expert advice and multiple adjustments, keywords with a frequency greater than or equal to 80 were selected (125 keywords) to plot the co-occurrence network of high-frequency keywords in nursing theory publications from 1990 to 2022 found on WoS (Figure 4). The research hotspots were summarized based on specific literature content, co-occurrence of high-frequency keywords, teaching experience, clinical experience, research experience, and the software's clustering function to ultimately obtain seven hotspots in nursing theory research from 1990 to 2022 as follows: primary health care, psychological ethics, social support, nursing intervention, nursing education and research, older people and chronic diseases, and quality of life (Table 8).

3.9. Topic Evolution of Nursing Theory Publications

3.9.1. 1990–2000. A total of 4047 keywords were identified. In this study, keywords (65) with a frequency greater than or equal to seven were selected to plot the co-occurrence network of high-frequency keywords in nursing theory

publications in WoS from 1990 to 2000 (Figure 5). The research hotspots were summarized based on specific literature content, co-occurrence of high-frequency keywords, teaching experience, clinical experience, research experience, and the software's clustering function to ultimately obtain 10 hotspots of nursing theory research from 1990 to 2022 as follows: psychology, ethics, family nursing, nursing outcomes, quality of life, primary health care, children and adolescents, nursing research, theoretical models, and cancer and chronic diseases (Table 9).

3.9.2. 2001–2011. A total of 14,367 keywords were identified. In this study, keywords (135) with a frequency greater than or equal to 20 were selected to plot the co-occurrence network of high-frequency keywords in nursing theory publications in WoS from 2001 to 2011 (Figure 6). The research hotspots were summarized based on specific literature content, co-occurrence of high-frequency keywords, teaching experience, clinical experience, research experience, and the software's clustering function to ultimately obtain 15 hotspots of nursing theory research from 2001 to 2011 as follows: health promotion, nurse decision-making, evidence-based practice, methodology, long-term care, parental care, women's health, home-based care, hospice care, older people, sexually-transmitted diseases (STDs), qualitative research, assessment, nursing practice, and philosophy (Table 10).

3.9.3. 2012–2022. A total of 30,457 keywords were identified. In this study, keywords (121) with a frequency greater than or equal to 40 were selected to plot the co-occurrence network of high-frequency keywords of nursing theory publications in WoS from 2012 to 2022 (Figure 7). The research hotspots were summarized based on specific literature content, co-occurrence of high-frequency keywords, teaching experience, clinical experience, research experience, and the software's clustering function to ultimately obtain eight hotspots of nursing theory research from 2012 to 2022 as follows: patient-centered, grounded theory, psychological ethics, nursing education, nursing intervention, nursing theory, quality of life, and aging (Table 11).

4. Discussion

4.1. *International Research on Nursing Theory Has Been Active.* Nursing is an interdisciplinary subject [9]. The number of publications related to nursing theory has shown an annual increase in recent years, with nearly 10,000 nursing theory publications involving more than two disciplines. The top eight journals with the highest number of publications are the *Journal of Advanced Nursing* (IF 3.057), *Journal of Clinical Nursing* (IF 4.423), *Nurse Education Today* (IF 3.906), *BMC Health Services Research* (IF 2.908),

Social Science & Medicine (IF 5.379), *Nursing Science Quarterly* (IF 0.833), *Qualitative Health Research* (IF 4.233), and *BMJ Open* (IF 3.007), with a cumulative percentage of 19.38%. The latest research findings of nursing theory may be learned and drawn on by paying more attention to these journals.

4.2. *The United States Has the Leading Nursing Theory Research Globally.* Foreign research institutions with publications on nursing theory were mainly found to be in economically developed countries, such as the United States and some European countries. Over 90% of the top 20 most highly productive authors were from universities and affiliated teaching hospitals. Over one-third of the foreign nursing theory research articles were from the United States. These publications received the most funding from the United States Health and Human Services Department and the National Institutes of Health, showing that the nursing theory research in the United States is at the forefront of the world, leading the developmental trends in nursing theory today.

4.3. *Cooperative Research Will Be the Trend for Future Nursing Theory Studies.* Scientific research cooperation is an effort that can significantly improve scientific research capacity without much investment and has become the mainstream method of social science research today. This study's results show that highly productive authors generally have collaborators, indicating the importance of cooperation among researchers.

4.4. *Cluster Analysis of High-Frequency Keywords Revealed That Nursing Theory Research Tends toward Focusing on Clinical Application and Verification.* Keywords are the natural language that reflects the core content of research. The more keywords appear in a document, the more the main research content can be represented. The more the number of co-occurrences of two high-frequency keywords, the stronger the association between the two. After clustering, the keywords may further reflect the focus of the research field and the academic topics in which researchers are interested.

We summarized the research hotspots based on the specific literature content and keyword cluster analysis. Finally, seven hot categories of nursing theory research from 1990 to 2022 formed, including primary health care, psychological ethics, social support, nursing intervention, nursing education and research, older people and chronic diseases, and quality of life. Nursing theory research has also focused on psychological ethics and social support on top of meeting patients' most basic primary health care requirements. There is more and more research on nursing theories, and a variety of nursing theories have been formed, such as Oram's self-care theory, Erickson's psychosocial development theory, and Piaget's cognitive development theory, which effectively guide clinical nursing practice and have been verified and tested in the process of clinical

nursing practice. In the 21st century, many countries have become aging societies, and nursing theory has also often been applied in the care of older people and chronic diseases to improve patients' quality of life. Theoretical research is inseparable from the development of nursing education. Further improvements in theory will require more research based on clinical practice.

From 1990 to 2000, there were 10 research hotspots related to nursing theory, including psychology, ethics, family care, care outcomes, quality of life, primary health care, adolescents, nursing research, theoretical models, and cancer chronic diseases. From 2001 to 2012, nursing theory research formed

fifteen research hotspots, including health promotion, nurse decision-making, evidence-based practice, methodology, long-term care, parental care, women's health, home care, hospice care, the elderly, sexually transmitted diseases, qualitative research, assessment, nursing practice, and philosophy. From 2013 to 2022, eight research hotspots related to nursing theory have been formed, including patient-centered, grounded theory, psychological ethics, nursing education, nursing intervention, nursing theory, quality of life, and aging. In terms of the research object, theoretical research has evolved from children and adolescents at the beginning to women's health and has recently moved its focus to application among older

7	Quality of life	Breast cancer, quality of life, rehabilitation, older adults, dementia, disability, depression, quality of care, stroke, long-term care, psychometrics, anxiety
8	Aging	Parenting, parental care, decision-making, aging, parents, recovery

5. Conclusions

In summary, bibliometric methods and VOSviewer software were used in this study to analyze the literature in English on nursing theory included in the WoS database during the 33 years between 1990 and 2022. Historical changes in nursing theory were explored based on the annual number of publications, and the authoritative academic journals of nursing theory were identified based on the number of articles published. Moreover, the leaders of the theoretical discipline and their academic research teams were identified according to the authors and institutions. Moreover, the research hotspots and developmental trends of nursing theory were explored based on keyword clustering and topic evolution analysis. Nursing theory research has been increasingly applied to clinical practice and tested or verified through disease intervention. The theoretical research is inseparable from the development of nursing education. The methodologies of theoretical studies should be specific and diversified. Further improvement in nursing theory requires patient-centered clinical practice [10]. Therefore, according to the suggestions and guidance of nursing theory and nursing practice in this study, the advancement of this study will be very conducive to improving and enhancing nursing management and thus has vital guiding significance for the nursing discipline.

Orientation. Trust is the central part of leadership and organizational culture and can often go unnoticed until it decreases. There is a lack of a comprehensive concept analysis of trust in the healthcare setting. *Research Purpose.* The research aim was to gather, assess, and synthesize previous empirical evidence from the field of healthcare about the concepts of trust in the leader and trust in the organization. *Motivation for the Study.* To create a comprehensive and generic concept analysis of trust in the leader and organization for the healthcare sector based on recent empirical studies. *Research Design and Method.* A concept analysis, which followed the method presented by Walker and Avant, was conducted as a systematic review that adhered to the PRISMA guidelines. A total of eight databases were searched for relevant literature and 42 articles were included. *Main Findings.* The definitions of trust in the leader and the organization were based on emotion and cognition. Trust in the leader emerged as a core feature of collaborative leader-employee relationships, whereas trust in the organization was a key construct of organizational functioning. Trust in the leader and the organization contributed to commitment, increased work production, enhanced collaboration, and improved workplace well-being. Defense mechanisms were identified as a new contrary concept, while justice was found to be a related concept. *Contribution.* Both trust in the leader and trust in the organization positively impact an organization, nurse leaders, and employees. Deeper knowledge of trust and its attributes will be critical to the operationalization and estimation of levels of trust in healthcare organizations. *Managerial Implications.* Trust in the leader and the organization can significantly influence the attractiveness of an organization, retention of personnel, productivity, and work-related well-being. Thus, this aspect should be measured and developed systematically while acknowledging the antecedents of trust building.

1. Introduction

Healthcare organizations constantly face strategic and operational changes due to various challenges, e.g., workforce shortages, inequalities in service coverage, and policy discrepancies [1]. At the same time, the general population is characterized by health inequalities, unmet health care needs, and demographic ageing [1, 2], factors which have considerably increased the amount of people with multiple health problems [3]. Responding adequately to these challenges requires healthcare reforms that involve innovative solutions

concerning the provision of patient-centered, high-quality care [2]. A crucial part of this is ensuring that all individuals, regardless of social challenges or characteristics such as financial situation, place of residence, age or multimorbidity, have equal access to healthcare [2, 4].

Leaders in organizations are tasked with maintaining service continuity in various situations and supporting the workforce through changes in service provision [5]. As such, a comprehensive assessment of leadership competencies is a prerequisite for healthcare reforms [6]. Strong leadership competencies translate into decreased change resistance,

which is inevitable during the implementation of reforms [7]. In addition to change leadership [8], along with visionary and encouraging leadership [9], leaders need to be well versed at developing and maintaining strong collaborative relationships with different stakeholders [6, 10, 11]. All of these aspects highlight the significance of trust in both the leadership and organization [12]. Trust is such an apparent part of leadership and the organizational culture that it often goes unnoticed until it decreases [13]. Thus, leadership should be periodically assessed, as well as measured prior to any large organizational changes as it has various positive effects [9, 13]; notably, increased cost-effectiveness [14], improved ethical competence [15], and work engagement among employees [16], along with enhanced overall quality of patient care [17].

The concept of trust is a topic of interest in several scientific disciplines, e.g., psychology, sociology, nursing, medicine [18], religion, philosophy, and business [19]. As such, it is unsurprising that trust is approached through several definitions and dimensions depending on the field of science [17, 19]. We identified three previous articles [17, 19, 20] that describe trust in the context of nursing. The oldest article, published in 2011, is a literature review that includes 20 studies published between the years 2002 and 2008 and limited to critical care. The results revealed that most of the published studies focused on trust within the nurse-patient relationship, with none of the articles describing relationships among healthcare staff [17]. Another article, published in 2014, presented the results of a concept analysis. The study material included interviews with 28 nurses and 11 nurse managers working in acute and community care. However, the analysis focused solely on the antecedents, attributes, and consequences of trust, while various definitions and related concepts were not considered [20]. Most recently, trust was approached by using concepts from other disciplines, e.g., arts or business, by employing Watson's theoretical perspective. The provided examples centered around the nurse-patient relationship as a helping-trusting relation, while the relationships between leaders and nurses were not assessed [19]. Thus, there is a limited amount of studies on trust from the healthcare setting. Furthermore, the studies that do exist are based on historical data and do not provide a comprehensive view of the concept of trust for the healthcare sector. This highlights the need for a comprehensive concept analysis on the issue of trust within healthcare. Furthermore, the nurse-patient relationship starkly differs from the nurse-nurse leader relationship, as well as the relationship between a nurse and the organization, due to imbalances in hierarchical power. Trust can be regarded as a dynamic social construct that changes over time [19]; this further proves that the empirical literature on trust in the healthcare sector needs to be updated. The present article fills this research gap by presenting a concept analysis of trust that is based on the systematic review of empirical data and performed according to the method introduced by Walker and Avant [21]. The present review identified empirical studies that described trust in leaders and/or healthcare organizations

with the underlying goal of developing an instrument for future studies. Even when leadership and the organization are closely intertwined, essential differences exist between them; thus, the contents and features of these two concepts have been differentiated.

The aim of this study was to gather, assess, and synthesize previous empirical evidence from the field of healthcare about the contents and characteristics surrounding the concepts of trust in the leader and trust in the organization. The research was performed under the guidance of the following questions:

- (1) How are the concepts of trust in the leader and trust in the organization described and defined and what kind of attributes have been associated with these concepts in empirical research?
- (2) Which antecedents and consequences of trust in the leader and trust in the organization have previously been identified?
- (3) What kinds of borderline, related, and contrary cases of trust in the leader and trust in the organization have been identified?

2. Materials and Methods

2.1. Design. A concept analysis based on a systematic review was conducted according to the PRISMA checklist [22] (Supplementary table 1) and the method presented by Walker and Avant [21].

2.2. Search Methods. A systematic literature search was conducted in March 2021 and updated in January 2024; the search was performed across the following eight databases: Medic; PsycINFO; MEDLINE (Ovid); SocIndex; PubMed; CINAHL; Web of Science; and Scopus. The search strategy was created in collaboration with an information specialist. The search terms (Table 1) covered trust-related terms in both Finnish and English that were combined by using Boolean operators. The inclusion and exclusion criteria are presented in Table 1, and the searches were limited to peer-reviewed articles published between March 2010 and December 2023 in Finnish or English.

The search yielded a total of 9,201 titles that were moved to RefWorks, after which the results of the updated search were transferred into Covidence. Following duplicate removal ($n = 2,308$), a total of 6,893 titles were independently screened by two researchers (VK and JR). Next, the abstracts ($n = 383$) of relevant articles were independently screened by two researchers (VK and JR), after which the results were compared. Consensus was achieved by discussion, and a third researcher (AT-M) was consulted when a consensus could not be reached. A total of 145 full-text articles were assessed for eligibility. The final data include 44 original articles (Figure 1). The results of the selection process were discussed with two other researchers (AT-M and AH-L), who provided an additional assessment of the relevance of chosen articles [23].

TABLE 1: Search strategy.

Databases	Search terms	Inclusion criteria	Exclusion criteria
Medic PubMed Scopus Web of Science CINAHL PsycINFO SocINDEX MEDLINE (Ovid)	luottamu* AND terveydenhuol* trust* AND "healthcare" AND (leadership OR management) AND NOT (patient* OR client*)	(i) Trust in the leader or in the organization (ii) Context of healthcare (iii) Empirical study designs	(i) Trust not defined (ii) No empirical evidence of trust (iii) Trust outside the leader or the organization (iv) Other context than healthcare (v) Reviews or meta-analyses (vi) Low quality of articles

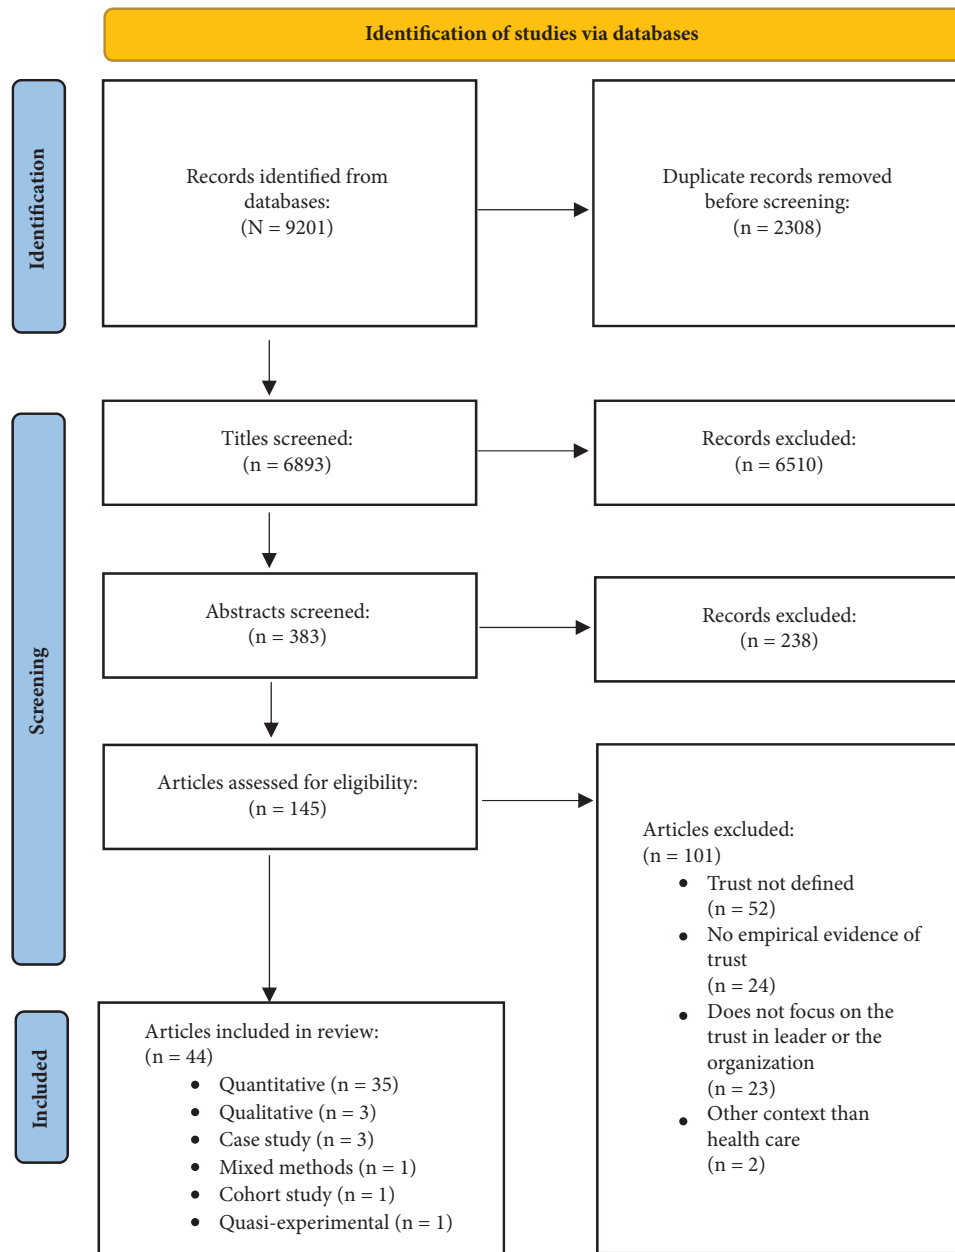

FIGURE 1: PRISMA flowchart of search results [22].

2.3. Quality Appraisal. The quality of all of the included studies was independently evaluated by two researchers (VK and JR) according to a checklist from the Center for Evidence-Based Management [24] (Supplementary table 2). The cutoff point for acceptance was set at 50% of the possible points [25].

A cross-sectional checklist (12 items) was used to appraise the quality of quantitative studies. The strengths of these studies included a clear research frame, solid methods, application of reliable instruments, and a clear presentation of the results. However, confounding factors were sparsely presented, which was assessed as a weakness. Articles which reported case studies, along with one mixed methods study, were assessed by the case study checklist (10 items). The

strengths of these studies were clear descriptions of settings, data collection, and credible outcomes, whereas unclear descriptions of the researchers' roles and analytical methods emerged as weaknesses. The qualitative checklist (10 items) was employed to appraise the quality of interview studies. The strengths of these studies included clear descriptions of study design, context, fieldwork, and outcomes. The most common weakness of the included qualitative studies was insufficient description of researchers' contributions and roles. The quality of the quasiexperimental study included in this review was appraised using the checklist of a controlled study (12 items); the checklist of a cohort or panel study (12 items) was employed to assess the quality of the one identified cohort study. The strengths of these studies

included strong methods and sufficient sample size as was the case in quantitative studies, and missing descriptions of confounding factors were assessed as the primary weakness.

Following the independent assessment of article quality, the two researchers (VK and JR) discussed their findings and consulted a third researcher (AT-M) in the case of any disputes. As a result of the quality assessment, two articles [26, 27] were excluded from the review due to a low level (<50%) of accrued points [25]. Thus, the review included a total of 42 articles.

2.4. Data Extraction, Concept Analysis, and Degree of Evidence. A matrix for the data extraction was developed for the purpose of this study. It included information about study design, aim, context, data collection, analytical method, and results concerning the concepts of trust. In the first phase of the analysis, the data were repeatedly assessed to identify any descriptions of trust in the leader and trust in the organization; this approach was in line with the concept analysis method presented by Walker and Avant [21]. The original expressions related to the research questions were condensed and then moved into the results section of the matrix. Next, condensed expressions of the definitions of trust in the leader and trust in the organization were compared according to their similarities and differences and then divided into three groups based on content. The condensed expressions concerning the attributes (Table 2) and antecedents (Table 3), along with borderline, related, and contrary cases as well as consequences (Table 4), of trust were then categorized into the following two groups: trust in the leader and trust in the organization. In the next step, the expressions were compared according to similarities and differences to identify sub, upper, and main groups. The identified groups were named according to their contents [69]. Lastly, the degree of evidence was evaluated to identify the essential main outcomes [70]. The strongest degree of evidence was indicated with A, consisting of meta-analyses, systematic reviews, and randomized control trials (RCTs). Degree B included cross-sectional studies, whereas C indicated studies with qualitative study design. The lowest degree of evidence was indicated with D, including observational designs. In addition, the study limitations, quality of results, and directness of evidence across different studies influenced the conclusion of the degree of evidence [70].

3. Results

3.1. Study Characteristics. The data consisted of quantitative surveys ($n=33$), qualitative interview studies ($n=3$), and case studies ($n=3$). In addition, one mixed methods study, one cohort study, and one quasiexperimental study were included in the data (Figure 1). All of the included articles were published between 2010 and 2023, with most ($n=32$) published after the year 2015. The studies were conducted in Turkey ($n=9$), the USA ($n=7$), Australia ($n=3$), South Africa ($n=3$), Canada ($n=3$), Finland ($n=2$), Norway ($n=2$), Pakistan ($n=2$), Spain ($n=2$), Sweden ($n=2$), Denmark ($n=1$), Iran ($n=1$), Israel ($n=1$), Korea ($n=1$),

and Nigeria ($n=1$). Moreover, two articles reported the results of a study that had been conducted in two countries, USA and England, as well as Finland and Norway (Supplementary table 3).

Of the identified studies, 24 focused on trust in the leader and 18 concerned on trust in the organization. The studies were mainly conducted in the context of public healthcare ($n=23$), while one study covered the private healthcare sector; three studies reported results concerning both the public and private healthcare sectors. It should be noted that 14 studies mentioned the healthcare context but did not clearly define it. In one of the included studies [62], the healthcare employees represented only 10% of the participants. A total of 29 articles reported employees' perspectives of trust, whereas four studies covered the leaders' perspective; both the perspectives of employees and leaders were described in nine articles (Supplementary table 3). Finally, the reference lists of the included studies were searched to determine the contents of the provided definitions. As a result, the definitions in the next section are based on original articles that were published outside of the time range included in the present review. The connection to the current data is presented in Supplementary table 4.

3.2. Definitions of Trust in the Leader. Trust in the leader was defined in 11 different ways, which could be divided into emotion-based and cognition-based trust. The emotion-based definitions described trust as the trustor's willingness to be vulnerable in a situation where they are performing an action which is important to them [71, 72]. In such situations, the leader or employee ventures into a position of interdependence [73], i.e., the trustor takes a risk of trusting the trustee without the ability to control their actions [71, 74, 75]. The emotion-based definitions of trust included reciprocal positive expectations of benevolence [71, 72, 74–77] in accordance with open interaction [73, 78]. The cognition-based definitions of trust were related to belief in the competence of the trustee [78, 79].

3.3. Definitions of Trust in the Organization. Trust in the organization was defined in 12 different ways, which could be divided into emotion based, cognition based, and predictability of the organization's functions. The emotion-based definitions included a trustor's willingness to be vulnerable when a group or organization performs an action that was important to the trustor [80–82]. Therefore, these definitions included trustees' positive feelings about organizational support and confidentiality [71, 83, 84]. The cognition-based definitions described the reciprocal expectation of competence and reliability [71] to promote mutual interests even in situations where the trustee could act based on self-interest [84, 85]. Trust in the predictability of the organization's functions was described as the integrity [86–88] and ethicality [89] of an organization's functions. In addition, trust was described as the trans-sectional presence of reciprocal trust across different organizational levels [81, 90].

TABLE 2: Attributes of trust in the leader and trust in the organization with references and level of evidence.

Attributes	Trust in the leader	Trust in the organization
The core collaborative leader-employee relationship	[28–34] Level of evidence: B	[35–43] Level of evidence: C
A key construct of organizational functions	[29, 30, 33, 34, 44–49] Level of evidence: B	[40, 41, 43, 50–52] Level of evidence: C
Positive expectations of benevolence	[29, 44, 48, 49, 53, 54] Level of evidence: B	[40, 43, 52, 55] Level of evidence: C
Social interaction	[34, 44, 45, 49] Level of evidence: B	
A leader's competence	[30, 33, 34, 45, 48, 56, 57] Level of evidence: B	
Risk and vulnerability		

TABLE 3: Antecedents of trust in the leader and trust in the organization with references and level of evidence.

Antecedents	Trust in the leader	Trust in the organization
Leadership skills	[30, 32, 44, 47, 49, 58, 59] Level of evidence: B	[36–38, 50, 55] Level of evidence: C
Consistent action	[28, 34, 44, 45, 48, 54, 59, 60] Level of evidence: B	
The role of employees		[37, 40, 52, 61] Level of evidence: C
Open interaction	[34, 44, 56, 60] Level of evidence: B	
Collaboration	[32, 34, 44, 48, 62] Level of evidence: B	

3.4. Attributes of Trust in the Leader. The attributes of trust in the leader could be described as the core collaborative leader-employee relationship, positive expectations of benevolence, social interaction, a leader's competence, and risk and vulnerability (Table 2). Descriptions of the core collaborative leader-employee relationship stated that trust is a critical foundation of all actions. Thus, it is recognized as a sensitive, reciprocal process that requires time to develop. Furthermore, it is considered a fragile construct that can be easily broken. The attribute of positive expectations of benevolence was described as the trustor's convictions about the trustee's motives, intentions, and actions. In other words, benevolence means that a trustee's ethical and moral actions are not based on self-interest. Moreover, a trustee's strategic actions are expected to lead to reciprocal benefits (Table 2).

According to the included articles, social interaction is realized as reciprocal and positive communication between the trustor and the trustee, whereas a leader's competence was described as the ability to lead, create a sense of security, and inspire employees through an expert role. As such, a leader's competence enables employees to demonstrate their professionalism and focus on their duties. The attribute of risk is based on the trustor's expectations that the trustee's actions or intentions cannot be controlled. Furthermore, trust creates a situation in which both parties (trustor and trustee) are willing to be exposed to reciprocal vulnerability (Table 2).

3.5. Attributes of Trust in the Organization. The identified articles included the following attributes of trust in the organization: a key construct of organizational functions; positive expectations of benevolence; and social interaction (Table 2). Trust, as a key construct of organizational functions, is an important tool in leading collaborative relationships and developing professionalism. It is also crucial for success across various organizational levels. The attribute of positive expectations of benevolence is related to situations in which employees trust that the organization will take care of employee well-being and problems. The attribute of positive expectations of benevolence describes how an employee functions within an organization, which includes interactions with the leader. Social interaction also included a leader's willingness to act honestly and predictably (Table 2).

3.6. Antecedents of Trust in the Leader. The antecedents of trust in a leader were leadership skills, consistent action, open interaction, and collaboration (Table 3). The leadership

style, which falls under leadership skills, favors collaborative relationships that advance trust, i.e., transformational, ethical, and authentic leadership. Trust could also be promoted by the appropriate use of different forms of power, namely, reward, legitimate, and referent power. Therefore, leadership skills were described through the readiness to modify leadership practices, for example, through actively informing and involving employees (Table 3).

Consistent action included a leader's benevolence, which includes the ability to identify employees' feelings. This attribute was described through a leader's ability to acknowledge the diverse and individual perspective of their employees. Furthermore, this attribute included the competent actions of consistent leaders, for example, ability to make decisions and motivate employees. A leader's presence manifests as authenticity, visibility, and integration into the work community, all of which support trust formation. Lastly, a leader's involvement, including employee encouragement, as well as employees' impact on planning processes or decision-making, was identified as antecedents of trust in terms of a leader's consistent action (Table 3).

Open interaction included knowledge sharing and the openness of the work community. Reciprocally, active listening, along with the provision of feedback and experiencing a connection through profound communication, were important to building trust and could be strengthened by a leader's positive attitude. In addition, collaboration consisted of commitment by both the leaders and employees, as well as reciprocal collectivity. Trust is built when there is responsibility in collaboration, i.e., each member of the team takes care of their own duties. Collaboration also includes employees' positive feelings about organizational actions, or—in other words—their ability to thrive at work (Table 3).

3.7. Antecedents of Trust in the Organization. According to the identified articles, the antecedents of trust in the organization are leadership skills and the role of employees (Table 3). Leadership skills, when considered in the context of the organization, include approaches such as authentic and transformational leadership. This can be extended to certain positive characteristics of an organization, such as stability, competence, honesty, and loyalty. The role of employees consists of employees' openness in sharing tacit knowledge. Therefore, this aspect was described through concepts such as work engagement, job satisfaction, and obsession with work performance. Moreover, this aspect includes employees receiving fair treatment and being committed to the organization both affectively and normatively (Table 3).

TABLE 4: Consequences of trust in the leader and trust in the organization with references and level of evidence.

Consequences	Trust in the leader	Trust in the organization
Commitment	[39, 40, 43, 44, 53, 54, 59] Level of evidence: B	[37, 40–43, 50, 63] Level of evidence: C
Increased productivity at work	[29, 30, 32, 44, 46, 48, 56, 58, 62, 64, 65] Level of evidence: B	[35, 36, 38, 42, 55, 66] Level of evidence: C
Increased collaboration	[44, 49, 57, 64, 67, 68] Level of evidence: B	[35, 42, 51, 61] Level of evidence: B
Increased workplace well-being	[29, 39, 44, 47, 65] Level of evidence: B	[41, 42] Level of evidence: C

3.8. Consequences of Trust in the Leader and Trust in the Organization. The consequences of trust in the leader and the organization consisted of commitment, increased productivity at work, increased collaboration, and increased workplace well-being (Table 4). When considered from the lens of trust in the leader, commitment to work was described as the commitment of the work community to the constant development of activities. As commitment is a reciprocal process, it can be categorized as affective, normative, and continuance organizational commitment. When shifting to trust in the organization, commitment was categorized into work and the organization. Additional definitions of organizational commitment stated that trust increases both continuance and affective commitment (Table 4).

When considering trust in the leader, increased productivity at work included better motivation and creativity to work, both of which increase innovativeness. For instance, work performance improved when a team or an individual successfully accomplished their work duties. In addition, trust in the leader increased leaders' and employees' experiences of efficiency. Furthermore, trust improved employee attitudes, which decreased cynicism towards changes. From the lens of trust in the organization, increased productivity at work included experiences of high-quality care and a concern for safe behavior. Furthermore, trust was found to increase the performance of a team, as well as organizational efficiency, productivity, and the conscientiousness of employees (Table 4).

In terms of trust in the leader, increased collaboration consisted of common goal orientation and shared decision-making. For instance, polite interactions between team members increased as employees felt encouraged to communicate with the leader, even about sensitive and/or confidential issues. Concerning trust in the organization, increased collaboration comprised good communication, cohesion, and an employee's ability to identify with the leader's values; the published research suggested that this makes clinical decision-making easier. Furthermore, this aspect of trust was described as an ethical atmosphere in which employees target common goals, are polite, and demonstrate selflessness (Table 4).

When considering trust in the leader, increased workplace well-being manifested as improved work satisfaction, especially among employees. Trust in the leader facilitates improvements in satisfaction with change processes and the organization. Furthermore, this aspect describes mental and physical health, which translates to safe overall behavior. From the lens of trust in the organization, increased workplace well-being improved job satisfaction among employees. Moreover, this trust enables employees to better manage their stress and perform high-quality work (Table 4).

3.9. Overview of the Main Results of the Concept Analysis. The antecedents, attributes, and consequences of trust in the leader and trust in the organization are presented in Figure 2, with the level of evidence specified for each finding.

The findings for trust in the organization showed lower levels of evidence when compared to findings for trust in the leader.

3.10. Borderline, Related, and Contrary Concepts of Trust in the Leader and Trust in the Organization. The borderline, related, and contrary concepts of trust in the leader and the organization included the same concepts, with the exception of defense mechanisms, which were a part of the contrary concept of trust in the leader. The psychological contract emerged as a borderline concept of trust because both concepts contained several joint attributes. At the same time, it was also seen as an antecedent of trust, as the psychological contract is based on reciprocal expectations of actions and keeping the promises of the trustee [44, 66]. Justice was identified to be a related concept of trust [52] as it is also part of the core of a healthy organization [59]. Furthermore, the concept of justice is embedded in the interactions that produce social welfare, as is trust [62]. Thus, interactional and distributive justice depends on the quality of the collaborative relationship when integrated into trust in the leader [60].

Distrust was recognized as a contrary concept to trust [34], with a lack of open communication and employees' perceptions of injustice exerting a negative influence on trust [31, 91]. Employees' experiences of betrayed promises, the inability to get involved in decision-making, and the lack of a leader's support enhance distrust [91]. Furthermore, defense mechanisms [46] emerged as a contrary concept of trust and described as the actions or thoughts that protect individuals, groups, or organizations when confronting unpleasant realities [48]. These unpleasant realities were described through decreased trust—mainly due to insufficient collaboration—and a lack of communication, both of which lead to situations in which the trustor is not willing to be vulnerable towards the trustee [48].

3.11. Model Case of Trust in the Leader and Trust in the Organization. A healthcare organization has recruited a nurse who will work in the ward. Another colleague introduces this nurse to the work. The colleague says, "Welcome to our ward and to our hospital. Here, we have warm, collaborative relationships with colleagues and especially with our leader (attributes: a key construct of organizational functions and a core of collaborative leader-employee relationship). I have learned to trust her because she always stands up for us and treats us fairly (attribute: positive expectations of benevolence). It is easy to talk to her, even about difficult things and feelings. She listens, seriously considers the issues we talk about, but also asks for our opinion (attribute: reciprocal social interaction). Our leader has a Master's degree (attribute: competence), but she is always willing to improve as a leader. She constantly asks us for feedback and wants to know what aspects she should develop further (attribute: vulnerability). Because of this, our

Trust in the leader			Trust in the organization

FIGURE 2: Antecedents, attributes, and consequences of trust in the leader and trust in the organization.

leader enables us to face our deficits, grow in our profession, and in that sense accept the risk of trusting each other (attribute: risk).”

The nurse continued, “This all is possible because the hospital invests in every level of the organization including employee well-being and keeps promises concerning professional development and employee involvement in decision-making (attribute: positive expectations of benevolence). The hospital strategy includes the following key values of leadership: open, honest, and predictable interactions (attribute: social interaction). Therefore, it is easy to expect that your leader will also behave in this way (antecedents: consistent action and open interaction). The hospital constantly educates leaders (antecedent: leadership skills) and develops forums for employee involvement (antecedents: the role of employees and collaboration).”

The nurse concluded, “Nurse turnover in the hospital and in our ward is the lowest in this city area (consequence: commitment). Our peers are innovative and work together efficiently (consequences: increased productivity at work and increased collaboration), and everyone demonstrates a positive attitude towards change without resistance (contrary concept: defense mechanisms). We do not have many absences from work (consequence: increased workplace well-being) and our hospital has been judged to be a fair workplace (related concept: justice). I appreciate this hospital a lot, as I have negative experiences with trust from previous workplaces. For example, one of my previous leaders had favorite employees and shared information with them that was withheld from the rest of us (contrary concept: distrust). We hope that you also share these values and can commit to the hospital (borderline concept: psychological contract).”

4. Discussion

To the best of our knowledge, this research represents the first concept analysis that is based on a systematic review of empirical studies and describes the concepts of trust in the leader and trust in the organization in the healthcare context.

Previous literature is characterized by limited descriptions of the concept of trust, most of which focus on either the nurse-patient relationship or a special context within healthcare; furthermore, other descriptions of trust are based on a single interview study [17, 19, 20]. The present study provides a comprehensive analysis of the concept that can be applied to the context of public healthcare. This concept analysis enhances the prevailing nursing literature by describing the definitions and characteristics of trust based on a systematic review of international literature. Furthermore, the topicality of the data in this study (published between 2010 and 2023) provides important insight into the current state and dynamic nature of trust between the leader, employee, and organization. Recent developments within healthcare, such as remote leadership, have caused trust to become recognized as one of the core factors of successful collaborative relationships [92].

The presented descriptions of trust in the leader emphasize the leader's role, whereas the identified components of trust in the organization mostly focus on the functioning of an organization. Trust in the leader was found to include more interactional elements, e.g., risk and vulnerability, than trust in the organization. Moreover, open interactions and collaboration were identified as antecedents of trust in the leader; this was not the case for trust in the organization. The similarities between the identified consequences of trust in the leader and trust in the organization mean that future research should focus on this content. Emotion- and cognition-based definitions were used to describe both trust in the leader and trust in the organization. Trust in the leader was found to be at the core of the leader-employee collaborative relationship and included positive expectations of benevolence, social interaction, the leader's competence, as well as risk and vulnerability. Trust in the organization was identified as a key construct of organizational functioning and also included positive expectations of benevolence and social interaction.

Based on the literature assessed in this review, trust in the organization has only received a limited amount of research attention, with most of the presented findings usually

characterized by weak evidence. Also, the borderline, related, and contrary concepts of trust in the leader and trust in the organization have only been covered in a handful of studies. The results concerning trust in the leader demonstrated the strongest overall level of evidence. The content analysis revealed that the definitions of trust could be divided into emotion- and cognition-based concepts, along with the predictability of organizational functioning. Nevertheless, this division was not possible for the attributes, antecedents, and consequences of trust in the leader and trust in the organization; thus, the concept of trust must be further examined in empirical healthcare environments. These results would be important to the eventual formulation of an instrument which could divide trust in healthcare organizations into leader- and organization-centric factors. It is important to note that the present review did not address trust in the client and trust in the coworker, which have also been recognized as important aspects in overall trust. Moreover, it has been found that the levels of trust in healthcare organizations, especially emotion-based trust, are rather low [93, 94]. As such, the presented results could be relevant to the development of healthcare as emotion-based trust was found to be firmly linked with the leader.

The presented results, which reflect empirical research, support the theoretical definitions of trust described in different disciplines of science [71, 78, 90]. Trust serves as one of the core pillars of an organization, with collaborative relationships—which include positive expectations of benevolence and interaction—typical of environments with high levels of trust. The presented results agree with what has been reported in previous concept analyses; nevertheless, there are also notable differences between the present review and prior research. For instance, Mullarkey and colleagues [17], along with McCabe and Sambrook [20], highlight the integrity, openness, and competence of a leader when discussing trust. Furthermore, Mullarkey and colleagues [17] emphasize that trust is a central driver of organizational success, expectations of behavior, as well as the presence of risk and dependence. In this study, risk and vulnerability, which involve a leader's competence, were linked with trust in the leader based on the analyzed studies. The results indicate that it is important to focus on these attributes to build trust both in the leader and in the organization.

The finding that leadership skills and the role of employees are antecedents of trust was supported by previous literature [17, 20, 95]. Destructive leadership was not extensively discussed in the included articles. This is logical because the research into this leadership style is sparse [96] and should be considered in further studies. There is some evidence from other disciplines that a leader's destructive behavior, for example, exercising coercion, invisibility, or impoliteness, will decrease trust [95, 97]. The identified antecedents highlight aspects which should hold a central role in organizational reforms that strive to achieve trust. For instance, reducing—and even possibly eliminating—destructive leadership is the key to building trust in the leader.

According to the research included in this review, integrity and workplace well-being are strong and clear consequences of trust in the leader and trust in the organization, a finding which mirrors previous concept analyses of trust [17, 20, 95]. As has been stated previously, trust positively affects individual well-being, the productivity of a team and its leader, as well as the quality of patient care [17, 20]. The finding that commitment is a consequence of trust is also supported by previous concept analyses [17, 95]. These consequences reinforce the importance of developing trust in the leader and in the organization.

4.1. Strengths and Limitations. The present study was influenced by several strengths and limitations. The primary strength of this study was that an extensive amount of data was collected from empirical research conducted in the healthcare context; these data provided broad answers to the research questions. Furthermore, the identified original articles mostly demonstrated sufficient quality, and the potential biases were acknowledged and described. More specifically, the identified original articles applied relevant methodologies and included adequate samples [98].

The level of evidence underlying the results presented in empirical studies included in this review was low due to the lack of randomized controlled trials; this can be regarded as a limitation of this study. Furthermore, determining valid, empirical reference definitions for trust was outside of the scope of this paper because it requires a qualitative approach; as such, this remains a challenge for future research. Nevertheless, the empirical example of a model case was included to strengthen the reliability of the presented results, according to the concept analysis method of Walker and Avant [21]. The fact that only one researcher performed the database searches decreased the trustworthiness of the research. Nevertheless, the other researchers supported the research process by assisting in searching for relevant knowledge and critically reviewing the formed concepts, with progression to the next study phase requiring a consensus. Furthermore, the conscious application of a negative term (not patient and client) in the Boolean operators might have removed some relevant outcomes from the search. Similarly, the decision to avoid gray literature could be considered a limitation [98].

5. Conclusions

The current review illustrates that there is a lack of concept analyses regarding trust in the leader and in the organization for the field of healthcare; there is a clear need for further empirical research into this phenomenon. Furthermore, the dimensions, definitions, attributes, antecedents, consequences, and other concepts of trust presented in this study need further clarification. There is far less data on trust in the organization, while the low level of evidence, determined via a clear methodology, necessitates further research. Furthermore, there is a need for an instrument that includes comprehensive descriptions of both concepts of trust, i.e., trust in the organization and trust in the leader. The

presented research is relevant because deep knowledge of trust and its attributes will be critical to the operationalization and estimation of levels of trust in healthcare organizations. Furthermore, the concept of trust is clarified when justice was identified as a new related concept to trust, while defense mechanisms represented a contrary concept. Hence, the presented findings could be used to develop interventions for building both trust in the leader and trust in the organization. It would be important to apply methodologies that can determine the organizational costs and effectiveness of these types of interventions.

6. Implications to Nursing Management

Trust in the leader and in the organization exerts significant consequences on the attractiveness of a certain organization, retention of personnel, productivity, and work-related well-being. Thus, it should be measured and developed systematically in a way that acknowledges the antecedents of trust building. The results of this concept analysis may be utilized in the development of such an instrument. Building and maintaining trust are strongly associated with open and honest communication and reciprocal interactions; these are aspects to which nurse leaders should focus on in their daily work. Organizations should support leadership practices that place interaction in the center of the concept, as this would be beneficial to both trust development and a psychologically safe organizational culture. More mentoring and education are needed in this regard. Furthermore, educational organizations may take the current results into account by planning and developing their curricula. In addition, the development of interventions that primarily aim to build and maintain trust, for instance, by preventing distrust and defense mechanisms, may be beneficial for healthcare organizations.

Data Availability

The data used to support the findings of this study are from previously reported studies, which have been cited.

Disclosure

The research was performed as part of the employment at the University of Eastern Finland and University of Turku.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

Open access funding was enabled and organized by FinELib 2023.

Supplementary Materials

Supplementary Materials include tables supplementing the research article. There is further information about the Materials and Methods, providing the PRISMA checklist of

the review process (Supplementary table 1) and the consensus of quality appraisal (Supplementary table 2). In addition, adhering to the Data section, there are summarized details about all reviewed articles (Supplementary table 3) and have tabulated the definitions of trust including in original articles (Supplementary table 4). Aim. To understand the current situation of upward bullying in the Chinese nursing field and explore the manifestations, reasons, and outcomes of upward bullying experienced by Chinese nurse managers. **Background.** Workplace bullying, a serious social problem, is characterised by recurring incidents of intimidating, aggressive, and hostile behaviour. Bullying in the nursing profession exhibits all or some of the above traits. The evidence of upward bullying by subordinate nurses against nurses in positions of authority or power is limited in China. **Methods.** This qualitative study was conducted with semistructured, in-depth interviews involving 12 hospital nurse managers in Wuhan, Hubei Province, between June and August 2023. The data were analysed using the Colaizzi seven-step analysis method with Nvivo 12.0 software as a support. **Results.** We grouped our findings into three main categories: manifestations of upward bullying; reasons for upward bullying; and outcomes of upward bullying. **Conclusions.** Nurse managers in China are exposed to upward bullying in many forms and for complex reasons. More emphasis needs to be given to creating a positive work environment for them to facilitate their managerial role. **Implications for Nursing Management.** This study probes the realities of upward bullying against Chinese nurse managers and highlights the need for managers to develop the skills needed to identify, manage, and prevent bullying from subordinates. By contributing to the development of interventions and strategies that address workplace bullying, this study shows promise for enhancing managerial effectiveness and improving the nursing practice environment.

1. Background

Workplace bullying has become a prominent global issue due to its prevalence in numerous work environments and the resulting public outcry. More than 30 years of research in various organisational settings have shown that it is one of the most complex and unpleasant occurrences in the workplace [1]. According to Giorgi et al., workplace bullying

is a negative behavioural situation that individuals accept over time and find difficult to resist [2]. It is characterised by repeated intimidating, aggressive, and hostile behaviour that includes name-calling, harassment, humiliation, cold aggression, and the devaluation of job results [3]. Both harmful and antisocial, workplace bullying is a very serious problem as it can adversely affect the physical and mental health of victims, resulting in feelings of helplessness, anxiety,

depression, sleep disorders, chronic fatigue, and a decline in job perception and creativity [4]. Its effects on organisations include brain drain, a tarnished image, etcetera [5].

Workplace bullying is not only found in businesses and companies but also prevalent within the nursing profession. The research found that 45% of 470 nurse educators in the United States felt they had been the target of workplace bullying in the past 6 months [6], and 53.3% of 240 nurses in China had suffered workplace bullying [7]. All of the traits of workplace bullying have been documented to various extents in the nursing literature, with nurses who experience even some of these traits exhibiting more negative coping styles, lower job satisfaction, lower staff morale, and poorer performance than their nonbullied counterparts, resulting in a potentially reduced quality of care [8–10]. Previous studies on workplace bullying in nursing have tended to focus on vertical abuse, such as toxic leadership behaviours inflicted by superior nurses on subordinates [11, 12], as well as interpersonal conflicts, known as “horizontal/lateral violence,” between nurses of the same rank [13]. However, anyone within a nursing organisation, regardless of their status, can become a victim of bullying. The victim might be a subordinate, a colleague, or a superior [14], although incidents of the latter being targets of workplace bullying are often overlooked. Managers and other high-ranking individuals are usually seen as authorities and decision-makers, and it is difficult to imagine that they can also be victims of bullying, let alone by subordinates. The modest information on bullying of nurses in managerial and executive positions, however, has suggested that subordinate nurses are the perpetrators of such behaviours [15, 16]. This type of bullying by subordinates toward their superiors is called upward bullying.

Upward bullying in the nursing workplace is defined as bullying behaviour by supervised nurses (including clinical nurses, practicing nurses, and nursing students) toward nurses in positions of authority or power (including leaders with managerial responsibilities such as nurse managers, directors of nursing, and nursing faculty) [17]. For the purpose of this study, which focused on upward bullying in the nursing clinical workplace, we considered only frontline nurse managers as the study subjects and excluded nurse educators. According to Mintzberg’s theory of managerial roles [18], nurse managers are responsible for ward administration, quality improvement, service enhancement, and benefit management, and they play multiple roles such as advocate, leader, supervisor, and coordinator. However, nurse managers may struggle to perform optimally in their workplace roles due to upward bullying and find it difficult to manage within nursing organisations. Whether they choose to retreat or confront the bullying head-on [16, 17], there may be no way of preventing upward bullying from taking a toll on the body, the quality of their work, and the economy [19]. A few literature studies mentioned that factors which may contribute to the victimisation of nurse managers are being in a state of insecurity in the organisation or a shift in power dynamics within the work environment [20]. For example, a young nurse manager who has just assumed their position is more likely to be ostracised by subordinate nurses than an experienced nurse manager.

WHO has recognised bullying as a multifaceted and significant public health problem that requires close attention from families, healthcare providers, and policy-makers [21]. Unfortunately, in China, there have been no reports of nurse managers’ experiences of upward bullying; all the information we have is based on international literature. Since the circumstances in which nurse managers are upwardly bullied can vary due to differences in workplace culture and structure, this study uses qualitative research methods to explore the manifestations, reasons, and outcomes of upward bullying among managers within Chinese nursing organisations with the aim of finding solutions that can improve the clinical environment and enhance their managerial effectiveness.

2. Methods

2.1. Design. We adopted a descriptive, qualitative study using a semistructured interview method. Qualitative research methods, such as semistructured interviews, are well suited for data collection and analysis of real-life bullying phenomena. This work complied with Tong and colleagues’ recommendations [22]. We thus adopted this method to help us identify the manifestations, causes, and outcomes of upward bullying experienced by nurse managers.

2.2. Sample. This study was conducted within the geographical limits of Wuhan, Hubei Province, China. Purposive sampling was used to recruit 12 nurse managers from two tertiary general hospitals and one secondary general hospital. Inclusion criteria were the following: (a) registered nurses; (b) having responsibility for staff; and (c) providing informed consent to participate in the study. Exclusion criteria included (a) nurses not on duty due to casual leave, sick leave, maternity leave, etcetera; (b) being unwilling to participate in the study; and (c) having experienced adverse psychological impact in the past 3 months, such as divorce. The previous study excluded participants with psychological distress to minimise the influence of unrelated factors [11].

2.3. Data Collection. A semistructured interview guide was developed, which was preliminarily drafted on the basis of a literature review and panel discussion and finalised after consultation with a nursing management expert and two pre-interviewees. The questions are presented in Table 1.

Interviews were conducted between June and August 2023, using a one-to-one semistructured in-depth interview method to collect data. Since previous research has found that telephone contact is more convenient for respondents [23] and we wanted to accommodate the busy schedules of nurse leaders, we presented the participants with the choice of face-to-face or online telephone interviews. Before the start of each interview, we explained the study’s purpose, content, and methodology to the participants, assured them of the confidentiality of their information, and obtained their informed consent. We used an outline to guide the main line of inquiry, adjusting the questions flexibly according to the interviewee’s responses. At all times, we

TABLE 1: Interview questions.

-
- (i) Please briefly introduce yourself (age, marital status, length of independent nursing practice, and nursing title)
 - (ii) Have you heard of the term “upward bullying”? What do you understand by “upward bullying”?
 - (iii) Have you ever been the victim of upward bullying or witnessed it among others since becoming a nurse manager?
 - (iv) If you have been exposed to upward bullying, what did you specifically witness or experience?
 - (v) If you have been the victim of upward bullying, why do you think it occurred?
 - (vi) How has upward bullying in the workplace affected you? How do you feel about it?
 - (vii) What measures are in hand to help reduce the incidence of upward bullying in your workplace?
-

avoided directional and inducing questions and encouraged the interviewees to express their true feelings about upward bullying. We stopped collecting data when information saturation was reached and no new concepts emerged [24].

2.4. Data Analysis. The data were analysed using Colaizzi’s seven-step method [25]. All interviews lasted from 24 to 36 minutes, with an average of 30 minutes, and the audio recordings were converted to text within 24 h of the interviews to create separate documents. First, the information was read independently and repeatedly by two researchers to extract relevant and meaningful statements. Next, key information was distilled and summarised so as to identify common characteristics among the statements. We then formed themes from the data and presented the themes in relation to the phenomenon under study, while also identifying responses that indicated similar points of view. Finally, the results were returned to the interviewees to verify the authenticity of the content. In cases of disagreement during data analysis, we reviewed the notes and recordings, and if there was still disagreement, the respondent was re-interviewed until agreement was reached. To assist in analysing the data, Nvivo 12.0 software was used.

2.5. Ethical Considerations. The study was approved by the Ethical Committee of Tongji Medical College, Huazhong University of Science and Technology (No. S044). Our work was conducted in accordance with the Declaration of Helsinki. All the people participating in the research voluntarily agreed to be interviewed and received information about the study as well as a letter of commitment to confidentiality signed by the research team. In addition, the participants all signed an informed consent form in accordance with said participation which indicated their right to discontinue their participation in the study at any time.

3. Results

3.1. Demographic Characteristics of Participants. All 12 respondents in nursing management positions met the inclusion criteria. All participants were female, all had the title of nurse-in-charge, and all had a bachelor’s degree or higher. Among the 12 participants, 11 were the head nurse of the unit and one was the deputy director of the nursing department, and they all managed an indeterminate number of staff. The age range of the participants was between 33 and 41 years with a mean age of 36.6 years. Table 2 presents the general demographics.

3.2. Categories and Themes Emerging from the Data. The interview data provided rich details of how and why nurse managers were bullied by those in subordinate positions during their current period of employment. Based on their narratives, we grouped the data into three categories from which we distilled and summarised eight themes, as shown in Table 3. In the sections that follow, we expand on these categories and themes and provide direct quotations (translated from Chinese) from nurse managers to support our inferences.

3.2.1. Manifestations of Upward Bullying. Manifestations of upward bullying refer to outward forms of bullying by subordinates toward nurse managers expressed in behaviour, words, etc. The main forms of bullying that emerged from this study included verbal aggression, threats, and disregard for authority.

(1) Verbal Aggression. Respondents indicated that they were receptive to ideas from their subordinates if the ideas were constructive and would like to work with their department members to create a better departmental atmosphere and improve the organisational climate. However, some subordinate nurses chose to express their opinions or dissatisfaction by launching verbal attacks, either in person or behind their backs. These attacks took the form of sarcasm, backbiting, and public humiliation. A head nurse said, “When I first took up my post, if there was any disagreement with the nurses, they belittled my ability to do my job and even called me “eye candy”, meaning “impressive but lacking real worth,” which I found demeaning and offensive” (N6). Another one said, “Nurses often talked privately about my lack of fairness and there was no shortage of public dislike for me” (N1).

(2) Imposing Threats. A few respondents claimed that some subordinate nurses would express their dissatisfaction with their job or managers by issuing threats. As a result, nurse managers were most often forced to compromise on their management style and alter their way of speaking. A head nurse who had been in management for 2 years recalled, “This really struck me. At that time, when I made new rules and corrected the young nurse’s missteps, she threatened to stop my management of her by “jumping off the roof”” (N5). Another head nurse said, “Some of the nurses threatened to leapfrog me [i.e., report me] by writing confidential letters. While I know I didn’t make a mistake, I still didn’t want to get myself in trouble” (N10).

TABLE 2: Demographics of participants (N = 12).

Participant no.	Female (F)/male (M)	Age (years)	Education	Professional title	Position	Level of hospital
1	F	39	Bachelor's degree	Nurse-in-charge	Head nurse	Tertiary
2	F	34	Master's degree	Nurse-in-charge	Head nurse	Tertiary
3	F	33	Master's degree	Nurse-in-charge	Head nurse	Tertiary
4	F	38	Master's degree	Nurse-in-charge	Head nurse	Tertiary
5	F	37	Bachelor's degree	Nurse-in-charge	Head nurse	Tertiary
6	F	33	Bachelor's degree	Nurse-in-charge	Head nurse	Secondary
7	F	41	Bachelor's degree	Nurse-in-charge	Head nurse	Tertiary
8	F	37	Master's degree	Nurse-in-charge	Head nurse	Secondary
9	F	40	Master's degree	Nurse-in-charge	Head nurse	Secondary
10	F	38	Bachelor's degree	Nurse-in-charge	Head nurse	Tertiary
11	F	33	Bachelor's degree	Nurse-in-charge	Deputy director of the nursing department	Secondary
12	F	36	Master's degree	Nurse-in-charge	Head nurse	Tertiary

TABLE 3: Summary of categories and themes.

Categories	Themes
Manifestations of upward bullying	Verbal aggression
	Imposing threats
	Diminished authority
Reasons for upward bullying	Conflicts of interest
	Differences in position
	Excessive workload
Outcomes of upward bullying (Positive and negative)	Self-reflection and improvement Sadness, anger, loss of trust, etcetera

(3) *Diminished Authority*. Authority typically confers a certain prestige and credibility in the minds of subordinates, although not always. Respondents indicated that subordinate nurses would challenge and undermine their authority as leaders in various ways. One manager said, “She would not follow my orders or instructions and even ignored me” (N2). Another head nurse explained her situation in these words, “I was treated with indifference and [the subordinate nurse] was not supportive of my decisions; she even tarnished my image in front of other nurses and instigated opposition toward me, which made my management job more difficult” (N7).

3.2.2. *Reasons for Upward Bullying*. Reasons for upward bullying refer to the conditions that cause or trigger bullying of nurse managers by subordinates. This study found three factors that prompted bullying: conflicts of interest, differences in position, and excessive workload.

(1) *Conflicts of Interest*. Respondents revealed that conflicts of interest, both between individuals and between individuals and the collective, was one reason for upward bullying. A new manager claimed, “The new head nurse is bound to change some of the management mode. And the nurses who have taken the “bonus” of the previous manager will have a gap in their hearts, thinking that their benefits have changed from more to less” (N3). Other respondents mentioned, “Meeting everyone’s needs is difficult to balance. Nurses resent me when they notice small inequalities” (N8). One manager said, “Some people think nursing is just a job and are not willing to make compromises for the sake of collective progress, which makes my work hard” (N12).

(2) *Differences in Position*. Some respondents pointed to conflicts that arise due to differences in the scope of work between nurses and managers. The deputy director of the nursing department explained, “I am in a position where I have to consider things on a more macro level. Some nurses are not mature enough to understand my intentions, and this leads to misunderstandings” (N11). A head nurse said, “The work mentality is different. For example, there are requirements for the placement of oxygen tanks, and some nurses think it’s most convenient to put them somewhere, but I will ask them to change the placement from the perspective of management, and that’s when we disagree” (N4).

(3) *Excessive Workload*. One external reason for upward bullying is the heavy workload of nurses, which leads to higher physical and mental stress and emotional backlog. A head nurse sighed, “At present, there is a shortage of human resources in the department; nurses work night shifts frequently, and they are physically and mentally exhausted. As a manager, I want to schedule shifts for my staff more effectively to reduce the burden, but the workload is objective and cannot be changed” (N9).

3.2.3. *Outcomes of Upward Bullying*. Outcomes of upward bullying refer to its effects on victims and organisations. This study grouped outcomes into two main categories: positive and negative outcomes. The following sections discuss the themes that were found within each of these categories.

(1) *Self-Reflection and Improvement (Positive Outcomes)*. Managers suggested that their experiences of upward bullying spurred them to engage in self-reflection so as to improve themselves and their practices. Specific actions included taking the initiative to improve their management skills, reinventing themselves, identifying and solving problems at work, and improving their mindset. The deputy director of nursing reflected, “Management work is not infallible, all things have room for improvement. Why people are sometimes in a bad mood is something I need to think about, and I will take the time to work on myself” (N11). One manager said, “I have not only asked senior nurse managers for advice on how to manage and communicate with my subordinates, but I have also taken relevant courses and referred to relevant books” (N2).

(2) *Sadness, Anger, Loss of Trust, Etcetera (Negative Outcomes)*. The negative effects of bullying behavior are unavoidable. On the individual side, the above behaviors can bring anger, sadness, and other emotions to nurse managers, depleting emotional resources; increase the pressure of managing and coordinating work; and also affect the establishment of managers’ personal authority, damaging leadership charisma and trust between supervisors and subordinates. On the organisational side, bullying behavior can affect the atmosphere of the department and undermine team cohesion. As two managers noted wearily, “It does come with a sense of loss and chills” (N12, N7). Another manager stated quite plainly, “If the abuser is someone who is a strong communicator and is used to complaining to others, it can disrupt the team atmosphere and reduce my managerial effectiveness” (N8).

4. Discussion

In this study, we used qualitative research techniques to explore nurse managers’ experiences with upward bullying in Chinese nursing organisations. The responses of 12 managers allowed us to determine that upward bullying does indeed exist in these organisations, and that there are both similarities and contrasts with findings from other regions. As WHO argues, bullying is a multifaceted and significant

public health problem, which is detrimental to creating a healthy, person-centred work environment in healthcare organisations.

When asked if they were aware of upward bullying, 75% of the respondents paused to reflect on the question. They indicated that they were more familiar with “horizontal violence” as well as “downward bullying” and that they were unaccustomed to viewing themselves from the perspective of a victim with respect to workplace bullying. After being informed of the definition of upward bullying, managers acknowledged that they did struggle with interpersonal conflicts with their subordinates, which caused some distress in their work environment and posed an obstacle to work advancement. In China, society is characterised by differentiated positions, and managers can usually achieve goals and solve problems quickly by relying on the authority invested in them [26]. However, this study shows that the ability of nurse managers to cultivate the charisma needed of a manager and to develop rapport and trust with subordinate nurses is significantly impeded by various forms of upward bullying, including verbal abuse, threats, fabrication of ratings, and deliberate negative feedback [15].

In line with the results of this study, the reported causes of upward bullying in the literature include an inflexible and heavy workload, differences in education and mindset, as well as jealousy and other emotions [17, 27]. It is worth noting that one of the themes emerging from the data in this study was “conflicts of interest,” which were manifested mainly in the differences in benefits that individuals receive and in the interests between individuals and organisations. There is a consensus among scholars that bullying is easier to comprehend when the organisational context in which it occurs is taken into account [28]. Since collectivism is one of the key social values of Chinese culture, individuals place high priority on relations with others and with the collective [29]. Chinese organisations guide and run teams with the goal of integrating individuals into the collective, and many individuals will voluntarily sacrifice their individual interests for the sake of the collective if harmony cannot otherwise be achieved [30]. With respect to organisational advancement, nursing managers want to promote their teams and units, which invariably mean adding to the burden placed on staff nurses. In response, staff nurses will sometimes accuse the nurse manager of implementing measures that violate their interests and engage in a number of bullying tactics to vent their frustration.

In addition, our findings are consistent with other studies showing that bullying has a variety of detrimental repercussions on nurse managers, including dwindling emotional resources, decreased productivity, poor physical health, and even jeopardised patient safety [15, 31]. When managers are the target of subordinates’ bullying, they themselves can be in a state of information disconnect, unable to effectively coach and manage their team. Struggling to take control of the whole team, they can become reactive, with effects that include organisational mismanagement and higher propensity to quit [15, 17].

Interestingly, the Chinese respondents in this study retained a positive attitude despite the upward bullying. They continued to pursue additional education, behave

positively, and serve the public in an effort to strengthen their personal charisma as the “head” of the unit. Research indicates that the types, causes, and manifestations of bullying in the nursing field have undergone staged changes over the last 4 decades, with nursing management having had a role to play in addressing the problem of bullying [32]. Nurses who take on management roles may be able to build up personal and organisational resources by taking positive action, as did respondents N11 and N2. Taking a proactive stance allows them to gain experience in managing upward bullying issues that are closely related to their own, as there is limited information on upward bullying in the Chinese nursing field. This article can help nurse managers to understand the ways in which upward bullying behaviour manifests itself in the profession and, most importantly, prompt managers to develop the necessary skills to identify, manage, and prevent bullying from subordinates in order to maintain their managerial effectiveness.

While antibullying laws and zero-tolerance campaigns have been tried in some countries to enable nurse managers to respond more adequately to the devastation caused by bullying, they fail to address the most fundamental problems [33]. According to Parchment and Andrews [15], nurse managers with authentic leadership styles report less bullying. Therefore, managerial training programs oriented to leadership development and improving interpersonal skills may be one way to strengthen the leadership skills of nurses and reduce bullying. However, addressing upward bullying in nursing is not solely the responsibility of nurse managers. Supervised senior nurses have a wealth of workplace experience and interpersonal communication skills that allow them to bridge the communication gap with managers and serve as a benchmark for younger nurses in China. Therefore, senior nurses also need to demonstrate leadership in their professional roles and show respect for their supervisors, colleagues, and the profession [32]. By role-modelling appropriate behaviour, they can help to reduce the incidence of upward bullying.

5. Limitations

The participants in this study were all from hospitals in Wuhan, Hubei Province, and further research should be conducted to expand the representativeness of the sample. Moreover, the study participants were all female, and whether gender is a factor in upward bullying remains to be explored. Finally, qualitative research methods cannot determine the true frequency of upward bullying in the Chinese nursing field.

6. Conclusion

In China, upward bullying is a reality in the field of nursing, with nurse managers encountering various degrees and types of bullying just as they do in other countries. In addition to objective changes in workload and psychological displeasure, other factors also trigger this type of bullying behaviour. Some Chinese nurse managers are strong-willed and responsible. They are able to turn a negative situation

into an opportunity for growth. Creating a positive work environment for them that facilitates management, however, is still something to be emphasised.

7. Implications for Future Nursing Management Research

Limited evidence exists of upward bullying in the field of nursing, especially in the Chinese context. This study can contribute to an understanding of why such bullying occurs and what its outcomes entail. Given that bullying behaviour is linked to turnover, we have concerns that the continuation of upward bullying will have a similar impact on the retention and turnover rates of nurse managers in China, which would pose a threat to organisational cohesion and management. We suggest, therefore, that the relationship between turnover rates and exposure to upward bullying among nurse managers in China be further investigated.

It is hoped that the findings of this study will enrich future research in the fields of nursing management and workplace health in China and inform large-scale quantitative studies that investigate the issue of upward bullying. And we anticipate that this study will contribute to the development of interventions and strategies to manage and address the upward bullying of nurse managers and that these actions taken will improve management effectiveness and the nursing practice environment. In addition, the conclusions of this study prompt us to rethink the importance of professional literacy training in nursing education.

As global populations age, a looming nursing shortage is anticipated to become a critical issue. Charge nurses have the responsibility of optimally allocating nursing resources to ensure the quality of patient care during a shift. Therefore, an accurate estimate of nursing demand is crucial. However, the ability to forecast future nursing demand remains underdeveloped, mainly because the nature of nursing demand is highly individualized and does not follow a definitive pattern. In practice, the nursing demand is often perceived as unpredictable, leading to an ad hoc approach to staffing. The primary objective of our study is to demonstrate that longitudinal data analysis can reveal strong statistical regularities in the temporal dynamics of nursing demand. This approach not only provides new possibilities for efficient resource allocation but also paves the way for data-driven prediction of nursing demand. Our study uses Sankey diagrams to visualize the temporal dynamics of nursing demand within each ward for each fiscal year, representing these dynamics as an overlay of trajectories from multiple individual patients. Consequently, our study reveals ward-specific statistical regularities in the temporal dynamics of nursing demand. In one ward, approximately 25% of patients experienced an increase in nursing demand from 1 to between 6 and 9 points from the second to the third day of hospitalization, while in another, only 0.1% showed such an increase. These findings suggest that patients admitted to the wards tend to exhibit a certain probabilistic change in nursing demand. This study can predict probabilistically the temporal variation of nursing demand among patients in the coming years by analyzing data on the temporal changes in nursing demand over the past years. Our findings are expected to significantly influence the forecasting of nursing demand and the estimation of nursing resources, leading to data-driven and more efficient nursing management.

1. Introduction

As societies globally progress towards a superaging demographic, a looming nursing shortage is anticipated to become a critical issue. While it is imperative to expand nursing education to augment medical resources, the onus is

also on charge nurses, who lead their nursing units during a shift, to ensure the optimal allocation of these resources [1]. This is paramount to maintaining the necessary quality of patient care, as research shows that increasing a nursing workload often leads to worse patient outcomes [2–4]. However, challenges remain in applying these findings to

clinical practice [5]. To achieve more realistic staffing, optimized nurse staffing has been examined, taking into account stakeholder decision-making involving nurses and patients [5, 6], as well as cost considerations [7]. Furthermore, a nonlinear staffing model has been proposed to address the complex relationships caused by path dependencies and feedback loops in staffing factors [8]. Among the complex factors, nursing demand is particularly important as a core factor due to its significant impact on various nursing resources [8]. Consequently, accurately estimating nursing demand emerges as a fundamental challenge that must be addressed.

Efforts to quantify nursing demand have been undertaken in several countries. The Nursing Activities Score (NAS) is utilized to measure both direct and indirect nursing activities in various countries [9, 10]. In Finland, the Oulu Patient Classification (OPC) is employed to evaluate the volume and intensity of nursing care provided to each patient [11, 12]. In Japan, the Intensity of Nursing Care Needs (INCN) serves as a measure of nursing demand. While progress has been made in quantifying current nursing demand, the ability to forecast and predict future demand remains under-researched.

A key challenge in estimating nursing demand lies in the highly individual nature of patient care demand [13]. Patients present with a wide array of physical and psychosocial backgrounds, leading to considerable variability in nursing demand. As a result, the daily nursing care required throughout a patient's hospital stay until discharge does not follow a simple, deterministic pattern. This variability persists even among patients hospitalized for similar diseases, as care demand can greatly differ from one individual to another. In practice, it is often assumed that nursing demand is inherently unpredictable, leading to an ad hoc approach in the allocation of nursing resources.

To address clinical challenges, many studies have attempted to predict nursing demand based on data. However, factors such as age [14, 15] and emergency situations [14] were not found to be associated with nursing demand. Instead, the relationship with sex varied depending on the situation [14, 15]. Furthermore, although some studies have reported that the length of stay and survival [15, 16] are useful variables, these factors cannot be incorporated into prospective prediction models. One study [13] suggested that nursing demand can help predict which patients will have stable nursing needs in the subsequent shift, but it did not address the ability to predict changes in nursing demand for patients. Less than half of the patients had stable nursing demand. Therefore, the development of a model applicable to all patients is ongoing. Nursing demand changes dynamically, which may complicate staff allocation based on nursing demand [13]. Consequently, it is essential to explore methods to predict dynamic nursing demand effectively.

The primary objective of this paper is to illustrate that longitudinal data analysis can reveal strong *statistical regularities* in the temporal dynamics of nursing demand. This serves as a preliminary step toward solving the nursing demand estimation challenge. Here, the term "statistical regularity" refers to consistent patterns within data that inherently contain

randomness. In other words, it describes empirical phenomena where observations do not yield the same outcome each time yet show statistical stability in their frequency [17].

The influence of patient individuality, which contributes to the diversity of nursing demand, can be statistically encapsulated within these regularities when considering the entire patient population as a collective entity. Successfully identifying these statistical regularities paves the way for formulating nursing demand forecasting and resource allocation as a stochastic, or probabilistic problem. This approach not only opens up new possibilities for efficient resource allocation in nursing management but also provides a data-driven method to anticipate nursing demand despite the seeming unpredictability of individual patient nursing demand over the course of hospitalization days.

In this study, we analyzed three years' worth of data related to item "B" of the INCN from a large Japanese hospital with over a thousand beds. As will be detailed in the Methods section, item "B" of the INCN evaluates patient's activities of daily living (ADL) and cognition. Importantly, nurses often encounter physical strain when caring for patients with low ADL and cognition. Such care tasks typically involve manual handling of patients, including positioning and transfers, which directly contribute to the physical workload experienced by nurses [18–20].

To provide insights that can be useful for nursing staff scheduling [21] and bed management [22], our focus is on the temporal evolution of nursing demand throughout the entire hospitalization period. The key to uncovering statistical regularities from this perspective is the utilization of a visualization tool known as *Sankey diagrams*.

Sankey diagrams, a type of flow diagram, are widely used in fields such as industrial engineering, economics, and finance to visualize the magnitude of various flows. In medical fields, it has been used to investigate usage paths in mobile electronic health record systems [23] or to visualize treatment courses for a group of patients [24]. When the nodes in these diagrams are appropriately aligned, they can provide a clear and comprehensive picture of the dynamic changes in nursing demand throughout the course of a patient's hospital stay. Nurses in clinical practice sites encounter highly individualized patients, which can obscure the regularities inherent in the patient population. Their knowledge is often limited to the patients for whom they are responsible, restricting their ability to gain an overview of nursing demand trends across the entire patient population. However, visualizing nursing demand with Sankey diagrams enables observation of these trends for the entire patient population from a bird's eye view, which allows for capturing the statistical regularities in the nursing demand dynamics of the patient population. As demonstrated in the following sections, this approach presents an effective way to understand the evolution of nursing demand over time.

2. Materials and Methods

2.1. Design and Setting. With Sankey diagrams, we visualized statistical patterns in the trajectories of nursing demand for each ward for each fiscal year. We analyzed the results from the following two perspectives (Figure 1):

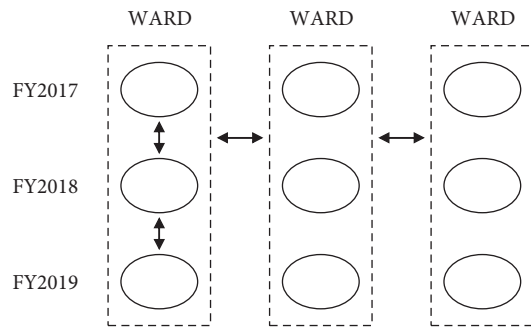

FIGURE 1: Overview of comparative analysis of patterns in the trajectories of nursing demand by fiscal year and ward. (1) Comparing the trajectories across fiscal years for each ward (↑↓). (2) Comparing the trajectories between different wards (↔).

- (1) For each ward, we assessed the similarity/dissimilarity in the visualized trajectories of nursing demand across fiscal years
- (2) We compared the visualized trajectories of nursing demand between different wards

2.2. Target Hospital. This study focused on a large university hospital in Japan with over a thousand beds. As a university hospital, the targeted hospital serves multifaceted roles: it functions as an educational institute for fostering medical professionals, as a research institute for the innovation of novel medical technologies, and as a central regional healthcare institution offering advanced healthcare provisions. Consequently, the hospital is responsible for treating patients requiring advanced medical care. In the wards studied, the ratio of the number of patients to that of nurses is 7:1.

2.3. Data Collection

2.3.1. Intensity of Nursing Care Needs. The INCN is an indicator used in Japan to measure the demand for nursing care. It comprises three components: items “A,” “B,” and “C.” Item “A” evaluates the expertise of nurses and encompasses subitems related to monitoring and treatment procedures, such as pressure ulcer care and syringe pump management. Item “B” assesses the level of caregiving for recuperation administered by nurses. It includes subitems that evaluate the patient’s ADL and cognition. Item “C” appraises surgical procedures considered urgent from a medical standpoint. It is scored based on the type and volume of medical procedures undertaken, such as craniotomy or open chest surgery, and it is assessed within a specific time frame in postprocedure. Nurses evaluate the nursing demand for each patient every day. The electronic medical record stores the resulting INCN scores, thereby preserving the data as a time series.

In this study, we utilized the score for item “B” of the INCN of individual patients. As mentioned above, Item “B” evaluates a patient’s ADL and cognition (Table 1). Each score is recorded once a day, reflecting the most severe condition observed between 00:00 and 23:59. For the “risk behavior,” if

patients engage in such behaviors within the past seven days, nurses mark “display risk behavior” for the target date. Risk behaviors include self-extubation during treatment or examination, falls, self-injury, as well as other behaviors that would lead to dangerous actions if left unaddressed. The score of item “B” ranges from 0 to 12, with higher scores indicating the need for more extensive or diverse types of nursing care.

2.3.2. Target Data. This study utilized daily scores of Item “B” in the INCN as an indicator of nursing demand. We focused on scores from the first day of hospitalization (hereafter referred to as day 1) to day 18 for each patient. This decision stemmed from the fact that inwards operating under the 7:1 patient-to-nurse ratio, the average patient stay is optimized to be within 18 days. This study population comprised patients who were admitted to the target hospital during any of the following periods: from April 1, 2017, to March 14, 2018; from April 1, 2018, to March 14, 2019; and from April 1, 2019, to March 14, 2020, reflecting the fact that fiscal years in Japan start at April 1. Furthermore, these patients had to occupy general beds in either the Orthopaedic Surgery Ward, the Neurosurgery Ward, or the Cardiovascular Medicine Ward for at least one day before day 18. We treated each admission date for the same patient as a separate case. We excluded patients with missing score data for at least one day between day 1 and day 18.

We chose the three wards categorized as musculoskeletal, neurology, and internal medicine departments. This selection was premised on the fact that the patients in these wards necessitated varied types of nursing care, aligning with their diverse diseases and corresponding treatment plans, which would result in different natures of nursing demand.

Many patients in the Orthopaedic Surgery Ward undergo procedures such as arthroplasty, tendon reconstruction, or tumor resection. In the Neurosurgery Ward, a large number of patients receive treatments such as craniotomy for brain tumors, vascular embolization, and stent placement. The Cardiovascular Medicine Ward sees many patients who require medication, cardiac catheterization, and in some cases, a heart transplant.

Along with the scores of item “B” in the INCN, we collected the following attributes for each record: the date, patient ID, admission date, discharge date, and details of the inpatient wards and beds occupied by the patient.

2.4. Ethical Considerations. Ethical approval for this study was granted by our hospital’s Ethics Committee (approval no. 22251 (T2)). All participant data were anonymized to ensure the protection of their personal information. Information about the study was made available to potential participants via the hospital’s website, providing the option for patients who stayed at the hospital during the study period to opt out if they wished.

2.5. Data Analysis. Figure 2 shows the flowchart of data analysis in our study. We collected data that met specific criteria, as mentioned previously in the Target Data section.

TABLE 1: Criteria for the score for item “B” in the intensity of nursing care needs.

System	Score		
	0	1	2
Rolling overact	Can do it	Can do it if holding onto something	Cannot do it
Transferring	Independent	Partial assistance	Full assistance
Oral health	Independent	Assistance	—
Dietary intake	Independent	Partial assistance	Full assistance
Changing clothes	Independent	Partial assistance	Full assistance
Instruction for medical care and treatment	Compliance with instruction	Noncompliance with instruction	—
Risk behavior	Avoid risk behavior	—	Display risk behavior

We processed the data to account for patient transfers to other wards and discharges, which allowed for the analysis of data for each ward over the course of hospitalization. We calculated the number and proportion of patients who transitioned from one point to another each fiscal year in each ward. These trends were visualized using a type of Sankey diagram, which illustrates the flow and transition of scores among patients. We conducted a comparative analysis of the results from the Sankey diagrams and the number of patients within the same ward across different fiscal years. In addition, we compared the results from the Sankey diagrams and the proportion of patients across different wards.

In this analysis, Python version 3.11.7 served as the primary programming language [25]. We use Pandas 2.1.1 [26] and NumPy 1.25.0 [27] for the identification of the eligible patient population and the quantification of the total number of eligible patients and specific conditions within this population. Furthermore, we use Plotly 5.15.0 [28, 29] to create the Sankey diagrams.

2.5.1. Data Processing. Each patient was assigned a daily score ranging from 0 to 12 points. Some patients were admitted to more than one ward or specialized beds such as Coronary Care Units during their hospital stay. If patients stayed in other wards or specialized beds, we replaced the scores with the label “staying in other wards or specialized beds.” For instance, when targeting a single ward and analyzing one patient, if this patient stayed in the target ward with a score of 0 points on day 1, in another ward or specialized bed with a score of 1 point on day 2, and back in the target ward with a score of 2 points on day 3, then we modified the sequence “0 points, 1 point, and 2 points” to “0 points, “staying in other wards or specialized beds,” and 2 points.” When a discharge was recorded, any data after the discharge record’s entry date were labeled as “discharged.”

2.5.2. Calculation. For each patient, the period of analysis was set to 18 days, as mentioned above, based on the average patient stay. Let d ($d \in \mathcal{D}$) denote the number of days elapsed after the admission to the hospital, where $\mathcal{D} = \{1, 2, \dots, 17\}$. Let \mathcal{E} and \mathcal{S} denote the set of eligible patients and the set of daily scores including discharge, where $\mathcal{S} = \{0, 1, \dots, 12\} \cup \{\text{staying in other wards or specialized beds, discharged}\}$. For $e \in \mathcal{E}$ and $i \in \mathcal{S}$, we define an indicator function $I_i(e, d)$ as follows:

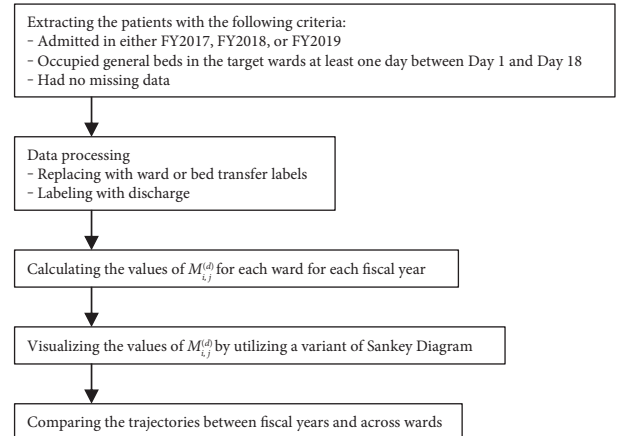

FIGURE 2: Flowchart for data analysis.

$$I_i(e, d) = \begin{cases} 1, & \text{if patient } e \text{ scored } i \text{ on Day } d, \\ 0, & \text{otherwise.} \end{cases} \quad (1)$$

The total number $M_{i,j}^{(d)}$ of patients who scored i on day d and scored j on day $d+1$ is then given by

$$M_{i,j}^{(d)} = \sum_{e \in \mathcal{E}} I_i(e, d) I_j(e, d+1). \quad (2)$$

With $M_{i,j}^{(d)}$ and the total number N_e ($N_e = |\mathcal{E}|$) of eligible patients, the proportion $P_{i,j}^{(d)}$ of patients who scored i on day d and scored j on day $d+1$ among eligible patients is calculated by

$$P_{i,j}^{(d)} = \frac{M_{i,j}^{(d)}}{N_e}. \quad (3)$$

2.5.3. Visualization. Sankey diagrams can visualize the flow of data between different stages. These diagrams clearly represent the distribution and transition of data points throughout the various phases by depicting the movement of quantities or information between numerous nodes in a system. The layout of the diagram is typically optimized and arranged automatically [30]. This method facilitates an intuitive understanding of the complex relationships and interactions within the dataset.

Unlike conventional automatically arranged Sankey diagrams, we arranged the vertical axis in descending order of scores for item “B,” while we aligned the horizontal axis

with equal intervals to depict the elapsed days after hospitalization. Nodes are represented by rectangles indicating the score, and the flows between them are depicted by curves leading from source to target nodes. The volume of each flow, represented by the $M_{i,j}^{(d)}$, is indicated by the thickness of the curve. In other words, the curve's thickness corresponds to the number of patients whose scores transitioned from i on day d to j on day $d + 1$. Note that, the Sankey diagram is composed of the volumes of flows between two days, which, in aggregation, also suggests typical trajectories of nursing demand. We visualized the values of $M_{i,j}^{(d)}$ for each ward for each fiscal year to investigate the statistical regularities in the temporal dynamics of nursing demand.

2.5.4. Trajectory Comparison. The thickness of the flows corresponds to both the probability of the score transitioning and the volumes of flows. With the resulting Sankey diagrams and $M_{i,j}^{(d)}$ values, we compared the trajectories of the scores of the patient population between different fiscal years for each ward. Furthermore, we incorporated $P_{i,j}^{(d)}$ values alongside $M_{i,j}^{(d)}$ to compare the trajectories of the scores between different wards. Comparing the trajectories allows for the inference of the existence of probabilistic patterns in score transition.

3. Results

The basic characteristics of the target patients are shown in Table 2. In the Orthopaedic Surgery Ward, the eligible patient count was 684, 688, and 691 in the fiscal years 2017, 2018, and 2019, respectively. In the Neurosurgery Ward, the numbers were 839, 873, and 959 for those years, respectively. For the Cardiovascular Medicine Ward, there were 994, 998, and 898 patients in those years, respectively. The proportion of these patients was 99.3%. In the Orthopaedic Surgery Ward, the majority of patients were female, with a mean age in the mid-50s, consistently across three fiscal years. In the Neurosurgery Ward, the sex ratio was almost equal, with a mean age in the late 50s, also consistently across three fiscal years. In the Cardiovascular Medicine Ward, the majority of patients were male, with a mean age in the mid-60s, consistently over the same period. The median scores on day 1 were 1 point in the Orthopaedic Surgery Ward, almost 1 point in the Neurosurgery Ward, and 0 points in the Cardiovascular Ward, respectively.

The number of inpatients gradually decreased over the course of hospitalization in all wards, primarily due to patients being discharged as their hospital stays progressed. The nature of changes in scores varied across the different wards (Table 3).

We will present results from the following two perspectives:

- (1) The statistical regularities in temporal dynamics of nursing demand across fiscal years within each ward
- (2) The ward-specific feature of the statistical regularities in temporal dynamics of nursing demand

3.1. The Statistical Regularities in Temporal Dynamics of Nursing Demand across Fiscal Years within Each Ward

3.1.1. The Orthopaedic Surgery Ward. All trajectories of the Orthopaedic Surgery Ward are shown in Figure 3. The x -axis represents the hospitalization day, and the y -axis represents the scores. A higher number of points indicates a greater nursing demand. The flows between the scores are depicted by curves leading from the source to the target. The thickness of each curve indicates the volume of the flow. The primary patterns observed in this ward are as follows. On day 1, a substantial number of patients had scores ranging from 0 to 2 points, with totals of 613, 608, and 608 in the fiscal years 2017, 2018, and 2019, respectively. From day 1 to day 2, the majority exhibited stable score trajectories: specifically, 446, 435, and 415 patients experienced a score change of 1 point or less in the fiscal years 2017, 2018, and 2019, respectively.

From day 2 to day 3, there was a noticeable rise in patient scores, especially among those whose scores shifted from 0 to between 6 and 9 points, numbering 154, 173, and 206 in the fiscal years 2017, 2018, and 2019, respectively. From day 3 to day 4, these patients' scores stabilized, specifically transitioning from between 6 and 9 points to between 6 and 8 points, with 232, 257, and 267 patients following these trajectories in the fiscal years 2017, 2018, and 2019, respectively. From day 4 to day 5, a declining trend was observed. In particular, 145, 128, and 136 patients with scores between 6 and 8 points saw their scores fall around 4 or 5 points in the fiscal years 2017, 2018, and 2019, respectively.

Beyond day 5, score changes from one day to the next were insignificant. For example, from day 5 to day 6, the scores of 385, 393, and 393 patients remained unchanged in the fiscal years 2017, 2018, and 2019, respectively. Moreover, from day 11 to day 12, the scores of 398, 427, and 401 patients did not change.

In the fiscal year 2017, there were instances of patients following an increasing trajectory, with scores rising from 7 to 10 points between day 9 and day 10, and from 10 to 11 points between day 10 and day 11. Subsequently, for several days, the score remained constant, settling at a high value. In fiscal year 2018, patient trajectories were seen to surpass 10 points between day 3 and day 12. In fiscal year 2019, some patients exhibited an increasing trajectory, with scores rising from 7 to 10 points between day 10 and day 11. Following this surge, the scores plateaued and remained unchanged for several days.

3.1.2. The Neurosurgery Ward. All trajectories of the Neurosurgery Ward are shown in Figure 4. The primary patterns observed in this ward are as follows. Scores of 0 or 1 point were consistent throughout the hospitalization period, suggesting that patients who scored 0 or 1 point on a certain day were more likely to maintain similar scores the next day. Particularly, from day 1 to day 2, 412, 414, and 410 patients followed such trajectories in the fiscal years 2017, 2018, and 2019, respectively. Furthermore, from day 2 to day 3, the numbers of patients with these trajectories were 303, 283, and 257 in the fiscal years 2017, 2018, and 2019, respectively. The remaining patients exhibited diverse trajectories; their progression was intricate and multifaceted.

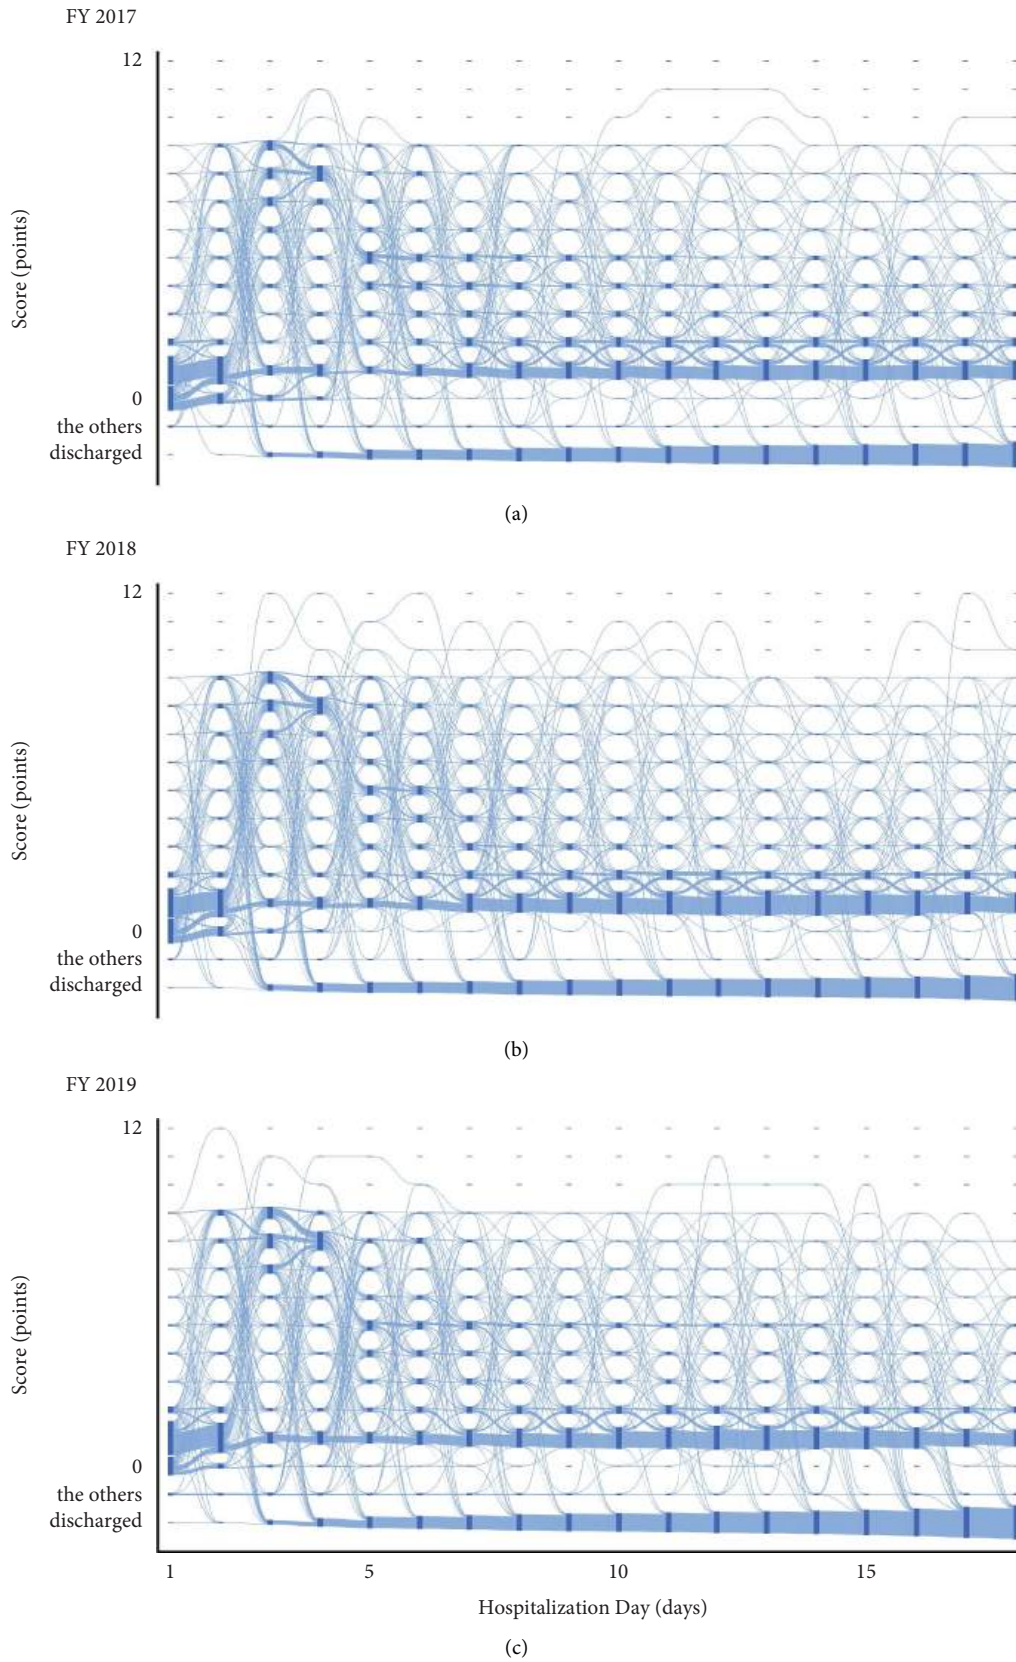

FIGURE 3: The trajectories of nursing demand in the Orthopaedic Surgery Ward for fiscal year (a) 2017, (b) 2018, and (c) 2019. Nodes are represented by rectangles indicating the score. The flows between them are depicted by curves leading from the source to the target nodes. The volume of each flow is indicated by the thickness of the curve. “The others” indicates “staying in other wards or specialized beds.”

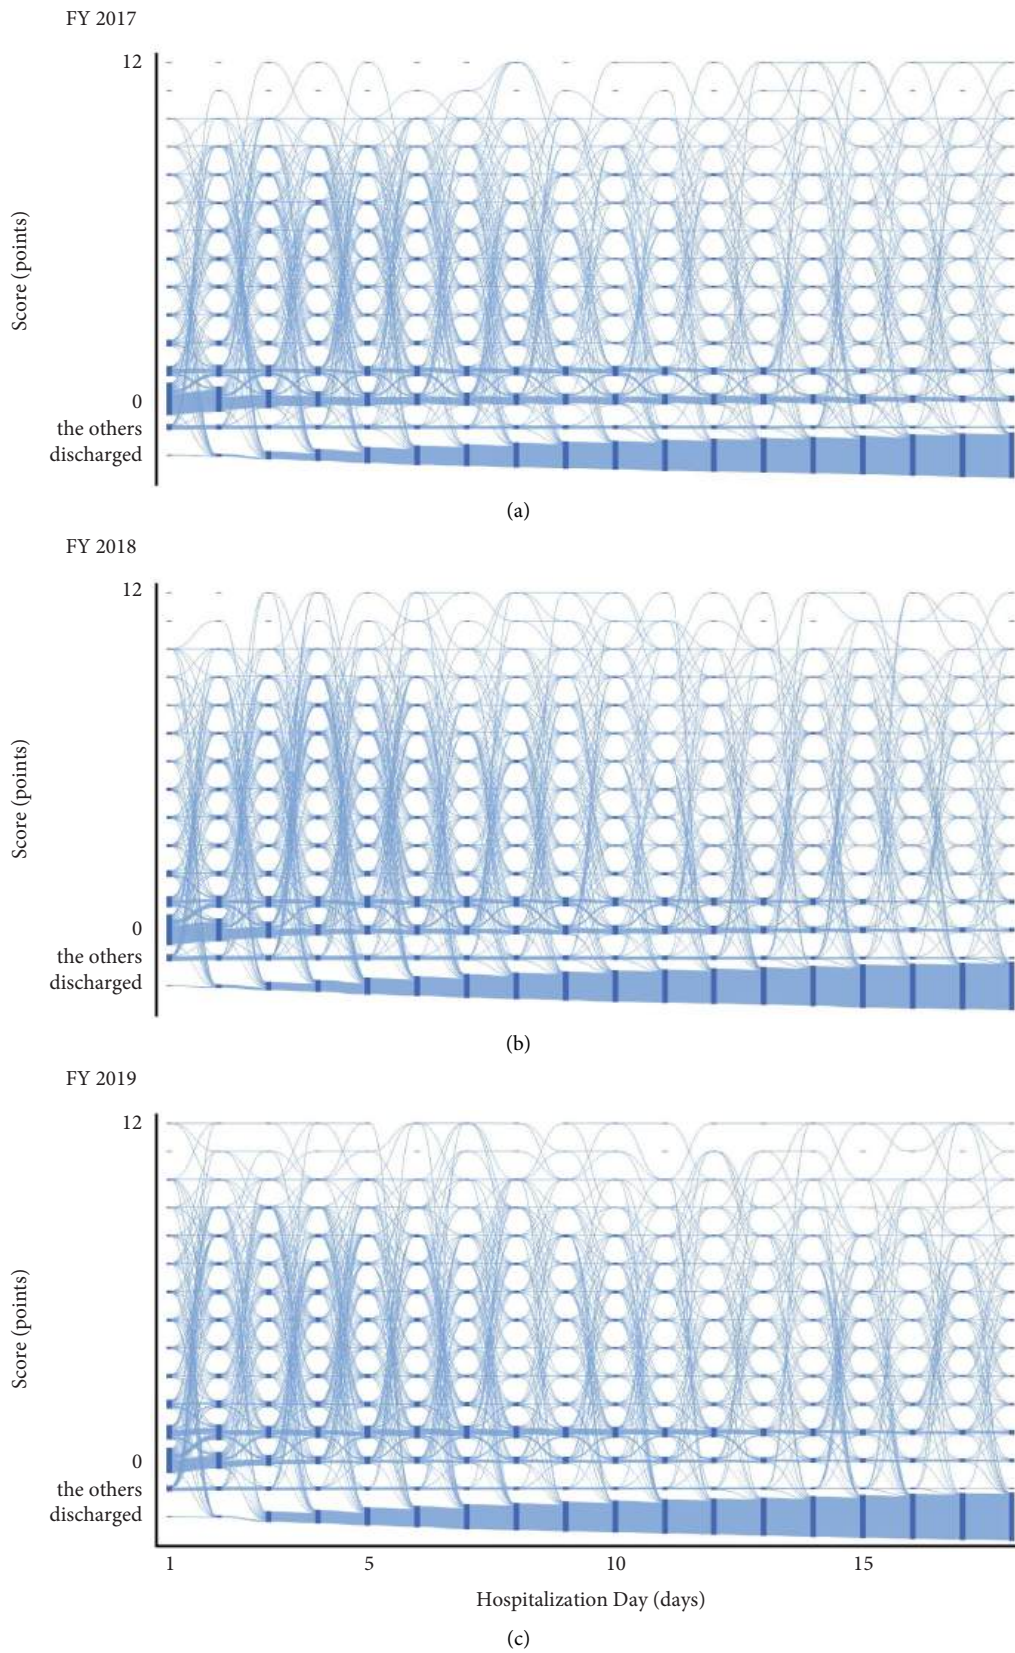

FIGURE 4: The trajectories of nursing demand in the Neurosurgery Ward for fiscal year (a) 2017, (b) 2018, and (c) 2019. Nodes are represented by rectangles indicating the score. The flows between them are depicted by curves leading from the source to the target nodes. The volume of each flow is indicated by the thickness of the curve. “The others” indicates “staying in other wards or specialized beds.”

During the hospitalization period, trajectories reaching scores between 10 and 12 points were observed daily. From day 1 to day 2, the numbers of patients experiencing these trajectories were 8, 11, and 15 in the fiscal years 2017, 2018, and 2019, respectively. From day 10 to day 11, the numbers of patients were 10, 13, and 9 in the fiscal years 2017, 2018, and 2019, respectively. From day 17 to day 18, 19, 11, and 8 patients experienced these trajectories in the fiscal years 2017, 2018, and 2019, respectively.

Notably, we observed trajectories that led from high scores, such as between 9 and 12, to “discharged.” During the hospitalization period, a total of 10, 16, and 24 patients experienced these trajectories in the fiscal years 2017, 2018, and 2019, respectively. We also observed trajectories from “staying in other wards or specialized beds” to high scores, between 9 and 12. From day 1 to day 2, the numbers of patients following these trajectories were 6, 5, and 8 in the fiscal years 2017, 2018, and 2019, respectively. From day 13 to day 14, these numbers were 4, 2, and 3 in the fiscal years 2017, 2018, and 2019, respectively. Although detailed numbers are provided for only a few days, this phenomenon was consistent, regardless of the day of admission during hospitalization.

3.1.3. The Cardiovascular Medicine Ward. All trajectories of the Cardiovascular Medicine Ward are shown in Figure 5. The primary patterns observed in this ward are as follows. On the first day, many patients (609, 594, and 478 in the fiscal years 2017, 2018, and 2019, respectively) scored 0 points. Approximately half of these patients followed a slightly ascending trajectory, with scores increasing to 1 or 2 points from day 1 to day 2. Specifically, the numbers were 243, 170, and 131 in the fiscal years 2017, 2018, and 2019, respectively. These patients then exhibited a downward trend, with their scores decreasing to 0 from day 2 to day 3, with patient counts of 209, 144, and 108 in the fiscal years 2017, 2018, and 2019, respectively.

A significant number of patients demonstrated patterns leading to “discharge” from day 3 to day 4 and from day 5 to day 6. From day 3 to day 4, 302, 281, and 220 patients were discharged in the fiscal years 2017, 2018, and 2019, respectively. From day 5 to day 6, the discharge numbers were 95, 107, and 94 in the fiscal years 2017, 2018, and 2019, respectively. We also noted trajectories of patients moving from “staying in other wards or specialized beds” to achieving higher scores, typically between 4 and 7 points. For instance, from day 5 to day 6, 12 patients exhibited these trajectories in each fiscal year.

A small proportion of patients followed near-flat trajectories, maintaining extremely high scores, such as between 10 and 12 points, throughout their hospitalization. For example, such trajectories were observed from day 5 to day 6 in the fiscal year 2017; from day 4 to day 5 and from day 15 to day 18 in the fiscal year 2018; and from day 1 to day 3 and from day 8 to day 9 and from day 16 to day 18 in the fiscal year 2019.

3.2. The Ward-Specific Feature of the Statistical Regularities in Temporal Dynamics of Nursing Demand

3.2.1. Trajectories of Scores. Here, scores of 0–2 were classified as low, 3–5 as medium, 6–9 as high, and 10–12 as very

high. This classification was provisional, used solely to describe the trajectory. This classification was used tentatively only to illustrate the characteristics of the trajectory. Trajectories from day 3 to day 4 were compared for low scores, medium scores, high scores, ultra-high scores, and from 0 to discharge in each ward in 2017. In Figure 6, scores are represented as follows: low scores in blue, medium scores in green, high scores in red, ultra-high scores in purple, and scores from 0 to discharge in orange.

In the Orthopaedic Surgery Ward, the largest group of patients exhibited a trajectory between high scores, with 265 patients (38.7%), followed by trajectories between low scores with 164 patients (24.0%), and medium scores with 27 patients (3.9%). There were no patients transitioning between ultra-high scores or from 0 to discharge. In the Neurosurgery Ward, the most common trajectory was between low scores with 314 patients (37.4%), followed by high scores with 110 patients (13.1%), medium scores with 39 patients (4.6%), from 0 to discharge with 22 patients (2.6%), and ultra-high scores with 8 patients (1.0%). In the Cardiovascular Medicine Ward, the most common trajectory was also between low scores with 325 patients (32.7%), followed by trajectories from 0 to discharge with 218 patients (21.9%), medium scores with 33 patients (3.3%), and high scores with 5 patients (0.5%). There were no patients transitioning between ultra-high scores.

Thus, in the Orthopaedic Surgery Ward, unlike other wards, a high percentage of patients transitioned between high scores. Also, the trajectories were biased towards high and low scores, indicating a distinct division in patient trajectories that was unique to this ward. In the Neurosurgery Ward, similar to the Cardiovascular Medicine Ward, the majority of patients followed the trajectory between low scores, and the proportion of patients was similar. However, trajectories in other scores were almost evenly distributed among patients, and there were patients transitioning between ultra-high scores, which was not observed in other wards. In the Cardiovascular Medicine Ward, like the Neurosurgery Ward, the most common trajectory was between low scores. However, unlike other wards, there was a higher percentage of patients transitioning from 0 to discharge, showing a bias towards trajectories between low scores and from 0 to discharge. In addition, compared to other wards, there were fewer patients transitioning between high scores and ultra-high scores.

3.2.2. Diversity of Trajectories. Using the same period and scoring classification, differences in the diversity of trajectories were compared. In Figure 7, the red trajectories represent the two most frequent paths, while the blue trajectories denote all other paths. In the Orthopaedic Surgery Ward, there were 84 trajectories out of 225 possible ones. The scores ranged from 0 to 11 points. 164 patients (24.0%) followed trajectories between low scores, 27 people (3.9%) between medium scores, and 265 people (38.7%) between high scores. No patients transitioned between ultra-high scores or from 0 to discharge. A notable 62.7% of patients were concentrated in the top two scoring layers, indicated in red. In the Neurosurgery Ward, there were 104

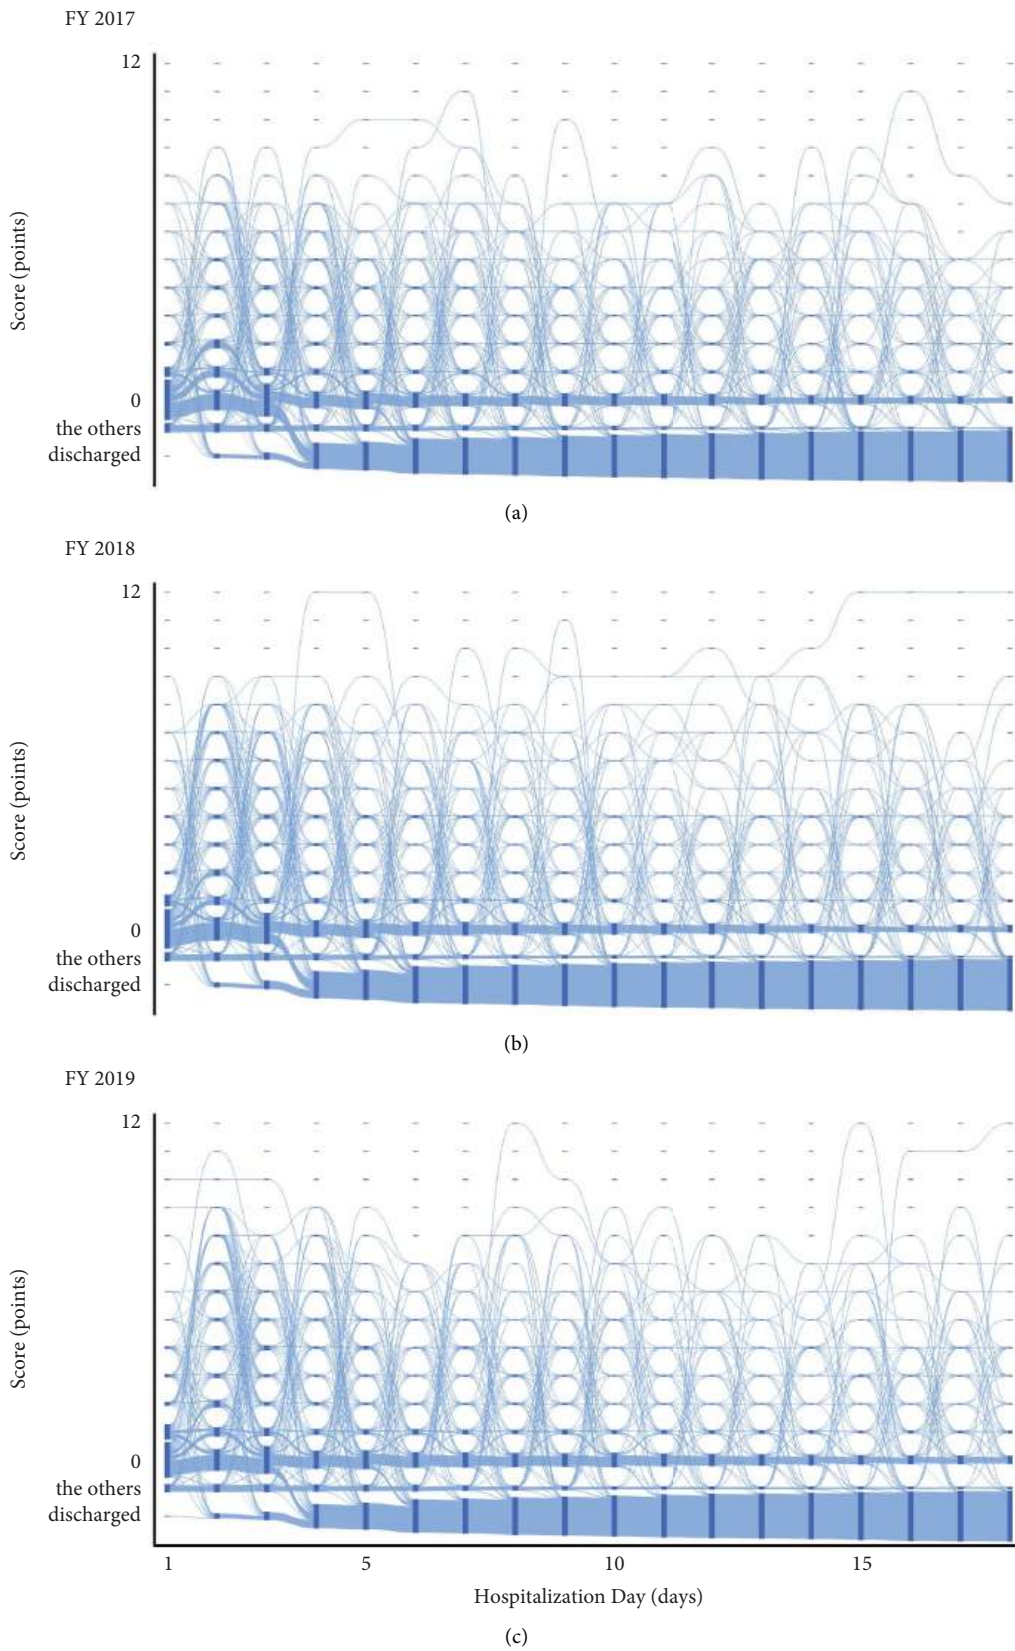

FIGURE 5: The trajectories of nursing demand in the Cardiovascular Medicine Ward for fiscal year (a) 2017, (b) 2018, and (c) 2019. Nodes are represented by rectangles indicating the score. The flows between them are depicted by curves leading from the source to the target nodes. The volume of each flow is indicated by the thickness of the curve. “The others” indicates “staying in other wards or specialized beds.”

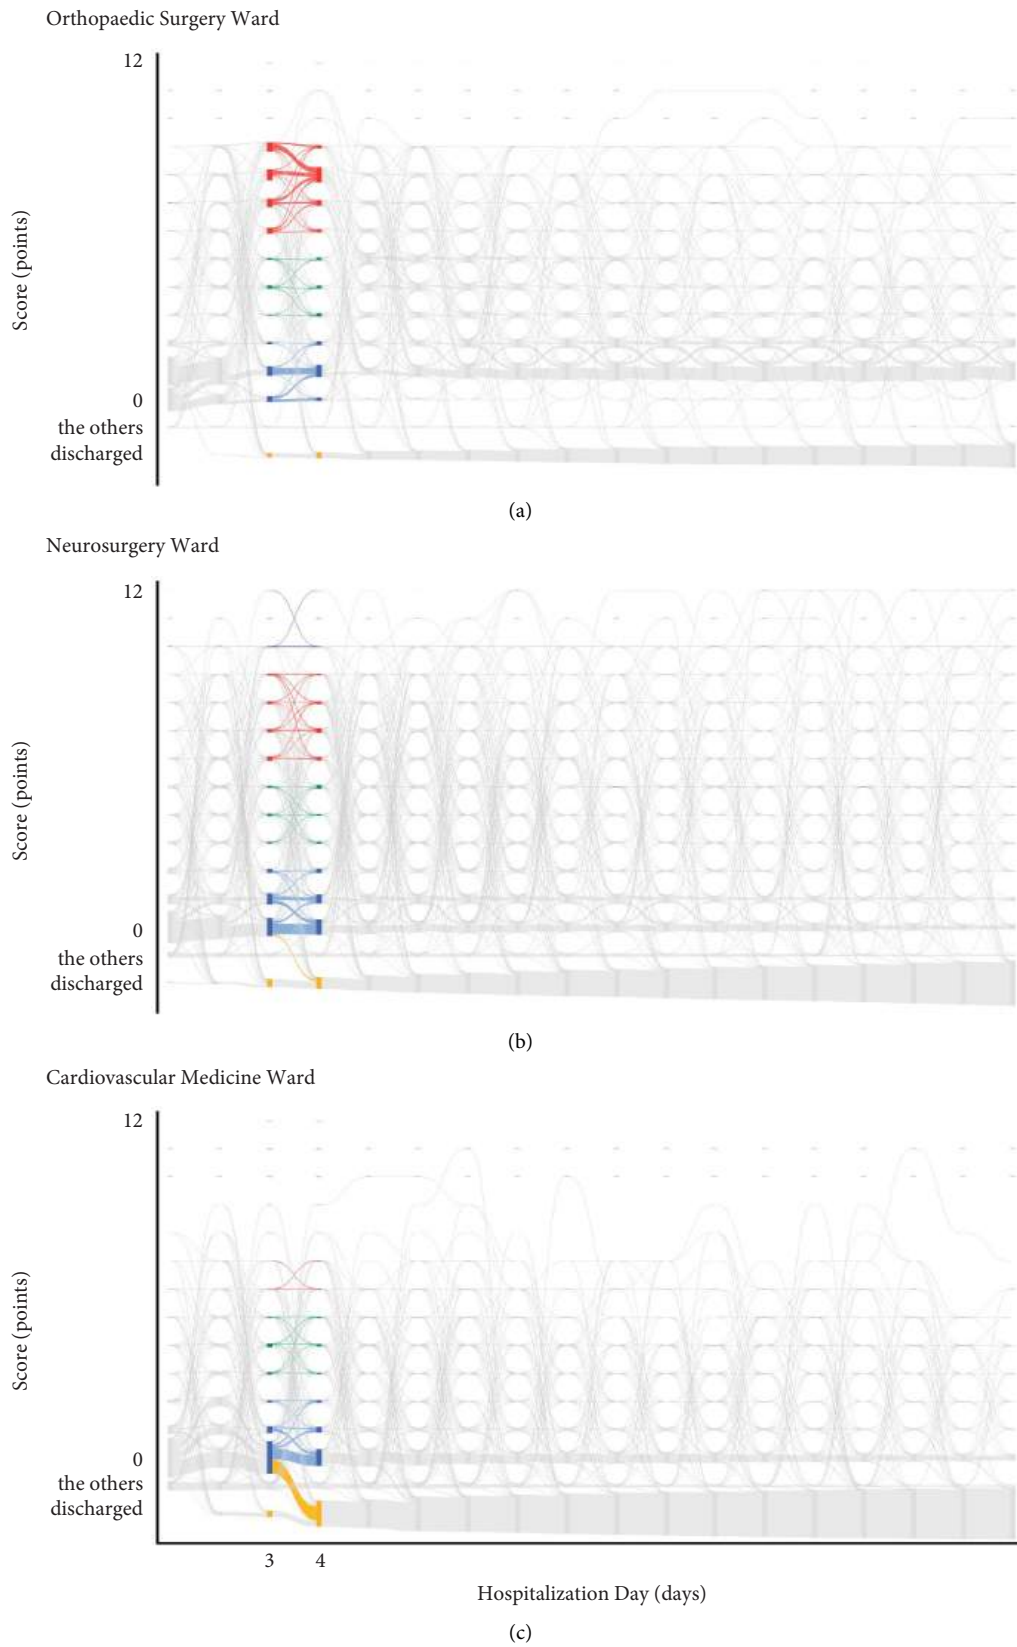

FIGURE 6: The trajectories of nursing demand classifications from day 3 to day 4 in each ward for fiscal year 2017 (a) in the Orthopaedic Surgery Ward, (b) in the Neurosurgery Ward, and (c) in the Cardiovascular Medicine Ward. The yellow trajectories indicate paths from 0 points to discharge, with blue for low scores, green for medium scores, red for high scores, and purple for ultrahigh scores. Nodes are represented by rectangles indicating the score. The flows between them are depicted by curves leading from the source to the target nodes. The volume of each flow is indicated by the thickness of the curve. “The others” indicates “staying in other wards or specialized beds.”

trajectories out of 225 possible ones, with scores ranging from 0 to 12 points. 314 people (37.4%) exhibited trajectories between low scores, 39 people (4.6%) between medium scores, 110 people (13.1%) between high scores, 8 people (1.0%) between ultra-high scores, and 22 people (2.6%) from 0 to discharge. A total of 50.5% of patients were concentrated in the top two scoring layers, shown in red. In the Cardiovascular Medicine Ward, there were 73 trajectories out of 225 possible ones, with scores ranging from 0 to 9 points. 325 people (32.7%) showed trajectories between low scores, 33 people (3.3%) between medium scores, 5 people (0.5%) between high scores, and 218 people (21.9%) from 0 to discharge. No patients transitioned between ultra-high scores. A total of 54.6% of patients were concentrated in the two highest-scoring layers, shown in red.

The Orthopaedic Surgery Ward showed a wider range of scores yet had the highest proportion of patients following notable trajectories, indicating not only a large bias towards notable trajectories but also other patients followed relatively limited trajectories. This was reflected in the diagram by thick red trajectories and a wide range of low-density blue trajectories. The Neurosurgery Ward, with a wider range of scores, had the lowest proportion of patients following notable trajectories, showing the most diverse patterns. This indicated a smaller bias towards significant trajectories, with other patients following a wide range of diverse trajectories. This was represented in the diagram by thin red trajectories and a wide range of high-density red trajectories. The Cardiovascular Medicine Ward, despite a moderate proportion of patients following notable trajectories, had the narrowest range of scores and the fewest trajectory patterns. While there were not many patients following notable trajectories, other patients were following specific trajectories within a narrow range. This was represented in the diagram by relatively thick red trajectories and a narrow range of low-density blue trajectories.

While each ward exhibited several prominent trajectories followed by a significant number of patients, we observed noticeable differences among these trajectories across the wards. Consequently, each ward exhibited unique features in the trajectory of nursing demand. As these features indicated, the trajectories of nursing demand were more similar when we compared them between fiscal years in the same wards than when we compared them between wards. Due to space constraints in this paper, we only presented results from the three wards. However, in practice, similar trends were obtained in the other 17 wards where the same indicator was used.

4. Discussion

4.1. The Statistical Regularities in Temporal Dynamics of Nursing Demand across Fiscal Years within Each Ward. The temporal dynamics of nursing demand are similar from year to year when the first day of each patient's admission is set as the starting point, and the dynamics are viewed from the perspective of the patient population. These similarities suggest the existence of statistical regularities in nursing demand. Clinically, the nursing demand with the

progression of hospitalization days in different groups of newly admitted patients may change probabilistically in the same manner.

These statistical regularities could, in part, be attributable to the decisions made regarding treatment and the support given to patients to follow the course of treatment according to their clinical pathways. In clinical practice sites, when treatment methods are determined, patients are considered to follow a certain predictable course, enabling the provision of nursing care to be aligned with the clinical pathways, excluding patients with multiple comorbidities, dementia, or advanced age. In addition, patients managed with clinical pathways exhibit higher protocol adherence and lower incidence of complications than those without clinical pathways [31, 32]. Thus, the decisions made regarding treatment and the implementation of the clinical pathways could potentially contribute to the similar nursing demand among the patient population in each ward.

The statistical regularities in nursing demand are also considered to be attributable to the biological healing process following a specific course. This is because, despite the clinical pathway compliance rate in the target hospital being less than 50%, more than half of the inpatients appeared to follow a similar trend. When a living body undergoes an invasive treatment, including surgical intervention, it triggers a stress response, striving to maintain homeostasis [33]. Furthermore, postintervention, the body recovers by passing through stages of "injury," "the turning point," "muscular strength," and "fat gain" [34]. Thus, the somewhat rule-based recovery process of a body following an invasive procedure could contribute to the regularities observed in temporal dynamics of nursing demand.

The existence of statistical regularities potentially indicates that we may be able to probabilistically forecast the temporal variation of nursing demand among patients in future years by utilizing historical data on nursing demand. That is because patterns of temporal dynamics of nursing demand are not coincidental but inherent characteristics of the respective wards, and the same phenomena could potentially occur every year. In essence, by creating a system that predicts temporal variations based on past nursing demand data, we may be able to forecast individual patients' temporal changes in nursing demand when this system is applied to future data.

Predicting nursing demand based on statistical regularities will enable the simulation of efficient staff allocation by determining which patients should be assigned to which nurses, ultimately ensuring patient safety with fewer nurses. Although, some prior studies have estimated the number of nurses needed for patient populations, there is a lack of evidence regarding the assignment of individual nurses to individual patients. The nursing shortage was reported to be resolved by securing a sufficient baseline number of full-time nurses and addressing any deficiencies with the addition of temporary staff [35]. However, increasing the number of nurses becomes progressively more difficult due to the looming nursing shortage. Even with additional temporary nurses, a lack of coordination among staff may leave the care undone, threatening patient safety [36]. Thus, we should

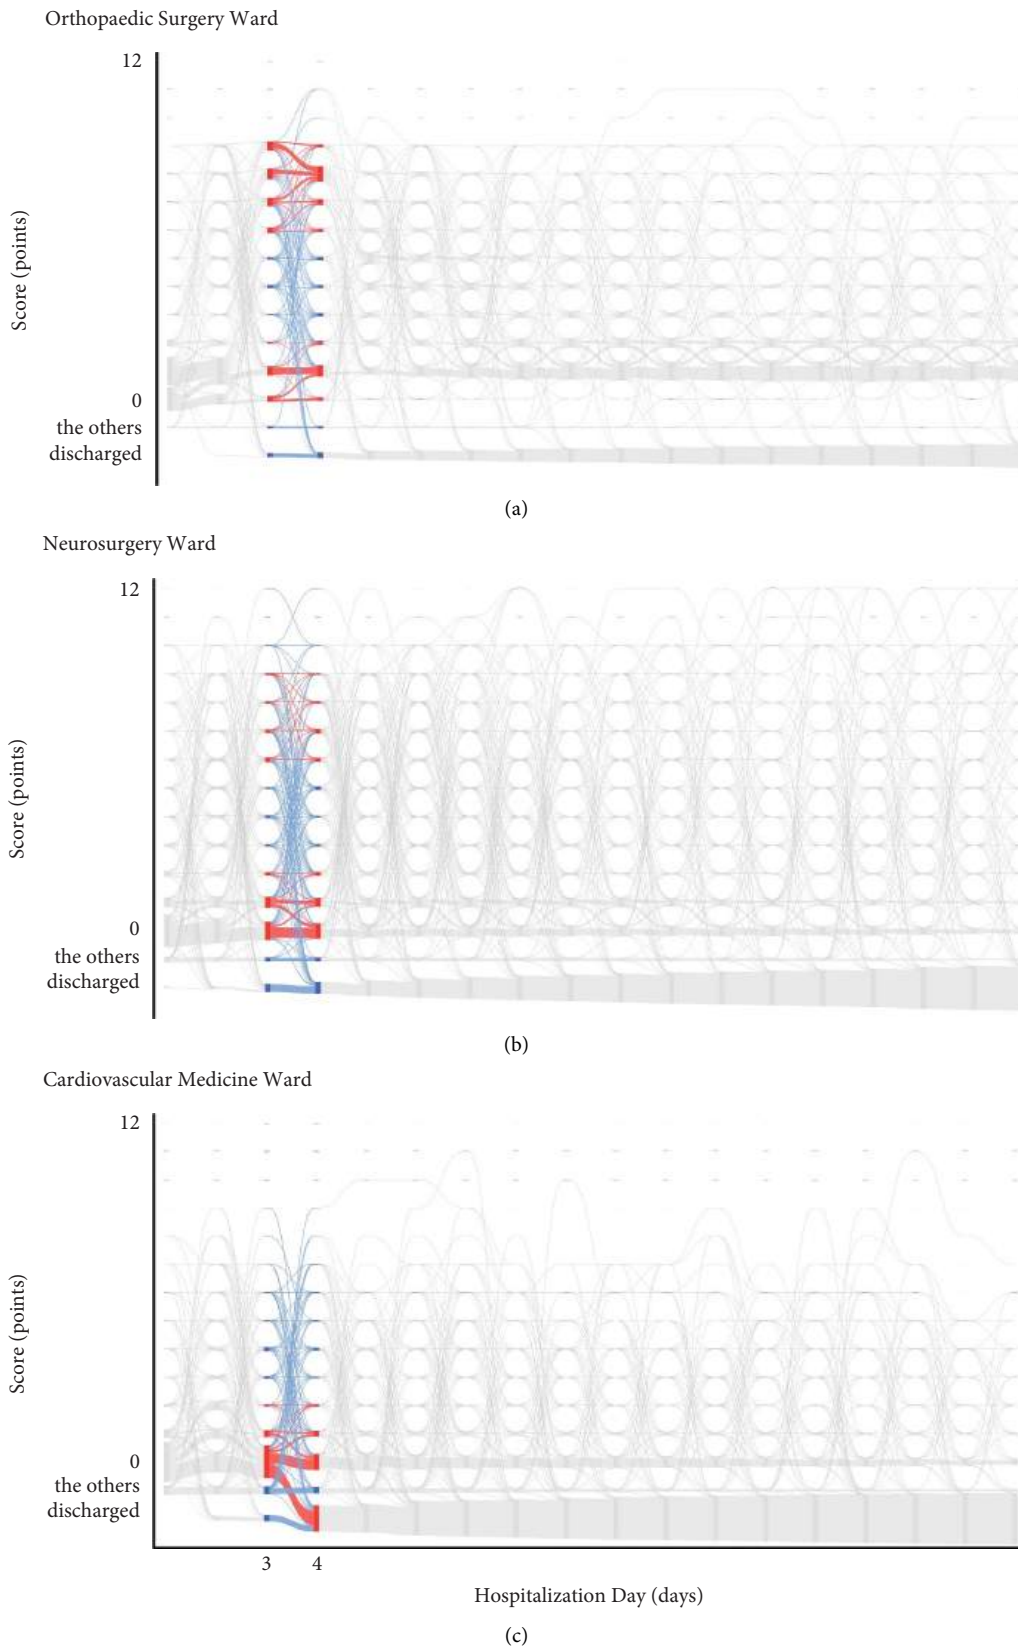

FIGURE 7: The diversity of nursing demand trajectories from day 3 to day 4 in each ward for fiscal year 2017 (a) in the Orthopaedic Surgery Ward, (b) in the Neurosurgery Ward, and (c) in the Cardiovascular Medicine Ward. The red trajectories represent the two most frequent paths, while the blue trajectories denote all other paths. The flows between them are depicted by curves leading from the source to the target nodes. The volume of each flow is indicated by the thickness of the curve. “The others” indicates “staying in other wards or specialized beds.”

assign the limited full-time nursing resources available to patients more efficiently. The inherent statistical regularities in nursing demand can predict changes in nursing demand and inform a simulation model. This model can calculate optimal solutions for assigning nurses to patients [37], thus facilitating the determination of efficient nurse assignments to meet the daily changing needs of individual patients. However, it should be noted that this application assumes equality in nurses' factors. When assigning individual nurses to individual patients, we must consider the nurses' abilities [38] and their perceived workload [39]. To apply these regularities to a staffing model, further examination of additional factors is necessary.

Our use of extensive data represents one of the significant strengths of this study. This allowed us to identify the full range of trajectories in the target wards and to investigate potential statistical regularities. In addition, our analysis was not affected by seasonality since we did not focus on a specific short-term period. Analysis of all patients admitted to the target wards of the target hospital over a three-year period, excluding those with missing data, greatly facilitated our ability to attain these results.

We observed a certain number of patients experiencing a sudden surge in scores or consistently transitioning with high scores each year, especially in the Orthopaedic Surgery Ward and the Cardiovascular Medicine Ward. This suggests that there are also statistical regularities among a small number of patients within the population. These patients had been likely to develop complications or exacerbate comorbidities. That is because, while the proportions vary, some patients have experienced variances in their clinical pathways [40, 41]. In addition, the occurrence of post-operative complications has been associated with an increase in nursing workload, that is, the increase in nursing demand [42]. Thus, the occurrence of complications is considered to result in increases in nursing demand. However, it remains unclear whether there is any regularity in the timing of these occurrences or the scores assigned to them. Future research should aim to elucidate these uncertainties and investigate the features of temporal changes in abnormal patients. This is crucial because, despite the challenges in forecasting sudden changes and abnormal recovery processes from an individual perspective, such occurrences necessitate a substantial amount of nursing care, which can place a significant burden on nurses [42]. To provide necessary care to these patients, as well as the broader patient population, it is essential to adjust nursing schedules and devote nursing resources. The ability to forecast patients with a rapid increase in nursing demand is thought to facilitate efficient, effective, and flexible nursing staff scheduling. In order to adequately devote nursing resources to address the occurrence of abnormal patients, it is necessary to investigate the statistical regularities in their temporal changes.

In the Neurosurgery Ward, it was not possible to clearly discern patients who were considered to experience complications and therefore to undergo a rapid change in nursing demand. The reason is that the patient population in this ward exhibited a greater variety of nursing demand change patterns compared to the other two wards. Each

patient followed various trajectories, meaning that the proportion of patients following each trajectory is low, or in other words, the "flow" is "thin." Consequently, the trajectories of such a small number of patients may have been masked.

4.2. The Ward-Specific Feature of the Statistical Regularities in Temporal Dynamics of Nursing Demand. The statistical regularity inherent in the trajectories of nursing demand is evidently ward-specific. This may be attributed to the different types or levels of nursing care required in different wards, as diverse diseases and treatments impair varying functions in patients [43, 44]. For instance, in the Orthopaedic Surgery Ward, nurses often need to provide considerable assistance to mobilize patients due to their physical dysfunction. A significant amount of care is especially needed just after surgery, and the level of care typically decreases as the days of hospitalization progress. Conversely, in the Neurosurgery Ward, they must manage risk behaviors caused by patients' cognitive dysfunction. The causes of cognitive impairments, such as delirium, often occur suddenly. Moreover, in the Cardiovascular Medicine Ward, nurses often offer various types of care related to ADL since patients often struggle to perform these tasks independently due to circulatory instability or fatigue throughout their hospital stay. Consequently, it is plausible that the specific nature of diseases and treatments gives rise to ward-specific regularities in the temporal dynamics of nursing demand. However, we did not identify the differences in diseases and treatments among participants. Therefore, the detailed causes of these variations in dynamics are speculative at best. Future research needs to pinpoint the factors contributing to the statistical regularities in temporal dynamics, as the amount and timing of nursing care needed to meet the demands of the patient population are likely dependent on its components.

It is essential to forecast the temporal changes in nursing demand on a ward-by-ward basis for nursing management. Indeed, wards serve as the fundamental units of nursing management, with nursing staff scheduling and bed management often implemented at this level. The ward-specific statistical regularities can offer valuable insights for managing nursing in practical settings.

The ward-specific statistical regularities can extend beyond utilization within the ward itself, potentially applying to staff allocations from the hospital to individual wards. By predicting and aggregating nursing demand for each ward, it is possible to estimate the range of basic nursing volume required by patient populations in each ward [45]. The estimated overall nursing demand can lead to estimations of the fundamental number of nurses needed for each ward [45, 46]. Furthermore, wards experiencing significant fluctuations in overall nursing demand may require more flexible staff allocations. Aggregation by ward can also inform the examination of the ratio between fixed and temporary staff numbers. This approach serves as one process in determining the number of nurse staff to be allocated from the hospital to each ward, representing the utilization of nursing management from a more macroperspective than

daily assignments. As previously mentioned, this application assumes equality in nurses' factors, such as abilities and perceived workload. Further research is necessary to identify the factors that should be considered in developing a staffing model.

Since various factors influence the nature of nursing demand [37], charge nurses and nurse managers, who focus more on administrative and managerial duties, have to devote daily nursing resources and permanent nurses based on the nursing demand forecasted from various perspectives. This study represents one such perspective necessary for forecasting nursing demand. Our findings are expected to contribute to forecasting nursing demand and estimating nursing resources, leading to data-driven, more efficient nursing management.

5. Conclusions

The main finding of this study is that the temporal changes in nursing demand demonstrate greater similarity when compared across fiscal years within individual wards than when compared between different wards. This observation suggests the existence of statistical regularity in the temporal changes in nursing demand within each ward. Furthermore, it implies that the temporal changes in nursing demand exhibit unique statistical regularities in each different ward.

As demonstrated in this paper, the statistical regularity is intuitively identified by viewing the temporal changes in nursing demand within each ward as an overlay of multiple trajectories. In addition, we were able to distill statistical regularities across multiple fiscal years by harnessing a substantial amount of data, by encapsulating the influence of individual patients within these regularities.

These findings suggest that patients admitted to the wards are considered to exhibit a certain probabilistic change in nursing demand. It can be inferred that the temporal changes in nursing demand of the patient population are potentially predicted probabilistically, which is useful for nursing management.

6. Limitation

This study has four limitations.

First, the inherent statistical regularities presuppose that the medical and nursing systems have not undergone significant changes over the fiscal years. In fact, a period of three years without such changes was selected for analysis. Specifically, data were extracted from a period without significant ward reorganization due to the COVID-19 pandemic. Changes in hospital operations, such as altering the patient-to-nurse ratio or patient characteristics, may result in a failure to recognize the statistical regularities in nursing demand. Consequently, additional Sankey diagrams may be required to identify new statistical regularities. After the nature of the patterns has changed, within a period where the situation remains unchanged, it will be possible to determine certain regularities, as mentioned in this study.

Second, although the data were thoroughly utilized for the management of the target hospital, the results may lack

generalizability as they were collected from a single acute hospital. The results may not be directly applicable to hospitals or facilities of different sizes or service offerings, particularly smaller healthcare facilities or those specializing in specific medical services. To address this, it would be beneficial to analyze data from patient populations admitted to each hospital in a similar manner. For example, a secondary analysis of data independently recorded at each hospital or facility can identify patterns of nursing demand inherent in the patient populations of those facilities.

Third, the score for item "B" in the INCN only quantifies certain aspects of nursing demand related to ADL and cognition. As such, it may not encapsulate the entirety of nursing demand. However, a statistical regularity is presumed to exist in the temporal dynamics of nursing demand when using this particular indicator.

Last, the score for item "B" in the INCN might not fully represent all nursing demands related to ADL and cognition encapsulated within item "B." This is because these scores are determined based on the actual provision of nursing care. In situations where patients require nursing care from a professional nursing perspective, but such care is not provided, no points are added to the score. Therefore, if the score truly represented nursing demand, the similarity of temporal dynamics between fiscal years might decrease.

7. Implications for Nursing Management

In this study, we identified ward-specific statistical regularities in the temporal dynamics of nursing demand. The existence of such regularities suggests the possibility of forecasting changes in nursing demand and strategizing accordingly [47]. Specifically, we could potentially forecast temporal changes in nursing demand by utilizing data from past fiscal years. This would enable charge nurses and nurse managers to staff efficiently from two main perspectives. First, on a ward-by-ward basis, charge nurses can assign individual nurses to patients daily more efficiently based on data. For example, an experienced nurse might be assigned to a patient for whom dynamic demand changes are expected; conversely, an inexperienced nurse might be assigned to a patient for whom few demand changes are expected. Charge nurses could assign available fixed nurses to patients to ensure patient safety even in situations where the nursing shortage makes it difficult to secure adequate staffing [36]. Second, in management from the hospital to each ward, by predicting and aggregating nursing demand for each ward, nurse managers can estimate the range of basic nursing volume required by the patient population [45]. They can adjust the ratio between fixed and temporary staff to meet these needs effectively. For instance, they should assign more fixed nurses in wards with small fluctuations in nursing demand and, conversely, more temporary nurses in wards with large fluctuations in nursing demand. Ward-specific patterns could also be utilized for hospital-wide management.

In various countries, it is possible to analyze data using the nursing demand indicators relevant to each nation. For instance, various countries employ the NAS to measure

direct and indirect nursing activities [10]. In Finland, the OPC instrument is used to assess the quantity and level of nursing care provided to individual patients [11, 12]. We anticipate that the identification of statistical regularities in nursing demand, as demonstrated in this study, will contribute to more efficient nursing management in various countries.

We strongly advocate for charge nurses and nurse managers to leverage the secondary analysis of extensive data. In the field of nursing practice, a variety of indicators are preserved as large volumes of data and used for different purposes. However, they are primarily employed only within the scope of their original intent. More meticulous management is necessary to ensure the adequate provision of various types and levels of nursing care, avoiding overworking nurses or straining hospital finances, especially in anticipation of future nursing resource shortages [5]. Nursing management is often executed based on assumptions and intuition derived from experienced experts such as chief nurses. However, it is crucial to base forecasts of nursing demand and estimations of necessary nursing resources on data analysis. Relying solely on expert insight could result in a decline in management quality in their absence. Given the aging and declining nursing population, concerns arise about potential future shortages of such experts. Data-driven forecasts and estimations allow nurses of all levels of experience to implement nursing management strategies with the same efficacy, regardless of their individual expertise. Future research should explore the combination of various existing data to implement data-driven nursing management, contributing to the development of nursing sciences.

Data Availability

The access data used to support the findings of this study have not been made available to protect personal information.

Aims and Objectives. To identify and explore assess factors that influence patients' readiness for hospital discharge (RHD) after total knee arthroplasty (TKA). **Background.** Evidence has suggested that most clinical staff use clinical laboratory indicators to determine discharge times, while paying little attention to patients' feelings and needs. Additional research findings have suggested a relationship between patients' self-reported readiness for hospital discharge and postdischarge complication rates, readmission rates, mortality, as well as quality of life. RHD is strongly associated with patient health outcomes. Identifying relevant influencing factors can provide guidance for early individualized interventions by healthcare professionals. **Design.** A cross-sectional study. **Methods.** During 2022, a total of 320 post-TKA patients were selected for this study. The patients were divided into the low-RHD group (<7 points) and the high-RHD group (≥7 points) according to the mean score of the Readiness for Hospital Discharge Scale (RHDS). Established scales were used to collect patients' information and to adopt univariate and binary logistic regression analysis to screen for independent factors. **Results.** In this study, the RHDS score of patients after TKA is 91.90 ± 7.05 , of which 12.8% are in the low-RHD group (mean score <7). The binary logistic regression results reveal that age, educational level, postactivity pain, self-efficacy, and family care have to be considered risk factors generating low-RHD in TKA patients. **Conclusions.** The present study suggests that over 1/8 TKA patients are not ready at the time of discharge. Physicians and nurses can improve patients' RHD by reducing postactivity pain and improving self-efficacy during their rehabilitation period. **Relevance to Clinical Practice.** The results of this study can help physicians and nurses early identify high-risk patients with low RHD and provide them with individualized interventions. In addition to this, it is important that nurses use RHDS to assess the readiness of TKA patients before they are discharged from the hospital.

1. Introduction

As the aging and obese population increases, the number of total knee arthroplasty (TKA) shows a yearly upward trend [1–3]. The annual number of TKA in China has also grown rapidly from 50,000 cases a decade ago to nearly 400,000

cases, with a growth rate of about 27.43% per year, and the number is still rising [4]. It is expected that TKA will become one of the most common surgical operations in the next decade [5].

In response to the healthcare management challenges from increasing number of TKA, hospitals are taking

measures to reduce the length of stay of patients [6–8]. However, the TKA patients usually require 3–6 months support for functional exercise [9]. Thus, as shorter hospital stays reduce the amount of time available to prepare patients for discharge, the risk that their readiness may be affected may increase. In addition to this healthcare management challenge, evidence has suggested that most clinical staff use clinical laboratory indicators to determine discharge times, while paying little attention to patients' feelings [10, 11]. Hence, additional research findings have suggested a relationship between patients' self-reported readiness for hospital discharge and postdischarge complication rates, readmission rates, mortality, as well as quality of life [12–14]. Already in 2017, evidence identified readiness for hospital discharge (RHD) as one of the key indicators of patient safety discharge, which include physical stability, adequate support, psychological ability, and adequate information and knowledge [15]. Identifying the current status and factors that affect RHD in patients after TKA can support physicians and nurses to improve and implement early, individualized interventions with positive impacts on the quality of health care. The literature review undertaken exposed the scarcity of studies on RHD in patients with TKA. Also, as people with different diseases tend to register different RHDS scores and different influencing factors [16], looking into the specificity of TKA patients is justified. In this sense, the main objective of this study is to investigate the current status of RHD in TKA patients and to identify influencing factors. The evidence generated in this article aims to provide guidance for physicians and nurses to improve the readiness to hospital discharge in TKA patients.

1.1. Theoretical Framework. Meleis introduced the concept of transition into nursing in the 1960s, developing the transition theory. Transformation theory mainly comprises the following 4 core notions: the transformed nature, the transformed conditions, the reaction mode, and the care therapy [17]. Based on this, we explore the transformed nature (BMI, type of surgery, etc.), the transformed conditions (age, gender, self-efficacy, etc.), and nursing therapy (discharge teaching) on the reaction mode (the RHD of post-TKA patients) (more details in Figure 1).

2. Methods

2.1. Study Design and Setting. This is a cross-sectional study. From January to May 2022, post-TKA patients from orthopedic departments are conveniently selected for this study in three third-grade A hospitals in Jinan, Shandong Province. In regression analysis, one should have a sample size of 5–10 times the independent variables. There are 25 independent variables involved in this study, and considering 10% ineffective questionnaires, thus requiring at least 275 patients.

2.2. Participants. Three hundred and twenty patients after TKA are recruited for this study. Participants are included according to the following criteria: (a) patients after TKA;

(b) from Shandong Province; (c) good at communicating with others; and (d) willingly join the research and give written consent. Participants are excluded according to the following criteria: (a) with a history of mental illness and (b) develop complications after surgery such as deep vein thrombosis and infection.

2.3. Data Collection. The collection of data is carried out by two graduate students, and both of them have completed 6 months of internship in the Orthopedic Department. The survey is conducted on the day of the patient's discharge, in a quiet room, and takes approximately 20 minutes per patient. Considering that some of the participants are older and have a lower educated level, this research uses a one-on-one question-and-answer format. That is, the graduate student asks the patients about the questionnaire entries and then presents their answers objectively on the questionnaire.

2.4. Instruments. Based on Galvin et al.'s conceptual analysis of RHD, physical (disease-related information), support (social support and family care), psychological ability (self-efficacy), and knowledge (pain control knowledge) are factors that influence a patient's RHD. In addition to this, the scales used in this study are also chosen according to Meleis' transition theory. In summary, we have used the following questionnaires and scales to assess data relating to patients after TKA.

2.4.1. General Information Questionnaire. It is developed by members of the group based on a review of the literature and consultation with clinicians, including demographic information and disease-related information.

2.4.2. Readiness for Hospital Discharge Scale (RHDS). The RHDS was developed by Weiss and Piacentine [18] based on Meleis' transition theory. We use a Chinese version of Lin et al. [19] for this study. The scale consists of 12 questions, each scored 0–10. A mean score of entries on the scale will be used to determine a patient's RHD, with a score of <7 indicating low RHD and ≥ 7 indicating high RHD [20]. There are 3 dimensions in total, which are "Personal Status," "Adaptive Capacity," and "Expected Support." The Cronbach's alpha coefficients for the overall and three dimensions are 0.883, 0.821, 0.851, and 0.778, respectively. The validated Chinese version of the Readiness for Hospital Discharge Scale (RHDS) has been used in previous studies [11, 21]. In addition, there was a pretest. This study used 30 patients in a presurvey, and the results showed that they could understand and answer the questionnaire well.

2.4.3. Visual Analogue Scale (VAS). The VAS is a widely used pain measurement tool to assess the intensity of a patient's pain currently or over 24 hours [22]. It is a 10-cm long straight line with a score ranging from 0 to 10, of which a higher score indicates stronger pain [23]. In this study, it is used to assess the postactivity pain in TKA patients. The

FIGURE 1: The theoretical framework of the research. Note: BMI = body mass index.

Chinese version of this scale has been widely used in studies [24, 25].

2.4.4. Quality of Discharge Teaching Scale (QDTS). The QDTS is developed by Weiss et al. [26] to measure the quality of discharge teaching as perceived by patients, which includes three dimensions, a total of 24 questions with 0–10 points each. Higher scale scores indicate better quality of discharge teaching for patients. The overall Cronbach's alpha coefficient is 0.863. The pretest of the Chinese-translated version was undertaken by many researchers [27, 28].

2.4.5. Self-Efficacy for Rehabilitation Outcome Scale (SER). The SER is developed by Waldrop et al. [29], which includes 12 questions of 0–10 marks each. The scale has been Sinicized and extensively adopted among the Chinese populace [30]. This study uses a total SER score to assess the beliefs of TKA patients in applying adaptive behavior during the rehabilitation period, with higher scores associated with greater self-confidence. The overall Cronbach's alpha coefficient is 0.908.

2.4.6. Pain Control Knowledge Questionnaire. The Pain Control Knowledge Questionnaire, developed by Wen Mei, Sichuan University, China, in 2007 [31], included 8 questions of 1–5 marks each. The researcher has obtained access to the scale via Email. The higher the score, the greater the patient's knowledge of pain control.

2.4.7. Social Support Rating Scale (SSRS). We use the SSRS developed by Xiao [32] to assess the current status of patients' social support. This scale has 10 items with a score range of 12–66, and the higher the total score, the better the social support. The overall Cronbach's alpha coefficient is 0.720.

2.4.8. Family APGAR Scale. The scale, designed by Smilkstein, consists of 5 items, each with a score of 0–2 [33], which

has been used in knee disease patients and has good reliability and validity [34]. In this study, we use the total score of the scale to assess the patient's subjective satisfaction with family functioning. The pretest of the Chinese-translated version was undertaken in a variety of populations [35, 36].

2.5. Data Analysis. We use SPSS (version 26.0) for statistical description and statistical analysis. Numbers and percentages are used to describe demographic information and disease-related information. Continuous variables are described by the mean \pm standard deviation (SD) if they conform to a normal distribution, and if not, by the median and interquartile range. An independent samples *t*-test, chi-square test, and Fisher's exact test are used to compare the differences between the two groups. A binary logistic regression is used to explore the factors affecting post-TKA patients' RHD, with the model applying a forward stepwise likelihood ratio. The significance level of the hypothesis test is set at $\alpha = 0.05$ (two sides).

Before the binary logistic analysis, a covariance diagnosis was carried out using SPSS 26.0 software, which showed that the variance inflation factor (VIF) values ranged from 1.114 to 3.391. In addition, the aim of this study is to investigate the several factors that influence the readiness of post-TKA patients for discharge rather than to analyse the effect of a particular variable on their RHD.

2.6. Ethical Considerations. This study has received approval from the Ethics Committee of the School of Nursing and Rehabilitation, Shandong University (2022-R-021). Before the study begins, the investigators obtained informed consent from the patients and assure them of the confidentiality of the study data.

3. Results

In this study, we collect effective data from 320 patients, with 41 (12.8%) patients with a mean score of less than 7 on the RHDS. The age of the patients ranges from 50 to 88 years, and the mean age is 66.49 years (SD: 7.02). More than three

quarters of them are women. The majority of patients are nonreligious (93.4%), married (80.6%), overweight or obese (80%), and with comorbidities (74.1%). Over 85% of the patients have their first TKA and have a unilateral replacement. The results of the univariate analysis shows that age, education level, marital status, per capita income, number of comorbidities, hospitalization time, postactivity pain, quality of discharge teaching, self-efficacy, pain control knowledge, social support, and family care are independent factors for RHD in patients with TKA ($P < 0.05$), more details in Table 1.

The patients' scores for total RHDS and scores for each dimension are shown in Table 2. First, we diagnose that there is no multicollinearity between variables which are statistically significant for univariate analysis and then perform a binary logistic regression analysis (forward: LR method). The results show that age, postactivity pain, education level, self-efficacy, and family care are independent factors, more details in Table 3. The Hosmer–Lemeshow goodness-of-fit test suggests that the overall model fit is adequate ($\chi^2 = 2.736$, $P = 0.950$). At the same time, the Nagelkerke R^2 reveal that the logistic regression model explains 69.0% of the variance.

The average length of stay for post-TKA patients was 5–7 days in the three hospitals.

4. Discussion

The results of this study show that the mean RHDS score of patients after TKA is (7.66 ± 0.59), an intermediate level. In this research, TKA patients have lower RHD than those medical and surgical patients who had a mean RHDS score of (8.62 ± 1.47) [37]. An analysis of the reasons for this may be as follows: on the one hand, as an invasive procedure, post-TKA patients often have pain and functional limitations [38]. Also, even up to 1/5 of the patients suffer from a fear of movement and a severe reduction in mobility [39], which affects their functional recovery. On the other hand, compared to other surgical operations, like hip arthroplasty, TKA patients require long-term rehabilitation at home [40], which may increase their discharge uncertainty and decrease their RHD. Of the three dimensions of RHDS, adaptive capacity has the lowest score and expected support has the highest score, a fact that is exactly the opposite of what is found in earlier studies [13]. The reason for this result may be connected to the traditional Chinese culture where family members take the initiative to provide patients with living support, encouragement, and favorable conditions for functional exercise. The results of Wang et al.'s study of cancer survivors indicate that Chinese collectivist-oriented culture promotes social harmony and makes it easier for patients to express their inner feelings and thus receive support [41]. On the contrary, low scores on adaptive capacity indicate that patients lack confidence in their ability to recover at home and care for themselves after surgery.

The results of binary logistic regression in this research suggest that the older the age, the worse the patient's RHD (OR = 1.187), which is consistent with previous studies [42]. Older patients are more likely to have poorer health and

more comorbidities, which could lead to difficulties in restoring their quadriceps strength and prolong recovery time. So, they are more likely to have a low RHD at the time of discharge. This suggests that doctors and nurses should pay more attention to older patients, formulate comprehensive rehabilitation plans through multidisciplinary consultation, and clarify their disease character. In addition to this, doctors and nurses should improve the patient's physical condition through nutrition, medication, and rehabilitative exercises before surgery, thus improving their RHD.

Postactivity pain is a risk factor for low RHD in patients (OR = 2.461). Postactivity pain is an important problem for TKA patients [43, 44]; about 60% of them experience pain after surgery [45]. Pain can trigger a systemic stress response in the patient, affecting the body's autonomy and immune system, causing a range of postoperative conditions and seriously affecting postoperative rehabilitation [46]. Consequently, physicians and nurses should pay more attention to patients' pain problems and actively adopt various methods such as multimode analgesia [47], a cold compress [48], as well as traditional Chinese medicine treatment [49] to alleviate postoperative pain so that patients can be ready for discharge soon.

Patients with high levels of education are more likely to have high RHD after TKA (OR = 0.093), which is in agreement with several previous studies [50, 51]. First, patients with a high educational level can better understand the content of discharge teaching and make full use of health information resources and second, they can effectively communicate with medical staff and get helpful information. So, nurses should focus on those patients whose education level is an elementary school and below and use easy-to-understand language for discharge teaching, avoiding medical jargon. At the same time, a good relationship should be established between the doctor and the patient so that the patients can truly express their inner needs to the doctors and nurses.

Different from previous findings, self-efficacy is a significant factor that affected patients' RHD in the present research (OR = 0.836), rather than the quality of discharge teaching [11, 21, 52]. Self-efficacy, as a cognitive mechanism regulating behavioral activities in the field of rehabilitation, can facilitate the translation of patients' motivation and willingness to engage in activities into the performance of specific activity behaviors [53]. The postoperative rehabilitation for TKA patients will directly affect the outcome of the surgery and is crucial to their ability to gain independent [54, 55]. Therefore, healthcare professionals could construct rehabilitation programs based on Bandura's self-efficacy theory to increase patients' self-efficacy levels and enhance their confidence in overcoming their illness, thereby improving their RHD.

Family care is also an important factor in RHD for people with TKA (OR = 0.344), not social support as in previous findings [13, 56]. Influenced by the traditional Chinese culture of "filial piety," children will play a supportive role in their parents' later years. Due to the trauma of the surgery, patients undergo physical and psychological changes after TKA, as well as increased dependency. To this

TABLE 1: Univariate analysis of RHD in TKA patients ($N = 320$).

Variables	Total ($n = 320$)	Low RHD ($n = 41$)	High RHD ($n = 279$)	$t/F/\chi^2$	P

end, the nurse should urge the families to give more care and support to the patients. A good family functioning is effective in reducing postoperative stress and strain, increasing the patient's level of hope, speeding up their recovery process and improving RHD. Thus, healthcare professionals can involve family members in the patient's discharge planning and teach them care skills. Moreover, family members can play a supervisory role in the patient's recovery process.

As the evidence generated in this article aimed to provide guidance for physicians and nurses to improve the readiness

for hospital discharge in TKA patients, the following are key recommendations for professionals around the world: First of all, physicians and nurses need to pay attention to patients' RHD and include their self-reported RHD as part of the discharge assessment plan. Then, the hospital should form a multidisciplinary discharge service team consisting of orthopedic specialists, anesthetists, dieticians, rehabilitators, and nurses so as to develop a personalized discharge plan for the patient based on their actual situation. Next, the hospital units could improve the quality of discharge teaching for patients by regularly organizing post-TKA nursing knowledge competitions, nursing skills competitions, teaching competitions, etc. It is also important to include patients' families in discharge teaching. Last but not the least, there should be timely and excellent communication between the higher hospital and the community sector regarding the patient's condition and recovery. Through mobile web-based devices, senior doctors can regularly guide community doctors in assessing patients' recovery to reduce their uncertainty after discharge from hospital.

4.1. Limitation. This research still has some limitations. First, the subjects of this study are all from Jinan, Shandong Province, with limited extrapolation of results. Second, this

study uses a one-on-one question-and-answer format to collect patient data, which may have some reporting bias. In the future, we could carry out multicenter studies to further explore the factors influencing RHD in patients after TKA.

5. Conclusions

The RHD of TKA patients is first brought to our attention. The results of this study shows that TKA patients have a moderate level of RHD and over 1/8 of the patients are not prepared at discharge. In particular, age, postactivity pain, education level, self-efficacy, and family care are factors influencing RHD in patients with TKA.

6. Implications for Practice

First, the results of this study provide a basis for clinical staff to identify high-risk patients with low RHD and provide them with individualized interventions. Second, it is important that nurses use RHDS to assess the readiness of TKA patients before they are discharged from the hospital. Third, hospital managers should adhere to a “patient-centered” management model and develop personalized discharge services for patients from the start of their visit. Finally, hospitals should work with the community to assign post-discharge rehabilitation plans for patients in the context of their condition in order to reduce their uncertainty after discharge and improve their RHD [57–60].

Data Availability

The data used to support the findings of this study are available from the corresponding authors upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

Na Li and Paulo Moreira are equivalent first authors.

Acknowledgments

First, we would like to thank all the patients who participated in this research. Second, we appreciate the support and guidance given by the teachers in the hospital department. Third, we would like to thank the project supervisors for their guidance and the students for their hard work. They are all important factors that enable this research to be carried out successfully. This study was funded by the Medical and Health Science and Technology Development Program of Shandong Province, China (202014021227).

Object. To explore occupational stressors among Chinese hospice nurses. **Methods.** A descriptive qualitative approach was used. We conducted semistructured interviews with 30 hospice nurses from 14 cities in China between August 2023 and February 2024. Data were analyzed using conventional content analysis. The study adhered to the COREQ checklist for reporting. **Results.** Hospice nurses perceived themselves as immersed in a persistent “negative energy magnetic field,” emphasizing the pervasive stress they experienced in their work. There are four different levels of occupational stressors among Chinese hospice nurses: (1) individual-level stressors such as difficulty in managing physical symptoms, dealing with futile resuscitations, and struggling with emotional boundaries; (2) organizational-level stressors encompassing insufficient financial support and human resources, negative leadership behaviors, and conflicting philosophies in healthcare; (3) societal-level stressors involving challenges such as avoidance of conversations about death, pragmatism, and implicit communication modes; and (4) acute stressors including patient suicide and sudden patient death. **Conclusions.** Diverse occupational stressors faced by hospice nurses are greatly influenced by culture. Future research should thoroughly examine these stressors at various levels and consider the cultural impacts on the stress experienced by hospice care nurses within a broader context.

1. Introduction

In China, the population aged 60 and above reached 280 million by the end of 2022, constituting 19.8% of the total population [1]. Meanwhile, the incidence of new cases of malignant tumors was 4.064 million, with a rate of 293.91 per 100,000 in 2016 [2]. As the elderly population grows rapidly and the number of cancer patients continues to increase, the demand for hospice care in China is rising. The government has shown considerable interest in advancing hospice care, as evidenced by the issuance of the “Healthy China 2030 Outline,” which explicitly emphasizes the necessity of bolstering the infrastructure of hospice care to ensure

comprehensive healthcare services spanning from prenatal care to end-of-life care [3]. To achieve this goal, the Chinese government launched the first batch of nationwide pilot work on hospice care in five cities in 2017 and subsequently increased the number of pilot cities twice in 2019 and 2023. Despite increased government support for hospice care in recent years, the development of hospice care in China is still in its infancy. This is mainly due to insufficient education about hospice care, inadequate staffing of hospice care teams, and uneven distribution across regions [4, 5].

Caring for terminal patients creates a challenging and high-pressure work environment for hospice nurses. Terminal patients seek more care, comfort, and emotional

support, and hospice nurses play a crucial role in providing these aspects. Hospice care aims to relieve patients' physical symptoms and extends its responsibility to address patients' psychological, mental, social, and spiritual needs [6]. The expectations of meeting diverse needs pose higher demands for hospice nurses. They must not only care for patients experiencing pain and other symptoms but also help them navigate the uncertainty surrounding their death [7]. Additionally, they are expected to fulfill families' various needs while facing potential risks in the process of caregiving, such as providing grief counseling for bereaved family members [8].

Occupational stress is an individual's subjective experience of stressors resulting from the imbalance and mismatch between work demands and response capacities [9]. Previous studies found that excessive occupational stress can have negative impacts on nurses' physical health and emotions during their work, leading to reduced productivity, compromised the quality of nursing care. Excessive occupational stress among nurses can lead to detrimental outcomes for all parties involved: nurses, patients, and hospitals [10–12]. Quantitative studies from Germany [13, 14] and Japan [12] reported that hospice nurses experienced a medium-to-high level of work-related stress, primarily due to main occupational stressors such as high workload, high emotional demands, and chronic exposure to death. One study on hospice nurses in the United States showed that the most significant occupational stressor among nurses was assisting patients and their families in coping with death, followed by workload issues, such as a shortage of human resources and insufficient time to provide psychological support to patients [15]. Additionally, relationships with patients, families, and team members were identified as both stressors and sources of energy for hospice nurses, depending on how they were perceived and managed [16]. Therefore, recognizing hospice nurses' stressors at an early stage and assisting them in effectively coping with and transforming stressors is critically important to improve nurses' psychological health.

Most studies on occupational stressors among hospice nurses have applied quantitative research methods. While quantitative research is helpful for identifying stressors using structured assessment measures, it may overlook significant stressors from nurses' perspectives and fail to consider cultural influences on these stressors [17]. Qualitative research serves to address this deficiency by understanding hospice nurses' occupational stressors from their own perspectives and experiences, aiding in the identification of previously neglected stressors [18]. Compared to Western countries, hospice care in China is in its early developmental stage, and hospice nurses may face specific stressors during this phase [19]. Additionally, stressors are affected by cultural backgrounds [20]. Different countries and regions have different perspectives on dying, death, and the afterlife due to their diverse cultural backgrounds, making hospice care highly culturally diverse. The psychological, spiritual, and social needs of terminal patients vary widely in different regions. The traditional Chinese worldview of life and death has a profound influence on patients' acceptance of hospice

care, their decisions about end-of-life treatment and care, and the way they express their personal care needs, which may affect the occupational stress of hospice nurses to some degree [21]. Specifically, the Chinese death culture is characterized by a "reverence for life and aversion to death," where death is seldom discussed openly as it is still considered taboo and inauspicious [22]. Most Chinese people tend to pursue longevity, rather than the quality of life. This cultural perspective on death causes terminal patients and their families to fear death, pursue treatment at all costs, and hold a negative attitude toward hospice care, viewing it as merely waiting for death [23]. This, in turn, leads to resistance against the care provided by hospice nurses, causing them considerable stress in their work.

To date, no studies to the authors' knowledge have comprehensively examined the occupational stressors experienced by hospice nurses in China. Existing literature has mostly discussed job burnout and compassion fatigue among hospice nurses [24–26]. Deepening our contextual knowledge of this area is crucial for cultivating supportive work environments to manage stress effectively. Therefore, this study aims to investigate the occupational stressors experienced by hospice nurses in China, contribute additional evidence on this topic for other countries, and provide insights for stress management among hospice nurses in culturally similar regions. Additionally, the findings of this qualitative study can lay the groundwork for developing specific stress screening tools and establishing coping strategies.

2. Methods

2.1. Design. A qualitative descriptive approach is beneficial for collecting detailed, direct, and firsthand descriptions of a phenomenon with limited available information [27]. This design is suitable for discovering and understanding a phenomenon, a process, or the perspectives and worldviews of individuals involved in research [28]. Therefore, in this study, this approach was selected to gain a comprehensive understanding of hospice nurses' perceptions regarding occupational stressors. This study was reported following the Consolidated Criteria for Reporting Qualitative Research (COREQ) checklist.

2.2. Settings, Recruitment, and Sampling. Participants for this study were recruited through invitations sent to institutions and at conferences. For institutional recruitment, we purposively sampled hospice care institutions in Taiyuan, Suzhou, and Changsha. Prior to entering these institutions, we sent a "Research Opportunities Inquiry at Your Institution" (Supplementary Material 1) to seek permission from administrators. Administrators then introduced the study to hospice nurses and recruited potential participants. For conference recruitment, the interviewer (YW) attended the National Hospice Care Nursing Advances Seminar hosted by the Chinese Nursing Association in July 2023 and the Guangdong Province Hospice Care Service Skills Training Workshop in October 2023. At these conferences,

the interviewer actively invited hospice nurses across China to participate in the study. Following these methods, interested participants were contacted and provided with detailed study information. They were given at least 24 hours to consider whether to participate in the study. Given the relatively limited number of hospice nurses in China and their dispersed distribution, snowball sampling was employed after each interview to invite qualified acquaintances to join the study, aiming to gather more comprehensive data [29]. Furthermore, small gifts were given to the research participants to acknowledge the time and effort they have provided in participating in the research.

2.3. Participants. From August 2023 to February 2024, researchers recruited hospice nurses from fourteen medical institutions nationwide. The inclusion criteria were: (1) having a hospice nursing qualification certificate and possessing more than one year of hospice care experience and (2) consenting to participate in the current study. The exclusion criteria were: (1) nurses who were not in the period of rotation of hospice care or had left this work and (2) standardized training nurses, refresher nurses, and nurse interns. The sample size was determined by the principle of data saturation, ensuring that no new emerging information was obtained [30].

2.4. Data Collection. The interviews were conducted by YW, a female doctoral student in nursing with training in qualitative interviewing, psychological counseling, and specialized hospice nursing. YW completed her master's degree in nursing in Suzhou and is currently pursuing her doctoral degree in nursing in Taiyuan. She audited a two-week specialized hospice nurse training course by the Chinese Nursing Association in Changsha. This background helped her quickly build rapport with participants and grasp cultural cues and dynamics during interviews. After piloting interviews with two hospice nurses and refining the interview guide, the final version covered two main areas: (i) general experiences in end-of-life care and (ii) stressful situations faced by hospice nurses at work. During each interview, further flexible probing and exploration were conducted based on the participants' responses. YW explained the interview purpose and procedures, obtained consent, and scheduled meeting times. Interviews were conducted in a quiet, safe, and private setting. Considering the dispersed nature of hospice nurses and limited financial and human resources, the study utilized both face-to-face and telephone interviews to enhance response rates [31]. All interviews were recorded, and reflexive field notes were taken to capture the researcher's reflections for subsequent interviews. After 27 interviews, data saturation was achieved, with an additional three interviews conducted for confirmation [32].

2.5. Data Analysis. Interviews were recorded and transcribed verbatim within 24 hours. The current study used conventional content analysis to analyze interview data [33].

This method takes a data-driven "bottom-up" approach to analyze data without specific research hypotheses. Instead, it allows researchers to actively identify codes, subcategories, and categories based on participants' responses. Specifically, the first and second authors independently delved into the interview data, repeatedly reading text files and immersing themselves in the context to gain a general sense of the data. Next, they read the text data word by word, condensed, and extracted meaningful units related to stressors of hospice nurses from the text, and then began coding. After the number of codes was saturated, the two authors organized the codes into subcategories and categories based on the connections among code attributes and codes. Lastly, they defined each category and subcategory. To ensure the consistency of the analysis, the research team discussed regularly and reached a consensus on codes, subcategories, and categories throughout the data analysis process.

2.6. Rigor. Guba and Lincoln's principles were adopted to ensure the rigor and trustworthiness of this study [34]. First, this study conducted interviews with hospice nurses from fourteen cities across east, south, west, north, and central China, representing wide-ranging age groups, various lengths of work experiences, different educational backgrounds, and varied professional titles to enhance the diversity of perspectives. Then, two researchers independently coded the data and regularly reported the results to the research group. This approach aimed to avoid the influence of researchers' presumptions on the analysis process and to enhance the credibility of the results. Finally, the first author conducted member-checking, returning research data to participants to verify the accuracy and alignment of the study results with their experiences.

2.7. Ethical Considerations. This study obtained ethical approval from the Ethics Committee of The First Hospital of Shanxi Medical University (Ref: NO. KYLL-2023-021) and the Shanxi Medical University Research Ethics Committee (Ref: 2024002). The researchers explained the purpose of study to the participants and received their consents before interviews. Written informed consent was obtained from all participants prior to the interview. Participants' identifiable information, including personal names and employer names, has been de-identified. All data were collected solely for research purposes and kept confidential and undisclosed to the public.

3. Results

Thirty hospice nurses were interviewed from fourteen cities across China. Researchers conducted in-person interviews ($n = 15$) with hospice nurses from Taiyuan, Suzhou, and Changsha. In addition, virtual interviews ($n = 15$) were conducted with nurses from the remaining cities due to personnel and financial reasons. Each interview took about 45 to 60 minutes. More details on the final participant characteristics are shown in Table 1.

TABLE 1: Characteristics of the participants (N = 30).

Nurses	Gender	Age	Education	Title	Hospice care experience (year)
N1	Female	46	Bachelor's degree	Supervisor nurse	15
N2	Female	37	Bachelor's degree	Associate professor of nursing	3
N3	Female	31	Bachelor's degree	Supervisor nurse	1
N4	Female	35	Bachelor's degree	Supervisor nurse	2
N5	Female	37	Bachelor's degree	Supervisor nurse	1
N6	Female	36	Bachelor's degree	Supervisor nurse	5
N7	Female	37	Bachelor's degree	Supervisor nurse	4
N8	Female	35	Bachelor's degree	Supervisor nurse	1
N9	Female	36	Bachelor's degree	Supervisor nurse	6
N10	Female	33	Bachelor's degree	Supervisor nurse	5
N11	Female	25	Bachelor's degree	Senior nurse	3
N12	Female	33	Bachelor's degree	Supervisor nurse	4
N13	Female	34	Bachelor's degree	Supervisor nurse	4
N14	Female	47	Associate's degree (3 years)	Supervisor nurse	8
N15	Female	38	Bachelor's degree	Senior nurse	7
N16	Female	25	Associate's degree (3 years)	Senior nurse	5
N17	Female	30	Master's degree	Senior nurse	2
N18	Female	33	Bachelor's degree	Supervisor nurse	1
N19	Female	41	Bachelor's degree	Supervisor nurse	2
N20	Female	25	Bachelor's degree	Senior nurse	3
N21	Female	29	Associate's degree (3 years)	Senior nurse	7
N22	Female	26	Bachelor's degree	Senior nurse	4
N23	Female	36	Bachelor's degree	Supervisor nurse	4
N24	Female	33	Bachelor's degree	Supervisor nurse	3
N25	Female	40	Master's degree	Associate professor of nursing	5
N26	Female	25	Bachelor's degree	Nurse	1
N27	Female	27	Master's degree	Supervisor nurse	1
N28	Female	29	Master's degree	Senior nurse	2
N29	Female	39	Bachelor's degree	Supervisor nurse	5
N30	Female	32	Bachelor's degree	Supervisor nurse	4

The “Negative Energy Field” model of hospice nurse stressors (Figure 1) draws on the structure of the “magnetic field” and the concept of “systems thinking.” Systems thinking argue that the only way to fully understand one thing is to understand the parts in relation to the whole [35]. Hospice nurses described feeling surrounded by various stressors in end-of-life care, creating a pervasive sense of being in “negative energy field” (e.g., “This is where many life pains converge, and stress permeates everything.”). Hospice nurses’ perceptions of occupational stressors were categorized into four types: individual-level stressors, organizational-level stressors, societal-level stressors, and acute stressors (see Figure 1). It is worth emphasizing that acute stressors may affect hospice nurses across individual, organizational, and societal levels. Therefore, based on the study findings and researcher reflection, acute stressors are depicted spanning each level in Figure 1. More details on categories, subcategories, and quotes can be found in Table 2.

3.1. Individual Level

3.1.1. Patient Care Difficulties. Terminal patients, who are the primary recipients of hospice care, directly influence hospice nurses through their suffering, leading to distress among the nurses. Specifically, the inability to relieve patients’ physical discomforts and to deal with patients’

complex and ever-changing mental states has contributed to significant stress for hospice nurses.

(1) *Difficulty in Managing Physical Symptoms.* Participants reported that symptoms of terminal patients were complex, and the final stages of diseases are often the most challenging to manage. This not only imposes a significant workload on nurses but also causes substantial stress when patients’ symptoms cannot be effectively relieved.

“Their [the patients’] wish in coming here is to be comfortable. They want to experience comfort during the last stage of life. Patient families also desire comfort, wishing for no pain, no suffering, and no depression. The most significant stress for us is that we sometimes struggle to manage patients’ symptoms despite our best efforts.” (N6).

(2) *Complex and Ever-Changing Mental States.* Mental states of terminal patients are constantly in an unstable condition due to the deterioration of illness and the approach of death. Hospice nurses reported feeling a high level of stress when facing such situations.

“The patients we work closely with are terminal patients. They may have a very bad temper and could suddenly curse

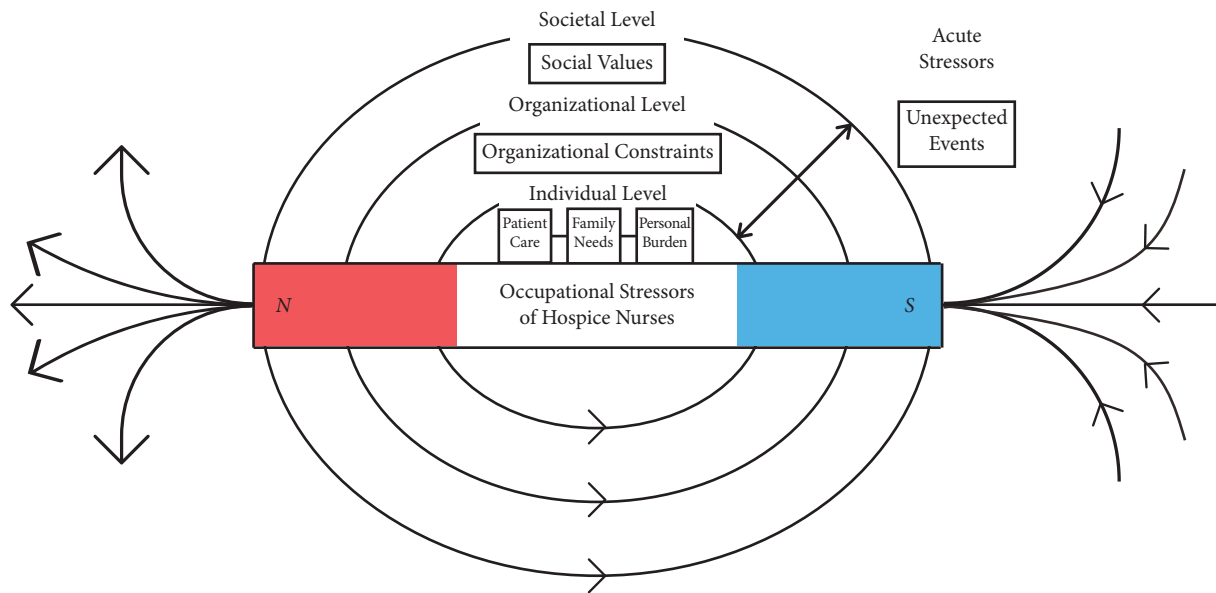

FIGURE 1: The “negative energy field” model of hospice nurse stressors.

or lose their temper while you are providing them with care. They also show negative attitudes toward you. It is not because of your care quality but because they need a place to vent their emotions.” (N8).

(3) *Lack of Standards in Spiritual Care.* Spiritual care is a significant component in hospice care. It is personalized, unstandardized, and requires specific techniques. Moreover, the spiritual needs of terminal patients differ from those of ordinary patients. In addition to enduring physical pain, terminal patients also confront the inevitable risk of death. Many participants expressed that spiritual care is often the most stressful aspect of hospice care.

“Individuals have varied spiritual needs, so there is no single correct answer or set procedures guiding you in providing spiritual care. It [spiritual care] changes all the time. Therefore, it’s quite stressful.” (N5).

3.1.2. *Family Needs.* In Chinese culture, the opinions and attitudes of the family are highly valued, particularly when making critical decisions. Therefore, hospice nurses must consider the feelings of the family when inquiring about patients’ preferences and discussing patients’ conditions and death. Nurses are often asked not to disclose patients’ true diagnosis and prognosis until consent is obtained from their families. This situation has made their work challenging, as the nurses are expected to consider the family’s needs while providing hospice care according to the patients’ preferences.

(1) *Futile Resuscitations.* Under the influence of China’s traditional culture of familism, families might request medical staff to actively resuscitate and treat patients when faced with the impending death of terminal patients. The unnecessary resuscitations conflict with the principles of

hospice care, which involve allowing patients to pass away with dignity, without pain, and the decision to forgo futile resuscitations. Therefore, hospice nurses often experience confusion and stress due to these futile resuscitations.

“Not every patient in our units can leave peacefully because some families persistently ask for resuscitations, possibly influenced by China’s traditional values. These families believe that they must resuscitate their parents to show filial piety and care. I find it painful to witness these resuscitations for terminal patients, but we must comply in most situations. That’s what the family asks for, and we must follow.” (N1).

(2) *Disease Concealment.* The families of patients may request that nurses withhold information about the patients’ actual medical conditions from the patients, seeking to prevent psychological shocks arising from awareness of their illnesses. Concealing these illness conditions has placed additional stress and challenges on the daily care duties of nurses.

“I believe that every patient family who conceals illness conditions from the patients will eventually regret it. While I would suggest not concealing such information, I respect the family’s decisions, and I have no right to interfere. Therefore, I will be more careful in handling these situations and feel stressed in the meantime.” (N8).

3.1.3. *Personal Burdens.* Hospice nurses can experience stressors related to personal factors at work, including worries about insufficient professional knowledge and skills to achieve the goals of hospice care, difficulties in managing nurse-patient relationships, and anxiety and fear about death due to prolonged exposure to patients’ deaths.

TABLE 2: Categories, subcategories, and exemplar quotations.

Categories	Sub-categories	Quotations
	Difficulty in managing physical symptoms	<p>Their [the patients'] wish in coming here is to be comfortable. They want to experience comfort during the last stage of life. Patient families also desire comfort, wishing for no pain, no suffering, and no depression. The most significant stress for us is that we sometimes struggle to manage patients' symptoms despite our best efforts. (N6)</p> <p>Patients have questioned me, "I am here to reduce symptoms. Why are there no solutions? Why can't you do it? What are you doing every day? I don't want to stay here anymore. Do you have any pills to poison me to death?" These questions are constantly shocking. Some patients even say, "Let me die," repeat this over and over. At that moment, you truly feel that the stress has reached its peak. (N10)</p> <p>You watch this situation hopelessly. You want to intervene, to alleviate some symptoms, but you are powerless. (N14)</p> <p>The patients we work closely with are terminal patients. They may have a very bad temper and could suddenly curse or lose their temper while you are providing them with care. They also show negative attitudes toward you. It is not because of your care quality but because they need a place to vent their emotions. (N8)</p> <p>The emotions of terminal patients are very unstable. You can easily sense their feelings of upset or depression. I find it challenging to talk with them. I don't know how to relieve their emotions, how to identify their problems, or how to assist them in expressing or releasing repressed emotions. (N12)</p> <p>The ever-changing emotions, symptom discomforts, and the lack of safety among the patients all contribute to bringing me stress. For instance, they may request me to help with a haircut, but after 10 or 15 minutes, they would say, "I'm dizzy now. I don't want to see you now. I want to stay alone." (N20)</p> <p>One day during the night shift, you might have a heart-to-heart talk with the patient. They would hold your hands and say, "Thank you for giving me strength and warmth." Then the next day, the patient doesn't recognize or remember you, or they even start to resist you. You don't know the reasons for it, which is very frustrating. (N23)</p> <p>Individuals have varied spiritual needs, so there is no single correct answer or set procedures guiding you in providing spiritual care. It [spiritual care] changes all the time. Therefore, it's quite stressful. (N5)</p> <p>We need to fulfill patients' emotional or spiritual needs before their deaths. I don't know how to take care of those patients or flow into their hearts. This can be stressful. (N8)</p> <p>Not every patient in our units can leave peacefully because some families persistently ask for resuscitations, possibly influenced by China's traditional values. These families believe that they must resuscitate their parents to show filial piety and care. I find it painful to witness these resuscitations for terminal patients, but we must comply in most situations. That's what the family asks for, and we must follow. (N1)</p> <p>Many patient families consent to hospice care, but when the patients are close to death, their families regret, change their minds, and force you to intervene. The families can't bear the judgments or infamies from society, so they ask for resuscitations and continue letting the elders live with pain and suffering. This situation is very stressful, but I can't make any changes. (N7)</p> <p>I believe that every patient family who conceals illness conditions from the patients will eventually regret it. While I would suggest not concealing such information, I respect the family's decisions, and I have no right to interfere. Therefore, I will be more careful in handling these situations and feel stressed in the meantime. (N8)</p> <p>It's very common for patient families to request that we conceal the real conditions of patients, not informing them about the limited time they have left. I find it challenging and distressing to provide hospice care while concealing. (N19)</p> <p>There are situations where I find myself unsure of how to handle them, possibly due to a lack of capabilities and techniques. I feel that I haven't learned enough or don't possess sufficient knowledge, and this can be quite stressful. (N5)</p> <p>Hospice care has high requirements for nurses, not only in terms of working experience but also in terms of personal insights and approaches to handling problems. I often find that my knowledge and techniques are still insufficient, which can be quite stressful when facing certain issues. (N12)</p> <p>I think that our job is kind of cruel. You need to build emotional relationships with patients, but every relationship has the same outcome—they will pass away. Therefore, I think it's very cruel and very sad for us, hospice nurses. This requires a strong psychological state. Every time I think of their leaves, I feel deeply sorrowful. (N11)</p> <p>I take care of them, listening to music together, going for walks, and investing both effort and emotions. We then build strong emotional relationships. When they pass away, it feels akin to losing a family member. It's a deeply sorrowful experience. You know that they will have a such end, but you can not control your tears. (N23)</p> <p>I believe that working in the hospice unit can be challenging because, at times, emotions are difficult to control. After witnessing patients' deaths, I occasionally find myself losing hope in life and feeling that things are meaningless. (N14)</p> <p>I contemplate my own mortality, acknowledging that one day I will experience the same fate. I also think about the eventual loss of my family members. There is no solution; I must accept it. Every time these thoughts raising, I feel hurried. (N26)</p>
	Complex and ever-changing mental states	
Patient care difficulties	Lack of standards in spiritual care	
	Futile resuscitations	
	Disease concealment	
Family needs		
	Lack of knowledge and skills	
	Struggle of emotional boundaries	
Personal burdens		
	Death anxiety	

TABLE 2: Continued.

Categories	Sub-categories	Quotations
Organizational level	Organizational constraints	<p>I feel stressful every day. The government provides minimal funding, and we receive low pay. Why am I still dedicated to this job? This is a crucial question many people are facing. The most basic reality is that no matter how passionate you are about hospice care, you must survive. While money may not be your top priority, you need to ensure, at the very least, your daily necessities. (N7)</p>
	Insufficient financial support and human resources	<p>Working here, there is an imbalance between your effort and your pay. In our hospital, as hospice nurses, we are the busiest but receive very low pay. (N16)</p> <p>Personnel are very lacking. Many hospice nurse specialists are not specially providing hospice care. Most of them must take on responsibilities in other wards and provide hospice care during their free time. So, this is very challenging. In fact, all our cases involving spending our own time and money to care for patients. (N8)</p> <p>Actually, hospice care is an additional responsibility. While tending to patients in the hospice wards, there are other patients you need to take care of as well. Initially, we didn't have the responsibility of hospice care, but now we have extra specialized tasks due to the addition of hospice wards. I currently handle it with my devotion. (N23)</p> <p>The head nurse frequently criticizes and scold us in the morning meetings. Working in a department where death is a common occurrence is already quite stressful. Having to face criticism early in the morning adds to the stress throughout the day. I find this situation very frustrating. (N2)</p>
	Negative leadership behaviors	<p>I feel like the head nurse doesn't really care about their duties. However, when their supervisor asks for task outcomes, they turn to you and request information. What can you do? You can't say it's not your responsibility. They never specify what I should do and what I don't need to do, which is quite annoying. They seem unwilling to take responsibility but frequently ask you to handle tasks. (N16)</p>
	Conflict philosophies in healthcare	<p>I think there is another major stressor. Hospice care has only been practiced well by nurses but not by doctors. The medical philosophies are mismatched. Many doctors have not recognized hospice care, and this is disadvantageous to cooperate as a team. (N16)</p> <p>Nurses have a higher passion for hospice care. But as a nurse, your voice is often not heard. After all, doctors have all the rights to decide how to treat patients, and they are seen as having a higher status by patients. Nurses face many stresses during their practices, especially when doctors don't recognize your work. (N19)</p>
	Avoid conversations about death	<p>China has a long history of Confucianism for thousands of years. Due to its influence, we only discuss births and lives but not deaths. Many people still avoid discussing or facing death; thus, the death education is very challenging. People generally have a low acceptance toward it. Hospice care is about discussing death, but no one is willing to engage in conversations about death. Therefore, this job is quite stressful. (N3)</p>
Societal level	Social values	<p>When we tried to promote hospice care to the patient, they did not accept it very well due to the impact of our Chinese traditional cultures. They would say that death bring bad luck, then they always avoid any conversations about it. People always misunderstand about hospice care, and this misunderstanding make you feel stressful. (N23)</p> <p>We provide some comforting services to the patients, such as meditation and aromatherapy, but they perceive these as ineffective for their illness. You meticulously prepare those services, but it doesn't come with positive feedback, then you would feel stressed. I even started to question the purpose of this job. (N6)</p> <p>They [patient families] don't care about it [comforting care] because they believe that it's not necessary or beneficial for their parents [the patients]. Comforting care is perceived as lacking practicality. I think this is detrimental to our work and feel a little frustrated. (N13)</p>
	Implicit communication mode	<p>The implicit expression of Chinese people makes it hard for them to express their emotions. It's very difficult for you to let them speak out. Hospice care encourage patients to reflect on their emotions and feelings, but we just can't do it. It's hopeless, and I don't know how to do it. (N2)</p> <p>Chinese people are often reserved, and many of them may not be adept at expressing themselves or do so in an ambiguous way. So, we can't have some deep conversations, and this could be another stress in my work. (N21)</p>
	Patient suicide	<p>We have a patient committed suicide during the night, without a single sign. You can't figure out why this happened. After that, I become very concerned about the patients, especially about their psychological problems. (N6)</p>
Acute stressors	Unexpected events	<p>One older patient suddenly passed away. I made rounds of the ward, and the nursing assistant did as well, but the patient suddenly died without warning. During our meeting, the head nurse and doctors questioned me if I did the scheduled word inspections and if I checked their breaths. I just stood there and started self-doubting. It's very stressful. (N11)</p> <p>Patients could pass away peacefully in their sleep, with stopped heartbeats and no breaths, even if they were not in a severe condition. When patient families touched their bodies, they found them cold. Overwhelmed with grief, they rushed to the nurse station, crying and eventually breaking down. You can imagine how stressful it was for us (N16)</p>

(1) *Lack of Knowledge and Skills.* Some hospice nurses believed that they lacked professional knowledge and skills, and they worried that they were not competent enough to provide high-quality care services to patients.

“There are situations where I find myself unsure of how to handle them, possibly due to a lack of capabilities and techniques. I feel that I haven’t learned enough or don’t possess sufficient knowledge, and this can be quite stressful.” (N5).

(2) *Struggle of Emotional Boundaries.* Because of the challenges in controlling the level of emotional involvement with patients, hospice nurses frequently encounter difficulties in handling their emotions after patients pass away, resulting in adverse emotional outcomes.

“I think that our job is kind of cruel. You need to build emotional relationships with patients, but every relationship has the same outcome—they will pass away. Therefore, I think it’s very cruel and very sad for us, hospice nurses. This requires a strong psychological state. Every time I think of their leaves, I feel deeply sorrowful.” (N11).

(3) *Death Anxiety.* The hospice nurses reported experiencing anxiety related to death and questioning the meaning of existence, after repeatedly facing the shocks of patient deaths.

“I believe that working in the hospice unit can be challenging because, at times, emotions are difficult to control. After witnessing patients’ deaths, I occasionally find myself losing hope in life and feeling that things are meaningless.” (N14).

3.2. Organizational Level

3.2.1. *Organizational Constraints.* In a team of collaborative members with diverse personalities and varied professional backgrounds, differences in opinions on patient treatment or care arise, and consensus communication is lacking. Hospice nurses also reported stressors stemming from the lack of resources and support for nursing work from management, including negative leadership behaviors.

(1) *Insufficient Financial Support and Human Resources.* Participants expressed that the current state of hospice care and the policy environment in China are still in their infancy. The funding and human resources for conducting hospice care are insufficient, resulting in a lack of adequate financial support for nursing work. Hospice nurses invest a significant amount of time and effort but receive comparatively minimal remuneration, which becomes a stressor for them.

“Personnel are very lacking. Many hospice nurse specialists are not specially providing hospice care. Most of them must take on responsibilities in other wards and provide hospice

care during their free time. So, this is very challenging. In fact, all our cases involving spending our own time and money to care for patients.” (N8).

(2) *Negative Leadership Behaviors.* Many participants indicated that head nurses, as pillars for nursing staff, exhibit negative leadership behaviors during the management process. For example, scolding nurses in public and adopting an unsupportive attitude toward their work, which are significant stressors for the nurses.

“The head nurse frequently criticizes and scold us in the morning meetings. Working in a department where death is a common occurrence is already quite stressful. Having to face criticism early in the morning adds to the stress throughout the day. I find this situation very frustrating.” (N2).

(3) *Conflict Philosophies in Healthcare.* Participants expressed that, at the current stage, China is actively cultivating specialized hospice nurses but lacks a focused training program for hospice specialized doctors. This has led to a certain level of mismatch in the medical and nursing philosophies in actual work. Many doctors have not provided sufficient support for hospice care, creating obstacles in the practice of hospice nursing care.

“Nurses have a higher passion for hospice care. But as a nurse, your voice is often not heard. After all, doctors have all the rights to decide how to treat patients, and they are seen as having a higher status by patients. Nurses face many stresses during their practices, especially when doctors don’t recognize your work.” (N19).

3.3. Societal Level

3.3.1. *Social Values.* China’s traditional culture, with Confucianism as the principal part, has shaped the values, beliefs, customs, and behaviors of Chinese people. It also has a profound influence on people’s attitudes towards hospice care.

(1) *Avoid Conversations about Death.* Chinese culture emphasizes the idea of “emphasizing birth and downplaying death.” Specifically, people rarely directly talk about death and even view death as a taboo and an inauspicious topic. This perspective has led to misunderstandings and rejections toward hospice nurses and their work, causing stress for the nurses.

“When we tried to promote hospice care to the patient, they did not accept it very well due to the impact of our Chinese traditional cultures. They would say that death bring bad luck, then they always avoid any conversations about it. People always misunderstand about hospice care, and this misunderstanding make you feel stressful.” (N23).

(2) *Pragmatism*. The Chinese style pragmatism emphasizes the most direct application and short-term benefits. Some terminal patients considered certain comforting care in hospice care as lacking practicality for treating illness. Therefore, they often express attitudes of skepticism and reluctance, and it has created a certain amount of stress for hospice nurses.

“We provide some comforting services to the patients, such as meditation and aromatherapy, but they perceive these as ineffective for their illness. You meticulously prepare those services, but it doesn’t come with positive feedback, then you would feel stressed. I even started to question the purpose of this job.” (N6).

(3) *Implicit Communication Mode*. In Chinese culture, people usually tend to follow the principle of restraint. They adopt implicit and veiled ways of expressing thoughts and emotions, further forming a culture that values reserved emotions. In hospice care, patients and their families often have ambiguity and flexibility in their expressions, presenting a challenge in nurse-patient communication. Nurses often find it difficult to accurately discern the genuine needs of patients and their families.

“Chinese people are often reserved, and many of them may not be adept at expressing themselves or do so in an ambiguous way. So, we can’t have some deep conversations, and this could be another stress in my work.” (N21).

3.4. Acute Stressors

3.4.1. *Unexpected Events*. When unexpected events occur, such as patient suicide or sudden patient death, nurses may experience acute stress across individual, organizational, and societal perspectives in the short term. Specifically, these events may result in blame from the patient’s family and self-doubt at the individual level; questioning from nursing managers or doctors about their patient monitoring abilities at the organizational level; and undermining the perceived value and acceptance of hospice nursing at the societal level.

(1) *Patient Suicide*. Hospice nurses have the mission of facilitating a peaceful death for patients. When confronted with situations where patients choose suicide to end their pain and suffering, hospice nurses are profoundly shocked, experiencing emotions such as anger, fear, and self-blame. Society also questions the professionalism of nurses.

“We have a patient committed suicide during the night, without a single sign. You can’t figure out why this happened. After that, I become very concerned about the patients, especially about their psychological problems.” (N6).

(2) *Sudden Patient Death*. Terminal patients may experience sudden deaths due to the severity of their illnesses. Families of the patients often struggle to accept these sudden deaths.

Additionally, doctors and nursing supervisors may attribute them to the nurses’ dereliction of duty. Hospice nurses, in turn, express feelings of self-doubt and self-blame regarding the sudden deaths of patients.

“Patients could pass away peacefully in their sleep, with stopped heartbeats and no breaths, even if they were not in a severe condition. When patient families touched their bodies, they found them cold. Overwhelmed with grief, they rushed to the nurse station, crying and eventually breaking down. You can imagine how stressful it was for us.” (N16).

4. Discussion

In this study, we employed a descriptive qualitative approach to directly investigate hospice nurses’ occupational stressors in their own words. Additionally, we used conventional content analysis, a data-driven “bottom-up” approach, to capture insights directly from participants. This method mitigates researcher bias and provides novel perspectives on the data. This study delves deeply into the occupational stressors from the perspective of hospice nurses. They perceived themselves as being immersed in a persistent “negative energy magnetic field,” highlighting a pervasive sense of being engulfed by layers of stress. Within this field, they not only encounter various stressors but are also surrounded by an insidious energy that casts a pall over the entire work environment. This depiction underscores the ubiquity of stress and conveys the complex and profound challenges that nurses face in their work. The field itself emits a vibe of “Like charges repel each other,” further emphasizing the intensity of the stress and its inescapable nature within the work setting.

The study found similar results to previous studies, indicating that the inability to alleviate patients’ physical symptoms [36], the complex and variable psychological states of terminally ill patients [37], the inability to adequately meet patients’ spiritual needs [38], and a lack of self-knowledge and skills [39] can contribute to a certain level of psychological stress for nurses. Furthermore, our findings indicated that the absence of emotional boundaries in nurses is also a major source of stress. Hospice care is a practice that involves both professionalism and emotion, making it difficult for nurses to entirely separate professional relationships from personal ones, especially within the context of relationally oriented Chinese culture [40]. The lack of emotional boundaries during patient care causes significant emotional distress (e.g., compassion fatigue and vicarious trauma) for hospice nurses [41, 42]. Establishing emotional boundaries is a key strategy in mitigating emotional distress. Although challenging in clinical practice, there are methods to maintain these boundaries. For instance, hospice nurses can prevent and alleviate emotional distress through self-awareness and mindfulness techniques [43]. Organizations should enhance emotional training, regularly assess mental health, and provide professional psychological support when needed [44]. The current literature offers limited practical techniques for hospice nurses to maintain emotional boundaries, indicating a need for future research in this area.

It is worth noting that some special requests from patients' families, such as futile resuscitation and concealment of the condition, also often put nurses under great pressure. Influenced by Chinese traditional familism, family decisions often take precedence over the wishes of terminally ill patients themselves. In addition, due to the traditional filial piety values in China, making every effort to save lives is generally regarded as the epitome of "filial piety" [45]. Consequently, family members often request medical personnel to actively resuscitate and treat patients who are on the brink of death. This often leads to overtreatment of terminally ill patients, in particular the use of cardiopulmonary resuscitation. This conflicts with the hospice care principle of allowing patients to die with dignity and without pain, and abandoning end-of-life resuscitation, which also causes stress for hospice nurses. The second stressor from patients' families is concealing the medical condition. Due to China's cultural background, families often choose to conceal a patient's terminal condition. [46]. It is assumed that disclosing the true condition aggravates the patient's condition and leads to tension and anxiety. Whether maintaining confidentiality regarding the illness or disclosing it to the patient presents a common source of stress and dilemma for hospice nurses. In China, families play central roles in hospice. Consequently, initiatives such as life and death education for the public should be implemented to gradually raise awareness of hospice care throughout society.

From an organizational perspective, insufficient funding and human resources are also stressors, consistent with the findings of Ling's research [4]. Furthermore, our findings showed that negative leadership behaviors have adverse effects on hospice nurses' emotions and motivations. The Chinese social context is characterized by collectivism and influenced by traditional Confucian thought, with deep-rooted concepts of hierarchical respect, causing significant distress to nurses due to negative leadership behaviors [47]. Additionally, conflicts between medical and nursing philosophies are also a prominent source of stress for hospice nurses. In the development of hospice care in China, nursing has taken the lead over medicine, with the nursing profession placing a stronger emphasis on the philosophy of hospice care. For instance, since 2019, the Chinese Nursing Association has been conducting training for hospice care specialty nurses, whereas there is currently no specialized training for hospice care doctors in China. The nursing profession also started offering degrees and graduate education in hospice care studies in 2024 [48]. Overall, hospice care competency training for doctors in China is insufficient. However, in clinical practice, doctors usually assume a leading role, leading to patient identification and trust in doctors' decisions. Conflicts between medical and nursing philosophies in such situations create stress for nurses.

From the social perspective, former studies emphasized how the public's fear of death puts pressure on hospice care nursing in China [39]. Within the Chinese cultural background, our study is the first to identify that pragmatism and implicit communication modes impact on the work of hospice nurses. Firstly, unlike the philosophical concept of

pragmatism, Chinese pragmatism places greater emphasis on "practicality" and stresses "immediate effectiveness" [49]. Some humanistic practices in hospice care, which patients believe are of no substantive or immediate benefit to their illness, often lead to questioning and reluctance to accept, which to some extent also causes distress for nurses. Furthermore, the lack of freedom of thought and expression formed by China's long-standing feudal autocracy and constraints from Confucianism deeply affects all aspects of Chinese society. "Harmony" is the core of the Confucian system of benevolence and a significant aspect of Chinese philosophy of life [50]. The concept of "harmony" dictates subtlety and indirectness in language expression. Chinese people often exercise restraint in expressing thoughts and emotions, forming a national psyche that values subtlety and implications. In hospice care, the subtlety and flexibility exhibited by patients and family members create communication pressures between nurses and patients, as nurses often struggle to identify the true needs of patients and family members.

Our findings also revealed that sudden events such as the unexpected death or suicide of patients represent a particularly acute source of stress for hospice nurses. The sudden death of a patient due to rapidly worsening conditions can be shocking for families. Doctors and nursing managers may consider whether nurses' rounds and observations of the condition were timely and appropriate. The societal perception of nurses' professional identity is compromised. Hospice nurses may consequently experience doubt and self-blame, subsequently facing significant psychological pressure from various sources in the short term. Moreover, hospice care strives to assist terminal patients in experiencing a peaceful end of life. However, when patients end their lives through suicide, it shakes the belief systems and sense of mission of hospice nurses, leaving them feeling pressured and apprehensive. The American Association of Suicidology has coined the term "Clinician Survivors of Suicide Loss," referring to professional caregivers who experience the suicide of their own patients [51]. Clinician survivors bear the dual roles of caregiver and bereaved, thereby placing tremendous pressure on them, such as undergoing self-review or feeling defeated. We recommend that clinics should improve emergency management in response to sudden incidents in hospice care and pay close attention to the psychological state of hospice nurses, offering proactive support as needed.

5. Limitation

Due to practical constraints, this study focused exclusively on female hospice nurses, thereby limiting the exploration of gender differences in stress perceptions and experiences. However, we ensured diversity in the interview sample by including nurses of various ages, work experience levels, educational backgrounds, professional titles, and geographic regions. Additionally, this study was conducted within the unique cultural context of China, which may limit the transferability of the findings to other distinct cultural settings.

6. Strengths and Implication

Despite these limitations, our study has several strengths compared to previous studies. First, culturally relevant stressors found in this study may be applicable to countries with similar cultural backgrounds. Hospice care is deeply connected to local death culture. It is also necessary to consider cultural influences when exploring stressors among hospice nurses across different countries. Second, the results of this qualitative study can serve as a foundation for creating targeted stress screening instruments and formulating effective coping mechanisms. Lastly, the study highlights that hospice nurses experience stressors such as unmet psychological or spiritual patient needs and conflicts in healthcare philosophies. This underscores the importance of proactively enhancing interdisciplinary collaboration within the hospice care team, comprising physicians, nurses, psychologists, social workers, and others, to better address the diverse needs of terminally ill patients. These efforts will promote a healthier work environment for hospice teams, benefiting terminal patients and the healthcare system as a whole.

7. Conclusion

This study provides a detailed understanding of occupational stressors among hospice nurses in China, which fills the gaps identified in previous research. The findings also describe how diverse and interconnected stressors may complicate their end-of-life care duties. Our evidence-based recommendations can inform the development and implementation of targeted strategies to cope with these stressors in hospice nurses across China and similar cultural contexts in the Asia-Pacific region. Future research should focus on fully understanding occupational stressors by examining stressors at various levels and considering the influence of culture on the stress experienced by hospice care nurses within the broader context.
