Background. The worldwide pandemic of COVID-19 had put enormous pressure on frontline healthcare workers. In December 2022, China released its “10 new measures,” signaling the end of the “dynamic zero COVID-19 strategy.” This triggered a period of peak infection, which shocked China’s healthcare system and affected the mental health of nurses. **Objective.** To explore the anxiety, depression, and social support levels of frontline nurses during the peak period of COVID-19 infection and to identify the main needs and concerns of nurses during this period. **Design.** A multicenter cross-sectional study. **Settings.** 18 hospitals of different grades in three cities in Hunan Province from December 21, 2022, to January 10, 2023, the peak period of COVID-19 infection. **Participants.** A total of 4,160 nurses completed the survey. **Methods.** The questionnaire included general information, symptoms, the preparation for nurses, GAD-7, PHQ-9, PSSS, and two open-ended questions investigating nurses’ needs and concerns. General linear models were used to analyze the factors influencing anxiety. Hospital preparation for nurses, nurses’ needs, and nurses’ concerns were categorized and subjected to frequency counts. **Results.** The median (P25, P75) scores for anxiety and depression among nurses were 7.00 (3, 12) and 8 (3, 12), respectively. Type of hospital, professional title, family structure, isolation staff lounge preparation, ibuprofen preparation, health status of parents, fever, chest distress, dyspnea, cough, insufficient protective equipment, number of children, and PSSS others were the influencing factors of GAD grades. The top 3 needs were free drugs and treatments (78.71%), shift breaks and paid leave (77.66%), and understanding and supports from hospitals and families (75.99%). The first three concerns were the fear of spreading the disease to family members (83.89%), the after-effects of infection (65.67%), and cross-infection with colleagues and patients (61.70%). **Conclusions.** Nurses’ anxiety was more severe during peak infection period. Overloaded work schedules and insufficient sleep became a common situation. Worries about family members became the main concern of nurses. Managers should make contingency plans for public health emergencies and provide frontline nurses with protective equipment, stress-relieving measures, and a rotation system. More importantly, they should pay attention to the needs of nurses’ family members and provide medical and care support. The media should also explain how hospitals operate and carry out their duties during these extraordinary times in order for the public to comprehend the condition of frontline epidemic fighters.

1. Introduction

The COVID-19 worldwide epidemic had lasted for three years since the outbreak was reported in central China's Wuhan city in December 2019. Because of the differences in social cultural, political, and economic contexts in different countries, there has been no consensus prevention policy about the public health strategy for COVID-19. Before December 7, 2022, the Chinese government had adopted a "dynamic zero COVID-19 strategy" to control the pandemic, in which restrictive measures were initiated and maintained until there were no documented COVID-19 cases in a particular geographic location [1]. In this period, facing with COVID-19 epidemic such as a catastrophic health emergency, the mental health status of frontline medical staff deserves attention [2]. Studies [3, 4] have shown that the prevalence of anxiety, depression, and sleep disorders among Chinese medical professionals during the epidemic ranged from 44.6% to 81.36%, 45.76% to 50.4%, and 34.0% to 97.88%, respectively. To deal with the situation, a national guideline for psychological crisis intervention for COVID-19 was released by the Chinese National Health Commission, marking the beginning of China's efforts to offer medical professionals' full psychological protection [5].

However, on December 7, 2022, the China National Health Commission issued "10 new measures" to further optimize the implementation of prevention and control of the COVID-19 epidemic [6]. The "10 new measures" required scientific and precise delineation of risk areas to minimize the impact of the epidemic on economic and social development, which indicated that China had relaxed its strict COVID-19 prevention and control measures. Thus, widespread infection—including among frontline medical personnel—was unavoidable. There were 13.983 million medical professionals working in China at that time, including 5.018 million registered nurses and 4.287 million practicing physicians and physician assistants [7]. Therefore, there would be more risk and strain on healthcare facilities and medical staff as a result of the new policy shift. Considering that previous research has found that during the COVID-19 pandemic, medical staff self-reported high rates of anxiety and depression symptoms, and psychological interventions for those at high risk of psychological disorders should be integrated into the work plan to fight the pandemic [8].

Most COVID-19 cases were mild. After infection, some people might not even exhibit any clinical symptoms [9]. On the other hand, a few people could develop a severe COVID-19 case. Age, gender, obesity, smoking, and comorbidity chronic diseases like hypertension, type 2 diabetes mellitus, and others were key risk factors [10, 11]. Yet, the population's immunity had further decreased due to the "immunization debt" caused by mask-wearing and reduced sociability policies that China had imposed over the past three years [12], as well as the country's rapidly aging population, which some had dubbed an "aging tsunami" [13]. These factors, in addition to China's huge population, fostered tremendous challenges for healthcare.

According to data released on the official website of the China Center for Disease Control and Prevention (CDC)

[14], the number of infections peaked around December 22, 2022, with a maximum of over 7 million new infections per day. The number of fever outpatient (clinic) visits nationwide (excluding Hong Kong, Macao, and Taiwan) peaked on December 23, 2022, at 2.867 million visits. The number of severely ill patients among newly coronavirus-infected patients in hospitals nationwide increased by nearly 10,000 per day from December 27, 2022, to January 3, 2023, and then decreased significantly on January 4 before reaching a peak of 128,000 on January 5th. The number of deaths from new coronavirus infections in hospitals reached a daily peak of 4,273 on January 4th. Such a large number of patients was undoubtedly an overload for healthcare workers, especially when they themselves were infected. The impact of such a large-scale infection in a short period of time on China's healthcare system was enormous and undoubtedly posed a huge challenge to the physical and psychological limits of medical workers [15].

This daunting task might cause not only significant psychological stress but also a shift in working state [16], especially in specific COVID-19 units and emergency departments [17]. Burnout, intentions to leave [18], and compassion fatigue [19] would emerge, especially in the absence of psychological counseling and professional support. Furthermore, sleep deprivation caused by heavy work might impair emotional awareness, resulting in decreased levels of empathy [20]. The situation seems even less promising in Chinese collectivist cultures. Collectivism requires a greater focus on the feelings of others and therefore risks neglecting one's own requirements [21]. Therefore, we need to focus on and enhance support for healthcare workers so that they can become aware of their emotions and can help them remain productive and focused during stressful events of a pandemic [22].

Nevertheless, studies on the psychological state and social support of medical staff during the COVID-19 peak infection period remained mostly unexplored, particularly in light of the large number of infections with COVID-19 and a shortage of medical staff in China. Therefore, this study aimed to investigate the anxiety, depression, stressors, social support, and needs of frontline nurses during COVID-19 peak infection period in China. This will provide the groundwork for healthcare workers' social support and psychological intervention during an epidemic.

2. Methods

2.1. Study Design. A multicenter cross-sectional survey was conducted in 18 hospitals in three cities: Changde, Changsha, and Chenzhou in northern, central, and southern Hunan Province in southcentral China, from December 21, 2022, to January 10, 2023, the COVID-19 peak infection period after the release of "10 new measures" by the Chinese government.

2.2. Settings. Randomized stratified sampling was used to select hospitals. First, three cities from the north, center, and south of Hunan Province were chosen. Then, six hospitals or

community health centers were randomly selected from each city, respectively. Among them, two were tertiary, two were secondary, and two were community hospitals. In all, eighteen hospitals in the three cities were selected. Following that, one emergency room, ICU, surgery, and medical department were chosen at random from each tertiary and secondary hospital. The survey was distributed to all of the nurses in the chosen department who met the criteria. Since there were not enough community nurses, the study included all of those who met the criteria. The specific process is shown in Figure 1.

2.3. Participants and Sample Size. Nurses were included in the study if they (1) were registered nurses; (2) were on duty; (3) did not have serious psychiatric disorders, such as schizophrenia and depression; and (4) gave informed consent to participate in this study. The exclusion criteria were (1) being on vacation or undergoing a training course in another hospital during the data collection period and (2) recently experiencing a major psychiatric event, such as divorce and death of a family member.

The sample size was calculated using the method of 10 EPV (events per variable) [23]. A total of 26 variables were analyzed in the influential factors of anxiety in this study, so at least 260 nurses with severe anxiety were needed. According to the references, the prevalence of severe anxiety among nurses during the COVID-19 epidemic was 3.1% [24], 4.5% [25], and 17.2% [26], respectively. In addition, we used a mean value of 8%. Therefore, at least $(260/0.08) = 3250$ nurses need to be surveyed. Assuming a 20% of attrition, we will recruit a minimum of 4063 participants.

2.4. Outcome Measures. The questionnaire included seven parts: demographic information, the preparation of the medical staff before the implementation of “10 new measures,” the patient health questionnaire 9, the general anxiety disorder 7, the perceived social support scale, the needs of nurses, and the concerns of nurses during COVID-19 peak infection period.

2.4.1. Sociodemographics and Symptoms of Infection. This part collected the nurses' gender, age, hospital classification, hospital category, professional title, marital status, education, vaccination, family structure, health status of parents, number of children, and whether nurses showed symptoms of infection (e.g., fever, malaise, and respiratory distress).

2.4.2. The Preparation for the Nurses. This part investigated what hospitals prepared for the nurses and their families, such as isolation staff lounge preparation, drugs preparation, children, and parents care preparation (e.g., medication emergency kits for the elderly and children) after the “10 new measures” implementation.

2.4.3. General Anxiety Disorder 7 (GAD-7). The GAD-7 is a seven-item self-report scale that assesses anxiety, which was developed by Spitzer et al. [27] and translated into

Chinese by He et al. [28]. Each item is scored from 0 to 3, with a total score ranging from 0 to 21. Anxiety symptoms can be categorized into four degrees based on total scores [28, 29]: no anxiety (≤ 4 points), mild (5–9 points), moderate (10–14 points), and severe anxiety (≥ 15 points). The GAD-7 is a reasonably accurate screening tool for anxiety disorders and symptoms, according to numerous research. In the current study, Cronbach's alpha for the GAD-7 was 0.80.

2.4.4. Patient Health Questionnaire 9 (PHQ-9). The PHQ-9 is a nine-item self-report measure that was developed by Kroenke et al. to assess depression symptoms [30]. The score of each item ranges from 0 to 3, and the total score ranges from 0 to 27. Symptom severity according to the total score can be divided into four grades: mild (5–9 points), moderate (10–14 points), moderately severe (15–19 points), and severe depression (≥ 20 points) [31]. The scale was shown to have good reliability and validity. The Chinese version translated by Chen et al. [32] was used in this study. Cronbach's alpha for the scale in the present study was 0.84.

2.4.5. Perceived Social Support Scale (PSSS). Zimet et al. [33] created the 12-item self-report measure that evaluates how much social support one receives from friends, family, and significant others on a subjective level. Every item is rated using a 7-point Likert scale. Total scores of 12–36 indicate a low level of support, 37–60 suggest an intermediate level of support, and 61–84 show a high level of support. The Chinese version translated by Chou [34] was used in this study. Cronbach's alpha coefficient for the total PSS was 0.89 in this study.

2.4.6. The Needs of Nurses. Nurses were asked to list up to five of their most pressing needs in response to an open-ended question to assess their circumstances while working on the front line of the epidemic fight.

2.4.7. The Concerns of Nurses. This section was also an open-response section that asked the frontline nurses to provide up to 5 of their current top concerns.

2.5. Data Collection. The anonymous self-assessment questionnaire for the survey was prepared using an online crowdsourcing platform in mainland China (<https://www.wjx.cn>), and it was sent to nurses via the Internet. Each hospital had a dedicated trained researcher assigned to it for quality control, data collecting, and hospital-to-hospital communication.

2.6. Statistical Analysis. Statistical descriptions and analyses were conducted for quantitative information using SPSS 26.0 for Windows (SPSS, Chicago, IL, USA). Normally distributed measures were presented as Mean (SD), and nonnormally distributed information was presented as Median (P25, P75). A generalized linear model (GLM) was used to explore factors leading to anxiety. All analyses were performed using a two-sided test $P < 0.05$. Answers to open-response questions were categorized by researchers.

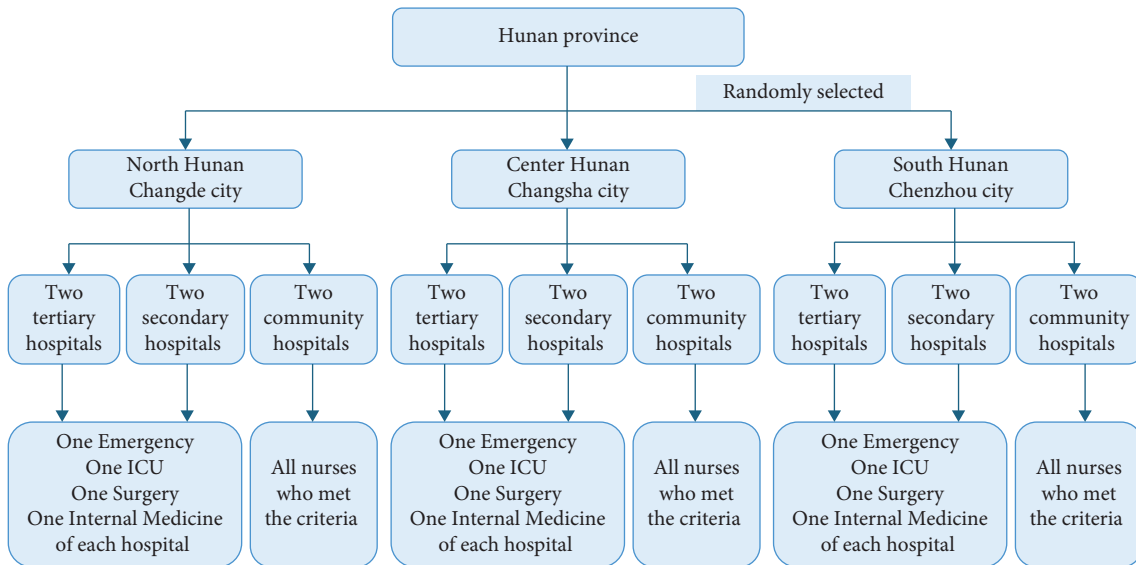

FIGURE 1: Flowchart of selecting settings.

2.7. Ethics Approval and Consent. The study was approved by the Ethics Committee of the Hospital (No. 2023-005-01). A covering letter explaining the objectives of the research and data privacy policies was given with the questionnaires distributed to the nurses. It was emphasized that participation was entirely voluntary and that completing the questionnaire or not would not affect their work and life in any way. The informed consent page presented two options (yes/no). Only participants who chose yes were taken to the questionnaire page, and participants could quit the survey at any time. To ensure data protection and confidentiality, codes were used for each hospital and participants were completely anonymous.

3. Results

3.1. Characteristics, Anxiety, Depression, and Social Support of Nurses. A total of 4,379 nurses met the inclusion criteria, and finally, 4,160 nurses responded and completed the questionnaire from December 21, 2022, to January 10, 2023. After excluding invalid questionnaires (e.g., choosing the same answer for all questions, or illogical responses, such as age 120 years), 4,128 valid questionnaires were finally included. The response rate was 95.00%, and the validity rate was 99.23%. The median (P25, P75) scores for anxiety, depression, and perceived social support among nurses were 7.00 (3, 12), 8 (3, 12), and 63 (52, 72), respectively. Higher GAD scores were reported by nurses who were females, worked at general hospitals or tertiary-level hospitals, held midlevel job titles, were divorced, held a bachelor's degree, were unvaccinated, belonged to three-generation households, had two or more children, and both parents were in poor health, while lower PHQ scores were reported among nurses in primary or community hospitals, senior nurses, widowed nurses, nurses with doctoral degrees, nurses who had completed vaccinations, nurses who lived alone, nurses whose parents were both in good health, and nurses who had no children. Additionally, higher PSSS scores were noted for

tertiary-level hospital nurses, general hospital nurses, nurses in senior positions, married nurses, nurses with a small family structure or couples living together, nurses with both parents in good health, and nurses with two children.

Demographic characteristics and the anxiety, depression, and perceived social support scores of nurses are shown in Table 1.

3.2. Nucleic Acid Test Results and Symptoms of Nurses. Nucleic acid tests were reported positively by 1532 (37.11%) nurses and negatively by 1338 (32.41%) nurses. Besides, 1258 nurses (30.47%) did not perform a nucleic acid test. The partitions of the chi-square method were used to compare each group's nurses' vaccination completion rates. A statistically significant difference in vaccine completion rates was identified between nurses with positive nucleic acid test results with symptoms versus those with negative test results and without any symptoms. The comparison of nucleic acid test findings with symptoms and vaccination implementation is shown in Table 2.

As for the specific symptoms, dyspnea was the most reported symptom, occurring in 89.07% of nurses. 90.75% (3746/4128) of the nurses reported at least one infection-related symptom, such as chest tightness and fever. Table 3 shows the specific symptoms of nurses.

3.3. The Preparation for the Nurses. Hospitals' preparations for healthcare workers following the adoption of the "10 new measures" are shown in Figure 2. The most prepared were ibuprofen and acetaminophen at 54.89% and 54.41%, respectively, while the least prepared were antitussive medicines and protective equipment, with only 33.99% and 17.81%, respectively.

3.4. The Generalized Linear Model of Anxiety. The GAD data were converted into hierarchical categorical variables (none, mild, moderate, and severe anxiety) due to the GAD scores'

TABLE 1: Demographics, anxiety, depression, and social support of nurses.

nonnormal distribution. Multivariate ordered logistic regression analyses were then carried out in a generalized linear model to examine the influence factors of GAD. GAD grades were analyzed as the dependent variable, meaningful demographics, hospital preparation for nurses, and whether nurses showed symptoms of infection were analyzed as independent variables. The results showed that type of hospital, professional title, family structure, isolation staff lounge preparation, ibuprofen preparation, health status of parents, fever, chest distress, dyspnea, cough, insufficient protective equipment, number of children, and PSSS others were the influencing factors of GAD grades. In contrast, gender, hospital grade, marital status, education level, and vaccination status were no longer statistically significant, see Table 4.

3.5. Nurses' Needs during COVID-19 Peak Infection Period. Figure 3 shows the major needs of nurses during COVID-19 peak infection period. The top three needs were free drugs and treatments (78.71%), shift breaks and paid leave (77.66%), and understanding and supports from hospitals and families (75.99%).

3.6. Nurses' Concerns during COVID-19 Peak Infection Period.

The main worries that nurses had during the COVID-19 peak infection period are depicted in Figure 4. The leading three concerns were the fear of spreading the disease to family members (83.89%), worry about the after-effects of infection (65.67%), and the fear of cross-infection with colleagues and patients (61.70%).

4. Discussion

This study examined the impacts of the Chinese government's release of the "10 new measures" and the cancellation of the "dynamic zero COVID-19 strategy" on the mental health of Chinese healthcare professionals during the rapid peak infection of COVID-19. Understanding the psychological issues and needs of frontline nurses during peak infection periods could help in the development of stress-relieving solutions for healthcare professionals, as well as mitigation strategies for future infectious disease pandemics or catastrophic disasters.

4.1. Psychological Pressure on Medical Staff Was Greater during Peak Epidemics. Medical staff will exhibit psychological symptoms including mental health conditions like anxiety and depression when faced with an outbreak during an infectious disease pandemic [35–37]. Even worse, the rapid rise of COVID-19 infections in China after the new policy was announced put a tremendous deal of strain on the country's healthcare system and increased psychological stress on medical workers. The median anxiety score in this study was 7, which was higher than the scores of 6, 6, and 4 in Spain [38], Australia [39], and Korea [40]. The reasons may include the following: Firstly, it had to do with the virus's increased contagiousness following mutations [41] that resulted in a higher number of infections in a short period of time. Secondly, older people were more likely to have severe cases of COVID-19 [42], while the Chinese population is aging rapidly [43]. Thirdly, Chinese people value collectivism and the idea that other people's interests and safety should come first in dangerous circumstances [44]. Lots of nurses worked with illness at the expense of their own and their families' well-being because of the sense of dedication, which would exacerbate their emotions of shame and anxieties for family members [45, 46].

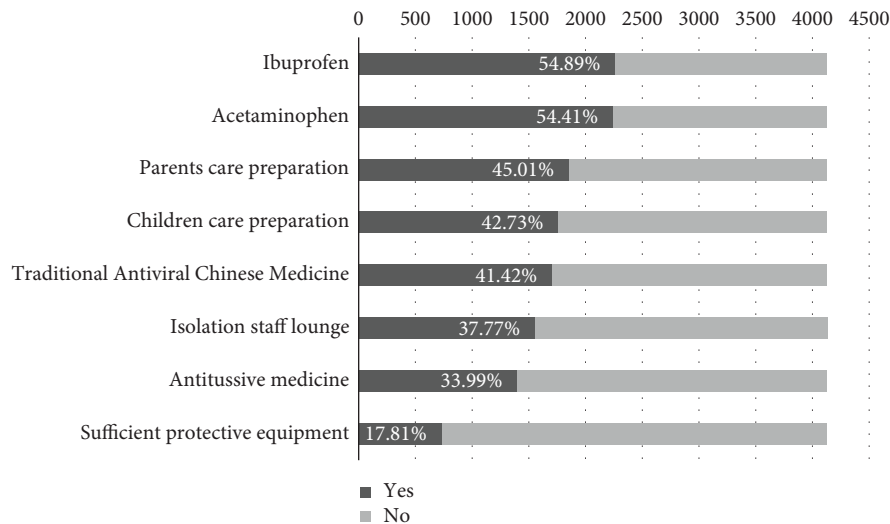

FIGURE 2: Hospital preparation for nurses before the peak infection.

4.2. Factors Associated with Nurses' GAD Grades during COVID-19 Peak Infection Period. The results showed that having a junior professional title, working in a general hospital, living with parents, husband and children, having parents in poor health, having 2 or more children to care for, having a fever over 39°C after infection, and having symptoms of chest pain increased the risk of anxiety among medical staff. Usually, the higher the professional title of the medical staff and the more years they have worked, the better their coping skills and psychological profile, which to some extent reduces the risk of anxiety and depression. This is similar to the findings of previous studies [4], where mid-level technical titles were associated with experiencing severe depression, anxiety, and distress. Furthermore, given the lack of adequate personal protective equipment in most hospitals and the fact that the majority of nurses contract infections while on the job, nurses in administrative or senior roles were less likely to be exposed to confirmed patients and, consequently, experienced less psychological impact.

Interestingly, there were differences in anxiety levels among nurses with different vaccination completion statuses, but vaccination status was not statistically significant in the generalized linear model. However, the chi-square test revealed that vaccine completion status did correlate with nucleic acid test results and symptoms. The vaccination may have prevented infection in some nurses, but this group was so small—only 3.75% of nurses with negative nucleic acid tests, no symptoms, and vaccination completion—that the nurses were unsure they would not contract the infection even after receiving the vaccination, especially given the majority of the population was infected. Secondly, a sizable percentage of nurses (28.56%) exhibited symptoms despite having a negative nucleic acid test result. It could not be ruled out, nevertheless, that some of these nurses experienced symptoms unrelated to infection as a result of intense workloads and excessive psychological stress. However, the

psychological effects of the vaccine were overshadowed by other factors since these nurses believed they were infected.

Our research also revealed a link between anxiety in nurses and COVID-19 infection symptoms as well as family members' health status. Previous research findings have demonstrated that direct contact with COVID-19 patients as frontline healthcare workers was an independent risk factor for all psychology symptoms [4]. It is conceivable that a significant proportion of healthcare workers would additionally unavoidably contract COVID-19 patients after the release of the new policy. As a result, physiological symptoms such as fever, chest tightness, dyspnea, and coughing that occur after infection aggravate nurses' anxiety. In addition, concerns about the health status of elderly parents also became an aggravating factor for the nurses' psychological burden. Because of the disease's dual effects of physical and psychological stress, frontline healthcare workers would be especially vulnerable to symptoms like anxiety, depression, insomnia, and distress, and their mental health required extra attention.

Interestingly, this study found that social support from the hospital affected nurses' anxiety levels, whereas support from family and friends did not. The possible reason for this is related to the collectivist culture mentioned above—nurses may feel guilty about their family and friends—so support from family friends did not reduce their anxiety. Compared to nurses working in general hospitals, nurses employed at specialized and community hospitals reported lower levels of anxiety. This is likely due to the fact that these institutions admitted fewer COVID-19 critically ill patients [47]. In addition, related research has shown that nurses working in COVID-19 facilities were 2.62 times more likely to have higher emotional eating behaviors compared to nurses in non-COVID-19 facilities [48]. This suggested that nurses in COVID-19 facilities may have higher levels of psychological stress and are more deserving of attention.

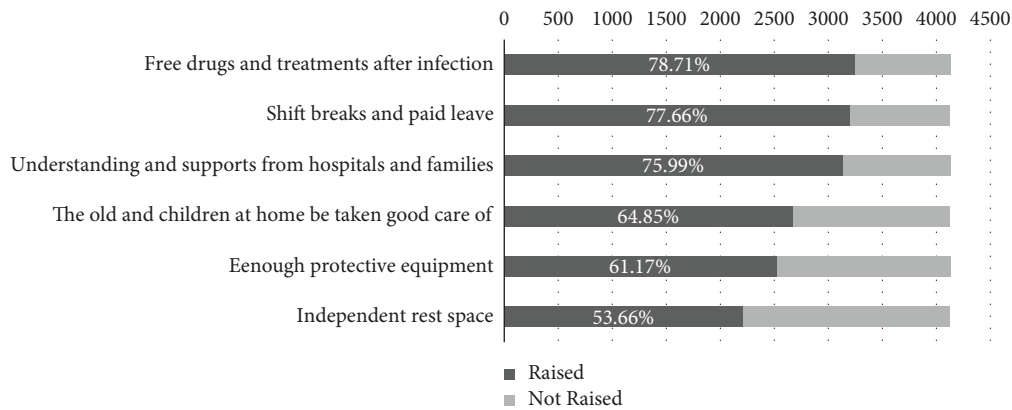

FIGURE 3: The major needs of nurses during COVID-19 peak infection period.

FIGURE 4: The major concerns of nurses during COVID-19 peak infection period.

4.3. Worries about Family Members Became the Main Concerns of the Nurses. The results of the two open-ended questions on nurses' needs and concerns showed that worries about family members had become the nurses' main concern. 83.89% of the nurses expressed the fear of spreading diseases to their family members, while 64.85% of the nurses expressed the needs to take care of old people or children at home, which was consistent with the findings of Nashwan et al. [49]. Firstly, it has to do with the predominant family structure of small family and three-generation family in China [50]. The study's general data also revealed that the two types of families—small families, which consist of couples and children, and three-generation families, which consist of parents, couples, and children—accounted for the majority of the components, which were 33.19% and 28.08%, respectively. In the two types of families, nurses were expected to take on the role of primary caregiver for family members, with a focus on the elderly and children. Secondly, nurses may infect their families with the virus when they return home from work. That is why 53% of nurses cited the need for separate rest spaces—they did not want to spread the virus to their families. Therefore, managers can appropriately protect and comfort the family

members of medical staff when making plans for the prevention and control of infectious diseases, which will lessen the stress of frontline medical professionals.

4.4. Overloaded Work Schedules and Lack of Rest Became a Common Situation. The findings showed that 76.31% of the participants had a fever of 39°C or above. Nurses with more severe symptoms really had to take time off from work, while nurses with less severe symptoms had to stay on the job and often even put in extra hours to make up for the personnel deficit caused by infection [51]. Therefore, in this study, many nurses raised the need for rest or paid leave. It was surprising to learn that 43.63% of the participants were worried about patient complaints. Studies do, in fact, indicate a link between higher complaint rates and a lack of human resources [52]. However, the majority of nurses were completing their work in a state of illness. Therefore, the media should publicize this more so that the public understands the working conditions of nurses and the high stress situations in which they work. Managers should provide more social support—it was also confirmed in this study that support from organizations (PSSS others) could significantly reduce nurses' anxiety state.

5. Limitations

The study had a few limitations. Firstly, asking nurses to fill out the questionnaire at a time when they were busy and under high stress may yield untrue results and add to their burden; secondly, as this study investigated the psychological state of nurses in the acute phase, depression was not discussed in depth—since the nurses were in a state of stress and showed more courage, while depressive states might continue to rise long after the stressful event is over [53], according to Selye's [54, 55] three-stage general adaptation syndrome (alarm, resistance, and exhaustion). Consequently, it is important to follow the psychological well-being of nurses and to implement interventions following the epidemic's peak; thirdly, this study was conducted in one province in China, which may have resulted in sampling bias due to differences between provinces or regions; fourthly, as had mentioned before, the study was conducted over a short period of time and lacked longitudinal follow-up. Due to the increasing severity of the situation, the mental health symptoms of healthcare workers may become more severe. Therefore, the long-term psychological impact of this population warrants further research.

6. Conclusions

This study investigated the psychological state of nurses at the peak of the COVID-19 outbreak in China after the abandonment of the “dynamic zero COVID-19 strategy.” Nurses' anxiety was more severe, with hospital type, family structure, protective preparation, medication preparation, symptoms, parental state of health, number of children, and social support being the main influencing factors. Most of nurses were infected during that period. Overloaded work schedules and lack of rest became a common situation. Worries about family members became the main concerns of the nurses.

7. Relevance to Clinical Practice and Education

In times of large-scale epidemics of infectious diseases, medical human resources are in short supply and medical staff are under greater stress. Managers should make contingency plans and consider the care and protection of medical staff's family members. The media should explain the operation and work of hospitals in extraordinary times so that the public understands the state of frontline epidemic fighters.

Data Availability

Data that support the findings of this study are available upon reasonable request. If necessary, please contact email 382731326@qq.com.

Additional Points

What Is Already Known. (i) Frontline nurses experienced significant psychological stress during the COVID-19 epidemic. (ii) After the Chinese government dropped its

“dynamic zero strategy,” a large number of people were infected, creating a peak period of the epidemic. (iii) Overloaded work schedules and insufficient sleep became a common situation during COVID-19 peak infection period. *What This Paper Adds.* (i) Nurses' anxiety levels were even worse during the peak of the epidemic. (ii) Worries about family members became the main concern of the nurses. (iii) Nurses were worried about complaints and expected understanding from the public during the peak of the epidemic.

Ethical Approval

The study was approved by the Ethics Committee of the First People's Hospital of Changde (No.2023-005-01).

Disclosure

The authors declare that this financial support did not influence the study design, data collection, analysis, interpretation of data, writing of the report, or the decision to submit the article for publication. There were no conditions attached to the funding, and the funding agency had no role in the research beyond the financial support provided. Thus, the authors maintain full scientific independence and integrity in the conduct of this research.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

Liuyi Zhang developed methodology, contributed software, and performed formal analysis; wrote the original draft; and performed project administration. Kemei Zhang investigated the study, collected resources, and curated the data. Li Tong investigated the study and curated the data. Yafen Guo and Jinhua Shen investigated the study and visualized the study. Xue-qing Zhang conceptualized the study and validated the study, reviewed and edited the study, and supervised the study. Pan Yang investigated the study and performed formal analysis.

Acknowledgments

The authors wish to thank all respondents for their contributions to the study, thank 13,983,000 Chinese medical staff who have always been on the front line of the fight against COVID-19 specially themselves under greater risk and pressure, and thank for the strong support of the Health Commission of Changde City. This work was supported by the Changde Science and Technology Bureau for Emergency Special Project of COVID-19 in Changde City, Hunan Province (Grant number: 2020SK002).

Aim. This study aimed to investigate the appreciation leadership, workplace belongingness, and affective commitment among nurses, with a specific focus on the mediating role of job crafting. **Background.** Leadership, particularly in healthcare care, significantly influences employee experiences and outcomes. Appreciative leadership fosters a positive work environment, valuing and motivating employees. However, its impact on workplace belongingness and affective commitment among nurses requires further exploration. Job crafting, a mechanism in which employees shape their roles to align with their preferences, strengths, and values, can serve as a mediator in the relationship between appreciative leadership and outcomes, such as workplace belongingness and affective commitment. **Subjects and Methods.** A cross-sectional descriptive study was conducted in nurses from two hospitals (Prince Mohammed bin Abdulaziz and Shaqra General Hospital) in Riyadh City, Saudi Arabia. Four standardized scales were used to assess appreciation for leadership, sense of belonging, affective commitment among nurses, and job crafting; 381 nurses were surveyed. AMOS structural equation modeling (SEM) was used to examine the hypothetical model of the study. **Results.** APL significantly affects job-crafting behaviors, belonging, and affective commitment among nurses. Furthermore, job-crafting behaviors significantly affect belonging among nurses and commitment. **Conclusions.** This indicates that when nurses perceive their leadership positively, their job-crafting behaviors increase, which in turn enhances their sense of belonging at work. Furthermore, these findings indicate that positive leadership perceptions directly improve nurses' commitment to their jobs. This study recommended that educational programs can upgrade leadership styles and change practice levels. **Implications for Nursing Management.** Nursing managers should focus on cultivating appreciative leadership behaviors, such as providing regular feedback, recognizing achievements, and fostering a supportive work culture. Organizations can encourage the creation of jobs among nurses by offering opportunities for autonomy, skill development, and flexibility in job roles.

1. Introduction

In contemporary organizational settings, the role of leadership in shaping employee experiences and outcomes has received

significant attention. Leadership becomes critical in healthcare settings, as nurse performance and well-being directly affect patient care. Appreciative leadership stands out among leadership philosophies in that it places a strong focus on

identifying and developing the potential and strengths of individuals to create a positive work environment [1, 2].

Appreciative leadership is characterized by its focus on strengths, opportunities, aspirations, and results (SOAR). Encourage leaders to cultivate a culture of appreciation, where employees feel valued, empowered, and motivated to contribute their best efforts [3]. Although the potential benefits of this leadership style have generally been acknowledged, more research is needed to fully understand how it can improve nurses' sense of affective commitment and belonging in the workplace [3, 4].

Workplace belonging refers to the sense of connection, acceptance, and inclusion that individuals experience within their work environment [5]. Affective commitment, on the other hand, reflects an employee's emotional attachment and identification with their organization, leading to greater loyalty and engagement. Both factors are crucial to promote a positive organizational environment and facilitate employee well-being and performance [6].

In addition, the concept of job crafting has emerged as a mechanism through which employees actively shape their roles and experiences to align with their preferences, strengths, and values. Job crafting involves proactive modification of job tasks, relationships, and perceptions to improve motivation, satisfaction, and performance [7]. Given its relevance to employee autonomy and engagement, the design of the job can serve as a key mediator in the relationship between appreciated leadership and outcomes such as belonging to the workplace and affective commitment [8].

This study aims to investigate the appreciative leadership, workplace belongingness, and affective commitment among nurses, specifically focusing on the mediating role of job crafting. By examining these relationships, insights can be gained into the mechanisms through which appreciative leadership influences nurse outcomes, thereby informing leadership practices and organizational interventions aimed at improving employee well-being and performance in healthcare settings.

In general, this research seeks to contribute to theoretical understanding and practical implications on the impact of leadership on employee experiences and results, with implications for fostering a supportive and engaging work environment in the nursing profession.

1.1. Theory and Hypotheses

1.1.1. Appreciative Leadership. The nursing field has faced previously unheard-of difficulties recently, which has highlighted the vital role that capable leadership plays. The pandemic's increased mental and physical demands on nurses resulted in considerable stress and burnout, which raised turnover rates in healthcare settings globally. These findings underline the necessity of leadership strategies that not only meet urgent clinical needs but also cultivate a positive and encouraging work atmosphere [9]. With its focus on identifying and fostering each nurse's unique talents and potential, appreciative leadership stands out as a particularly pertinent strategy. Appreciative leadership can

mitigate burnout and strengthen nurses' emotional ties to their organizations by emphasizing positive reinforcement, personal development, and the value of each team member's efforts. This could potentially stabilize workforce dynamics in these challenging times [10].

The benefits of grateful leadership have been highlighted in recent research, especially in the healthcare industry. Research has continuously shown a substantial correlation between improved job satisfaction and decreased workplace stress and appreciative leadership methods, which emphasize employee strengths acknowledgment and empowerment. For example, Janet (2017) observed that patient care outcomes and nurse retention were significantly improved in hospital settings when appreciative leadership was implemented [11]. In a similar vein, the authors in [12] found that healthcare personnel who used appreciative leadership demonstrated higher levels of creativity and cooperation. These results highlight how grateful leadership can improve operational efficiency and create a favorable organizational climate in healthcare settings.

Notwithstanding these encouraging signs, there are still large gaps in our knowledge of the precise ways in which appreciating leadership affects important psychological outcomes like affective commitment and workplace belongingness in nurses. The majority of previous research has concentrated on work satisfaction and retention in general, paying less attention to the more profound emotional and psychological processes that mediate these associations [13]. Moreover, not enough attention has been paid to the function of job crafting as a potential mediator in the dynamics between appreciating leadership and nursing outcomes. This vacuum in the literature points to the urgent need for targeted studies that explore these connections while also elucidating the mechanisms by which appreciating leadership can bring about change in the nursing setting [14, 15]. By addressing these gaps, our study aims to provide a more comprehensive understanding of how appreciative leadership can be strategically applied to improve both the well-being of nurses and the overall quality of healthcare delivery.

1.1.2. Workplace Belongingness. Workplace belongingness, the sense of acceptance and inclusion within an organization, is crucial for employee well-being, performance, and job satisfaction among healthcare professionals, particularly nurses [16] argue that a sense of belonging is derived from interpersonal interactions between employees at work, which is necessary for a relational value to be a part of that system. Another way to describe belongingness to the workplace is the extent to which a person feels personally acknowledged, respected, included, and supported by others at work. The idea of belonging holds that when one feels that justice has been done, one feels extremely intimate and connected to the other members of the group. According to [17], concerns about justice support moral and logical reasons that result from three fundamental needs: a need for control, a need for purpose in life, and a desire for a sense of belonging.

1.1.3. Affective Commitment. An emotional bond with the organization defines the affective commitment feature of organizational commitment. According to this hypothesis, which has its roots in organizational behavior research, nurses who have a strong emotional bond with their organization are more likely to demonstrate traits like loyalty, initiative, and corporate citizenship. Affective commitment is impacted by things like job happiness, leadership efficacy, and perceived organizational support [18]. An employee's affective commitment is his or her emotional attachment to the organization for which he or she works. Strong affective commitment among staff members makes them more dedicated, engaged, and motivated to achieve organizational goals. Organizational management methods often have a direct impact on this kind of dedication [19].

Sometimes affective commitment is referred to as an affective attachment to an organization characterized by shared values, a desire to remain in the organization, and a willingness to exert effort on its behalf [20]. Workers with affective attachment tendencies are more likely to have a sense of identification and belonging, which increases their involvement with work, motivation to work toward the organization's objectives, and desire to stay with the organization. For this reason, the affective dimension appears to be significant. As a result, the authors in [21] saw commitment as a discriminant between dedication and loyalty. Affective commitment is recognized as a more powerful and reliable measure of organizational commitment than normative or continuous commitment.

1.1.4. Job Crafting. Nurses' work is frequently subjected to psychological stress; therefore, it is essential to create a welcoming work environment and implement administrative regulations that improve nurses' combination with their workplace and promote job crafting [22]. The proactive practice of "job crafting" describes how nurses modify job standards and resources to better suit their skill sets and preferences. The job-creation model identifies three dimensions: growing or focusing on social networks that boost structural resources, lowering onerous job demands, and raising demanding job expectations. Nurses manage their careers by modifying the level of demands and resources associated with their jobs [23]. In the same way, job crafting is divided into three subfactors: task crafting, which involves changing job tasks; relational crafting, which involves changing the dynamics of interactions at work; and cognitive crafting, which involves changing how employees view the importance and meaning of their jobs [24].

H1: Appreciative leadership positively influences the sense of belonging of nurses.

Fostering a sense of belonging requires a team to have trust and more social exchanges, which are both improved by appreciative leadership. Leaders who emphasize talents and contributions make nurses feel more important and a part of the team [25]. Research

has indicated that emphasizing positive feedback and recognition in leadership greatly enhances staff members' sense of community and belonging [26].

H2: Appreciative leadership positively influences affective commitment among nurses.

Commitment theory states that employees' emotional attachment to the organization is strengthened by leadership that shares their beliefs and aspirations, which results in increased affective commitment. Developing strategies and systems that involve and uphold seasoned employees, honor their commitments, and lessen their desire to depart the organization requires strong leadership [27]. Nursing faces burnout due to demanding work, staffing shortages, and hierarchical structures. Appreciative leadership, a relationship-based style, promotes empowerment, encouragement, and positive reinforcement, improving nurses' engagement, work happiness, and commitment to the organization [28, 29].

H3: Job crafting positively influences nurses' sense of belonging.

Job crafting allows individuals to reshape their work environment and interactions, thereby enhancing their fit within the organization and increasing their sense of belonging [30]. Research demonstrated that job-crafting activities, particularly those modifying social aspects of work, significantly boost employees' sense of belonging [31].

H4: Job crafting positively influences affective commitment among nurses.

Employee loyalty to the organization increases when they can better connect their work with their personal beliefs and interests through job crafting, which makes their work more fulfilling and meaningful. According to a study, when workers participate in job crafting, their affective commitment rises as a result of better job satisfaction and a stronger alignment with the organization's aims [32].

H5: Job crafting mediates the relationship between appreciative leadership and belonging among nurses.

By allowing nurses to customize their responsibilities, appreciative leadership may promote job crafting. This increases nurses' sense of belonging as they feel more important and incorporated into the team [30].

H6: Job-crafting behaviors mediate the relationship between appreciated leadership and affective commitment among nurses, with a significant indirect effect.

The job-crafting behaviors of nurses are probably improved by appreciative leadership, and this has a favorable impact on their affective commitment. This process takes place when nurses experience increased emotional attachment to the company as a result of feeling competent in their tasks and being encouraged by their management [33].

According to a study, work crafting has a crucial mediating function in the relationship between affective commitment and leadership styles, hence bolstering the indirect impact of job crafting on leadership [34].

Taking into account the seven hypotheses mentioned above, the conceptual research model is presented as follows (Figure 1).

1.2. The Study Objective. This study aims to investigate the consequences of appreciative leadership on workplace belongingness and affective commitment among nurses, specifically focusing on the mediating role of job crafting.

2. Methodology

2.1. Study Design. A cross-sectional descriptive study was selected.

2.2. Study Setting. The study was carried out in two hospitals (Prince Mohammed bin Abdulaziz and Shaqra General Hospital) in Riyadh City, Saudi Arabia.

2.3. Participants. Because this study is descriptive and the primary outcome is a continuous variable, the sample of nurses was estimated from the addition of the hospital mentioned above, an open-source sample size calculator was used to determine the required sample size by determining the total population size of the previous two hospitals (Prince Mohammed bin Abdulaziz and Shaqra General Hospital). When a population-level outcome factor (p) = 50% \pm 5 was hypothesized, and 2000 nurses were studied with confidence limits as % of 100 (absolute \pm %) (d) = 5%, design effect (for cluster surveys—DEFF) = 1, confidence level = 95%, and sample size $n = [DEFF * Np(1 - p)] / [* (N - 1) + p * (1 - p)] / [(d^2/Z^2 - \alpha/2 * (N - 1))]$, and 377 was the minimum sample size needed. An additional 30% of nurses needed to compensate for an estimated dropout rate or uncompleted response [35]. The final sample size was 491, and the final sample size recruited for analysis was 381, with a response rate of 77.6%.

A two-phase sampling approach was adopted to enroll nurses as follows:

Phase 1: Using stratified sampling, the number of participating nurses in each hospital was determined.

Phase 2: In each hospital, nurses were recruited using convenience sampling. Nurses of licensed staff, those who worked during the study period, and those with at least six months of experience in their present hospital were included. Of the 400 questionnaires distributed, 390 were returned and 9 were invalid. As a result, the final sample size was 381, resulting in a 97.6% effective rate.

2.4. Instruments Used in the Study. Data for this study were collected using four standardized scales that were originally developed and used in English.

2.4.1. Appreciative Leadership Scale (ALS). Appreciative leadership was measured with an 18-item scale developed by [36]. It had been used to find out how nurses felt about their nurse leader's appreciation. There are six elements on this scale for each of the three dimensions listed below: inclusive inquiry, inspiring illumination, and integrity. The internal consistency reliabilities for each subscale according to the early subscale were 0.889, 0.850, and 0.899. A five-point Likert scale was used to rate each item on the scale (1 = all not so to 5 = very different from), where a higher score indicated a higher level of nurses' perception of their nurse leader's appreciation.

2.4.2. Job Craft Questionnaire (JCQ). Reference [37] created the JCQ to assess the particular types of activities that represented the craft of the job among nurses, which was evaluated using a 15-item scale comprising five items for each of the three dimensions: task creation, cognitive creation, and relational creation. Participants indicate the frequency with which they have participated in each job-crafting activity from 1 (hardly ever) to 6 (very often). According to Slemple and Vella-Brodrick, the reliability scores for task, relational, cognitive, and overall job crafting were, in order, 0.87, 0.89, 0.83, and 0.91.

2.4.3. Workplace Belongingness Scale (WBS). The belongingness of the workplace among nurses to their job and organization was measured using the 12-item scale developed by [38]. All elements of the instrument were positively formulated, and the nurses' responses were rated on a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree), where higher scores represent a greater degree of belonging in the workplace.

2.4.4. Affective Organizational Commitment Scale (AOCS). Reference [39] created this six-item measure to assess nurses' affective organizational commitment levels. Higher scores indicate a higher level of affective organizational commitment among nurses. The nurses' responses were scored on a five-point Likert scale, with 5 representing strong agreement and 1 representing strong disagreement.

2.4.5. Demographic Information of Study Participants. The demographic information of the participants was collected, including their age, sex, education, marital status, years of nursing experience, current unit, and hospital.

2.5. Pilot Study. A preliminary investigation was carried out to assess the clarity of the questionnaires and the time required for their completion. Additionally, a preliminary mean of the outcome variables was calculated to estimate the necessary sample size. The 38 nurses who were selected from participating hospitals for the pilot study were later not included in the final study sample. The questionnaire took 20 to 25 minutes to complete, and the pilot nurses attested to its clarity and understandability. In terms of internal consistency, Cronbach's alpha coefficients were 0.86 for the total

FIGURE 1: Conceptual model.

appreciation scale for leadership, 0.95 for the total scale for job creation, 0.89 for belonging to the workplace, and 0.90 for the scale of affective organizational commitment, indicating high and acceptable reliability.

2.6. Data Collection. Data collection for this study was conducted from February to May 2023, utilizing self-reported assessments from staff nurses. Prior to the commencement of data collection, the necessary ethical approvals were secured. The primary investigator initially met with the chief nurses of each hospital unit to explain the study's objectives and to seek their support in facilitating the data collection process. To enhance the perceived anonymity and reduce potential response bias, nurses meeting the inclusion criteria were provided with sealed envelopes containing the survey questionnaires. These envelopes were distributed in their work areas during their shifts. The cover letter of the questionnaire clearly stated the study's purpose, reassured the participants of the anonymity and voluntary nature of their responses, and instructed them to reflect on their experiences with a specific nurse manager. To further ensure confidentiality and reduce any pressure, nurses were asked to return their completed questionnaires in the sealed envelopes to a designated drop box located in a common area within each unit by a specified deadline. Participation was implied through the voluntary completion and submission of the surveys. This method aimed to minimize any direct interaction with the research team during the submission process, thereby fostering a more confidential and unbiased environment for providing genuine responses.

2.7. Ethical Considerations and Consent to Contribute. The Faculty of Nursing Ethics Committee approved ethical approval (No. 21-2-2023). Potential ethical concerns such as participant well-being, privacy, and anonymity were upheld throughout the research procedure. Participants were informed of all study-related materials and their ability to withdraw at any point while the study was in progress. Furthermore, only the authors had access to the sensitive participant data, which was held in a locked, secured cabinet. Lastly, everyone had the guts to raise any pertinent queries.

2.8. Statistical Design. AMOS 25 and IBM SPSS 27 were used for data analysis. The study variables and the nursing characteristics were presented using descriptive statistics. Variations in job development, workplace belonging,

affective commitment, and appreciation of leadership were examined about sample characteristics using independent *t*-tests and analysis of variance (ANOVA). Pearson's correlation was used to examine the bivariate correlations between the research variables and related subdomains. The proposed model was investigated using AMOS structural equation modeling (SEM). The validity and reliability of the study constructs were evaluated. *p* values with two tails less than 0.05 denote statistical significance.

3. Results of the Study

Table 1 shows demographic data samples and differences in study variables. The participants were predominantly between 30 and 35 years of age (39.1%). Most of them (60.6%) were women. Most of them were single (53.3%), 82.7% had a Bachelor's degree in Nursing, and 45.9% had <3 years of experience.

Table 2 analyzes the correlation coefficients among the variables studied, and several significant relationships emerged. In particular, cognitive crafting demonstrated strong positive correlations with relational crafting ($r = 0.674^{**}$), total job crafting ($r = 0.902^{**}$), and workplace belonging ($r = 0.612^{**}$).

Furthermore, affective commitment exhibited a robust positive correlation with workplace belonging ($r = 0.821^{**}$) and a notable association with total job creation ($r = 0.690^{**}$). This implies that staff nurses who feel a sense of belonging in their workplace are more likely to be affective, committed to their roles, and involved in crafting their jobs.

The belonging of the workplace demonstrated a remarkably high positive correlation with the integrity subscale of appreciation of leadership ($r = 0.654^{**}$), suggesting that people who feel like they belong to the workplace are more likely to exhibit integrity in their actions.

Furthermore, inspiring illumination and integrity showed a substantial positive correlation ($r = 0.509^{**}$). This may imply that nurses who perceive their leaders as inspiring and illuminating also tend to perceive them as having high levels of integrity.

Table 3 shows the effect of mediation of the appreciation of staff nurses for the leadership between workplace belongingness, affective commitment, and job design, and Figure 2 shows that appreciative leadership significantly affects job-crafting behaviors ($\beta = 0.45$, $p < 0.001$), workplace belonging ($\beta = 0.66$, $p < 0.001$) and affective commitment among staff nurses ($\beta = 0.78$, $p < 0.001$). Furthermore, job-crafting behaviors significantly affected

TABLE 1: Participants' demographics and differences in study variables (N = 381).

Characteristic	Category	No. (%)	Job crafting		Workplace belonging		Commitment		Appreciative leadership

TABLE 3: Mediation effect of staff nurses' appreciative leadership among workplace belongingness, affective commitment, and job crafting (N = 381).

Indirect effect	β	p	BC 95% CI Lower/upper
Appreciative leadership on workplace belonging	0.19	0.001	0.15/0.27
Appreciative leadership on affective commitment	0.18	0.002	0.13/0.24

FIGURE 2: Mediation effect of staff nurses' appreciative leadership among workplace belongingness, affective commitment of staff nurses, and job crafting (N = 381).

belonging among nurses ($\beta = 0.43$, $p < 0.001$) and affective commitment ($\beta = 0.40$, $p < 0.001$). The indirect effect of job-design behaviors on the relationship between appreciative leadership and belonging to the workplace was significant ($\beta = 0.19$, $p = 0.001$, 95% CI 0.15/0.27). The indirect effect of job-design behaviors on the relationship between appreciated leadership and affective commitment was significant ($\beta = 0.18$, $p = 0.002$, 95% CI: 0.13/0.24), indicating that job construction behaviors among staff nurses mediated relationships between appreciated leadership, belonging to the workplace, and affective commitment among staff nurses.

4. Discussion

To improve nurse well-being and retention, it is critical to comprehend how appreciative leadership, affective commitment, workplace belongingness, and job crafting interact. This knowledge will help build focused treatments and organizational policies [40]. Thus, the purpose of this

study is to investigate how job crafting functions as a mediator in the relationship among nurses between appreciative leadership, workplace belongingness, and affective commitment. Organizations can create conditions that support the growth of their nursing staff by clarifying these routes, which will eventually improve patient outcomes and organizational success. Results showed that appreciative leadership has a strong and significant direct effect on workplace belongingness. This finding is valuable because it indicates that nurses' perceptions of their leadership directly contribute to their sense of belonging at work. These results are in line with [41] earlier studies, showing that the direct effect of appreciative leadership on workplace belongingness is significant. Also, the authors in [30] agreed with these findings and reported that appreciative leadership has a positive effect on workplace belongingness. In addition, the findings of the study showed that the effect of appreciative leadership on workplace belongingness is significant [29].

The results of the present study reported that appreciative leadership also has a robust direct effect on affective commitment, indicating that positive leadership perceptions directly enhance nurses' affective commitment to their jobs. These results were supported by [41], who showed that the direct effect of appreciative leadership on affective commitment is significant. Also, the authors in [33] revealed that there is a noteworthy direct correlation between appreciating leadership and affective commitment. Furthermore, according to [42], commitment and appreciative leadership have a favorable relationship with the intentions to turnover. These results are in line with those of [43], who reported that appreciated leadership has a major influence on employee satisfaction and that the relationship between appreciated leadership and affective commitment is accepted.

Related to job-crafting behaviors' effects, the current study showed that job-crafting behaviors have a significant positive effect on workplace belonging, highlighting the importance of these behaviors in fostering a sense of belonging among nurses. These results are consistent with those of [44], who found that job crafting significantly and favorably affects faculty members' sense of belonging at work. Furthermore, this result is in line with a study [41], which discovered a favorable correlation between job crafting and a sense of belonging at work. However, these results are contradictory with [29], who reported that job crafting has an insignificant effect on workplace belongingness.

Furthermore, job-crafting behaviors also positively affect commitment, further establishing the role of job crafting in enhancing organizational commitment. This leads to the same conclusion as [35] who found that highly bonded employees can reduce the severity of stressors and initiate proactive job crafting. He came to the conclusion that job crafting, which raises employee performance, requires a high level of commitment. Also, the authors in [45] it was observed that as organizational commitment rises, job performance increases. When job crafting is added to this relationship, the effect is even higher. This finding is consistent with that of [46], who found a negative relationship between turnover intention and organizational commitment. These results suggest that allowing workers to engage in job-crafting behavior may lessen the intention of turnover, which will eventually increase employee engagement and satisfaction. Furthermore, [47, 48] results showed a moderated effect of affective commitment on the job crafting and concluded that those employees with high levels of need commitment independent of their job crafting.

Finally, appreciative leadership significantly affects job-crafting behaviors, workplace belonging, and affective commitment among nurses. This results congruence with [33], who indicated that the results demonstrate that affective commitment and workplace belongingness are positively impacted by appreciative leadership. Job crafting, however, has a favorable impact on affective commitment but a negligible influence on workplace belongingness. The relationship among job crafting, workplace belongingness, and appreciative leadership is significantly mediated by affective commitment. Also, this result agrees with [41]. The results of this study demonstrate the substantial direct

impact that job crafting and appreciative leadership have on a workplace's sense of belonging. Additionally, there is a noteworthy direct impact of appreciating leadership and job designing on affective commitment.

5. Conclusion and Recommendations

- (i) Leadership perception: Nurses' perceptions of leadership play a crucial role in shaping their work experience, directly influencing their sense of belonging and commitment and indirectly affecting these outcomes through job-designing behaviors.
- (ii) Job crafting: Engaging in job-crafting behaviors appears to be a vital mechanism through which nurses can enhance their sense of belonging and commitment in the workplace.
- (iii) Positive work environment: Promoting a positive perception of leadership and encouraging job-building behaviors may lead to a more committed and engaged nursing workforce, which is essential for the well-being of both the staff and the patients they serve.

5.1. Implications for Nursing Management. Nurses in the hospital are likely to have high turnover intentions and feelings of disengagement. To ensure higher levels of engagement and lower turnover intentions, management could take the following actions: Nursing managers should focus on cultivating appreciative leadership behaviors, such as providing regular feedback, recognizing achievements, and fostering a supportive work culture. Training programs can be developed to enhance leaders' skills in appreciative communication, conflict resolution, and emotional intelligence. Organizations can encourage the creation of jobs among nurses by offering opportunities for autonomy, skill development, and flexibility in job roles. Policies and practices should align with the principles of appreciation leadership and job crafting, focusing on the importance of employee well-being, engagement, and professional development. These actions are crucial to reducing turnover intentions and disengagement among nurses on the staff.

Data Availability

The data that support the findings of this study are available from the corresponding author upon reasonable request. Also, all data generated or analyzed during this research are included in this manuscript.

Ethical Approval

The Faculty of Nursing Ethics Committee granted ethical approval (No. 21-2-2023). Potential ethical concerns such as participant well-being, privacy, and anonymity were upheld throughout the research procedure. Participants were informed of all study-related material and their ability to withdraw at any point while the study was in progress. Furthermore, only the authors had access to the sensitive participant data, which was held in a locked, secured cabinet.

Lastly, everyone had the guts to raise any pertinent queries. The authors confirm that all the methods were performed in accordance with the relevant guidelines and regulations.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

The authors thank the Deanship of Scientific Research at Shaqra University for supporting this work.

Background. Second victim experiences have long-term impacts on the personal and professional well-being of nurses. Individual-centered support is necessary to help nurses cope with the various stages of the second victim experience. **Objectives.** To explore personal and workplace factors that facilitate or hinder coping styles for second victim experiences from the perspectives of both frontline nurses and nurse managers. **Design.** This was a descriptive qualitative study that incorporated semistructured interviews. **Methods.** Purposive sampling was employed to enlist a total of eight nurses and seven nurse managers selected from five tertiary hospitals located in Hunan Province, China. The study participants included nurses who had suffered second victim experiences and nurse managers who had grappled with their nurses' second victim experiences. The data were transcribed verbatim and analysed using thematic analysis. **Results.** The analysis revealed four main themes that influenced nurses' ability to cope with second victim experiences: source of emotional trauma, personal factors, job stress, and support system. In contrast, emotional trauma from patients and relatives, negative personal traits, shadows from the second victim experience, and unsupportive workplace environments were obstacles to coping with second victim experiences. **Conclusion.** The study highlights facilitators and barriers that nurses cope with second victim experiences, providing insight to develop targeted interventions that support nurses and mitigate the negative impacts of second victim experiences. A comprehensive approach is more effective in supporting nurses in coping with second victim experiences, improving patient safety, and enhancing the quality of care.

1. Introduction

According to the Lancet Global Health Commission, patient safety issues remain a critical challenge worldwide, with 134 million adverse events occurring annually in low- and middle-income countries [1]. In China, adverse event reporting is a crucial criterion for evaluating patient safety in hospitals, but it often lacks effective support systems for nurses, resulting in punishment and isolation [2, 3]. Despite the continuing challenge to nurses of an unprecedentedly burdened, complex, and ever-changing work environment [4], the specific personal and workplace factors that arise during adverse events are still unknown.

Over the past two decades, nurses encountering adverse events have been characterized as “second victims.” This term describes nurses who undergo emotional and psychological distress following such events, which can significantly impact their well-being and professional performance [5, 6]. Studies have indicated that more than two-thirds of nurses involved in second victim experiences troubling memories, anxiety, anger, and distress. Troubling memories were found to be the most prevalent symptom, with a frequency of 81% [5]. The most commonly reported symptom among nurses involved in second victim experiences was hypervigilance, and doubts about their skills and knowledge were also reported frequently [7]. Furthermore,

the research found that the symptoms of second victim experiences were more enduring and severe among nurses than physicians [8]. The COVID-19 pandemic exacerbated the stress and anxiety faced by nurses, including challenges to their health [9]. As reported, empowering nurses with confidence, tools, and skills is critical to improving patient safety and could result in 1,000 lives saved each year by 2024 [10]. Gaining insight into the obstacles and requirements faced by nurses impacted by second victim experiences is crucial for aiding their recovery and progression [11].

Additionally, there is a lack of evidence on effective coping styles for nurses in second victim experiences. Coping refers to the thoughts and behaviours that individuals use to manage the internal and external demands of stressful events [12]. Several studies have highlighted that nurses may struggle with effective coping with second victim experiences due to poor awareness and delayed access to support programmes. For example, Edrees et al. [13] found that delays in receiving support programmes were a theme related to coping with second victim experience among nurses. Similarly, previous studies reported that seeking support and forgiveness from peers and managers was a common coping strategy among nurses [14, 15]. However, there is a lack of literature that provides a comprehensive understanding of the specific personal and workplace factors that influence coping among nurses in second victim experiences, highlighting the need for further research. Moreover, a recent study by Steven et al. [16] highlights the importance of coping as a significant professional practice for nurses in managing emotional and relational tension in clinical settings. However, existing literature has only briefly addressed the tendency to delay accessing support programmes in second victim experience, which can lead to a worse professional quality of life and negative consequences for patient safety [17, 18]. While a mixed methods systematic review by Pollock et al. [19] found that awareness of frontline workers' needs can facilitate mental health support, minimal research has focused specifically on the coping process of second victim experiences, especially from the perspectives of nurses and nurse leaders. Studies have shown that nurse managers play a crucial role in maintaining a creative work environment and the well-being of patients and nurses, but constraints such as time, workload, and resources can lead to poor communication, condescending attitudes, and bullying towards nurses [20, 21]. Moreover, nurse managers themselves can also experience negative effects when supporting nurses involved in second victim experiences [13], underscoring the challenges nurse managers face in maintaining their well-being while assisting their staff. It is therefore presumed that the well-being of nurse managers and their experiences of stress and emotional challenges may exacerbate the causes of poor mental health among nurses.

This study results emphasize the significance of comprehending the factors that influence coping strategies in nurses who undergo second victim experiences, taking into account the viewpoints of both the nurses and their nurse manager. This research centers on identifying the barriers and facilitators that shape coping styles among nurses who

have endured second victim experiences. Additionally, it aims to offer empirically grounded insights that can aid in crafting effective coping styles. These styles are designed to equip and support nurses in managing the challenges associated with second victim experiences.

2. Method

2.1. Study Design. This study utilised a descriptive, qualitative approach through individual face-to-face semi-structured interviews. The study recruited nurses as participants from tertiary care hospitals using purposive sampling, while nurse managers were identified through snowball sampling. This process continued until data saturation was reached, indicating that no new information could emerge from the data. [22]. The data collected were analysed using Braun and Clarke's [23] method of thematic analysis in NVivo Version 12, based in Lumivero, USA. The researchers followed the report guidelines of consolidated criteria for reporting qualitative research [24]. To prevent any unintended impact from relationship dynamics, there were no pre-existing relationships among the researchers, nurses, or nurse managers involved in the study.

2.2. Participants. The research was carried out in five tertiary hospitals in Hunan Province. Nurses and nurse managers who had previously participated in an online survey regarding second victim experiences and agreed to share their insights were involved in this study [25]. Furthermore, nurse managers were enlisted through snowball sampling, leveraging referrals from participating nurses and existing nurse managers within the study. The criteria for selecting nurses included the following: (1) had second victim experience and (2) at least one year of being employed full-time. For nurse managers, the criteria were as follows: (1) holding a pivotal leadership role within the hospital's nursing team, tasked with overseeing nursing operations in a medical unit, which encompasses planning work schedules, supervising the implementation of nursing care, mentoring junior nurses, and facilitating communication between doctors and patients and (2) having experience in providing support to nurses who have faced second victim experiences. The researcher (XZ) contacted and invited participants who had completed an online survey on second victim experience between 2021 and 2022. A total of 15 participants, comprising 8 nurses and 7 nurse leaders, were interviewed individually to obtain their perspectives.

2.3. Research Team Characteristics. The research team was exclusively female and consisted of three nurses (XZ, LW, and ZQ), two nurse managers (YM and AL), and two nursing science lecturers (CMC and CCC). Nurse XZ was a PhD candidate at the University of Malaya, LW was a PhD candidate at King's College London, and ZQ was a master's student at Central South University. Three team members (CMC, CCC, and YM) hold a PhD qualification and have expertise in qualitative research. The nursing science lecturer CMC, an Associate Professor at the University of Malaya,

has extensive experience in qualitative analysis and is not affiliated with the hospital to avoid any potential impact from relationship dynamics.

2.4. Data Collection. Data were collected between February 2022 and August 2022. Participants were recruited through an advertisement on a WeChat page that provided information about the study, and interested individuals were screened for eligibility criteria before providing consent to participate. The interviews were conducted by XZ at a mutually convenient time and location for the participants. Nurses LW and ZQ were the field note-takers, with LW joining the interviews with participants identified as RN01–08 and ZQ joining the interviews with participants identified as NL01–07. Each interview lasted between 40 and 60 minutes and was audio recorded. The interviews took place in the medical unit's designated rest area, which is furnished with a comfortable sofa and provides a quiet atmosphere. Participants were able to book the rest area for at least an hour and had the option to lock the door during the interview for privacy. The interviews were scheduled for either noon or after the participants' duty hours to ensure their availability. The interviews aimed to obtain insights into the barriers and facilitators of coping with second victim experiences among nurses. Demographic data were collected, including the gender, age, length of working experience, position, title, medical unit, and education level. The interview guide was developed by the authors (XZ and LW) based on the previous literature and is presented in Table 1. To ensure consistency, all interviews were conducted by XZ. Data collection was considered completed when data saturation was achieved. Audio recordings of the interviews were transcribed verbatim immediately.

2.5. Data Analysis. This study followed the six-step thematic analysis method developed by Braun and Clarke [23] and utilised NVivo v12 to manage and analyse the qualitative data. The data were transcribed and anonymised before being coded by XZ and LW independently for each participant. The first step involved familiarising the researchers with the data sets and generating initial codes. To ensure completeness, the coded data were compared with the transcripts and returned to the participants; there are no comments and corrections from the participants. The third step involved identifying potential themes, which were reviewed and refined during the fourth step. Several rounds of discussion were conducted to ensure the representation, consistency, and accuracy of the themes. The refined themes were then converged to ensure consistency and accuracy. The fifth and sixth steps involved defining and naming the themes and presenting thematically the results of the study. The thematic presentation aimed to provide an in-depth understanding of the facilitators and barriers that nurses face when coping with second victim experiences. The rigorous analysis approach helped to ensure the trustworthiness and reliability of the findings.

2.6. Rigour and Trustworthiness. To increase the credibility of the findings, this study used member checking and peer debriefing. Member checking involved presenting the research findings to participants to confirm accuracy and receive feedback, while peer debriefing involved other researchers reviewing the study design, data collection, and analysis.

Triangulation was used to increase the understanding of the phenomenon. Triangulation is important when studying frontline nurses and nurse managers because it recognises the differences in their roles and responsibilities. These roles often result in different understandings, priorities, and perspectives between the two groups. Moreover, this approach entails gathering and analysing data from various sources, encompassing both interviews and observations. Observational methods enable researchers to capture data that participants might not readily convey in interviews, thereby offering a more comprehensive perspective on the phenomena being investigated. This holistic approach aids in fostering a dependable understanding of perceptions regarding the second victim experience. This triangulation approach significantly increases the validity and rigour of the research findings [26].

The utilization of observation notes during data collection involves three primary stages, encompassing both interviews and observational methods. Initially, after transcription, observation notes are amalgamated with interview transcripts. These annotated records, serving as observational insights, are seamlessly integrated into the transcribed manuscripts, enriching the initial coding phase with a comprehensive perspective. Subsequently, the transcribed manuscripts and observation notes undergo review with research participants to elucidate any potential ambiguities in conveyed meanings. Once themes are established, they undergo further examination in conjunction with observation notes to validate and refine emerging patterns. The incorporation of observational data throughout this methodology significantly enhances thematic analysis, fostering a deeper understanding and more nuanced insights. Post-transcription, the integration of observations with interview data affirms the coherence and expansion of emerging themes across diverse data sources.

The researchers (XZ and LW) compared the information gathered from each source. By including the perspectives of both frontline nurses and nurse managers, this study was able to gather a complete understanding of the facilitators and barriers to coping with second victim experiences. In addition, member checking was used as a verification technique upon the full development of themes, thereby bolstering the validity of the research findings.

2.7. Ethical Consideration. Before conducting this study, ethical approval was obtained from the Research Ethics Committee at the Second Xiangya Hospital of Central South University (no. LYF2022003). All participants were provided with research statements, and informed consent was obtained, with opportunities for questions and the right to withdraw from the study at any time. This study was

TABLE 1: Interview guide.

-
- (1) What are some of the most challenging adverse events you (your colleagues) have experienced in your career?
 - (2) How did it affect you (your colleagues)?
 - (3) How did you (your colleagues) cope with the events?
 - (4) How did the organisation manager manage the events?
 - (5) How did interactions between you and your team influence your experiences?
-

conducted following ethical principles and guidelines for research involving human subjects. Participants who experienced psychological distress and wished to receive help would be evaluated by project team members and provided with assistance. If any discomfort arose during the interview process, participants could contact a mental health professional from the Department of Psychiatry at Xiangya Second Hospital, Central South University, at 0731-85295555, if necessary.

3. Results

3.1. Demographic Characteristics of Participants. Table 2 presents the demographic characteristics of the 15 participants in this study. The majority of the study's participants were female, comprising 93% of the sample, while male participants constituted a smaller portion at 7%. The average age of the participants was 38.9 years, and they had an average professional experience of 16.7 years. Nearly half of the participants (47%) held advanced professional titles, and 40% had intermediate titles. The most represented medical units were internal medicine and surgery, each contributing a third of the participants, followed by a smaller percentage in specialties such as paediatrics, obstetrics, and gynaecology, which accounted for 13%. In terms of educational background, 20% of the participants, amounting to 3 individuals, possessed a bachelor's degree, whereas the majority, 80% or 12 participants, held a master's degree.

3.2. Themes and Subthemes. This study aimed to explore personal and workplace factors that facilitate or hinder coping styles among nurses who have second victim experience. It employed a thematic analysis of semistructured interview transcripts, which resulted in 4 main themes and 12 subthemes (Table 3). The 4 main themes that emerged from the analysis were the source of emotional trauma, personal factors, workplace environment, and support systems. Each theme was further divided into subthemes, providing more specific information from both nurse and nurse manager perspectives.

3.2.1. Source of Emotional Trauma. In the second victim experience, nurses are exposed to trauma from different sources that can impact their coping styles.

(1) Patients' Consequences. When patients experience adverse consequences, nurses often internalise a sense of

responsibility, leading to guilt and self-blame. This emotional burden can intensify feelings of stress and anxiety and impede their ability to cope effectively.

NL02: Their blood pressure is too high! and then, er. . . the patient told me, uncomfortable and crappy, you know what I mean? It's so dangerous. . . If it is not dealt with in time, the consequences will be disastrous.

(2) Response of Patients' Relatives. Patients' relatives can respond in various ways, including hostility, blame, denial, or lack of cooperation. These responses can increase the nurse's stress and emotional distress, leading to feelings of anger, resentment, and burnout.

NL05: The family, in fact, had similar views to his; that is, the family couldn't understand, and was also very anxious, er. . . like can't listen to the explanation, very angry.

3.2.2. Personal Factors. This refers to individual traits, experiences, abilities, and attributes that may influence how a nurse copes with the second victim experience.

(1) Personality. Sensitivity may lead to increased emotional distress. However, positive thinking may help nurses find meaning and purpose in their work, contributing to their well-being.

RN07: Having worked for over ten years, and I'm a relatively sensitive and fragile person, the way I deal with this, always be impressive in my mind.

RN05: I was shocked, and I have learned a lesson from this incident, so I will not handle this pipeline problem recklessly again. In the future, I will take the initiative to ask the seniors to look at any problem that I think I am not sure about or any problem of this kind.

(2) Shadows of Experience. It highlights personal factors following adverse events that affect how nurses cope with the second victim experience, referring to the emotional, physical, occupational, and long-term consequences that negatively affect coping styles.

Emotional echoes: Nurses experiencing anxiety and fear lead to avoidance coping styles, while those dealing with guilt might adopt more conflictual coping styles.

TABLE 2: Demographic details of participants (N = 15).

Variable	Category	%(N)/mean ± SD
Gender	Female	14 (93)
	Male	1 (7)
Age (years)		38.9 ± 8.5
Years of working		16.7 ± 9.1
Title	Junior	2 (13)
	Intermediate grade	6 (40)
	Advanced title	7 (47)
Medical unit	Internal medicine	5 (33)
	Surgery	5 (33)
	Paediatrics, obstetrics, and gynaecology	2 (13)
	Acute and intensive care	3 (20)
Education level	Bachelor	3 (20)
	Master	12 (80)

TABLE 3: Themes and subthemes of the study.

Themes	Subthemes
Theme 1. Source of emotional trauma	1.1. Patients' consequence
	1.2. Response of patients' relatives
Theme 2. Personal factors	2.1. Personality
	2.2. Shadows of experience
	2.2.1. Emotional echoes
	2.2.2. Physical reaction
	2.2.3. Occupational challenges
Theme 3. Job stress	2.2.4. Enduring silence
	3.1. Workload
	3.2. Ineffective management
	3.3. Organisational culture barriers
	3.3.1. Inadequate awareness
Theme 4. Support system	3.3.2. Punishment effects
	4.1. Supportive network of colleagues
	4.2. Continuous professional development
	4.3. Availability of referral resources
	4.4. Family and community support

RN07: After the incident, but er... There was, at the time, a lot of nerves...and when I'm wrong, it's really aggravating, scary and helpless.

Physical reactions: Physical discomfort or illness may limit the energy and resources available for coping, leading to a preference for less active or avoidance-based styles.

RN04: Just sitting on the floor, crying ah. Sometimes, sometimes sitting on the bed without moving, can really sit for 12 hours without eating or drinking.

Occupational challenges: To highlight how adverse events can damage nurses' confidence in their clinical skills and decision making, impact their professional identity, and lead to negative coping styles as a result of avoidance.

NL03: Eventually, for a while, I did notice that she was kind of wandering around at work. Then she said she wasn't right for the position... She mentioned resigning later. She wrote her resignation letter anyway.

Enduring silence: It suggests that nurses' struggle with unresolved emotions without effective processing may exacerbate chronic worrying and rumination, thereby influencing the adoption of negative coping styles.

RN05: It was about, over 10 years ago, and I am still so sad, every time I mentioned it, oh my God...

NL02: But, that long process is really completely insomnia, that is the bad event for her to cause this kind of damage, this event for her this life is really to be engraved in the heart, afraid to mention to anyone to talk about.

3.2.3. *Job Stress.* The physical and psychological conditions of the work setting can affect nurses' response to the second victim experience, including organizational culture, job demands, and workload.

(1) *Workload.* It refers that the high level of workload led to avoiding the stressor.

RN01: Some time ago, because of the lack of manpower and the seriousness of the patient's condition, during the New Year, there were more unplanned extubating, for example, It seems that we can't change anything, out of control, hard to believe. . .

(2) *Ineffective Management.* This refers to a situation where the management fails to provide adequate resources, support, and guidance to nurses in dealing with the second victim experience.

RN01: To report adverse events, you must do courseware and PPT, and all nurses involved should report. . . It will increase the workload, and everyone will be very stressful. . .

(3) *Organisational Culture Barriers.* Cultural barriers within a healthcare organisation can hinder the ability of nurses to manage the second victim experience effectively.

Inadequate awareness: Insufficient knowledge or comprehension of the second victim experience escalates the risk and hampers the capacity to cope effectively.

NL03: Regardless of whether there are consequences or not, it really feels like an adverse event, and an adverse event is that I did not do well. . .

Punishment effects: Punishing nurses without a supportive environment can lead them to develop unhealthy ways of coping with the stress and emotional impact of second victim experiences.

RN03: In fact, at that time, I have the feeling that there are no set rules and regulations when it comes to punishment; it's more like decisions are made on the basis of the thoughts of the heads of medical units or nursing units, without a clear basis. . .

3.2.4. *Support Systems.* Support systems can play a critical role in how nurses cope with the second victim experience, and they refer to networks of individuals, groups, and organizations that provide emotional, practical, and informational support to nurses.

(1) *Colleague Network.* A colleague network for nurses refers to a group of colleagues who can provide support to the nurse in the second victim experience, including practical advice and emotional support.

RN07: The support of the nurse managers and the doctor, for example, the doctor went to help the patient, and after explaining and apologising together, the attitude of the patient eased up. My, this emotion, this nervous anxiety, this helpless emotion, There is a noticeable decline.

(2) *Continuous Professional Education.* This refers to ongoing education and training on skills and knowledge related to reviewing adverse events. Such education can help nurses

gain a better understanding of the second victim experience and how it can be prevented. It includes understanding the signs of mental health conditions, knowing how to seek help, and recognising the importance of wellness.

RN04: I hope he can guide me in the future, when I encounter such accompanying family members, guide nurses on how we should skilfully resolve this conflict.

NL05: You analyse it, you analyse it all, you do it all, and the next time he'll know how, yeah. . . How to understand this matter. I'm going to handle it, how I'm going to do it. I'm not going to be passive, and I'm going to be proactive. . . Especially, I can accept myself as a nurse, and I also need to seek help.

(3) *Availability of Referral Resources.* This refers to the presence of adequate resources that can assist the nurses in effectively coping with second victim experiences, such as time and mental health services.

NL03: During the rest time, we would accompany her to see a doctor later. . . After talking with the director, I also talked to a few members of our nursing core team about this matter, for protecting. . .and helping her.

(4) *Family and Community Support.* This refers to the role that family members and the community can play in supporting nurses who are involved in the second victim experience.

RN08: But in the end, I still face it by myself. Of course, my family has always supported me. Even if they don't study medicine, they are not very capable. They are very clear about the whole process, but they will accompany me.

4. Discussion

The findings of this study underscore crucial elements that can either hinder or aid nurses in dealing with second victim experiences. These factors play a significant role in influencing how nurses manage and recover from such challenging situations. Although qualitative studies from various countries, such as Australia, Switzerland, and the United Kingdom, highlight the significance of individual-centered coping styles that are based on the different stages of the second victim experience [11, 27, 28], there is still a lack of in-depth evidence on the factors that impact these coping styles. This study considered the perspectives of both nurses and nurse managers and identified several dimensions that play a role in the coping process. The results of this study indicate that coping with second victim experiences is shaped by emotional trauma origins and personal traits. Additionally, the study uncovers that workplace-related challenges significantly add to the stress of second victim experiences, consequently impeding the efficacy of the coping process for nurses. Conversely, a multilevel

support system is unanimously recognized by both frontline nurses and nurse managers as a critical facilitator in managing second victim experiences. This comprehensive support structure plays a pivotal role in aiding nurses to effectively navigate and cope with the challenges arising from these experiences.

The theme of the source of emotional trauma in this study revealed a complex association between patients' outcomes, relatives' responses, and the second victim experience among nurses. It emphasizes that patients' consequences directly impact the nurses, aligning with studies indicating that nurses can feel responsible for patient consequences and fear disciplinary action, leading to negative coping strategies such as avoidance, denial, or self-blame [6]. Researchers have identified marked disparities in how adverse events are perceived by nurses, patients, and their families [29, 30]. Additionally, difficulties in the interactions between nurses and patients' relatives have been documented in a qualitative meta-analysis [31]. This study further emphasizes the deep-seated connection between patients' relatives and nurses who have gone through second victim experiences. The participants of this study shared that relatives often undergo feelings of anger, grief, and loss after adverse events, and these emotions are frequently projected onto the involved nurses. In some cases, this can escalate to legal actions, which intensify the nurses' challenge in coping with their second victim experiences. These observations underscore the necessity for healthcare organizations to enhance communication and coordination following adverse events [32, 33]. Implementing standardized procedures that enable nurses to effectively communicate about adverse events and ensure patients' families have a clear understanding of what occurred can help mitigate blame and conflict. Such measures could significantly improve nurses' ability to manage and recover from second victim experiences.

This study has pinpointed several personal factors such as personality and overall damages from adverse events as crucial determinants influencing the coping styles of nurses. To begin with, personality traits have a significant impact on how nurses handle second victim experiences [34]. It has been observed that participants who exhibit positive thinking are generally more adept at coping with these experiences. Supporting this, prior research indicates that nurses often display higher levels of extroversion compared to professionals in other fields, which can influence their coping methods [35]. However, the study also notes that nurses with high sensitivity might experience increased emotional distress when dealing with second victim experiences, indicating a nuanced relationship between personality traits and coping effectiveness. These findings align with those of previous research, which indicates that nurses can feel threatened when there is a significant disparity between their expectations and reality [36]. Importantly, some participants—three nurses and two nurse managers—revealed that even though as many as 15 years have passed since the second victim experience, the sadness, fear, and anxiety of the event still lingers as they recount their experiences. Some of the nurse managers reported long-

term effects such as depression and career changes. Findings in the shadow of experience add to the growing evidence that multiple harms following adverse events significantly influence coping styles. [8, 37]. It highlights the need to break the cycle of silence and promote healing of emotional, physical, and professional dimensions, as well as ongoing reflection to recover from trauma.

The third theme in this study emphasized the challenges related to the job stress for nurses in coping with the second victim experience; in particular, it highlights the recognition of the burdens posed by the intricate nature of the prevailing management processes. Some participants of this study reported that high levels of workload cause nurses to experience higher levels of stress, leading to increased negative coping to the second victim experience. Significantly, convoluted reporting processes during adverse events can subject nurses to pressure and a lack of support within the context of the second victim experience. In turn, it can lead to deficient factor analysis and the adoption of ineffective coping styles [38]. Furthermore, the findings of this study suggest that in the absence of these supportive mechanisms, nurses may face difficulties in effectively processing their emotions and experiences. This challenge could potentially result in prolonged psychological distress, an increased risk of burnout, and could even lead to nurses leaving the profession. The importance of adequate support structures is thus underscored, as they are critical in helping nurses navigate the complexities of their experiences and maintain their mental health and career longevity. A ten-year national survey recommends the importance of fostering a supportive work environment where nurses feel valued and heard and where they can openly discuss their experiences and receive appropriate support to cope with the emotional impact of the second victim experience [39].

Theme four of this study highlights the most significant findings in facilitating coping with the second victim experience among nurses. The study discovered that having a network of colleagues is advantageous, echoing findings in the existing literature that highlight how colleague networks are integral to shaping an organization's culture and in providing a safe environment for expressing emotions. Previous research has underscored that when nurses are part of a supportive peer network, they feel more empowered to manage complex situations without fear of judgment or criticism [28]. However, an interesting point raised by participants in this study, which appears to be underrepresented in current literature, is that the most immediate and effective support often comes directly from colleagues. This aspect emphasizes the crucial role of peer support in the immediate aftermath of challenging incidents, indicating a potential area for further exploration and emphasis in future research and organizational policies. Continuous professional education is revealed in this study, as Goh et al. [40] and Davis et al. [41] supported that it is crucial for maintaining resilience, collaborative practice, and patient safety. Previous studies have similarly demonstrated a link between mental health literacy and adaptive coping styles [42, 43]. Enhancing mental health literacy among nurses can better prepare them to manage the emotional

challenges associated with the second victim experience. Continuous learning and skill development can empower nurses to effectively navigate the demands and stressors of these experiences. Moreover, the findings from our study suggest that mental health literacy can also benefit nurse managers in supporting nurses during complex situations. Younas et al. [21] revealed that mental health literacy plays a crucial role in enabling nurse managers to address their emotions effectively and implement successful management strategies. The concept of the second victim remains a topic of debate, with some critics such as Tumelty [44] arguing that it might detract from the focus on patient harm. Despite these contentions, findings from this study reveal that frontline nurses often face a lack of clear guidance on how to seek help for second victim experiences, which can lead to the adoption of negative coping mechanisms. On the other hand, nurse managers are in favor of creating a structured referral system. Such a system, as suggested by Norvell et al. [45], would be designed to swiftly identify nurses experiencing second victim phenomena and provide them with appropriate mental health services. This approach could potentially bridge the gap between the immediate needs of affected nurses and the long-term goal of maintaining high standards of patient care, while also addressing concerns about the potential overshadowing of patient harm. This can ensure that nurses receive timely and appropriate care and support to cope with the emotional and psychological effects of their experiences. In Chinese culture, both family and community constitute fundamental pillars of an individual's support system [46, 47]. In addition, it is imperative to recognise that nurse managers, who simultaneously occupy family roles as mothers, wives, and daughters, play a central role in providing immediate support to fellow nurses. Consequently, the findings underscore the importance of a robust support system, including both family and community, that not only assists nurses with guilt and anxiety but also provides nurse managers with an essential resource that facilitates their prompt and effective support of nursing staff.

4.1. Strengths and Limitations. The strengths of this study are its rigorous qualitative design and triangulation. Frontline nurses are the ones directly involved in the second victim experience, while nurse managers have a broader view of the organizational context. By including both perspectives, this study demonstrates that coping with second victim experiences is not only a personal issue. It is also influenced by organizational and managerial factors.

Limitations include potential selection bias from different experience timeframes and gender bias. This highlights the need for ongoing research and interventions to support nurses in coping with second victim experiences.

5. Conclusion

The findings from this study strengthen the understanding of facilitators and hurdles in managing second victim experiences as reported by frontline nurses and nurse

managers. It highlights the critical need for a comprehensive approach involving patients, their families, and healthcare institutions. By incorporating an understanding of multiple factors influencing dealing with the second victim experience, we can develop interventions that address multiple aspects to support effective coping styles among nurses.

Data Availability

The datasets generated during and/or analysed during the current study will be shared only on request with the approval from the Universiti Malaya.

Ethical Approval

The procedures used in this study adhere to the tenets of the Declaration of Helsinki. This work was approved by the research Ethics Committee in the Second Xiangya Hospital of Central South University (no. LYF2022003).

Consent

The participants agreed to the informed consent before starting to fill in the questionnaire. Informed consent was obtained from all participants included in the study, which was a completely voluntary, anonymous, and unrewarded study.

Disclosure

AI Use. No AI has been used in the preparation of the manuscript.

Conflicts of Interest

The author(s) declare that they have no conflicts of interest.

Acknowledgments

Partial financial support was received from the health research project of the Hunan Provincial Health Commission (202214053970). The author would like to acknowledge the efforts of and thank the frontline nurses and nurse managers who participated, as well as the organizations that helped with recruitment.

Background. Nurses, who comprise the largest proportion of healthcare professionals, must advocate for public health in a changing healthcare environment. Therefore, nurses have a social responsibility to be interested in politics, political participation, or healthcare policy interventions as leaders in healthcare policy reforms. However, previous research has reported that nurses' political interests and participation are insufficient in most countries. **Aim.** This study systematically reviewed and synthesized qualitative data to identify the barriers and facilitators influencing nurses' political participation and healthcare policy interventions. **Methods.** This study performed a systematic review and qualitative meta-synthesis. Literature searches were conducted using seven databases to comprehensively examine published journals, including doctoral dissertations, until December 31, 2023. The selection criteria for this study were articles analyzed using phenomenology, ethnography, qualitative research, and grounded theory, targeting nurses with extensive experience in healthcare policy intervention and political activities. Two researchers, professors in nursing with extensive experience in healthcare policy interventions and qualitative research screened the qualitative studies and extracted the data. Eighteen papers were analyzed, and the quality of each study was evaluated using the Critical Appraisal Skills Program Qualitative Checklist. Meta-ethnography was applied as the qualitative meta-synthesis method using ATLAS.ti. **Results.** Barriers include nurses' lack of political interest and competence, nursing education, restrictive organizational cultures, and the nursing profession's political activities. Facilitators include recognizing social responsibilities, enhancing political competence, innovating organizational environments, and strengthening nursing organizations' political activities and policy interventions. **Conclusions.** This study could be used as data to enhance nurses' political participation and to plan policy interventions and strategies. **Implication for Nursing Management.** To activate nurses' political participation in the future, it is necessary to develop strategies, such as developing nursing political education programs and expanding opportunities for policy intervention.

1. Introduction

Since the United Nations (UN) introduced 17 sustainable development goals (SDGs) in 2015 [1], the World Health Organization (WHO) has encouraged countries to reform healthcare policies and achieve key health-related SDGs [2]. Furthermore, the UN and WHO emphasize the need to enhance healthcare professionals' political participation and

healthcare policy intervention based on their social responsibility to accomplish the SDGs [2].

Politics is an authoritative distribution of social values [3], and healthcare professionals can contribute to the effective maintenance and development of a limited-resource healthcare system through political participation and policy interventions in policy-making processes [2]. Political participation is defined as activities that directly or indirectly

influence government policies, such as election voting, election campaigns, rallies, legislative lobbying, and petitions [4]. Regarding this, 27.9 million nurses, accounting for approximately 59% of the world's largest healthcare workforce [2], must advocate for public health and nurses' rights in a changing healthcare environment, as specified by the International Council of Code of Ethics for Nurses [5]. In addition, nurses have a social responsibility to be interested in politics and to engage in political participation or policy interventions as leaders in healthcare policies [6–9]. In this regard, analytical studies have been reported in some countries, such as the United States, South Korea, and Iran, on the activities and successes of nurse political activists in contributing to the reform or introduction of healthcare policies [10–14]. However, it has been reported in many countries that nurses' political interest or participation is insufficient [6–9, 15]. Therefore, based on the experience of the political participation of skilled nurse activists, it is necessary to explore the barriers to and facilitators of political participation to strengthen the political competencies of nurses.

Although there have been a few systematic review studies related to nurses' political participation or healthcare policy intervention, there have been few meta-comprehensive studies, and they mainly analyze nurses' political competence or role, policy intervention, and policy advocacy experience [8, 15–18]. In this regard, Benton et al. [16] analyzed a mixed study on the status and results of research on nurses' political competence and policy pursuit. Etowa et al. [8] performed a systematic review of the significant involvement of nurses and midwives in policy development in low- and middle-income countries, focusing on their experiences. Hajizadeh et al. [15] conducted a systematic review identifying factors that influence nurses' participation in health policy-making, highlighting three main themes: nursing-related factors, management and organizational factors, and the creation of a positive work environment. Meanwhile, Fernández et al. [17] analyzed the literature on the political role of nurses over a 10-year period but did not derive the concept of barriers or facilitators to nurses' political participation or policy interventions through qualitative synthesis. In addition, the study by Chiu et al. [18] was not in terms of nurses' social and political activities but rather focused on nursing representative organizations and labor unions. Like this, most of the studies were limited to systematic reviews or scoping reviews rather than deriving concepts by meta-synthesizing individual qualitative studies on barriers or facilitators to nurses' political participation or involvement in health policy.

Therefore, this study aimed to explore the barriers and facilitators to nurses' political participation and healthcare policy intervention through a systematic review and meta-synthesis of previous studies.

2. Materials and Methods

2.1. Research Design. This study was designed as a qualitative meta-synthesis study that provides a broad understanding of social phenomena by integrating the results of qualitative research [19] to explore the barriers and facilitators

influencing nurses' political participation and healthcare policy intervention using meta-ethnography [20]. There are a variety of major qualitative meta-synthesis methods, including meta-ethnography [20], grounded theory synthesis [21], and critical interpretive synthesis [22]. Among these, the meta-ethnography method, which consists of seven stages by Noblit and Hare and is suitable for higher-level analysis and the formation of new interpretations above the discoveries of individual qualitative studies [20], was used for this study (Figure 1). The review question was as follows: what are the barriers and facilitators that influence nurses' political participation or healthcare policy intervention? This study was registered in the PROSPERO International Prospective Register of Systematic Reviews (registration ID: CRD42022346992).

2.2. Search Strategy. A systematic literature search was conducted using the CORe search electronic databases of COSI (CORe Standard, Ideal) presented by the National Library of Medicine (NLM): PubMed, CINAHL, Medline, Embase, Web of Science, and Scopus [19]. A manual search was performed using Google Scholar for a comprehensive literature search. First, two researchers, professors in the Department of Nursing with extensive experience in healthcare policy interventions and qualitative research, independently conducted preliminary searches and established a search strategy while mutually confirming the correspondence between the searched literature. The search strategy was Nurse* OR Registered nurse* OR Licensed nurse* OR Nursing staff OR Nursing personnel OR Nursing profession AND Policy OR Policies OR Politics OR Political OR Advocac* AND Empirical research OR Focus group* OR Experience* OR Qualitative* OR Interview* OR Semistructured OR Semistructured OR Unstructured OR In-depth OR In-depth OR Face-to-face OR Grounded theory OR Phenomenolog* OR Ethnograph* OR Fieldwork OR Fieldwork (see Supplementary Materials). To select articles, two researchers reviewed the title, abstract, and full text using Endnote 20 after excluding duplicate studies according to the selection or exclusion criteria. In addition, a consensus was reached on inconsistencies in this process after sufficient discussion between the two researchers (Supplementary Table 1).

2.3. Study Selection and Quality Assessment

2.3.1. Selection Criteria. Based on the PICOTS-SD criteria, the participants of this study were nurses. Articles that analyzed nursing students, non-nurses, or nurses with other healthcare professionals or politicians were excluded (Table 1). The phenomenon of interest and the main outcomes were to explore the barriers and facilitators that influence nurses' political participation in healthcare policy interventions. The search was conducted from January 20, 2021, to April 28, 2023, and targeted all journals (including doctoral dissertations) in English published before December 31, 2023. Articles on hospital organization or patient advocacy, policy analysis or development, nursing policy

FIGURE 1: The phases of the meta-ethnography approach by Noblit and Hare (1988).

education, and practical experience in nursing were excluded. This study design included phenomenology, ethnography, qualitative descriptive studies, and grounded theory. Articles on quantitative research, letters, and editorials were excluded.

2.3.2. The Result of Study Selection. A total of 35,583 studies were identified, of which 19 individual studies were included in the qualitative meta-analysis using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guideline [23]. The PRISMA 2020 guideline provides reporting checklist for systematic reviews by consisting of a 27-item checklist, expanded recommendations, an abstract checklist, and revised flow diagrams to reflect methodological advancements in study identification, selection, appraisal, and meta-synthesis [23]. The databases initially searched for documents were PubMed 3,781, CINAHL 6,152, Medline 6,355, Embase 9,615, Web of Science 9,379, Scopus 301, and Google

Scholar 30. After excluding 23,717 duplicate articles, the titles of 11,866 articles were reviewed. After excluding 11,090 articles unrelated to the research, the abstracts of 776 articles were reviewed. The full texts of 168 articles were then reviewed, excluding 608 articles that analyzed national health policy, hospital or long-term care institution policy, policy education, and nursing administration policy. Consequently, 149 articles that were not related to nurses' political or health policy intervention activities were excluded (Figure 2) (Supplementary Table 2). The criteria and processes for selecting studies to be analyzed were carried out in continuous discussion with two researchers. The result of the PRISMA 2020 assessment for reporting systematic reviews is in Supplementary Table 3.

2.3.3. Quality Assessment and Characteristics of the Selected Individual Studies. To evaluate the quality of the final included individual studies, this study used the Critical Appraisal Skills Program (CASP) qualitative checklist, which is commonly used to assess studies and ensure the internal validity of qualitative research meta-synthesis [24]. To reduce the bias of individual studies and secure the internal validity of meta-analyses, evaluating the quality of the primary study to be analyzed is a top priority [25]. The CASP is a tool used to evaluate the reliability, truthfulness, and rigor of qualitative research and consists of ten questions. The higher the score satisfying the questions, the more likely it was that an individual study was systematically conducted. Individual studies were evaluated based on ten questions on the CASP criteria to determine whether they were satisfied. Each researcher independently evaluated and compared the results. In cases of disagreement, consensus was reached through discussion. According to the CASP criteria, 94.7% ($n = 18$) of 19 articles met a high ($n = 17$) [7, 10, 11, 13, 14, 26–37] or high-moderate ($n = 1$) [38] level of research methodological quality (≥ 0.7), and one article [39] had a low-moderate quality level (0.5). In general, CASP score of less than 0.7 indicates low methodological quality; thus, the meta-analysis results derived from inputting individual studies whose quality has not been verified are challenging to secure internal validity; therefore, one low-quality study was excluded [39] (Table 2).

The 18 studies included in the analysis were conducted in the United States ($n = 7$), Brazil ($n = 2$), Ghana ($n = 2$), Iran ($n = 2$), New Zealand ($n = 1$), Canada ($n = 1$), South Korea ($n = 1$), Thailand ($n = 1$), and Kenya ($n = 1$). Of these, 16 individual articles used qualitative research methods: phenomenology, ethnography, grounded theory, and descriptive analysis, and two articles used mixed methods [32, 35]. For data collection, individual in-depth interviews, focus group interviews, and the Delphi technique were used through purposive sampling. Eleven articles received prior research ethical approval. The participants used in the analysis were 329 nurses, general nurses or nurse managers in hospitals, community public health nurse leaders, civic group activists, government officials, elected politicians, professors, and healthcare policy committee members or policymakers. They had extensive experiences in political activities and healthcare policy reforms in the National Assembly, public institutions, central or local governments,

TABLE 1: Selection criteria for the study.

Classification	Inclusion criteria	Exclusion criteria
Participants	(i) Nurses (ii) Registered nurses (iii) Licensed nurses (iv) Nursing profession	(i) Non-nurse occupations, healthcare personnel, healthcare profession, and other occupation (ii) Nurses with other healthcare professionals or politicians
Interventions/exposure	(i) Nurses' experiences in healthcare, political advocacy, policy intervention, policy reform, or political activities	(i) Non-nurses' experience in political participation or policy reform activities (ii) National/local government policy or political activities (iii) International policy or politics (i) Not applicable
Comparisons/control	(i) Not applicable	(i) Results of healthcare policy analysis (ii) Policy and political nursing education (iii) Factors of political involvement and political activity of nurses (iv) Effectiveness of healthcare policy reform (v) History of work experiences of the nurses (vi) Patient advocacy in the hospital (i) Articles published after December 31, 2023
Outcomes: phenomenon of interest	(i) To explore the perception of nurses about their experiences of political participation and healthcare policy reform (ii) To evaluate barriers and facilitators of political participation and healthcare policy intervention	(i) Policy and political nursing education (ii) Factors of political involvement and political activity of nurses (iv) Effectiveness of healthcare policy reform (v) History of work experiences of the nurses (vi) Patient advocacy in the hospital (i) Articles published after December 31, 2023, by each database of search
Time	(i) Articles published from the first publication to December 31, 2023, by each database of search	(i) Articles published after December 31, 2023
Setting	(i) National/local healthcare policy or advocacy or politics (i) Qualitative study (ii) Descriptive study (iii) Exploratory study (iv) Empirical research (v) Grounded theory (vi) Phenomenology (vii) Ethnography (viii) Case study (ix) Focus group interviews (x) In-depth interviews (xi) Semistructured interviews (xii) Unstructured interviews (xiii) Face-to-face interviews	(i) Organizational policy or politics (ii) Non-English papers
Study design	(i) Qualitative study (ii) Descriptive study (iii) Exploratory study (iv) Empirical research (v) Grounded theory (vi) Phenomenology (vii) Ethnography (viii) Case study (ix) Focus group interviews (x) In-depth interviews (xi) Semistructured interviews (xii) Unstructured interviews (xiii) Face-to-face interviews	(i) Quantitative studies (ii) Mixed methods' research with absent or uncertain qualitative data (iii) Not a primary study: interview, conference material, commentary, perspective, review, and letter

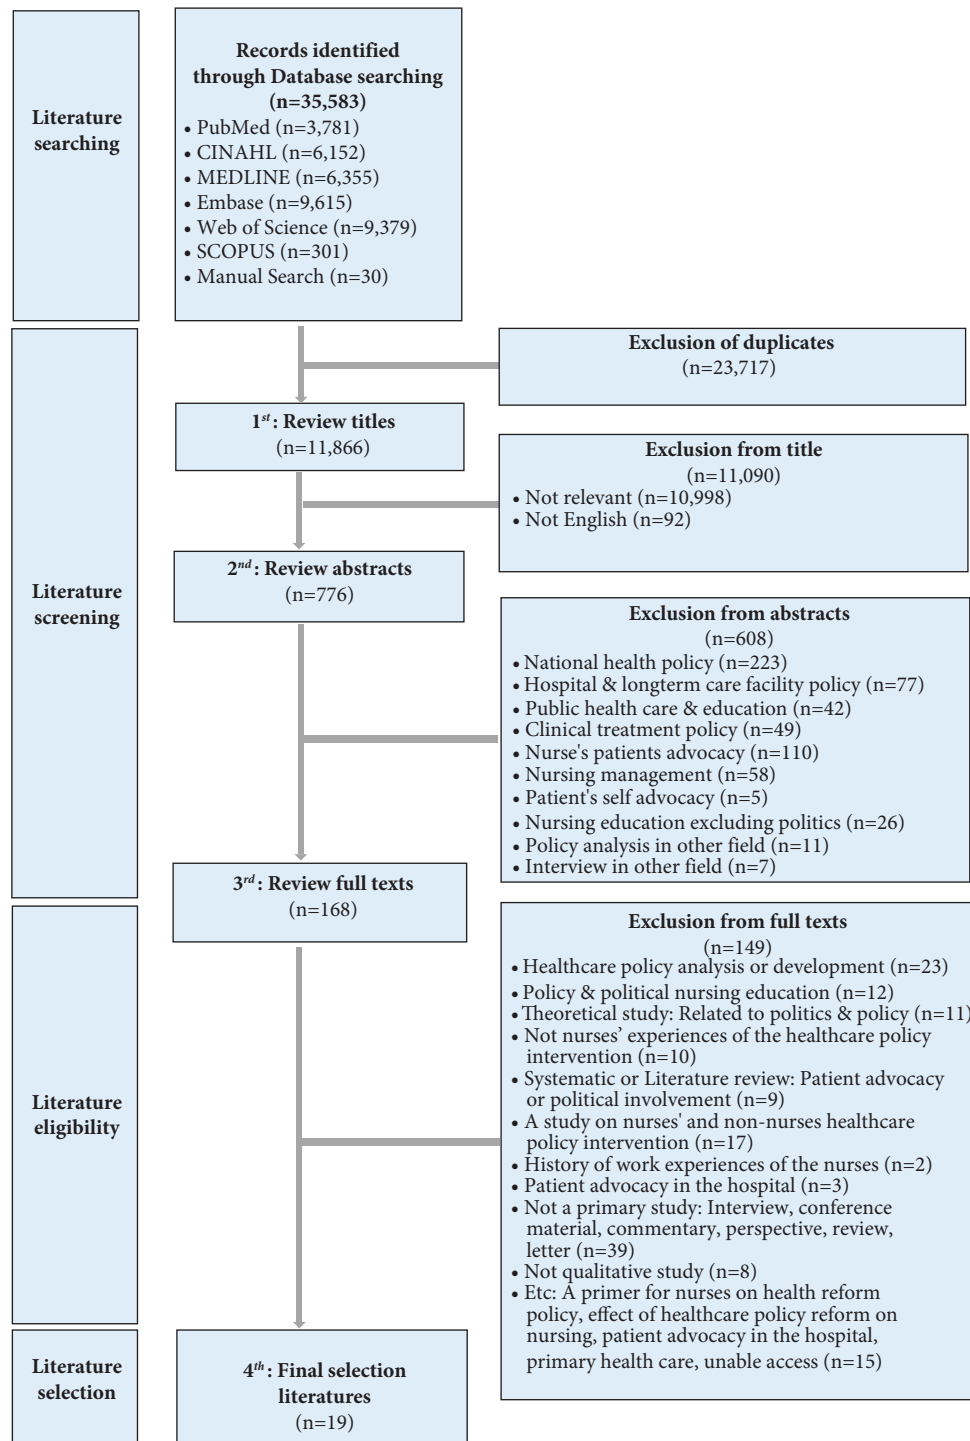

FIGURE 2: PRISMA (2020) flow diagram of the study selection process.

government committees, nursing colleges, nursing representative organizations, communities, civic groups, communities, and hospitals. The research topic explored not only the political and policy reform activities of nurses but also the concepts of barriers and facilitating factors, political competence, advocacy, and strategies based on their experiences (Table 3) (Supplementary Table 4).

2.4. Data Extraction and Synthesis

2.4.1. Data Extraction. The researchers independently extracted qualitative data for the study using the format presented by the Joanna Briggs Institute [40]. Any discrepancies between researchers during the extraction process were corrected through joint discussion. Data extraction

TABLE 2: Results of the appraisal of methodological quality by the CASP criteria.

Studies	1	2	3	4	5	6	7	8	9	10	Total	Score	Quality

Note. Score: <0.50: low quality; 0.51–0.65: low-moderate quality; 0.66–0.79: high-moderate quality; ≥0.80: high quality. Q1: was there a clear statement of the aims of the research? Q2: is a qualitative methodology appropriate? Q3: was the research design appropriate to address the aims of the research? Q4: was the recruitment strategy appropriate to the aims of the research? Q5: was the data collected in a way that addressed the research issue? Q6: has the relationship between the researcher and participants been adequately considered? Q7: have ethical issues been taken into consideration? Q8: was the data analysis sufficiently rigorous? Q9: is there a clear statement of findings? Q10: how valuable is the research?

was performed with reference to the categories or topics specified by the original authors, focusing on research objectives, phenomena of interest, methodology, participant characteristics, and results. ATLAS.ti version 24, qualitative data analysis software, was used to enter and categorize the data to facilitate a more systematic approach to data extraction and analysis. ATLAS.ti is a qualitative data analysis tool. Thus, it can be used to classify, sort, and code input data, which can help researchers explore and understand the nature of the phenomenon of interest. After analyzing the quotes from the individual papers in this study, 232 findings were derived: 114 barriers and 118 facilitators of nurses' political participation or involvement in health policy. The findings were then synthesized into categories of personal, organizational, and professional factors, resulting in eight themes and 22 subthemes for barriers and seven themes and 21 subthemes for facilitators (Table 4) (Supplementary Table 5).

2.4.2. Synthesis by Meta-Ethnography. In this study, a qualitative meta-synthesis analysis was performed based on the meta-ethnography [20] developed by Noblit and Hare in the field of education in the 1980s. This method clarifies the purpose and focus of the research, selects individual studies that fit the research topic, reads individual study results several times, extracts data on the characteristics and analysis of the papers, and identifies common themes and concepts. It determines the relevance between individual study results, further specifies the identified themes and concepts, translates them into each other (first- and second-order constructs), and based on this, synthesizes them into

new, more developed concepts (third-order constructs). The interpretative process compares individual research results to explore commonalities and contradictions (reciprocal translation), refutes the relevance of contradictory explanations (refutational synthesis), and uses argument-synthesis strategies to provide new insights. The final step is completed by representing the synthesized results.

The purpose and reason for using meta-ethnography were presented in the first stage of this study. In the second stage, the data were extracted using ATLAS.ti to analyze the selected individual study results after a systematic literature search of the database. In the third stage, after reading the contents of the individual studies several times, the characteristics and results of individual studies were extracted and organized on a data extraction sheet, and notes were used to identify important data. In stage 4, ATLAS.ti was used to identify the relevance and concepts of individual study results, and each author separately coded all sentences by line; if unclear, a mutual discussion process was used to reach an agreement. According to Barnett-Page and Thomas [25], the translation of research participants is classified into "first-order constructs," the researcher's translation in the primary study forms "second-order constructs," and the translation provided through qualitative meta-synthesis is classified into "third-order constructs" at various levels of interpretation. Therefore, the researchers analyzed both first- and second-order constructs to explore the barriers to and facilitation of political participation and policy intervention by nurses. Coding was repeated until the themes and concepts of the statements were clarified. Subsequently, researchers classified themes and concepts using tables to

TABLE 3: Characteristics of selected articles.

Study/country	Phenomena of interest	Design/analysis	Setting/context/culture	Participants	Data collection
Acheampong et al. [26], Ghana	Exploring the participation of nurses in healthcare policy development and reforms	Exploratory: descriptive qualitative study-content analysis	Six regions: hospitals, educational institutions, health directorate offices, and the nursing council	15 general nurses and 15 midwives in key leadership positions in their workplaces	Purposive sampling; semistructured individual interviews; open-ended in-depth interviews
Barry [27], the United States of America	Describing the political socialization processes of nurses who had attained specialized roles in the governments	Exploratory: descriptive qualitative study-analysis of responses	Positioning in congressional offices, regulatory agencies, or state legislatures, and willingness to participate	33 nurses who had attained specialized roles in public policy development in the federal and state governments	Purposive sampling; semistructured/open-ended in-depth individual interviews; face-to-face and by telephone
Deschaine and Schaffer [13], the United States of America	Identifying factors that affect the ability of public health nurse leaders to influence health policy	Exploratory: descriptive qualitative study—Longest's (2002) public policy-making framework	A city or county public health agency	Eight PHN leaders representing rural, suburban, and urban in public health nursing	Semistructured individual interviews based on Longest's (2002) public policy-making framework
Digaudio [28], the United States of America	Investigating phenomena of policy-making by nurses as experienced by those in the field	Grounded theory	At least a baccalaureate degree in nursing	20 nurses who could identify and discuss a policy-making activity they experienced	Purposive sampling; semistructured individual interviews; open-ended in-depth interviews
Dollinger [14], the United States of America	Exploring how effectively nurses function as advocates in the federal health policy process	Grounded theory	Current or past experience in the legislature or an executive branch agency of the federal government	11 registered nurses who had experience as staff in government offices, committees, or federal agencies	Purposive snowball sampling; semistructured individual interviews; open-ended in-depth interviews
Donovan et al. [29], New Zealand	Examining perceptions of policy and political leadership in nursing	Exploratory: descriptive qualitative study-constant comparative analysis	Fellows of the college of nurses who volunteered through a standard solicitation of the college, Aotearoa (NZ) Inc.	18 nurse leaders from across the country	Volunteer sampling; semistructured interviews; face to face (16 nurses), telephone (2 nurses)
Hajjzadeh et al. [10], Iran	Exploring the barriers and facilitators concerning nurse managers' participation in the health policy-making process	Exploratory: descriptive qualitative study-thematic analysis	Iranian nationality; nurses ≥25 years; a university degree; worked in administrative positions with an experience of at least 3 years in hospital	16 nurse managers who are involved based on their leadership positions and responsibilities in the hospital or governmental offices	Purposive sampling; semistructured individual interviews; open-ended in-depth interviews
Hajjzadeh et al. [7], Iran	Exploring the nurse managers' attitudes and perceived benefits in the health policy-making process	Thematic analysis	Tabriz University of Medical Sciences which has over 15 teaching hospitals northwest of Iran	16 nurse managers, government officials, and faculty members	Purposive sampling; semistructured individual interviews; open-ended in-depth interviews
Han [11], South Korea	Exploring the healthcare policy reform activities of Korean nurses engaged in civic organizations	Phenomenology	Korean civic organizations' activities for more than 5 years with a bachelor's or higher degree	Seven Korean civic activist nurses who had led successful healthcare policy reforms through policy interventions	Purposive; snowball sampling; semistructured individual interviews; in-depth interviews

Wichaikhum et al. [35], Thailand	Developing a strategic model of participation in policy development for nurses in Thailand	Mixed method: qualitative, descriptive, and quantitative study—qualitative analysis; quantitative analysis; validity	Having participated in policy development at the organizational or national level and/or working for nursing professional organizations with at least 10-year experience	15 nurse experts who have participated in policy development	Purposive sampling; 3-round Delphi method; round 1—open-ended individual interviews; round 2: assessing the probability of statements; round 3: finding agreement among the panel experts
Williams [36], the United States of America	Gaining understanding of the concept and practice of advocacy aimed at public policy development	Grounded theory	Working in the states in various nursing/political advocacy roles	10 nurses who were active in political advocacy as part of their nursing practice	Purposive sampling; semistructured individual interviews; open-ended in-depth interviews
Wilson et al. [37], Canada	Exploring why and how nurses became politically active and what they achieved	Grounded theory	Canadian nursing organizations to gain volunteers	10 elected or politically active Canadian nurses who had been elected to a political position	Volunteer sampling; semistructured individual interviews; telephone interviews

TABLE 4: Synthesized findings.

Categories	Themes	Subthemes	References	Findings	
<i>Barriers of political participation or policy intervention</i>					
Personal factors	Lack of political interest of nurses	Gap in political beliefs and values	[7, 11, 13, 14, 26–28, 33, 36, 37]	6	
		Lack of political efficacy	[7, 10, 11, 14, 26, 28, 33, 36, 37]	8	
Organizational factors	Lack of political competence of nurses	Lack of political knowledge and information	[7, 10, 11, 13, 14, 27–29, 33, 36, 37]	2	
		Lack of political skill	[7, 10, 11, 13, 14, 28, 29, 33, 36]	4	
		Lack of participation in activities of nursing representative organizations	[28, 33, 36, 38]	3	
	Nurses' working environment constraints	Lack of political participation	[7, 10, 11, 14, 26, 28, 29, 33, 36, 37]	2	
		Lack of awareness of the policy process	[7, 10, 11, 14, 26, 28, 29, 33, 36, 37]	4	
	Barriers to organizational culture	Poor working environments	[10, 11, 26, 28, 31, 33, 36]	6	
		Time and resource constraints	[10, 11, 14, 26, 28, 33, 36]	3	
	Stereotypes of the nursing profession	Nepotism and favoritism within the organization	Hierarchical and structural organizational culture	[26, 28, 33, 34, 36]	2
			Generation differences among nurses	[10, 26, 28, 30, 31, 33, 36, 37]	7
		Undervaluation of nurses' expertise	Gender biases	[27, 28]	2
Insufficient education and training in political competence			[7, 10, 14, 26, 28–30, 33, 36]	5	
Professional factors	Lack of political nursing education	Gender biases	[13, 26, 28, 30, 31, 33, 36, 37]	5	
		Insufficient education and training in political competence	[7, 10, 11, 14, 26–30, 33, 34, 36–38]	16	
	Limitation of support for nurses by nursing representative organizations	Lack of mentorship and legislative internship	[7, 10, 11, 26, 28, 29, 33, 36]	7	
		Insufficient advocacy efforts for nurses	[7, 28, 33, 34, 36, 37]	3	
	Lack of political power of nursing representative organizations	Deficiency of political resources and minimal encouragement for political participation	[10, 28, 29, 33, 36, 37]	5	
		Lack of political network-building and communication skills	[10, 11, 28, 33, 34, 36]	5	
	Facilitators of political participation or policy intervention	Recognition of social responsibilities	Lack of conflict management capabilities among interest groups	[10, 11, 14, 26, 28, 29, 33, 34, 36]	5
			Interaction barriers with legislators and difficulty articulating nursing perspectives	[10, 11, 14, 26, 28, 33, 34, 36]	3
		Enhancing nurses' political competence	Insufficient intervention in policy decision-making processes	[7, 10, 11, 14, 26, 28, 29, 31, 33, 34, 36, 37]	11
	Personal factors	Enhancing nursing professional values	Enhancing nursing professional values	[7, 11, 28, 30–38]	5
Awareness of healthcare problems			[7, 10, 11, 14, 27–38]	9	
Organizational factors	Innovating organizational environments	Accumulating of political knowledge, information, and skills	[7, 11, 13, 14, 27–29, 31–36, 38]	3	
		Engagement in nursing representative organizations' activities	[7, 11, 14, 27–29, 32–36, 38]	5	
Organizational factors	Participation in political activities or policy intervention	Participation in political activities or policy intervention	[7, 11, 14, 27, 28, 31–38]	9	
		Improvement of nursing work environments	[11, 28, 33, 36]	3	
Organizational factors	Postering supportive organizational culture	Postering supportive organizational culture	[10, 11, 28, 33, 36]	4	

TABLE 4: Continued.

Categories	Themes	Subthemes	References	Findings
		Development and operation of systematic nursing political education curriculum	[7, 11, 14, 26, 28, 29, 32-38]	8
	Enhancing political nursing education	Activating political nursing education for nurturing nursing political activists	[7, 11, 26-29, 33, 36, 38]	6
		Development and operation of experiential mentoring and legislative programs	[7, 11, 27-29, 33, 35-37]	5
		Strengthening evidence-based research for policy development	[7, 11, 13, 14, 28, 29, 32-36, 38]	4
	Promoting a supportive system by nursing representative organizations	Establishing a politically supportive system for nurse activists	[10, 11, 14, 28, 31, 33, 34, 36]	12
Professional factors		Enhancing cohesiveness in nursing representative organizations	[11, 13, 27, 28, 31, 33-36]	3
		Building political networking as a source of power	[7, 11, 13, 14, 27-29, 31-38]	8
		Persuasion using effective communication in the political arena	[7, 11, 14, 28, 29, 32-36, 38]	6
	Activating nursing organizations' political activities	Enhancing various political activities through developing networks	[7, 11, 13, 14, 28, 29, 31, 33-37]	4
		Formation of social opinion using media	[7, 11, 14, 28, 33-37]	9
		Development of healthcare policy reform alternatives	[7, 11, 13, 14, 27-29, 31-36]	3
	Enhancing nursing representative organizations' intervention in healthcare policy reform	Lobbying and petitioning policymakers to reflect the nursing perspective	[7, 11, 13, 14, 28, 29, 33, 34, 36, 37]	2
		Participating in healthcare policy-making process	[7, 10, 11, 14, 27-29, 31-38]	8
		Implementing and ongoing monitoring of proposed policy reform legislation	[11, 34]	2

enhance their understanding of the research phenomena and analyze the relevance and impact of each concept. In stage 5, the coding results were translated, themes and concepts were further specified to reflect the meaning of each individual study, initial codes and themes were reviewed, and similar themes were combined. As a result of the analysis, the statements of the individual study participants and interpretation authors were similar, and better information on barriers and facilitators was provided. In stage 6, the translated concepts and the relationships between them were used to create new arguments. During this process, the researchers engaged in ongoing discussions while sharing mutual feedback and insights. In the final step, the results of the synthesis of concepts using meta-ethnography are shown in the following tables (Tables 3 and 4), and the reliability of the qualitative evidence synthesis findings was tested using the GRADE-CERQual assessment [41] (Supplementary Table 6). This approach facilitated the assessment of the reliability of the results derived through the synthesis of qualitative research [41]. The authors have diverse academic backgrounds, such as majors in nursing or public health and teaching community health nursing and nursing management, as well as experience in various healthcare policy advisory roles in Korea, concept development, measurement tool development, and qualitative research. Therefore, the authors demonstrated sufficient capabilities for deriving in-depth and insightful research results during each analysis process. The result of the eMERGe reporting criteria for meta-ethnography is in Supplementary Table 7.

3. Synthesis Findings

3.1. Barriers' Factors. The eight themes were inductively synthesized as follows: personal factors (lack of political interest of nurses and lack of political competence of nurses), organizational factors (nurses' working environment constraints and barriers to organizational culture), and professional factors (stereotypes of the nursing profession, lack of political nursing education, limitation of support for nurses by nursing representative organization, and lack of political power of nursing representative organization).

3.1.1. Personal Factors. Personal barriers affecting nurses' political participation or policy interventions were synthesized into two themes and eight subthemes: the "lack of political interest of nurses" (subthemes: gap in personal beliefs and values and lack of political efficacy) and the "lack of political competence of nurses" (subthemes: deficiency of political knowledge and information, lack of political skill, lack of participation in activities of nursing representative organizations, lack of political participation, and lack of awareness of the policy process).

Most nurse activists who participated in the study stated that the "lack of political interest of nurses" was one of the personal barriers to political participation [7, 11, 13, 14, 26–28, 33, 36, 37]. In particular, it was reported that nurses' interest in political participation varies depending on nurses'

gap of political beliefs and values [7, 11, 13, 14, 26–28, 33, 36, 37], and it tends to be low due to the lack of political efficacy of nurses' political participation influencing the field of healthcare policy [7, 10, 11, 14, 26, 28, 33, 36, 37].

They also reported that most nurses' "lack of political competence" [7, 10, 11, 13, 14, 27–29, 33, 36–38] is due to the lack of political knowledge and information [7, 10, 11, 13, 14, 27–29, 33, 36, 37] regarding political processes, policy development, and advocacy strategies, as well as lack of political skills such as communication skills and political networking [7, 10, 11, 13, 14, 28, 29, 33, 36]. In addition, although healthcare policy interventions were feasible to maximize the strengths of individual nurses through collective action [34], they face a limitation that nurses' lack of participation in activities of nursing representative organizations diminishes their collective voice in policy-making [28, 33, 36, 38]. The lack of political participation reflects nurses' minimal involvement in political activities, such as advocacy, lobbying, and interaction with legislators or policymakers [7, 10, 11, 14, 26, 28, 29, 33, 36, 37]. In addition, nurses' lack of awareness of the policy process, without a clear grasp, may make them ill-equipped to contribute to policy discussions or effectively advocate for policy changes [7, 10, 11, 14, 26, 28, 29, 33, 36, 37].

3.1.2. Organizational Factors. The organizational barriers affecting nurses' political participation or policy interventions were inductively synthesized into two themes and five subthemes: "nurses' working environment constraints" (subthemes: poor working environments and time and resource constraints) and "barriers to organizational culture" (subthemes: nepotism and favoritism within the organization, hierarchical and structural organizational culture, and generation differences among nurses).

Poor working environments [10, 11, 26, 28, 31, 33, 36], as a subtheme of "nurses' working environment constraints," are a significant barrier to nurses' political participation by limiting their capacity and motivation to engage in activities beyond their immediate clinical responsibilities [10, 11, 26, 28, 31, 33, 36]. A challenging work environment characterized by high stress, shift work, long hours, insufficient staffing levels, and a lack of resources leaves nurses physically and emotionally drained, reducing their availability and energy for political advocacy or policy-making activities. Furthermore, poor working environments create time and resource constraints for nurses, which act as a barrier to political participation because it requires time, resources, and sacrifice at an individual level [10, 11, 14, 26, 28, 33, 36].

The subtheme of nepotism and favoritism within the organization under the theme "barriers to organizational culture" refers to practices within healthcare and nursing educational institutions where opportunities for involvement in policy-making are unfairly allocated based on personal relationships rather than merit, skills, or professional qualifications [26, 28, 33, 34, 36]. This creates significant barriers for nurses who seek to participate in political and policy intervention activities but find

themselves excluded or marginalized because of these biased practices. Furthermore, the hierarchical and structural organizational culture within healthcare institutions, with rigidly stratified and formal organizational structures, may impede nurses' political participation [10, 26, 28, 30, 31, 33, 36, 37]. Meanwhile, "generational differences among nurses" may act as barriers to cohesive action and participation in policy intervention due to the varying levels of interest, engagement, and methods of communication preferred by different generations [27, 28].

3.1.3. Professional Factors. The professional barriers affecting nurses' political participation or policy interventions were inductively synthesized into four themes and 10 subthemes: "stereotypes of the nursing profession" (subthemes: undervaluation of nurses' expertise and gender biases), "lack of political nursing education" (subthemes: insufficient education and training in political competence and lack of mentorship and legislative internship), "limitation of support for nurses by nursing representative organization" (subthemes: insufficient advocacy efforts for nurses, deficiency of political resources, and minimal encouragement for political participation), and "lack of political power of nursing representative organizations" (subthemes: lack of political network-building and communication skills, lack of conflict management capabilities among interest groups, interaction barriers with legislators and difficulty articulating nursing perspectives, and insufficient intervention in policy decision-making processes).

Relating to the "professional stereotypes of the nursing profession," the subtheme of undervaluation of nurses' expertise reflects a systemic issue in which nurses' knowledge and contributions are not fully valued in society or the political arena [7, 10, 14, 26, 28–30, 33, 36]. In addition, the nursing profession, historically and predominantly female, faces gender biases that further compound the issue of undervaluation [13, 26, 28, 30, 31, 33, 36, 37]. In a world where men are primarily responsible for policy-making roles, the gender limitations of women in nursing professions also negatively affect performing policy-making functions [13, 26, 28, 30, 31, 33, 36, 37].

Most nurse activists pointed out that the "lack of political nursing education" is a serious professional barriers that undermine nurses' political participation [7, 10, 11, 14, 26–30, 33, 34, 36–38]. In this regard, most nurse activists pointed out insufficient education and training in political competence [7, 10, 11, 14, 26–30, 33, 34, 36–38] and a lack of mentorship and legislative internship [7, 10, 11, 26, 28, 29, 33, 36], especially political mentorship, which is crucial for developing nurses' political skills and policy competence [28, 32, 33, 36]. Without the guidance and support of an experienced mentor, aspiring nurse activists may struggle to find a pathway to political engagement, develop the necessary confidence and skills, and navigate the challenges of policy advocacy and political participation [7, 10, 11, 26, 28, 29, 33, 36].

The subthemes of insufficient advocacy efforts for nurses [7, 28, 33, 34, 36, 37], deficiency of political resources, and

minimal encouragement for political participation [10, 28, 29, 33, 36, 37] under the theme "limitation of support for nurses by the nursing representative organizations" were also reported as professional barriers. Nurse activists pointed out that although nursing representative organizations are making efforts to improve the poor working environment of nurses and defend the public's right to health, it is still insufficient, and improvements are needed [10, 28, 29, 33, 36]. In addition, without encouragement and support for political participation from representative organizations, nurses may not perceive political participation as a professional responsibility [34].

Furthermore, most nurse activists stated the "lack of political power of nursing representative organizations [10, 11, 14, 26, 28, 33, 34, 36]." Relating to this, the specific barriers are not only a lack of political network-building and communication skills and conflict management capabilities among interest groups [10, 11, 14, 26, 28, 29, 33, 34, 36] but also interaction barriers with legislators and difficulty articulating nursing perspectives [10, 11, 14, 26, 28, 33, 34, 36] and insufficient intervention in policy decision-making processes [7, 10, 11, 14, 26, 28, 29, 31, 33, 34, 36, 37]. In particular, the lack of political network-building indicates a lack of platforms or environments that facilitate meaningful connections between nurses, policymakers, or influencers in the health policy arena [10, 11, 28, 33, 34, 36]. These limitations restrict the ability of nursing professionals to form alliances, share knowledge, and collaborate on policy initiatives, significantly reducing their influence on health policy interventions [34]. Meanwhile, nurses often encounter competition from other healthcare professionals during policy-making [11]. Therefore, interprofessional competition may manifest as a struggle for influence, recognition, and resources, making it challenging for the nursing profession to assert its interests and contributions [34]. In addition, nurse activists reported feeling excluded from decision-making processes in health policy, which could lead to difficulty in articulating nursing perspectives in policy-making.

3.2. Facilitators Factors. The seven themes were inductively synthesized as follows: personal factors (themes: recognition of social responsibilities, enhancing nurses' political competence), organizational factors (themes: innovating organizational environments), and professional factors (themes: enhancing political nursing education, promoting a supportive system by nursing representative organizations, activating nursing organizations' political activities, and enhancing nursing representative organizations' intervention in healthcare policy reform).

3.2.1. Personal Factors. The personal facilitators affecting nurses' political participation or policy interventions were inductively synthesized into two themes and five subthemes: "recognition of social responsibilities" (subthemes: awareness of healthcare problems, enhancing nursing professional values) and the "enhancing nurses' political competence" (subtheme: accumulation of political knowledge,

information, and skills, engagement in nursing representative organizations' activities, and participation in political activities or policy intervention).

The motivation for nurse activists' participation in political or healthcare policy interventions was awareness of healthcare problems affecting the public's right to health and nurses' working environments and recognition of social responsibilities to advocate for them as a nursing profession [7, 10, 11, 14, 27–38]. Therefore, increasing nurses' "recognition of social responsibilities" through awareness of healthcare problems [7, 10, 11, 14, 27–38] and enhancing nursing professional values [7, 11, 28, 30–38] are factors in encouraging a commitment to political participation or policy intervention among nurses.

Most nurse activists emphasized "enhancing nurses' political competence" [7, 11, 13, 14, 27–29, 31–36, 38]. They tried strengthening inner political power by accumulating political knowledge, information, and skills on public health problems and policy-making [7, 11, 13, 14, 27–29, 31–36, 38]. They also began to lead healthcare policy reform based on internal and external power accumulated through active political activities, that is, political competence [33, 36]. During this process, they actively participated in political activities within the nursing profession [7, 11, 13, 14, 27–29, 31–36, 38]. Therefore, it is important to enhance political competence and encourage participation in political activities or policy interventions [7, 11, 14, 27, 28, 31–38] through the accumulation of political knowledge, information, and skills [7, 11, 13, 14, 27–29, 31–36, 38] and engagement in nursing representative organization' activities [7, 11, 14, 27–29, 32–36, 38].

3.2.2. Organizational Factors. The organizational factors affecting nurses' political participation or policy interventions were inductively synthesized into one theme and two subthemes: "innovating organizational environments" (subthemes: improvement of nursing work environments and postering supportive organizational culture).

To improve poor working environments, which is one of the organizational barriers, efforts are needed to ensure adequate staffing levels, improve nursing working environments [11, 28, 33, 36], and provide adequate compensation to nurses [27, 28]. Also, by improving the job satisfaction and morale of nurses through "innovating organizational environments," nurses could be encouraged to participate more actively in political activities [10, 11, 28, 33, 36]. In addition, to overcome the limitations of organizational culture, such as favoritism, hierarchical and structured organizational culture, and generational differences, nursing organizations and healthcare institutions need to foster a culture of collaboration and inclusivity [27, 28]. Furthermore, encouraging open communication, shared decision-making, and flattening hierarchical structures are necessary for postering supportive organizational culture, which could promote active policy debate and political competence of nurses [10, 11, 28, 33, 36].

3.2.3. Professional Factors. The professional factors affecting nurses' political participation or policy interventions were inductively synthesized into four themes and 14 subthemes: "enhancing political nursing education" (subthemes: development and operation of systematic nursing political education curriculum, activating political nursing education for nurturing nursing political activists, development and operation of experiential mentoring and legislative programs, and strengthening evidence-based research for policy development), "promoting a supportive system for nurses by nursing representative organizations" (subthemes: establishing a politically supportive system for nursing activists and enhancing cohesiveness in nursing representative organizations), "activating nursing organizational political activities" (subthemes: building political networking as a source of power, persuasion using effective communication in the political arena, enhancing various political activities through developing networks, and formation of social opinion using media), and "enhancing nursing representative organizations' intervention in healthcare policy reform" (subthemes: development of healthcare policy reform alternatives, lobbying and petitioning policymakers to reflect the nursing perspective, participating in healthcare policy-making process, and implementing and ongoing monitoring of proposed policy reform legislation).

Among the professional factors promoting nurses' political participation, the most frequently stated by nurse activists was "enhancing political nursing education" [7, 11, 14, 26, 28, 29, 32–38], and they reported that education promotes nurses' professional values such as identity, vision, passion, and confidence [11, 28, 32–36, 38]. Most of them stated that they obtained political knowledge, skills, and information through work or political experience more than formal nursing education due to the lack of formal education [11, 13, 26–28, 33–37]. Accordingly, development and operation of systematic nursing political education curriculum, a variety of formal and informal education, are required for nurses [7, 11, 14, 26, 28, 29, 32–38]. In addition, the developing and operating of experiential mentoring and legislative programs are effective in activating political nursing education and nurturing nursing political activists [7, 11, 26–29, 33, 36, 38]. By providing training in political skills for nurses to improve practical interpersonal skills such as communication, persuasion, and negotiation, it could develop nurses' political competence [7, 11, 26–29, 33, 36, 38]. Furthermore, strengthening evidence-based research for policy development is critical for reflecting nursing perspectives into healthcare policies [7, 11, 13, 14, 28, 29, 32–36, 38].

Some nurse activists emphasize "promoting a supportive system by nursing representative organizations" [10, 11, 13, 14, 27, 28, 31–34, 36] through the establishment of a politically supportive system for nursing activists [10, 11, 14, 28, 31, 33, 34, 36]. In addition, to secure political opportunities for nurses, who account for most healthcare professionals, it is crucial to enhance cohesiveness in nursing representative organizations or civic organizations

[11, 13, 27, 28, 31, 33–36]. This makes it possible contributing to a unified social voice of the nursing profession [34].

Meanwhile, most nurse activists stated that building political networking as a source of power [7, 11, 13, 14, 27–29, 31–38] is most important for “activating nursing organizations’ political activities [7, 11, 13, 14, 27–29, 31–38].” Networking is a strategy that influences health policy and contributes to expanding nurses’ political participation by securing a basis for communication and support from politicians, including members of the National Assembly [11, 34]. In addition, establishing social solidarity with various patient groups, healthcare representative organizations, and municipal government organizations is effective in exercising political influence by nursing organizations’ enhancing various political activities through developing networks [7, 11, 13, 14, 28, 29, 31, 33–37]. Mainly, it is necessary to be familiar with the language and laws used by politicians and to conduct persuasion using effective communication in the political arena, such as writing, listening, presentation, and conflict resolution skills with perseverance [7, 11, 14, 28, 29, 32–36, 38]. In addition, one of the effective facilitating strategies is the formation of social opinion using media, such as letters, campaigns, parliamentary debates, public hearings, voting, securing political funds or sponsoring politicians, and lobbying [7, 11, 14, 28, 33–37].

Relating to “enhancing nursing representative organization’s intervention in healthcare policy reform [7, 11, 13, 14, 27–29, 31–38],” nurse activists sought policy intervention by identifying issues and analyzing healthcare problems, then development of healthcare policy reform alternatives [7, 11, 13, 14, 27–29, 31–36], and lobbying and petitioning policymakers to reflect the nursing perspective [7, 11, 13, 14, 28, 29, 33, 34, 36, 37]. Nurse activists emphasized that healthcare policy reform alternatives should be developed first to activate healthcare policy intervention [7, 11, 13, 14, 27–29, 31–36]. Thus, it is proactively necessary to understand issues and policy-making processes to predict current and future healthcare problems [7, 11, 13, 14, 27–29, 31–36]. Then, lobby or petition to persuade legislators, elected officials, and politicians [7, 11, 13, 14, 28, 29, 33, 34, 36, 37] and those experiences create opportunities for participating in the healthcare policy-making process as members of the government policy deliberation committee, members of parliament, and city councilors [7, 10, 11, 14, 27–29, 31–38]. This ultimately contributes to the realization of the proposed healthcare policy reform legislation reflecting the nursing perspective [11, 13, 29, 33, 34, 36]. In this process, nurses must implement and monitor the proposed policy reform legislation to properly implement the reform policies or bills without distortion in the field [11, 34].

4. Discussion

This study conducted a systematic review and meta-synthesis to analyze the barriers and factors influencing nurses’ political participation and healthcare policy intervention. Three categories, personal, organizational, and

professional, affected the barriers and factors of nurses’ political participation or policy intervention.

Among the barriers affecting nurses’ political participation or policy intervention, personal factors include their lack of political interest and political competence. The organizational barriers were reported as limitations of nurses’ work environments and barriers to organizational culture. Furthermore, professional barriers were noted, such as stereotypes of the nursing profession, a lack of political nursing education for nurses, the political power of nursing representative organizations, and the limited support for nurses from these organizations. Relating this, previous studies in political science suggest that political interest is a significant predictor and motivator of political activity [4, 42]. However, nurse activists mentioned that most nurses’ political interests were insufficient [6–9, 11, 13–15, 26–28, 33, 36, 37]. In this regard, political scientists Clore and Huntsinger [43] emphasized the importance of creating a public atmosphere because people who lack political knowledge or information generally make vague judgments that negatively affect political participation. Therefore, it is necessary to refer to research results that show a high correlation between political interest in social issues or efficacy and political participation in political science research [44–46]. Meanwhile, nurse activists pointed out the environmental factors of shift work, lack of nursing staff, and gender issues, which are consistent with previous studies suggesting heavy workload, time constraints [10, 11, 26, 28, 33, 36], and male-centered gender issues [13, 26, 28, 33, 36]. Therefore, to revitalize the participation of nurses in politics, improvements in the working environment and sexual problems must precede. Regarding the lack of participation in nursing organizations and activities due to political barriers, most nurses were not members of professional organizations, and the results coincide with those of previous research [7, 47]. Another barrier to nurses’ political participation is the lack of nursing education, which has been continuously raised in previous studies [7, 10, 11, 14, 26–30, 33, 34, 36, 38]. According to political scientists, this barrier can be addressed through political socialization, the process of learning, and internalizing the political culture, knowledge, and value attitudes of an individual society [48].

The factors affecting nurses’ political participation and policy interventions as personal factors were recognizing social responsibilities and enhancing political competence. In addition, professional factors such as enhancing political nursing education, promoting support systems for nurses by nursing representative organizations, activating nursing organizational and political activities, and enhancing nursing representative organizations’ interventions in healthcare policy reforms were noted. Nurse activists began their political activities when they recognized the social responsibility of the nursing profession, which coincided with that presented in previous studies as professional nursing responsibilities [6, 8, 9, 15]. In this regard, Cohen et al. [49] suggested buy-in, self-interest, political sophistication, and leading role as the stages of nursing professionals’ political participation. Among them, the

perception of political activism was emphasized to achieve the purpose of the nursing profession in the first stage of political participation [49], consistent with the results of this meta-analysis, which recognized healthcare problems and social responsibility as most nurse activists began their activities.

In addition, factors of political participation or policy intervention included promoting awareness of nursing profession values, acquiring political knowledge and information, training political skills by enhancing nursing education, strengthening cohesiveness in professional organizations, building political networking, effective communication, and collaboration, and participating in various political activities to enhance nurses' political competence. First, reinforcing the value for nursing professionals derived from the synthesis of factors promoting political participation refers to nursing identity, confidence, and social advocacy responsibility. Almond and Verba [50], political scholars who first proposed the concept of political competence in political science, related it to personal political competence, political efficacy, objective political competence, and political self-confidence. It may be necessary to prepare measures to improve expectations, attitudes, and confidence in politics that increase political efficacy [50]. More importantly, nurses' pride in the nursing profession must be high to realize their social responsibility and provide opportunities to actively participate in politics actively [9]. Therefore, the development and operation of formal or nonregular curricula, mentoring, and internships at universities or nursing organizations are essential to strengthen attitudes as nursing professionals, political knowledge, and technical education through political socialization.

Meanwhile, nurse political activists not only built political knowledge, information, and political skills such as networking but also actively performed various social solidarity activities and media use [7, 11, 13, 14, 27–29, 31–38]. Like this, strengthening political competence is crucial to activate nurses' political participation and policy intervention. The concept of nurses' political competence, which was derived as a factor that facilitates nurses' political participation, was developed by Han and Kim [9] in 2020 by integrating the concepts presented in previous nursing studies and political science with nurse political activists' interview during the fieldwork phase and categorized into political knowledge, political efficacy, political interaction, and political activity. Previous studies in political science have reported that political competence acts as a motivation or attitude variable and affects the degree of political participation depending on the level of competence [3, 4, 50]. Therefore, since nurses' political participation is possible when the level of political competence is high [9], it is necessary to maximize political influence by improving political competence based on nursing representative organization-centered solidarity [9]. Furthermore, the process through which nurse activists lead policy reform by developing healthcare policy alternatives is consistent with the leading role stage suggested by Cohen et al. [49]. Through these steps, nurses' political competence was strengthened, reflecting the views of the nursing profession

when enacting laws or policies on national health and enabling them to advocate for public health rights [42]. Finally, strategies for activating policy intervention and developing policy reform alternatives should be prioritized by conducting healthcare policy analyses and research based on an understanding of healthcare problems and policy decision-making processes. Activation of policy intervention refers to the reinforcement of policy competencies, consistent with Arabi et al. [51], suggesting policy awareness, nurse power, and advocacy of the nursing profession as attributes of the concept of policy impact. This is also consistent with previous studies showing that nurses used academic preparation for policy development for policy interventions, evidence-based research ability to influence policy decision-making based on awareness of health policy issues and understanding of legislative policy processes [26]. Therefore, nurses should activate entry into the political arena by resolving barriers to political participation based on the lessons learned from nurse activists' political experiences and by strengthening their political and policy competencies to advocate for the public and improve the working environment. Through these, the nursing profession can expand its political influence beyond traditional stereotypes.

This study minimized the omission of research results because it analyzed all papers related to the subject of this study without the limitations of language or publication period. Researchers with extensive experience in qualitative research and healthcare policy interventions conducted sufficient discussions throughout the process, from article selection to analysis, in order to ensure the validity and accuracy of the research results. The limitations of this study are the results of a qualitative meta-synthesis that analyzed the experiences of nurses with different personal backgrounds and in some countries with different political and cultural environments; therefore, the study results cannot be generalized. In addition, the risk of selection bias was not entirely excluded by analyzing the participants without considering environmental conditions such as political activity and policy intervention experiences, roles, and workplaces. Some studies included in the analysis did not meet the methodological quality evaluation criteria, and there is a limitation in the analysis based on papers published in a journal rather than receiving and analyzing original data from the authors of the study.

5. Conclusions

This study conducted a systematic review and qualitative meta-synthesis of existing research results to comprehensively analyze the barriers and factors influencing nurses' political participation or healthcare policy intervention. The research results synthesized the barriers and factors of political participation or healthcare policy intervention into three categories: personal, organizational, and professional factors, with eight themes and 22 subthemes for barriers, and seven themes and 21 subthemes for facilitators.

The barriers to political participation or policy intervention of nurses were composed of themes, personal factors (lack of political interest of nurses and lack of

political competence of nurses), organizational factors (themes: limitations of the work environments of nurses and barriers to organizational culture), and professional factors (themes: stereotypes of the nursing profession, lack of political nursing education, limitation of support for nurses by nursing representative organizations, and lack of political power of nursing representative organizations). Factors of political participation were composed of themes, personal factors (themes: recognition of social responsibilities and enhancing political competence), organizational factors (themes: innovating organizational environments), professional factors (themes: enhancing political nursing education, promoting a supportive system by nursing representative organizations, activating nursing organizational political activities, and enhancing nursing representative organizations' intervention in healthcare policy reform).

This study can be used as main data for enhancing nurses' political participation, policy interventions, and preparation strategies. The study is significant in where most of the participants in this study have experienced as nurse political activists; there is no previous study on the experience of general nurses' political participation to develop a more detailed strategy for activating political participation in the future. There are some studies on the effects of education, despite the lack of nursing education. However, research on the development of nursing programs is necessary because there are few studies on the development of nursing education. Furthermore, development studies measuring nurses' political competence and theories of strengthening nurses' political competence are needed [45].

6. Implications for Nursing Management

Nurses' political participation is required to optimize the quality and equity of health services provided to patients and to improve their working environments [12, 30]. Based on the growth process as a nursing political activist synthesized in this study, the barriers to and facilitating factors for nurses' political participation, and the concept of activating policy interventions, a theory for strengthening nurses' political competencies can be developed. To activate nurses' political participation, nursing organization leaders in practice and in various nursing fields must refer to this study. Through this, nurses can improve their working environment, increase their interest in politics, share political information and knowledge, join the nursing representative organization, and encourage participation in various political activities. Furthermore, instructors in nursing education should organize curricula, develop programs, and systematically implement them to strengthen political nursing education. Finally, based on the results of this study, nursing representative organizations can prepare a strategy for activating nurses' political participation, provide them with opportunities to engage in political activities and policy interventions, and promote the revitalization of politicians.

Data Availability

The data used to support the findings of this study are available from the first author upon reasonable request.

Ethical Approval

The study used secondary data and did not require ethical approval.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

Nam Kyung Han conceptualized and visualized this study, performed formal analysis and data curation, wrote the original draft, and reviewed and edited the manuscript. Gwang Suk Kim conceptualized the study, performed formal analysis and data curation, wrote the original draft, and reviewed and edited the manuscript. The authors are the only contributors to this study.

Supplementary Materials

Supplementary Materials include seven files that provide further information about search strategies, excluded articles based on the full-text review, the PRISMA 2020 checklist, a list of the selected articles for analysis, the findings (barriers and facilitators), the GRADE CERQual assessment, and the eMERGEe reporting result. Aims. This study was designed to investigate the impact of inclusive leadership on challenge-oriented citizenship behaviors and examine the mediating role of organizational justice on the relationship between inclusive leadership and challenge-oriented citizenship behaviors among nurses. **Background.** Leaders exhibiting an inclusive leadership style have the potential to create a positive work climate and motivate members of the organization. However, the mechanisms by which organizational justice contributes to this process remain to be explored, particularly in terms of how it motivates challenge-oriented organizational citizenship behaviors. **Method.** A cross-sectional questionnaire survey was conducted among nurses in China at the end period of the COVID-19 pandemic. A total of 527 registered nurses were enrolled and completed the self-report questionnaires including inclusive leadership scale, organizational justice scale, and challenge-oriented citizenship behavior scale. The hypotheses were tested using hierarchical multiple regression analyses and structural equation modelling. **Results.** The results of empirical tests revealed that nurse leader's inclusive leadership had a positive relationship on nurses' challenge-oriented organizational citizenship behaviors ($\beta = 0.823$, $p < 0.001$) after controlling several demographic covariates. Meanwhile, inclusive leadership was positively linked to organizational justice ($\beta = 0.747$, $p < 0.001$), and the indirect effect of inclusive leadership on nurses' challenge-oriented citizenship behaviors through organizational justice was statistically significant ($\beta = 0.641$, $p < 0.001$). Furthermore, the model fit indices were $\chi^2/df = 1.952$, RMSEA = 0.043, CFI = 0.979, and TLI = 0.977, indicating that the model had high quality. **Conclusion.** This study could help nurse leaders with inclusive leadership style have a better understanding and taking the advantages of the influence mechanism of organizational justice in inspiring nurses' challenge-oriented citizenship behaviors. While nurse managers can inspire challenge-oriented organizational citizenship behaviors through inclusive leadership, they should also emphasize the evaluative and behavioral-shaping effects of organizational justice. Both leadership and organizational justice are essential to motivate challenge-oriented organizational citizenship behaviors and to foster organizational development. Moreover, managers should focus on the process and conditions of implementing organizational justice to ensure fairness within the organization and to create a conducive environment for challenge-oriented organizational citizenship behaviors.

1. Introduction

Nurses operate within high-pressure and high-intensity environments, commonly encountering unpredictable circumstances which necessitate effective responses to challenges [1]. Apart from possessing seasoned professional

expertise and exceptional clinical skills, nurses also require competent team leadership and organizational support [2]. For instance, during the COVID-19 pandemic, nurses had to carry out extensive medical and public health tasks requiring them to address issues related to complex and stressful circumstances [3], communication [4], work pressure [5],

psychological stress [6], and burnout [7]. Consequently, they must frequently restructure and refine their professional skills, working procedures, and management systems, while undertaking extrarole behaviors [8].

Inclusive leadership is often emphasized to motivate nurses to make a greater contribution at work and achieve their full potential. Nonetheless, the practical challenge lies in the complexity of nursing work, which necessitates responses to patient and public health needs based on factors such as the nurse's ability level, patient physical state, and the operational status of the healthcare institution. As a result, the nurse's work is frequently challenging to delimit precisely, and expectations regarding their performance are frequently high. Social exchange theory posits that an individual's behavior is influenced by their perception of justice [9]. In uncertain work environments, nurses possess the drive and demand to exhibit organizational citizenship behaviors; however, this does not necessarily lead to the occurrence of such behaviors, particularly when they are not explicitly defined in formal work duties and can introduce changes and challenges to existing organizational work procedures. This can also lead to relational conflict [10], underscoring the necessity for challenge-oriented organizational citizenship behaviors to have corresponding requirements for the organization's leadership style and atmosphere.

While the interest in inclusive leadership continues to gain traction among scholars, current research predominantly focuses on nurses as research subject to explore the role of inclusive leadership in promoting nurses' psychological perception and behavioral abilities [8]. The inclusive practices of leaders are not only instrumental in shaping employees' personal and group experiences but also the inclusiveness requirements and strategies of an organization [11]. Therefore, the occurrence of certain behavior must be contextualized. Furthermore, the conditions and processes that determine the effectiveness of inclusive leadership, and the factors that facilitate or hinder its role, require extensive exploration and elucidation.

To bridge the research gap, this study intends to investigate the relationship between inclusive leadership and challenge-oriented organizational citizenship behaviors among nurses. Drawing upon the social exchange theory [12], we argue that inclusive leadership facilitates nurses' perception of organizational justice [13], which leads them to feel that they are being treated fairly, whether it is tangible or intangible and consequently enhances their morale, work motivation, loyalty, and stability. Moreover, organizational justice plays a mediating role in stimulating positive challenge-oriented organizational citizenship behaviors while reducing the potential conflicts caused by such behaviors.

2. Theory and Hypotheses

2.1. Inclusive Leadership. The concept of inclusive leadership was first described by Nembhard and Edmondson [14] as "words and deeds by a leader or leaders that indicate an

invitation and appreciation for others' contribution." Carmeli et al. [15] further defined it as the core of relational leadership, a leadership style that exhibits openness, availability, and accessibility in interactions with subordinates. Inclusive leadership implies that leaders not only exhibit the characteristics of recognizing employee's differences [16], collaborating during decision-making [17], promoting creativity through cognitive mechanism [18], and cultivating the ability of the employee to learn and work as a catalyst for the achievement of organizational goals [19] but also means that the entire organizational team is concerned about new opportunities [20], prepares for organizational change [21], and supports for organizational structure and culture [22], thus having a tremendous impact on the creative process of the organization [15, 23].

2.2. Inclusive Leadership and Challenge-Oriented Citizenship Behaviors. Challenge-oriented organizational citizenship behaviors are a kind of extrarole behaviors [24]. It refers to the active and intentional participation of individuals in organizational development and performance improvement, by putting forward creative ideas or encouraging change efforts related to working methods, policies, and processes in promotive forms [25]. Meanwhile, it is also a kind of proorganizational behavior "that can neither be enforced on the basis of formal role obligations nor elicited by contractual guarantees of recompense" [26, 27].

Interestingly, challenge-oriented organizational citizenship behaviors have a double-edged sword effect. On the one hand, challenge-oriented behaviors may undermine task performance and relationships with team colleagues because these suggestions require changes to the status quo, yet change means that people affected by these changes have to adapt to something new and often involve setbacks and failure [28]. On the other hand, the most prominent form of facilitation of challenge-oriented citizenship behaviors is employee voice, which is characterized by constructive suggestions for the benefit of the organization [26, 29].

Inclusive leadership may have positive impact on challenge-oriented organizational citizenship behaviors in three ways. First, inclusive leadership provides space and emotional ties to challenge-oriented organizational citizenship behaviors [30, 31]. The supportive behaviors of inclusive leaders result in employees feeling that they are treated well and with respect, which motivates the receiving party attempts to reciprocate with something equally valuable [32]. Second, inclusive leadership provides positive guidance for challenge-oriented organizational citizenship behaviors, thus avoiding the risk of the prohibitive forms of challenge-oriented behaviors in damaging relationships with others [25, 33]. The effective behaviors of inclusive leadership are conducive to resolving the negative impact of relationship conflicts [34]. Finally, when employees observe that leaders have characteristics of inclusive leadership, they are more inclined to express their concerns and voices to the leader, and communication with good response and reciprocity further strengthens the possibilities of trust-building and problem-solving [35], which makes inclusive leadership

as a precondition to challenge-oriented organizational citizenship behaviors. Based on this reasoning, we propose the following hypothesis:

H1. Inclusive leadership of nurse managers has a positive effect on nurses' challenge-oriented citizenship behaviors.

2.3. The Mediating Role of Organizational Justice. Organizational justice is based on Equity Theory [36] and can be used to describe and explain employees' perceptions of fairness and honesty of the treatment they received [13], including procedural justice, distributive justice, and interactional justice. First, procedural justice refers to the fairness of rules and procedures and is fostered "when authorities provide employees with input into key decisions and when authorities utilize procedures that are consistent, accurate, unbiased, correctable, representative of group concerns, and ethical" [37]. Second, distributive justice refers to the perceived fairness of the outcomes that individuals receive from organizations and is fostered when outcomes conform to implicit distributive norms, such as equity or equality [38]. Third, interactional justice refers to the individuals' perception and judgment on the quality of interpersonal treatment received during the execution of a procedure [39], including informational justice (the provision of adequate information and social accounts) and interpersonal justice (the dignity and respect that one receives) [40, 41].

Inclusive leadership has an impact on challenge-oriented organizational citizenship behaviors via organizational justice. First, the open and supportive behaviors of inclusive leaders can improve procedural justice in organizations, as employees have the perception that their voices are heard by managers and that they are included in the decision-making process [42]. In terms of procedural justice, the involvement of team members in the decision-making process is of great significance, which determines and achieves an organizational decision-making process that is consistent, accurate, unbiased, correctable, and ethical [37]. At the same time, it shapes member's assessment of the authority's trustworthiness [43] and reflects employees' concerns about the evaluation of procedural justice and the participation in challenge-oriented organizational citizenship behaviors [44]. Second, the perceived organizational justice makes employees feel trust in the process and distribution of outcomes of their work and therefore inspires their extrarole behaviors that contribute to effective organizational functioning [43]. In particular when employees feel that the distribution of rewards based on their work input is fair, that the process of allocating resources and rewards is transparent, and that they are treated with mutual respect, these feelings create a sense of obligation to give back to the organization [45]. Third, under inclusive leadership, employees tend to feel respected, which indicates an increased level of interactional justice in the organization [46]. The open behaviors in discussing with employees reinforce the perception of interactional justice, as employees are more likely to feel that they have received all the necessary

information and that well-developed interpersonal justice allows them not to be disturbed by interpersonal relationships, which in turn motivates them to change organizational rules or policies that are nonproductive or counterproductive, which also makes it possible to mitigate the potential conflicts in challenge-oriented organizational citizenship behaviors and stimulate positive effects. In recent years, studies on healthcare teams have revealed that organizational justice has effects on work engagement and nursing care quality [47], reducing turnover intention [48], and motivating the performance and productivity of nurses [49]. Therefore, we argue that inclusive leadership has a positive contribution to the perception of organizational justice, and meanwhile, organizational justice is a connecting mechanism in the relationship between inclusive leadership and challenge-oriented citizenship behaviors. Thus, the following hypotheses were developed:

H2. Inclusive leadership of nurse managers has a positive effect on organizational justice

H3. Organizational justice mediates the relationship between inclusive leadership of nurse managers and nurses' challenge-oriented citizenship behaviors

3. Methods

3.1. Research Design and Participants. We conducted a cross-sectional survey to examine the relationship between inclusive leadership and challenge-oriented citizenship behaviors and the moderating role of organizational justice among nurses in China at the end period of the COVID-19 pandemic. The study followed the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) guidelines. Convenient sampling was used to recruit the nurses who were registered full-time nurses and had more than six months of tenure in their current hospital and were willing to participate in this study. The minimum sample size was estimated by the maximum one of following two methods [50, 51]: (1) using PASS (Version 20.0, <https://www.ncss.com/software/pass>) with 90% power, alpha of 0.05, a medium f^2 effect size of 0.15 and 34 predictors, and assuming an attrition rate of 20%, 303 samples were estimated; (2) multiplying the number of items of the instruments by ten with assuming an attrition rate of 20%, $(9 + 20 + 5) \times 10 \times (1 + 20\%) = 408$ samples were estimated. In general, a sample size of approximately more than 400 would provide sufficient support for this study.

3.2. Instruments

3.2.1. Inclusive Leadership Scale. The inclusive leadership scale was used to measure the nurse manager's inclusive leadership style [15]. The scale consists of nine items based on three dimensions including openness (three items), availability (four items), and accessibility (two items). A sample item is, "The manager is open to discuss the desired goals and new ways to achieve them." Each item is scored on a 7-point Likert scale, ranking from one (strongly disagree) to seven (strongly agree). A total inclusive leadership score

was obtained by averaging the three dimensions, where the higher score indicated a higher level of nurses' perception of their leader's inclusive leadership.

3.2.2. Organizational Justice Scale. The organizational justice at work among nurses was measured using the scale developed by Colquitt [40]. It consists of twenty items divided into four subscales: procedural justice, distributive justice, interpersonal justice, and informational justice. The first subscale is procedural justice, with 7-item statements that ask nurses to consider the procedures their supervisor uses to make decisions about evaluations, promotions, and rewards. The second subscale, distributive justice, has 4-item statements that ask nurses to consider how they were treated by their supervisor during the implementation of procedures. The third subscale is interpersonal justice, with 4-item statements that ask nurses to consider the outcomes they received from their supervisor, including their evaluations, promotions, and rewards. Finally, the fourth subscale is informational justice, with 5-item statements that ask nurses to consider their perceived adequacy of explanations from their supervisor during the implementation of procedures. The items are scored on a 7-point Likert scale ranging from one (strongly disagree) to seven (strongly agree), with the items being answered based on how often the nurses encounter each statement. The total score was created from the average of all items, with higher scores representative of greater organizational justice.

3.2.3. Challenge-Oriented Organizational Citizenship Behaviors Scale. A 5-item measure validated by Mackenzie et al. [25] was used to measure challenge-oriented citizenship behaviors, which was drawn from the original scale developed by Van Dyne and LePine [24]. Each item is scored on a 7-point Likert scale, ranking from one (strongly disagree) to seven (strongly agree). A total challenge-oriented citizenship behaviors score was obtained by averaging all items, where the higher score indicated a higher level of nurses' challenge-oriented citizenship behaviors.

3.3. Data Collection. For the convenience of the participants and to expand the scope of the survey, the questionnaire of this study was conducted both offline and online. In the offline survey, printed questionnaires were sent to participants by the authors and recorded into the database after the questionnaires were completed. The online questionnaire was set up using a widely used electronic questionnaire collection platform named Questionnaire Star (<https://www.wjx.cn>). The internet link to the electronic questionnaire was first sent through the authors to nurses in different cities and hospitals, and they were invited to continue sharing the questionnaire with nurses in other regions and hospitals they knew. A cash coupon of RMB 5 for each offline participant and a random electronic cash coupon of RMB 5 to RMB 10 for each online participant were provided in this study, which was implemented through the Questionnaire Star platform. In order to ensure the quality of the

questionnaire design and responses, on the one hand, we designed reverse repetition questions in the questionnaire to check whether the participants answered the questionnaire carefully. On the other hand, we invited 30 nurses to conduct a pilot study for evaluating the clarity and time needed to fill out the questionnaires. The questionnaire took approximately 8–15 minutes to complete, and with reference to the previous literature [52], we removed the samples with response time less than 3 minutes and no variation in all response items; for example, all items were selected as "strongly disagree." The survey was available from October 10, 2022, to February 10, 2023, and 527 valid questionnaires were obtained for this study.

3.4. Analysis. Statistical analyses were conducted using IBM SPSS (Version 26) and AMOS (Version 26). Descriptive statistics, which included frequency and proportions, were employed to summarize the demographic characteristics of age, gender, education, marital status, years of experience in nursing, job title, and the experience in frontline work against COVID-19 in the past three years.

Hierarchical multiple regression analysis was performed to estimate the direct effect of inclusive leadership on challenge-oriented citizenship behaviors after controlling other variables. Structural equation modelling (SEM) with multiple indices criteria was conducted to determine the influence of inclusive leadership and organizational justice on challenge-oriented citizenship behaviors. In addition, to evaluate the measurement and factor structure of the study variables, confirmatory factor analysis (CFA), including KMO, Bartlett test of sphericity, and the average variance extracted (AVE) were performed to ensure the validity of the study construct, and Cronbach's alpha and composite reliability (CR) were estimated to ensure the reliability of the items of the scale used in this study [51, 53, 54].

3.5. Ethical Considerations. After scrutinizing all the necessary documents, including design of this research, written questionnaire, academic review opinions, subject informed consent, researchers' biographies, and description of source of foundations, the Biomedical Ethics Committee of the West China School of Medicine and the West China Hospital of Sichuan University granted permission to conduct this study (#2022-1479; approved on 9 September 2022). The first page of the questionnaire stated the purpose of the study, while emphasizing the voluntariness, anonymity, and confidentiality of the answers, and the participants began to answer the questionnaire survey after agreeing to the above contents.

4. Results

4.1. Demographic Profile of Participants. It can be seen in Table 1 that predominant participants had age between 26 and 40 years (59.8%), were female (85.39%), had a bachelor's degree (65.84%), and had married (71.35%). From the distribution characteristics of the participants, their years of work experience were relatively evenly distributed, ranging

TABLE 1: Demographic profile of the participants ($n = 527$).

Characteristics	Frequency (f)	Percentage (%)
<i>Age (years)</i>		
18–25	124	23.53
26–30	113	21.44
31–40	202	38.33
>40	88	16.70
<i>Gender</i>		
Female	450	85.39
Male	76	14.42
Non-disclosure	1	0.19
<i>Education</i>		
Diploma or lower	132	25.05
Bachelor	347	65.84
Master	38	7.21
PhD	10	1.90
<i>Marital status</i>		
Unmarried	144	27.32
Married	376	71.35
Divorced or other	7	1.33
<i>Years of experience</i>		
1–5 years	134	25.43
6–10 years	133	25.24
11–15 years	127	24.10
More than 15 years	133	25.24
<i>Job title</i>		
Nurse and senior nurse	459	87.10
Leader of nurse team	58	11.01
Nurse supervisor or above	10	1.90
<i>Frontline nurses in COVID-19</i>		
Yes	293	55.60
No	234	44.40

from 24.10% to 25.43% in the four levels classified in this study. In terms of the participants' job titles, 87.10% of the participants were nurse or senior nurse, 11.01% were leader of nurse team, and 1.90% of the participants were nurse supervisor or above, and these distribution characteristics were consistent with our estimation of the overall pyramid structure. In addition, more than half of the participants (55.60%) were involved in frontline work against COVID-19 in the past three years.

4.2. Reliability and Validity. Construct reliability was analyzed, Cronbach's alpha and CR, to verify the internal consistency of the instruments in the study (Table 2). Cronbach's alpha should be preferably over the recommended level of 0.7. In our study, Cronbach's alpha values ranged from 0.911 to 0.948 for all first-order scales, showing a high degree of internal consistency within the scales. In addition, the CR values exceeded the recommended level of 0.7 for all dimensions in our study scales, indicating a high degree of convergence and internal consistency [51].

Meanwhile, construct validity was verified the degree to which the instrument accurately represents the concept is defined in the study. First, the Kaiser–Meyer–Olkin (KMO) test and Bartlett test of sphericity were used to examine sampling adequacy. The KMO value should be at least 0.60, and the Bartlett test of sphericity should be statistically

significant at $p < 0.05$. The results revealed that the KMO and Bartlett test of sphericity values were 0.965 ($p < 0.001$) for the inclusive leadership scale, 0.968 ($p < 0.001$) for the organizational justice scale, and 0.913 ($p < 0.001$) for the scale of the challenge-oriented citizenship behaviors. Second, the factor loading of all constructs employed in this study exceeds the threshold value of 0.7, indicating a high degree of correspondence between the variable and the factor. Furthermore, the average variance extracted (AVE) values were higher than 0.50 thresholds for all dimensions of the study variables, indicating that the convergent validity is well-supported.

4.3. Hypothesis Test Results. Table 3 presents the results of the hierarchical multiple regression analysis to test the effect of inclusive leadership on nurses' challenge-oriented citizenship behaviors. After controlling the demographic variables in Model 1 (age, gender, educational background, marital status, years of experience, job position, and the work experience in COVID-19) as covariates, the inclusive leadership statistically significantly enhances nurses' challenge-oriented citizenship behaviors ($\beta = 0.823$, $p < 0.001$) in Model 2, with 50.6% increasing of adjusted R^2 . Thus, H1 was supported.

Table 4 and Figure 1 illustrate that inclusive leadership was positively associated with organizational justice ($\beta = 0.858$, $p < 0.001$), which supported H2, and organizational justice was positively associated with nurses' challenge-oriented citizenship behaviors ($\beta = 0.747$, $p < 0.001$). In addition, after incorporating organizational justice into the model, the direct effect of inclusive leadership on nurses' challenge-oriented citizenship behaviors was no longer statistically significant ($\beta = 0.075$, $p > 0.05$). In the bootstrap test with AMOS (Version 26), the results of 5000 bootstrapping resamples revealed that the estimated coefficient of the indirect effect of inclusive leadership on nurses' challenge-oriented citizenship behaviors was statistically significant ($\beta = 0.641$, $p < 0.001$). In sum, these empirical results indicated that organizational justice acts as a mediator in the relationship between inclusive leadership and nurses' challenge-oriented citizenship behaviors. Furthermore, the model fit indices were $\chi^2/df = 1.952$, RMSEA = 0.043, CFI = 0.979, and TLI = 0.977, indicating that the model had high quality. Thus, H3 was supported.

5. Discussion

Nurses operate in demanding and intense work environments where the leadership style demonstrated by leaders is considered crucial in facilitating effective nursing practices. In our research, we argue that inclusive leadership does not automatically result in challenge-oriented organizational citizenship behaviors, particularly those that lack clear definition within formal job responsibilities and tend to disrupt and question existing organizational practices. By integrating social exchange theory [12] and organizational justice theory [13] into our investigation, we have discovered that inclusive leadership positively influences nurses'

TABLE 2: Test results of reliability and validity.

Scale	No. of items	Mean (SD)	KMO	Bartlett test	Loading range	α	CR	AVE

inclination towards engaging in challenge-oriented organizational citizenship behaviors, with organizational justice serving as a mediating mechanism.

This paper contributes theoretically and practically in several ways. First, previous research has highlighted the

crucial role of effective managerial support in fostering organizational citizenship behaviors. Team members can assess their level of engagement in such behaviors by observing the conduct of inclusive leaders. Inclusive leaders who exhibit supportive and helpful behaviors, such as being

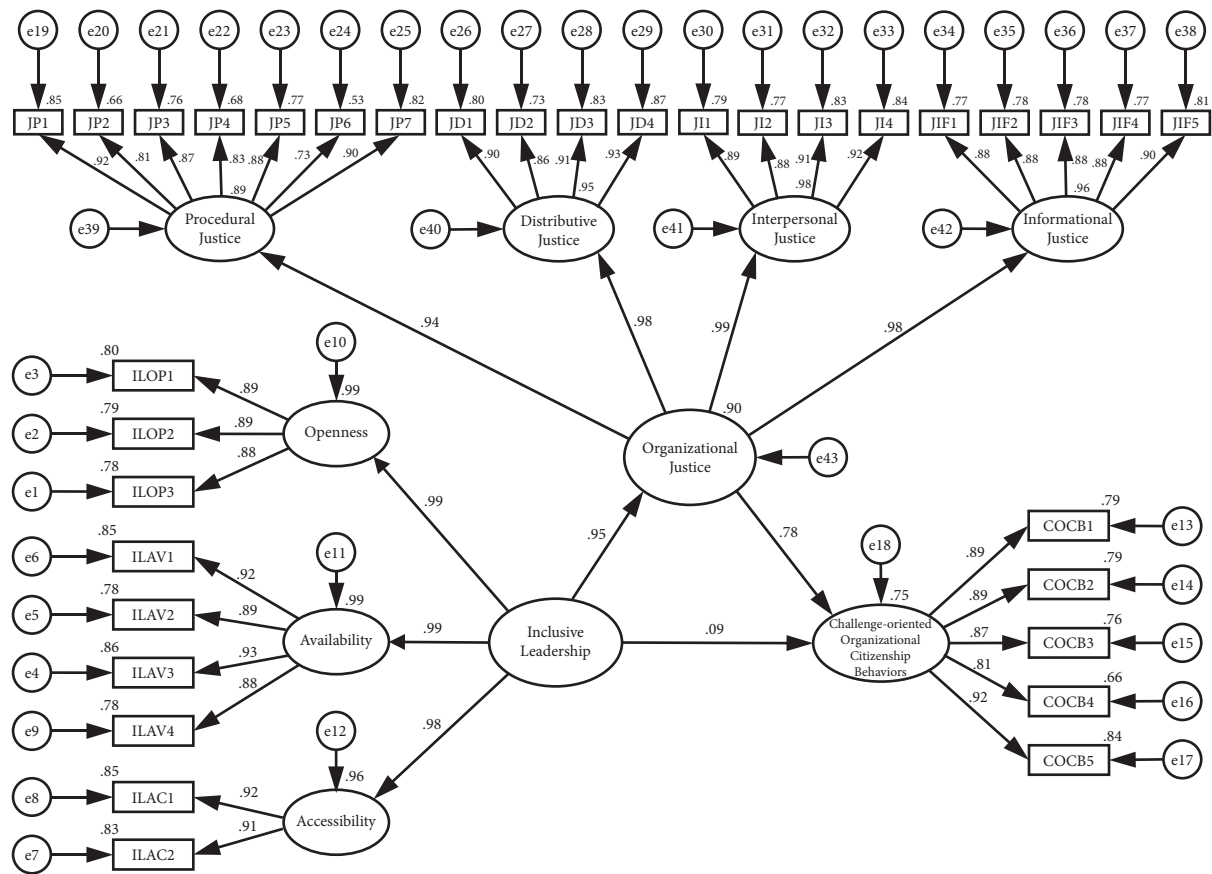

FIGURE 1: Structural equation model results.

readily available to assist others, are perceived as trustworthy by team members. As a result, team members are more likely to exhibit extrarole behaviors towards their colleagues. The supportive behaviors of inclusive leaders contribute to the development of trust among team members. When inclusive leaders demonstrate tolerance towards suggestions and mistakes, they create an open and autonomous organizational environment that encourages active employee participation, proposal of solutions, and surpassing of organizational goals. However, previous research has largely overlooked the significance of procedural safeguards and incentives, particularly in challenging work environments like nursing. In other words, although a manager's

leadership style may mitigate the negative effects of job-related friction and conflict, it does not guarantee the occurrence of positive extrarole behaviors among team members. Our research emphasizes that, drawing from social exchange theory, the supportive behavior of inclusive leaders fosters a perception among nurses that they are treated favorably, thereby motivating them to reciprocate towards the leader and the organization. Simultaneously, based on the establishment of organizational justice, this process provides safeguards for the behavior of organizational members and offers incentives for compatibility.

Second, organizational justice plays a crucial role as a motivator and mediator in this process. Existing literature

has highlighted that when employees perceive fairness from their supervisors or the organization, they are more likely to engage in organizational citizenship behaviors. In our study, we argue that organizational justice influences challenge-oriented organizational citizenship behaviors for three primary reasons. The first fundamental reason is that a high level of perceived organizational justice fosters employee satisfaction with both the work process and the organization, thereby motivating them to actively participate in extrarole behaviors [24]. The second reason is that organizational justice cultivates trust in the organization and its operational mechanisms [55], thereby reducing perceived anxiety and threat associated with engaging in challenge-oriented organizational citizenship behaviors. Lastly, inclusive leadership and organizational justice operate synergistically. Previous research has predominantly focused on the behavior-driven aspects of inclusive leadership, neglecting the evaluation mechanisms that influence the occurrence of challenging behaviors within organizations. Our findings suggest that fair evaluation mechanisms and confidence in their effectiveness lead organizational members to believe that their creative ideas and challenge-oriented organizational citizenship behaviors, aimed at enhancing organizational performance, will be appropriately recognized. This insight enhances our understanding of the effectiveness of inclusive leadership and organizational justice.

In addition, this study provides guidance to nurse management leaders and nurses in their work practices. On the one hand, inclusive leadership respects and recognizes the commitment and abilities of subordinates, cares for their needs and work status, and reinforces the social exchange of material and emotional relationships, leading to more positive work attitudes and innovative practices based on well-intentioned starting points. On the other hand, inclusive leadership implies a more tolerant attitude towards behaviors that may drive organizational change, which obviously have the potential to cause friction and conflict in the organization; however, organizational justice means that these behaviors are evaluated objectively and appropriately, thus creating a positive motivational effect on the functioning of the organization, which also implies that the leader becomes a facilitator rather than a controller [56]. In sum, how to promote organizational justice and how to motivate challenge-oriented organizational citizenship behaviors is what each member of the organization needs to contemplate, both as an effective working tool in the practice of nurse management, which in many cases is already a necessity, and as the ultimate purpose of achieving iterative renewal of the organization itself.

6. Limitations and Future Research

We recognize that this study has some limitations, in that they also offer directions that could be investigated in the future. First, the cross-sectional study design employed in the current study restricts the ability to establish causal relationships. Consequently, future studies should consider both longitudinal and experimental study designs. Second, the study results are based on self-reported data, which may

be subject to response bias and subjectivity. Therefore, the findings are only applicable to the sample and responders of the study and cannot be generalized to all contexts, particularly those with unstable organization and structure. Finally, more about individuals, organizations, and the relationships between them and nurse-specific contexts needs to be investigated in future research. On the one hand, as the results of this study, inclusive leadership promotes organizational justice and motivates challenge-oriented organizational citizenship behaviors, then under conditions of such motivational compatibility between individuals and organizations, Person-Organization Fit can be enhanced [57], especially considering the level of compassionate behaviors of the nurses when serving patients, which may not only change the underlying contexts and thresholds at which inclusive leadership functions, but Person-Organization Fit and organizational justice may also complementarily motivate the extrarole behaviors of nurses. On the other hand, in view of the characteristics of nurses' work, they often need to pay more attention to the needs of others for help, which include both physical and psychological, then positive thinking plays an important role as a positive personal resource, which can help nurses self-regulate their negative emotions into a more positive direction, so that they can achieve a higher level of positive emotions and psychological flexibility [58], especially in the context of high-intensity nursing care, leading them to engage in more behaviors beyond their own self-interest.

7. Conclusion

The current study provides additional evidence of the necessity of inclusive leadership in building organizational justice and inspiring nurses' challenge-oriented organizational citizenship behaviors. At the same time, this study reveals and validates the mediating role of organizational justice in the mechanism of inclusive leadership on challenge-oriented organizational citizenship behaviors. Nurse leaders can motivate such extrarole behaviors by consciously establishing organizational justice, which also means that organizational justice has the dual property of being the purpose and the effective methods of nurse management.

Background. Sleep is a crucial factor affecting an individual's physical and mental health. Psychiatric nurses work under high stress and load, and it is necessary to understand the sleep quality of psychiatric nurses and the influencing factors. However, individual-centred studies of psychiatric nurses' sleep are limited. **Aims.** To explore the heterogeneity in sleep quality among psychiatric nurses, to identify the factors influencing different subtypes, and to provide targeted strategies and measures to improve their sleep quality. **Methods.** From August to October 2022, 298 psychiatric nurses working in a mental health centre in Liaoning Province were selected as the participants. The study involved administering the following two questionnaires: the general information questionnaire and the Pittsburgh Sleep Quality Index (PSQI). Data analyses included latent profile analysis, Kruskal–Wallis *H* test, and multiple logistic regression. **Results.** The prevalence of poor sleep quality (PSQI >5) among psychiatric nurses was 54.7%. The sleep quality of psychiatric nurses could be classified into the following three distinct profiles: good sleep quality, moderate sleep quality, and poor sleep quality. Nurses who were over 40 years of age, unmarried/divorced/separated/widowed, worked more than 40 hours per week, experienced significant life events in the past year, had poor nurse-patient relationships, and had chronic diseases were more likely to have poorer sleep quality. **Conclusions.** There was significant heterogeneity in sleep quality among psychiatric nurses. Age, marital status, work schedule, total weekly working hours, night shifts, special life events, nurse-patient relationships, and chronic diseases were associated with their sleep quality. **Implications.** The heterogeneity and influencing factors of sleep quality in psychiatric nurses provided evidence for individualized interventions in the future. This trial is registered with ChiCTR2200062347.

1. Introduction

Sleep as a periodic and reversible resting phenomenon is one of the most important life activities in human daily life. Chronic sleep problems accelerate aging and fat accumulation [1] and increase the occurrences of serious diseases of cardiovascular and cerebrovascular diseases [2, 3]. At present, scholars generally measure sleep quality at the subjective and objective levels [4]. However, objective definitions are hard to be used, as they are limited to physiological and behavioral aspects and are difficult to be obtained [5]. Thus, self-reported subjective feelings remain the most consistent measure of sleep quality [6]. On a subjective level, Buysse's definition has been the most

widely used [7], which claims that sleep quality is an overall concept that integrates the seven components of subjective sleep quality, and assesses the level of sleep quality by the Pittsburgh Sleep Quality Index (PSQI). The cutoff scores of PSQI cutoff vary across populations [8], in which sleep quality of nursing staff PSQI >5 is the most commonly recognized [9].

Psychiatric nurses, who belong to a highly specialized occupational group, are required to care for patients with psychiatric problems and often behave abnormally with self-harm and aggressive behavior. In addition, some patients may also be accompanied by physical illness and complications. Psychiatric nurses need to attend to the various needs of patients and changes of patients' physical and

mental states [10]. Encountered with numerous challenges, psychiatric nurses are subject to high tension and sleep deficit due to long hours of pressurized work [11]. According to studies, the prevalence of poor sleep quality among psychiatric nurses in China is 53.08%–71.50% [12, 13], significantly higher than that of general nurses in previous studies, which indicates that psychiatric nurses have serious sleep problems due to their professional particularity.

Poor sleep quality among psychiatric nurses damages their physical and mental health and affects the efficiency and safety of their nursing work [14]. The harmful impacts include the fluctuation of immune biomarkers [15], periodontal disease [16], headache [17], anxiety or depression [18], and cognitive impairment [19]. In addition, it can negatively affect nurses' attention, memory, judgment, and the ability to communicate effectively. As a result, they may become slower to respond, less motivated, less productive at work, and changes in the patient's condition may go unnoticed or even risk medical errors [20]. Therefore, improving the sleep quality of nurses and managing their occupational health has become a public health concern to the whole society.

Spielman [21] proposed the "3P" theoretical model of insomnia, indicating that individual sleep quality is affected by predisposing factors, precipitating factors, and perpetuating factors, and chronic insomnia will occur when these three types of factors interact [22]. Among them, the predisposing factors of insomnia refer to the personal characteristics of insomnia, that is, who is more prone to insomnia. The precipitating factors of insomnia refer to the causes of insomnia in the first place. The perpetuating factors are the factors that make insomnia last for a long time, including unhealthy behavioral habits and incorrect cognition. Based on the abovementioned theoretical model, we selected age, gender, marital status, education, and monthly income as the predisposing factors of poor sleep quality of psychiatric nurses; working age and working mechanism. Working hours per week, night shifts, special events, nurse-patient relationships and chronic diseases were cited as the precipitating factors [23, 24]. The abovementioned influencing factors on the sleep quality of nurses are the basic support for managers to intervene nurses' sleep.

At present, many studies on the sleep quality of nurses determine their sleep quality status based on the total score of sleep-related scales, and the exploration of the influencing factors of sleep quality of nurses also ignores the heterogeneity of their sleep-related problems [25, 26]. "Heterogeneity" means that individuals differ in their characteristics and attributes, leading to differences in behaviors, beliefs, needs, abilities, and other aspects. The existence of heterogeneity indicates that each individual may have different sleep quality problems [27].

Some studies have suggested an individual-centred approach rather than a variable-centred approach to differentiate between individuals in terms of heterogeneity in sleep quality. Some scholars have found group heterogeneity in the sleep quality of nurses; Han et al. [28] divided 465 nurses into a high-symptom group and a low-symptom group based on their scores on the General Sleep

Disorder Scale. Slavish et al. [29] classified nurses' sleep status as "poor overall sleep," "nightmares only," "good overall sleep," "only nightmares," and "overall good sleep" based on their sleep diary records.

Although previous studies have provided us with information on the validity of the latent profile analysis (LPA), a person-centred method that reveals heterogeneous subgroups of individuals with the expressions of multifaceted features, the subtypes of sleep quality in psychiatric nurses are currently unknown. Due to the specificity of the patients they serve, psychiatric nurses are under higher levels of stress and their sleep quality is expected to be different from general nurses in other departments. Therefore, the identification of psychiatric nurses' sleep quality subtypes is important for the subsequent development of specific sleep interventions.

2. Materials and Methods

2.1. Design. This study is an exploratory, quantitative, individual-centred cross-sectional study.

2.2. Participants. The sample size was calculated by the following formula:

$$n = \frac{Z_{1-\alpha/2}^2 \times p(1-p)}{d^2}. \quad (1)$$

The confidence level was 95% (two-sided), $Z_{1-\alpha/2}$ (standard normal variate) was 1.96, p was 60% for the estimated prevalence of poor sleep quality among psychiatric nurses according to the results of previous studies, and d was 6% for the margin of error. Thus, we identified 257 as the minimum sample size for this study.

In addition, a 20% nonresponse rate was considered. In this study, 330 questionnaires were distributed to professional nurses from a mental health centre in Liaoning Province from August to October 2022. The inclusion criteria were as follows: (a) obtaining a nurse practitioner's license and having it in force; (b) nurses registered and working for ≥ 1 year; and (c) frontline nurses working in psychiatric wards. Exclusion criteria for nurses were as follows: (a) nurses on maternity leave, sick leave, sabbatical leave, study, and further training during the survey period and (b) trainee nurses. The researcher contacted hospital administrators to distribute the questionnaire to nurses who met the criteria. Nurses whose responses did not fit the internal logic of the questionnaire were excluded, and 298 valid questionnaires were actually collected with an effective rate of 90.3% in this study.

2.3. Instrument

2.3.1. Sleep Quality. Sleep quality was measured using the Pittsburgh Sleep Quality Index developed by Buysse et al. [7], the Chinese version was revised and compiled in China by Liu and Tang, and the Cronbach's alpha coefficient of the seven main components and each item of the Chinese version of PSQI is higher than that of Buysse's test results

and has high internal consistency, reliability, and validity. It is widely used in the Chinese population [30]. The PSQI comprises the following seven components: (A) subjective sleep quality (number of items=1), (B) sleep latency (number of items=2), (C) sleep duration (number of items=1), (D) sleep efficiency (number of items=2), (E) sleep medication (number of items=9), (F) sleep disturbance (number of items=1), and (G) daytime dysfunction (number of items=2). Scoring involved 7 components, 18 items with each component receiving a score of 0–3 after secondary calculation. The total score ranged from 0 to 21, where higher scores indicated poorer sleep quality for individuals. Previous studies have established various cutoff values for the PSQI across different populations, ranging from 4 to 10 points. In the nursing population, it is generally accepted that a PSQI score >5 indicates poor sleep quality [31, 32]. The scale has been widely used to evaluate the sleep quality of nurses and has good reliability and validity. The Cronbach's alpha coefficient in the study was 0.876, so there was good internal consistency of the Chinese version of PSQI [30].

2.3.2. General Information Questionnaire. The study utilized a self-designed general information questionnaire that focused on gathering demographic and sociological information from psychiatric nurses. The questionnaire included age (≤ 40 years and >40 years), length of service (≤ 10 years and >10 years), gender (male and female), marital status (married or cohabiting and unmarried/divorced/separated/widowed), education (junior college and below and bachelor's degree and above), monthly income (CNY) (≤ 5000 yuan, >5000 yuan), work schedule (fixed schedule and shift work), total weekly working hours (≤ 40 h and >40 h), night shifts (yes and no), whether experienced any special life events such as the death, illness of a relative, promotion, and marriage of children within the past year (yes and no), nurse-patient relationship (good and poor), and whether they suffered from chronic diseases such as hypertension, diabetes, and arthritis (yes and no).

2.4. Data Analysis. This study used SPSS 21.0 and Mplus 8.3 for data analysis. The enumeration data were described as n (%), and the normality of measurement data was tested by Kolmogorov–Smirnov. The normal data were expressed as mean and standard deviation (SD), and the skewed data were expressed as the median and interquartile range. We first conducted the normality test and common method bias test on the data and conducted latent profile analysis with the scores of each dimension of sleep quality of psychiatric nurses as the dominant variables. LPA is a statistical method that is based on multiple continuous indicators to assess individual characteristics across different components. Through probabilistic calculations, it identifies the subgroup to which an individual is most likely to belong. This method aims to classify individuals into distinct subtypes by identifying similarities in their characteristics. The best classification model is selected based on the merits of the fit indices and the practical significance of the profile.

Table 1 shows the model fit indices [33, 34]. The sleep quality of psychiatric nurses in the three groups did not conform to the normal distribution ($P < 0.05$), so the median and interquartile range were used to describe the sleep quality of nurses. Then, the Kruskal–Wallis H test was used for one-way analysis of variance, and the Dunn's method with a Bonferroni correction for multiple tests was used for post hoc test to compare the differences in demographic characteristics among different subtypes; the statistically significant variables were included in the multivariate multiple logistic regression analysis to identify the influencing factors between different sleep quality subtypes. Two-tailed $P < 0.05$ was considered statistically significant.

2.5. Ethical Considerations. Ethical approval for this study was obtained from the Research Ethics Committee of China Medical University. Informed consent was completed by all participants. The registered number is ChiCTR2200062347.

3. Results

3.1. Common Method Bias Test. The data were tested for common method bias using Harman's single-factor test. The two conditions are that there is more than one factor with eigenvalues greater than 1, and the maximum factor has a variance explained of less than 50% [35]. The results showed that there were 4 factors with characteristic root greater than 1, and the variance explanation of the first factor was 36.23%, which was less than the critical standard of 50%, indicating that there was no serious common method bias in the data of this study.

3.2. Descriptive Statistics. The median score of sleep quality was 6 (3, 10). Among them, 135 nurses (45.30%) reported good sleep quality (PSQI ≤ 5), while 163 nurses (54.70%) had poor sleep quality (PSQI >5), accounting for 54.70% of the total population. Table 2 presents the demographic characteristics of psychiatric nurses. Their median age was 35 (31, 42.5), and the median length of service was 12 (8, 22).

3.3. Identifying the Potential Subtypes of Sleep Quality. The heterogeneity of sleep quality in psychiatric nurses is shown in Table 3. First, based on the scores of seven components of the PSQI scale, one to four latent profile models were sequentially fitted. When the number of profile models increased from 3 to 4, AIC, BIC, and aBIC values reached their minimum, while BLRT was still less than 0.001, and VLMR-LRT was greater than 0.05. However, the entropy value was lower than that of the 3-profiles model, indicating that the 4-profiles model was not better than the 3-profiles model. Finally, the 3-profiles model was chosen as the optimal model because its AIC, BIC, and aBIC values were close to the minimum, BLRT P value and VLMR-LRT P value were less than 0.05 (better than the 2-profiles model), it had the highest entropy value, and the class probability was more than 5%. The posterior probability of the latent profile of psychiatric nurses in the

TABLE 1: The model fit indices for LPA.

Indicators	Criteria
AIC	The smaller the value, the more accurate the classification of the model
BIC	The smaller the value, the more accurate the classification of the model
ABIC	The smaller the value, the more accurate the classification of the model
Entropy	Entropy >0.8 means 90% of individuals are accurately classified
BLRT	The <i>P</i> value of <0.05 indicates that the class <i>k</i> model is superior to the class <i>k</i> -1 model
VLMR- LRT	The <i>P</i> value of <0.05 indicates that the class <i>k</i> model is superior to the class <i>k</i> -1 model
Probability of class	Models with a probability of at least 5% for each category were classified more reasonably

three-category model in this study was 100%, indicating that the model fit quality was high, and the model was reliable.

3.4. Latent Profile Characteristics According to the Profiles of Sleep Quality. Table 4 and Figure 1 present the sleep quality scores for each profile identified in this study. Three distinct classes of nurses were identified. Class 1 comprised 110 nurses, accounting for 36.9% of the total population. This profile exhibited standardized scores lower than the other two profiles, with scores below zero in all seven components. Consequently, it was labelled as “good sleep quality”. Class 2 consisted of 116 nurses, representing 38.9% of the total sample. The standardized scores for various components of the PSQI indicated a moderate level of sleep quality, leading to its designation as “moderate sleep quality.” Class 3 included 72 nurses, making up 24.2% of the total participants. This profile demonstrated the highest standardized scores across all components, particularly in subjective sleep quality and sleep medication use. These findings suggest that the overall sleep quality of psychiatric nurses in class 3 is poor, with a higher frequency of sleep medication use and a general perception of poor sleep quality. Accordingly, this class was named “poor sleep quality.”

3.5. Kruskal-Wallis *H* Test of Factors Influencing Sleep Quality Profiles. As shown in Table 5, the Kruskal-Wallis *H* test indicated that there was a significant difference ($P < 0.05$) in age, marital status, education, work schedule, total weekly working hours, night shifts, special life events, nurse-patient relationships, and diseases among different potential profiles across three groups.

Post hoc comparisons using Dunn's method for multiple tests and the Bonferroni method were used to correct the *P* value to indicate that there were significant differences in age (corrected $P = 0.003$), length of service (corrected $P = 0.007$), marital status (corrected $P = 0.024$), education (corrected $P = 0.025$), working schedule (corrected $P = 0.001$), total weekly working hours (corrected $P < 0.001$), night shifts (corrected $P < 0.001$), special life events (corrected $P < 0.001$), nurse-patient relationship (corrected $P = 0.002$), and disease (corrected $P < 0.001$) between the good and poor sleep quality groups. There were significant differences in working schedule (corrected $P = 0.014$) and total weekly working hours (corrected

CNY is the standard currency symbol for China Yuan. *Note.* As long as there is the same marked letter, the difference is not significant. Any difference with different marked letters was considered significant ($P < 0.05$).

$P = 0.003$) between the medium and poor sleep quality groups. There were significant differences in night shifts, special life events (corrected $P = 0.002$) and disease (corrected $P = 0.009$) between the good sleep quality group and the moderate sleep quality group.

3.6. Multivariate Logistic Regression Analysis of Factors Influencing Sleep Quality Profiles. Table 6 shows that nurses who are over forty years of age (OR = 2.600 and 95% CI: 1.186–5.698) and experienced special life events (OR = 2.966 and 95% CI: 1.355–6.495) were more likely to belong to the “moderate sleep quality” group compared to the “good sleep quality” group. Then, nurses who were over forty years of age (OR = 3.002 and 95% CI: 1.072–8.409) unmarried, divorced, separated, widowed (OR = 0.365 and 95% CI: 0.154–0.862), worked more than 40 hours per week (OR = 0.273 and 95% CI: 0.121–0.615), experienced specific life events (OR = 4.375 and 95% CI: 1.826–10.479), had a poor nurse-patient

relationship (OR = 0.432 and 95% CI: 0.184–0.971), and had chronic diseases (OR = 2.910 and 95% CI: 1.354–6.252) were more likely to be in the “poor sleep quality” group compared to the “good sleep quality” group. In addition, nurses who worked 40 hours or less (OR = 0.442 and 95% CI: 0.212–0.920) were more likely to belong to the “moderate sleep quality” group compared to the “poor sleep quality” group.

4. Discussion

This study examined the heterogeneity of sleep quality among psychiatric nurses through different aspects of sleep quality. The study used an individual-centred approach to identify the subtypes of sleep quality among psychiatric nurses. The findings revealed that the main reasons for psychiatric nurses belonging to the “poor sleep quality” group were poor subjective sleep quality and frequent use of hypnotic medication. Moreover, the study investigated the

impact of nurses' individual family life and work characteristics on their sleep quality, thereby opening up the perspective of the research on the influencing factors of sleep quality among psychiatric nurses.

4.1. Sleep Quality in Psychiatric Nurses. The median of PSQI score for the 298 psychiatric nurses in a mental health centre in Liaoning Province was 6 (3, 10). Among the participants, 135 nurses (45.30%) had good sleep quality (PSQI \leq 5) while 163 nurses (54.70%) experienced poor sleep quality (PSQI $>$ 5). These findings indicate a relatively high incidence of poor sleep quality among psychiatric nurses in Liaoning Province, suggesting a more severe sleep problem that may be related to their professional characteristics and work pressure.

This study analyzed the sleep quality of psychiatric nurses using the LPA method. Based on the fitness indicators, the sleep quality of psychiatric nurses could be divided into the following three subgroups: the "good sleep quality" group, the "moderate sleep quality" group, and the "poor sleep quality" group.

The "moderate sleep quality" group had the highest number of nurses, which accounted for 38.9% of the total participants. The group exhibited relatively balanced scores across the seven components of the PSQI, indicating that more than one third of psychiatric nurses commonly experienced comprehensive sleep issues without any specific sleep problems. The "poor sleep quality" group of psychiatric nurses comprised 24.2% of the total participants, with the median PSQI score of 13 (11, 15). Within this group, subjective sleep quality and the use of hypnotic medication scored the highest compared to the other five components, suggesting that these two issues have a significant impact on impairing sleep quality. This may be attributed to the irregular behaviors and emotions displayed by psychiatric patients, which impose additional pressure and challenges on nursing work, leading to physical and mental burdens on nurses [10]. This contributes to poor sleep quality and increasing their demands for sleep medication.

4.2. Influencing Factors of Sleep Quality Profiles in Psychiatric Nurses

4.2.1. Age. The findings indicated that nurses aged over 40 years were more likely to belong to the "moderate sleep quality" and "poor sleep quality" groups compared to the "good sleep quality" group. Chang et al. showed that nurses over 40 years old were more likely to have sleep disorders [36], and other studies proved that older age was a risk factor for poor sleep quality among nurses [37]. Most female nurses over 40 years old are experiencing menopause or menopause, and the fluctuation of body hormone levels affect their sleep quality [38]. In addition, older nurses may have to bear more responsibility and pressure at work and at home and are more likely to suffer from chronic diseases or other occupational diseases for

a long time, which are the reasons for poor sleep quality of older nurses (especially those over 40 years old) [39]. Therefore, managers should provide enough rest time for older nurses to recover energy and balance various relationships, reduce the work intensity, arrange assistance personnel, and optimize work processes to improve the sleep problems of older nurses.

4.2.2. Marital Status. The result indicated that unmarried/divorced/separated/widowed nurses were more likely to belong to the "poor sleep quality" group compared to the "good sleep quality" group, suggesting that these nurses had poorer sleep quality. Previous studies also had similar findings, showing that sleeping with the spouse can effectively improve sleep quality and overall health [40, 41]. Clinical and epidemiological studies consistently demonstrate that feelings of loneliness can have a detrimental impact on sleep quality [42]. Conversely, having a supportive spouse or partner has been found to contribute to better sleep quality. Moreover, the emotional support and sense of security provided by a significant other can positively influence an individual's mental wellbeing, further enhancing their sleep quality [43].

4.2.3. Total Weekly Working Hours. The result indicated that nurses who worked more than 40 hours per week were more likely to belong to the "poor sleep quality" group compared to both the "moderate sleep quality" and "good sleep quality" groups. This finding aligns with previous studies that have shown a correlation between longer working hours and poorer sleep quality among nurses [44]. The reason may be that longer working hours need nurses to maintain a high level of concentration and endure long hours of standing to handle demanding nursing tasks. Both mental and physical fatigue can contribute to an increased sense of fatigue among nurses, thereby increasing their risk of experiencing poor sleep quality [45].

4.2.4. Special Life Events. The findings of the study indicated that nurses who experienced special life events in the past year were more likely to belong to the "moderate sleep quality" and "poor sleep quality" groups compared to the "good sleep quality" group. Both negative and positive life events can have an impact on the sleep quality of psychiatric nurses. Previous research has also arrived at similar conclusions, stating that psychological stress resulting from negative events can affect the sleep quality of nurses [46]. However, there exists a complex relationship between positive life events, such as getting married, being promoted, or receiving awards, and sleep quality. Despite these events being positive, they can still lead to sleep disturbances due to arousal [47].

4.2.5. Nurse-Patient Relationship. The study found that nurses who had a poor nurse-patient relationship were more

likely to belong to the “poor sleep quality” group compared to the “good sleep quality” group. A discordant nurse-patient relationship has been identified as a significant predictor of increased work-family conflict [48] and has been found to have a negative correlation with job satisfaction [49]. The increase in work-family conflict and the decrease in job satisfaction can contribute to deterioration in sleep quality [50, 51].

4.2.6. Disease. The result showed that nurses who had the disease were more likely to belong to the “poor sleep quality” group compared with the “poor sleep quality” group. Previous studies have also found a strong association between chronic disease and sleep quality [52, 53]. Nurses with chronic diseases are more likely to experience pain, fatigue, and negative emotions such as depressive symptoms, which can impair sleep quality [54, 55]. Chronic illness can also lead to changes in the social status, career, and family relationships, even increasing their financial burden. Dealing with and adapting to these changes can be psychologically stressful for nurses, which in turn increases the risk of poor sleep quality.

Nurses who were over forty years of age, unmarried/divorced/separated/widowed, working more than 40 hours per week, have experienced significant life events in the past month, had poor nurse-patient relationships, and had chronic diseases were more likely to have poorer sleep quality. In order to improve the sleep quality of older nurses, nursing managers should regularly communicate with nursing staff, assign work assistants, and help nursing staff establish a work-family balance. For nurses without partners, managers should provide adequate care and support. In addition, managers should develop flexible work schedules to help nurses balance clinical and research duties and avoid excessive work hours and fatigue. Managers should pay attention to the psychological state of nurses, understand the recent life experience of nurses, and communicate and intervene in time. Managers should also organize regular training sessions to enable nursing staff to build positive relationships with patients. The organization should organize regular physical examination, grasp the health status of nursing staff in time, arrange work reasonably for nurses with chronic diseases, and give them enough time for rest. In addition, psychiatric nurses who have poor subjective sleep quality and rely on the use of sleep drugs can improve their sleep quality through aromatherapy [56], adequate dietary nutrition [57], cognitive behavioral therapy [58], light therapy [59], breathing relaxation training [60], sleep education [61], exercise [62], and other intervention methods.

4.2.7. Limitations. This study considered the heterogeneity of sleep quality among psychiatric nurses by examining different components and adopting an individual-centred perspective to identify variations within this group. The aim was to provide theoretical guidance and empirical evidence for targeted intervention strategies to improve their sleep quality. However, several limitations should be mentioned.

First, this study is cross-sectional, which means that it could not establish exact causal relationships between variables. Second, the use of self-reported questionnaires introduces the potential for information bias in the study results. Third, the participants were limited to nurses from a specific psychiatric health centre in Liaoning Province, which may limit the generalizability of our findings. Fourth, this study only investigated whether nurses suffered from chronic diseases, ignoring that different types of chronic diseases may lead to different results. Therefore, future research should consider expanding the sampling scope and increasing the sample size and consider the impact of different kinds of chronic diseases on sleep quality of nurses.

5. Conclusions

This study used a person-centred approach and categorized the sleep quality of psychiatric nurses into the following three subgroups: good sleep quality, moderate sleep quality, and poor sleep quality. This suggests that for nurses with poor sleep quality, managers should prioritize addressing their subjective sleep quality and sleep medication use. Age, marital status, work schedule, total weekly working hours, night shifts, special life events, nurse-patient relationships, and chronic diseases were associated with their sleep quality. Managers need to pay attention to psychiatric nurses' sleep and take targeted intervention methods to improve their sleep problems. Individuals should also cultivate healthy behaviors and lifestyles to improve sleep quality.

Aim. Identify the characteristics of leadership competency for the nurse manager and describe the most cited leadership styles in the literature. **Background.** Leadership is a fundamental competency for nurse managers, as it plays an important role in the healthcare environment to achieve Sustainable Development Goals and promote people-centered organizations. Therefore, understanding the characteristics of leadership and the leadership style to be employed is important. **Methods.** A scoping review was conducted from January 2009 to January 2024 using the design of González Garcia et al., the Arksey and O'Malley framework, and databases including Web of Science, Scopus, and PubMed. Articles reporting on the characteristics of leadership for nurse managers were reviewed. The authors performed the review based on a search syntax, inclusion and exclusion criteria, and the data extraction process. **Results.** Sixty-two studies were included in the final review. The review identified 38 characteristics related to leadership competency, among which we highlighted caring for nurses as individuals, being a visionary, knowledgeable, a change agent, and a communicator. This review highlights the prevalence of transformational leadership, which constitutes 69.57% of the leadership styles cited, and underscores its pivotal role in improving the work environment, effectiveness in nursing care, conflict management, team commitment, and adaptability to change within healthcare settings. **Conclusions.** The most commonly cited characteristics of leadership include caring for the team, effective communication, and a vision for change. Transformational, people-centered, and motivational leadership is the most appropriate style. **Implications for Nursing Management.** The characterization of leadership competency will allow the development of training adapted to the current requirements for nursing leaders. This training could be developed in simulation and virtual reality environments. It also allows for a deeper understanding of how leadership competency affects teams and their functioning.

1. Introduction

Leaders in healthcare organizations must inspire coordinated actions and foster a social movement to achieve the Sustainable Development Goals (SDGs), which require the development of people-centered ethical behavior [1, 2]. This leadership style can be defined as one that focuses on achieving the highest levels of motivation of people through the development of four components: idealized influence, inspirational motivation, intellectual stimulation, and

individual consideration [3]. They should be responsible for positive changes in social and health systems throughout the world, taking into account not only the interests of the organization but also the interests of the society in which it operates [4]. The SDGs refer to the global challenges facing countries and their populations [5].

Nurses are associated with the SDGs, as their work involves concern for the health impact on patients and populations [6]. It is important to note that nurses, from a crucial position, address social determinants of health,

understanding the link between public health conditions and their impact on the population [7]. In this sense, the nurse should exercise a participatory and collaborative leadership style within work groups and society [8]. Furthermore, nurses' leadership focused on the SDGs would have clear benefits related to improving global health, progress toward gender equality, and strengthening economies [9]. Similarly, the World Health Organization (WHO) highlights the relationship between nursing leadership and its influence on education (SDG 4), gender relations (SDG 5), and work and economic growth (SDG 8) [10]. Benton et al. [11] also noted that the 17 SDGs have a significant impact on people's health, underscoring the crucial role of nursing leadership in coordinating actions to achieve these goals.

Furthermore, the nurse managers play a relevant role in the success of healthcare institutions in the management of governance, quality, and sustainability, as well as in terms of health objectives and the SDGs [12]. In addition, nurse managers establish strategies that guide nurses in their professional actions, generate environments for nursing practice, and support organizational development, influencing public health policies and positioning nurses in an ever-changing healthcare environment [13]. Thus, developing competencies to effectively manage healthcare organizations becomes crucial, especially when these roles serve as a vital link to clinical practice [14].

In this sense, the competency model for the nurse manager developed by González García [15] provides a core of eight competencies that nurses must develop in managerial roles in healthcare organizations [16]. These core competencies described by González García [15] include leadership.

The leadership competency of the nurse manager could be defined as the ability to influence other professionals to achieve common objectives and a shared vision [17, 18]. This competency is especially important in healthcare organizations because it is responsible for generating professional commitment, reducing conflicts in workgroups, and creating relationships between team members [19]. Furthermore, research has found that the leadership style of the nurse manager is a key determinant of the quality of care provided by nurses [20, 21]. Research also identifies the transformational leadership style as the most relevant style in the healthcare setting [18, 22] due to its ability to achieve commitment, reduce stress, prevent burnout, and achieve better health outcomes and higher quality nursing care [23, 24].

The relationship between the SDGs, leadership, economic, and sustainability policies with respect to the need to provide quality healthcare is the starting point for the present research [25–27]. However, the review of the literature indicates that it is necessary to deepen the knowledge of leadership competence and its characteristics in the healthcare setting [28–30].

1.1. Aim. The objectives of this scoping review were: (1) to identify and describe the characteristics of leadership competency for the nurse manager and (2) to identify the most common leadership style in the literature.

2. Materials and Methods

2.1. Design. A scoping review synthesizes knowledge, explanations, and interpretations from both qualitative and quantitative research to address the research question. A scoping review is useful for exploring emerging evidence, identifying knowledge gaps, and providing rigorous and transparent methods for identifying and mapping available evidence [31]. This methodology enables the systematic and meaningful extraction of data [32]. According to Tricco et al. [33], this research adhered to the checklist proposed by PRISMA-ScR.

In addition, this scoping review followed the methodology conducted by Gonzalez-Garcia et al. [34], as this article belongs to the line of research focused on the development of competencies for nurse managers. The same keywords were used to refer to the nurse manager, as well as the same approach to competencies and characteristics. Likewise, the same article selection and quality criteria were used. Regarding data extraction and coding systems, the same tools and strategies adapted to the purpose of the competency that is the focus of this part of the research were used.

2.2. Search Methods. The scoping review was conducted according to Arksey and O'Malley [31], which involved: Identifying the research question, identifying relevant studies, choosing studies, identifying data, collecting, summarizing, and reporting results.

The research questions were as follows:

- (1) What are the characteristics of leadership competency for the nurse manager?
- (2) What are the characteristics of leadership competency that are most often cited in the literature?
- (3) What is the most cited leadership style in the literature?

Relevant articles published between 2009 and 2024 were searched in electronic databases, including Web of Science, Scopus, and PubMed. The search terms included references to nurse managers and leadership competency (Table 1).

The inclusion criteria for the articles in this scoping review included quantitative, qualitative, and mixed methods studies, theses and dissertations, and reviews. Articles published between January 1, 2009, and January 30, 2024, in English or Spanish, were included to guarantee the synthesis of updated knowledge, considering that the role of nurse managers and leadership has evolved in recent years. The exclusion criteria included conference abstracts, editorials, and discussion papers, as well as articles with no data on the leadership characteristics of the nurse manager.

We limited our search to the articles that resulted from our search equations and did not include gray literature. Additionally, we did not conduct a snowballing search.

2.3. Quality Appraisal. An evaluation of the quality of the included articles was performed. Since developed and validated tools for assessing the different methodologies of the

TABLE 1: Search strategy.

Database 2009–2024	Search terms
WOS	TI = (leader*) AND TI = (“nurs* manage*” OR “nurse supervisor” OR “nurse program manager” OR “nurse unit manager” OR “chief nurse executive” OR “nurs* administrat*” OR “director of nurs*” OR “head nurs*” OR “frontline manager” OR “nurs* director” OR “nurs* executiv*”) AND TS = (“head nurs*” OR “frontline manager” OR “nurs* director” OR “nurs* manag*” OR “first line nurs* manage*” OR “nurse supervisor” OR “nurse program manager” OR “nurse unit manager” OR “chief nurse executive” OR “nurs* administrat*” OR “director of nurs*” OR “nurs* executiv*”) AND TS = (leader*)

Source: own elaboration.

included publications are lacking, the development of a specific tool to serve this purpose was necessary. To this end, parts of the method presented by Hölbl et al. [35] were used and modified as appropriate (Table 2). The initial quality assessment of the articles was performed by SPG and was independently reviewed by reviewers 2–6 (PMS, AP, CB, AGG, and CLP). Although some studies had medium scores, the authors’ intention was not to remove studies but to assess the overall quality of the existing knowledge base. No articles were excluded according to the quality assessment process.

2.4. Data Extraction. Data extraction was performed using specially designed forms. The following data were extracted from the studies: type of study, sample size, participant characteristics, countries, leadership types, and leadership characteristics. Data analysis was performed using Microsoft Excel.

The authors met regularly to resolve any disagreements about whether the articles met the inclusion criteria. Each of the selected full-text articles was read thoroughly several times by the authors to capture all relevant information and ensure that nothing important was missed. The data set for the paper was constructed by extracting findings that were relevant to the research questions.

Studies, characteristics, and leadership styles were coded using the following process to correctly identify them:

Articles: Coded with the letter “A” followed by three digits, beginning with A001 for the first article.

Characteristics: Coded with the letter “C” followed by three digits, beginning with C001 for the first characteristic.

Leadership style: These were encoded with the letter “L” followed by three digits, beginning with the code “L001.”

For example, the characteristic encoded as “A003 C007” can be identified as characteristic 7 belonging to Article 3. Furthermore, the leadership style encoded as “A003 L003” can be identified as leadership style 3, as described in Article 3.

Using this methodology, we initially cataloged the characteristics of leadership competency described in the articles and assigned a unique code to each. Subsequently, these characteristics were analyzed and grouped if they were identical, and their frequency of repetition was tallied. Any disagreements were resolved by a fourth reviewer (CB).

In this review, the “leadership characteristic” is defined as a description that distinctly recognizes a leadership trait.

3. Results

The selection process is shown in Figure 1. A total of 622 articles were identified from electronic databases and imported into Mendeley for screening. After screening the titles and abstracts, 141 studies remained for full-text review. Finally, 62 studies were included in this scoping review.

3.1. Bibliographic Overview. Sixty-two articles were included in the current scoping review. Table 3 presents the characteristics of the included studies. Of the 62 studies, most were conducted in the USA (54.8%), Finland (7.54%), Iran and China (5.66% each), Australia and Jordan (3.77% each), and 1.88% came from the UK, Saudi Arabia, Singapore, Greece, South Africa, Italy, Japan, Brazil, Lithuania, and Sweden. As a result, 339 characteristics were identified in the 62 articles analyzed. Following the identification of the characteristics, their meanings were analyzed, and those referring to the same leadership characteristics were grouped together. This analysis resulted in 38 leadership characteristics (Table 4).

3.2. Quality Assessment. The highest possible score was 10, while the lowest was 0. The overall average score was 6.70. The average scores for the individual items were as follows: Q1 = 1.34 ± 0.51, Q2 = 1.49 ± 0.60, Q3 = 1.05 ± 0.43, Q4 = 1.59 ± 0.64, and Q5 = 1.21 ± 0.55.

3.3. Most Cited Characteristics. Regarding the five most cited leadership characteristics in the literature, each with a frequency greater than five, they were “Caring for nurses as

TABLE 2: Quality assessment tool adapted from Hölbl et al. [35].

Domain	Indicator (0–2)
Q1-Is the nurse manager leadership characteristics described?	No-moderately-yes
Q2-Are the research objectives clearly outlined?	No-moderately-yes
Q3-Are the main contributions well described to the nurse management leadership?	No-moderately-yes
Q4-How appropriate is the problem-solution fit?	No-moderately-yes
Q5-Are the proposed solutions feasible (scalable, economical, implementable)?	No-moderately-yes

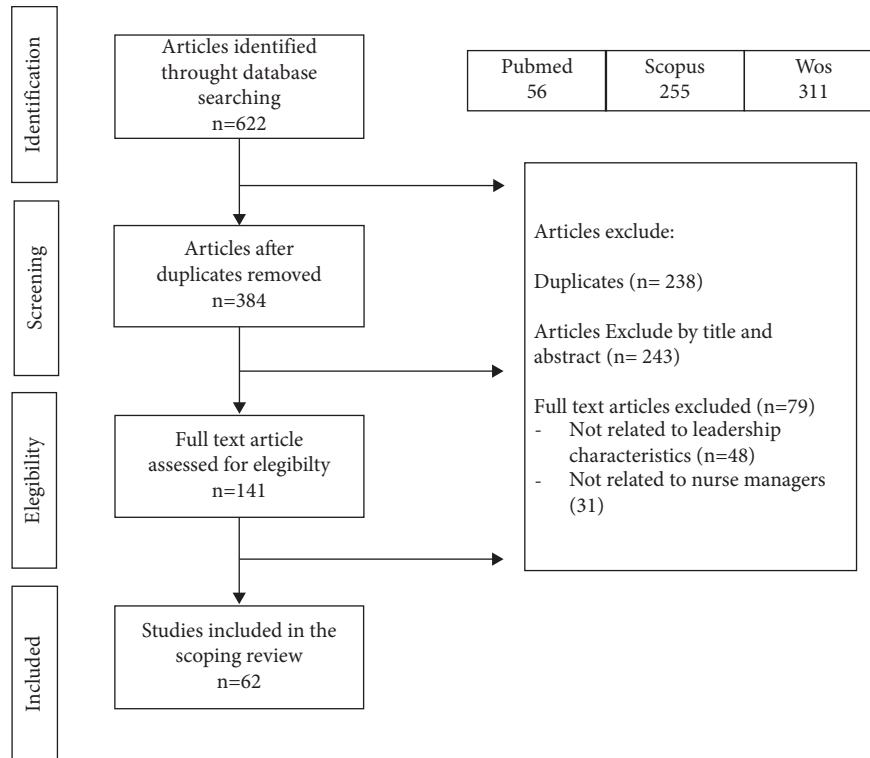

FIGURE 1: Flowchart of the study.

individuals,” “Being visionary” (creating and clearly communicating a personal vision to guide change and enable others to achieve their purpose and take action), “Knowledgeable,” “Change agent,” and “Being a communicator” (Table 4). This requires a combination of personality traits and communication skills.

3.4. Leadership Styles. Furthermore, the leadership styles from which the extracted characteristics originated were analyzed, including a study of their frequencies, resulting in 22 leadership styles, as shown in Table 5. Given the way leadership was referred to in the various articles, it was pertinent to analyze and classify them based on how they were defined. From this analysis, four leadership styles emerged (Table 6). A significant finding was that 69.57% of the articles referred to transformational leadership, as seen in Table 6.

Consequently, the identified leadership characteristics were classified into the four defining dimensions of transformational leadership (Table 7). The most cited characteristics in each of the four dimensions were: in the intellectual stimulation dimension, the most cited characteristic was “knowledgeable” (14.49%); in the individualized

consideration dimension, the most cited characteristic was “Caring for nurses as individuals” (32.34%); “Empowerment” (25.42%) was the most cited in the idealized influence dimension; and “Being visionary” (28.57%) was the most cited in the inspirational motivation dimension.

Subsequently, an analysis was conducted on the influence of leadership on key aspects of nursing team management, such as job satisfaction, effectiveness in patient care, conflict management, team commitment, and adaptability to change in the nursing environment, as shown in Table 8. The results indicate that transformational and relational leadership achieve the highest levels in all areas of analysis, demonstrating a significant impact on job satisfaction, effectiveness in patient care, conflict management, team commitment, and adaptability to change.

4. Discussion

The objectives of this scoping review were to identify the characteristics of leadership competency for nurse managers and to identify and describe the leadership styles most commonly referenced in the literature. The strengths of our methodology include rigorously defined inclusion criteria,

TABLE 3: Description of the articles included in the review.

Author/year	Method	Description/context	Results	Limitations
(Abdelhafiz et al., 2016) [36]	Quantitative, descriptive, and comparative method	The aim is to explore how nurse leaders' leadership styles affect nurses' job satisfaction	The increased development of transformational leadership behaviors increases nurses' job satisfaction and thus contributes to higher nurse retention	Not described
(Albagawi, 2019) [37]	The multifactor management questionnaire was applied to evaluate supervisors' methods of management	Hail City Public Hospitals	The objective is to determine the management style of nurse managers and its consequences in Hail public hospitals	Not described
(Al-Hussami et al., 2017) [38]	Pre-experimental design	61 nurses participated, with a pretest and posttest group in Jordan	The objective is to establish a leadership orientation program that can advance nurses' knowledge while improving their leadership skills and quality of work to promote their readiness for change in healthcare organizations	Not described
(Anderson et al., 2010) [39]	Survey and focus groups	To assess aspects of leadership that help create a healthy work environment that supports the delivery of quality care	The authors discuss their findings and propose a theoretical model to explain the specific characteristics of nursing leadership that support job satisfaction and retention of nursing staff	Not described
(Batson and Yoder, 2009) [40]	Descriptive	Analyzes the influence of nurse manager coaching as a transformational leadership skill and describes an effective coaching process for staff	Although each employee is unique, generational differences that directly affect coaching have been identified	Not described
(Bellack and Dickow, 2019) [41]	Descriptive	The leadership literature is rich with research on characteristics and behaviors that cause leaders to derail	This research examines career derailment risks and explores opportunities to prevent or recover from leadership failure	Not described
(Bernard, 2014) [42]	Descriptive	The Centura Nurse Executive Residency Program is designed for nursing leadership development	Developing high-potential leaders is a critical factor for preparing a cadre of nurse executives	Not described
(Bikmoradi et al., 2018) [43]	Cross-sectional study using Bradberry's emotional intelligence and Metzcas and Bardon's leadership style questionnaires	370 nurse managers from hospitals of Hamadan University of Medical Sciences were surveyed	The emotional intelligence of nurse managers has a significant positive correlation with a people-oriented leadership style and, in contrast, no correlation with a task-oriented leadership style	The emotional intelligence and leadership style of the managers were measured from the managers' own perspectives
(Bish et al., 2015) [44]	Qualitative descriptive study	Semistructured in-depth interviews with rural nursing managers to identify factors influencing leadership	Recognizing factors that influence rural nurse leaders' approaches can help implement context-sensitive leadership development initiatives	Not described

TABLE 3: Continued.

Author/year	Method	Description/context	Results	Limitations
(Cathcart et al., 2010) [45]	Narrative experiences on professional practice	Utilizing Benner's methodology of practice articulation, 32 nurse managers wrote and interpreted first-person narratives of their practice	Complex leadership challenges can be a significant source of experiential learning for individuals and groups	Not described
(Cheng et al., 2018) [46]	Qualitative interviews	Secondary qualitative analysis of 15 nurse manager interviews	Nurse manager leadership is crucial for the successful implementation of evidence-based nursing Managers who completed more leadership courses had implemented significantly more types of innovations and had higher scores on the innovation scale	There is a potential risk of overinterpretation in secondary data analysis studies
(Clement-O'Brien et al., 2011) [47]	Survey method	Directors of acute care hospitals participated in a survey to determine their capacity for innovation		The selection of the state setting limits the generalizability of the findings
(Ebrahimzade et al., 2015) [23]	Cross-sectional study with questionnaire	207 hospital nurses completed a questionnaire assessing demographic characteristics, a measure of burnout, and the Multifactor Leadership Questionnaire (MLQ)	This study sheds light on the effective role of transformational leadership in improving nursing management and reducing burnout among nurses	Not described
(Echevarria et al., 2017) [48]	Predictive correlational design	148 nurse managers used the Genos Emotional Intelligence Inventory, the Multifactor Leadership Questionnaire, and a demographic questionnaire	The study's results underscore the need for continuing education programs in emotional intelligence, leadership development, and leadership assessment	It does not determine the participants' regions and practice environments
(Fennimore and Wolf, 2011) [49]	Descriptive study	The UPMC leadership development for nursing Middle managers program was designed within a conceptual framework. Twenty-five nurse managers participated in the pilot program	Effective nurse manager leadership is vital for successful hospital outcomes, leading to increased nurse retention, reduced turnover costs, and improved quality and financial outcomes for healthcare institutions There is a consensus on specific factors that play a significant role in an organization's safety climate. Generally, the leader's demonstration of commitment to safety is key to cultivating a patient safety culture	There was minimal opportunity to measure the longitudinal impact of the program
(Fischer et al., 2018) [50]	Systematic review on leadership and safety climate and expert panel	A group of 25 international experts in leadership and safety participated in a Delphi study with three rounds of Likert-scale surveys	Social networks, when used wisely, can be a valuable leadership communication tool for today's nurse leaders	Not described
(Flury, 2017) [51]	Descriptive opinion	Nursing leaders in the USA must include social media in their communication strategy to lead healthcare transformation	Cultural competence as a strategic priority can be improved by providing training and holding managers accountable	Not described
(Gergely, 2018) [52]	Qualitative surveys and interviews	132 nurse leaders from AONE were electronically surveyed on influences on the delivery of culturally competent care delivery; interviews with six nurses		Not described

TABLE 3: Continued.

Author/year	Method	Description/context	Results	Limitations
(Goh et al., 2018) [53]	Survey	Nurses in four inpatient wards of an acute hospital in Singapore completed various leadership and commitment questionnaires	RNs observed nurse leaders who showed transformational and transactional behaviors, with less laissez-faire behavior	Not described
(Grubaugh and Flynn, 2018) [54]	Secondary analysis	Data from 257 nurses across 50 medical-surgical units used for secondary analysis, originally collected from a 2012 study	The findings emphasize that the skilled leadership and conflict management of the nurse manager are crucial	Limited by the variables and measures of the original study
(Henriksen, 2016) [17]	Descriptive opinion	Framework for leadership transformation requires redefining the role of the nurse manager	Identifies six key attributes of a chief nursing officer and the effectiveness of an innovative learning approach	Not described
(Heuston and Wolf, 2011) [55]	Descriptive	Discussion on Kouzes and Posner's model and the five practices of exemplary leadership	Highlights the increasing value of leaders who can transform the workforce amid healthcare reforms	Not described
(Hopkinson et al., 2019) [56]	Literature review and focus groups	Constructs identified through literature search and refined via focus groups	Eight constructs emerged in regard to leadership development methods	Communication training was not covered
(Hughes, 2019) [57]	Oral history method	Examines Air Force nursing development through the experiences of a notable military nurse leader between 2004 and 2008	Provides information on the development and impact of air force nursing in a historical, social, and global context	Oral history centered around the experiences of a single nurse
(Kallas, 2014) [58]	Cross-sectional survey	Profile of an excellent nurse manager developed through responses from highly rated US nurse managers	The leadership attributes and competencies of an excellent nurse manager are outlined, in response to the nursing shortage	The tools necessary to identify these attributes are not present in the literature
(Kelly et al., 2014) [59]	Cross-sectional descriptive survey	Survey of 512 hospital managers to assess leadership characteristics	Formal training affects one component of transformational leadership (TL), helping leaders model behavior for employees	The path to leadership positions in nursing remains unclear
(Khan et al., 2018) [60]	Descriptive correlational design	Survey at 2016 Magnet Conference, including full-time nurses with 6+ months of experience	Moderate correlation between transformational leadership of nurse managers and structural empowerment of staff; less so for transactional leadership	The sample is convenience-based, primarily from magnet hospitals or those pursuing the designation
(Kodama et al., 2016) [61]	Cross-sectional study	Nurses assessed leadership styles of nurse managers and related factors of engagement	Intellectual stimulation from transformational leadership can increase staff retention by increasing affective engagement	The convenience nature of the sample limits generalizability
(Kvist et al., 2019) [62]	Cross-sectional survey	Nurses evaluated nurse leaders using the transformational leadership scale (TL)	Nurse managers' qualities were rated moderate by nurses	E-surveys tend to have low response rates

TABLE 3: Continued.

Author/year	Method	Description/context	Results	Limitations
(Lappalainen et al., 2020) [63]	Electronic questionnaires	Finnish nurses responded to electronic questionnaires incorporating the transformational leadership scale (TLS) and the medication safety Scale (MSS)	There is a relationship between nurse managers' transformational leadership and medication safety	The response rate to the questionnaire was not specified
(Lehtonen et al., 2018) [64]	Electronic questionnaire	Nursing staff in Finland evaluated their manager using a leadership and management competencies scale in 2016	Nurses highly value the professional competence in nursing leadership and management. Greater appreciation requires managers to demonstrate education and competence	The results are limited to the specific hospital where the research was conducted
(Liukka et al., 2018) [65]	Semistructured interviews	Eleven nurse managers were interviewed about their actions after adverse events	Certain transformational leadership elements are significant in nurse managers' actions after adverse events	Participant feedback may have increased study validity
(Li and Wivatvanit, 2016) [66]	Delphi technique	Twenty experts participated, focusing on leadership competencies for first-line nurse managers	The consensus on competencies can guide leadership development programs in Shanghai, China	Not described
(Mackoff et al., 2013) [67]	Participatory action research	One-year study to develop "leadership laboratories" with nurse managers as participants and evaluators	Positive results in leadership skills from all laboratories	Not described
(Manning, 2017) [68]	Descriptive correlational design	Survey of 441 nurses in the USA using engagement and leadership questionnaires	Transactional and transformational leadership positively influenced engagement; passive leadership had a negative effect	Not described
(McKinney et al., 2016) [69]	Survey method	Surveys on leadership and intention to leave completed by 3,609 nursing directors	Complexity leadership approaches were correlated with better care outcomes	Not described
(Millet and Porche, 2017) [70]	Descriptive opinion	Discussion on leadership during natural disasters	The unique talents of nurses are crucial in health emergencies and disasters	Not described
(Morsiani et al., 2017) [71]	Two-phase mixed method	Initial phase using the Multifactor leadership questionnaire to associate leadership style with job satisfaction Inclusion of full-time nonsupervisory nurses with more than a year of experience	Italian nurse managers must improve their transformational leadership skills Higher satisfaction with transformational leadership styles over transactional leadership styles	Not described
(Negussie and Demissie, 2013) [72]	Nonexperimental correlation design	Explored nurse managers' perceptions of leadership styles and their impact on patient safety in an academic hospital	Identified common leadership styles among nurse managers and challenges to improve patient safety Leadership is linked with communication and ethics; limited training opportunities postgraduation	Limited to one health sector; could benefit from more in-depth data
(Palweni et al., 2023) [73]	Qualitative exploratory and descriptive study			
(Pereira et al., 2015) [74]	Quantitative study	Study with 15 nurses in hospital management in Brazil		Team strength is a barrier to leadership exercise

TABLE 3: Continued.

Author/year	Method	Description/context	Results	Limitations
(Pishgooie et al., 2019) [75]	Cross-sectional and correlational study	Survey of 1,617 nurses in Iranian government hospitals	Transformational and transactional leadership styles can reduce nurse job stress	Not described
(Player and Burns, 2015) [76]	Descriptive opinion	Discussion on the universality of basic leadership skills	Leadership skills are essential, regardless of the career path; mentoring is a strong motivator	Not described
(Prado-Inzerillo et al., 2018) [77]	Quantitative descriptive study	Survey of 56 hospital chief nursing officers to describe leadership and participation	First study to add to the development of leadership of executive-level nurse leaders in Magnet hospitals	Not described
(Prezerakos, 2018) [78]	Review	Search in electronic databases (PubMed, Scopus, CINAHL) for articles published in English or Greek from 2000 to 2017	Emotional intelligence is a useful tool for nurse leaders and contributes significantly to effective healthcare management	Not described
(Qtait, 2023) [79]	Systematic review of quantitative studies	Study examining the impact of head nurses' leadership styles on nurse performance	Transformational and democratic leadership styles positively impact nurse performance	Not described
(Reyes et al., 2013) [80]	Qualitative study with in-depth interviews	Interviews with 7 directors of nursing about leadership challenges and characteristics during 2008-2010	Challenges include leadership dissonance and leading through ambiguity. Suggests supporting leaders with defined competencies	Not described
(Richey and Waite, 2019) [81]	Organization-wide employee engagement survey	Ann and Robert H. Lurie Children's Hospital/Chicago	The evaluation of data led to the development of the leadership engagement academy (LEA) for frontline nurse managers	Not described
(Saiki et al., 2023) [82]	Cross-sectional study	Assessing the Japanese version of the implementation leadership scale (ILS) among nurse managers and staff nurses	The Japanese ILS is a reliable and valid tool for evaluating leadership in the implementation of evidence-based practice	Not described
(Sandström et al., 2011) [83]	Systematic literature review	Review of leadership and its influence on the implementation process	The review included seven articles and identified three main areas of findings	Not described
(Sharpp et al., 2019) [84]	Interviews and focus groups	Nurse managers' perspectives on technology, communication influence and leadership in the US healthcare system	Nurse leaders need training to fully utilize technology for patient care and management	Participating nurses did not fully share their experiences
(Sherman et al., 2013) [85]	Action-research design for program development and evaluation	Develop and promote an innovative master's degree program in nursing administration for emerging young leaders	Emerging nurse leaders may be well positioned with the right skills to lead in the new era	Not described
(Smamah et al., 2023) [86]	Descriptive correlational cross-sectional study	Examines the relationship between the leadership styles of nurse managers and the motivation and intentions of nurses to change in Jordan	Supportive leadership style scored highest. Positive correlation with nurses' motivation, but no significant correlation with turnover intention	Focus on private hospitals in Jordan, potential self-report bias, limited generalizability

TABLE 3: Continued.

Author/year	Method	Description/context	Results	Limitations
(Spano-Szekely et al., 2016) [87]	Descriptive study to correlate emotional intelligence and transformational leadership practices of nurse managers	Convenience sample of nurse managers at the Magnet 2014/USA conference	Emotional intelligence was positively correlated with transformational leadership	Self-assessment nature of the study
(Swinton and Haverkamp, 2023) [88]	Quality improvement project	Evaluate the effectiveness of nurse leader laboratories in improving leadership competencies among nurse managers	Postintervention increases in emotional intelligence assessment scores and nurse manager skills inventory categories	Small sample size, focus on a specific health system
(Tau et al., 2018) [89]	Quantitative, descriptive, and correlational design	Two questionnaires were used: Wagnild and Young's resilience scale questionnaire and empowering leadership questionnaire	Relationship between nurse manager resilience and leader behavior; high resilience scores linked to greater leader empowerment	Limited to one health sector; individual discussions could provide more in-depth information
(Tyczkowski et al., 2015) [90]	Descriptive and exploratory study design	Study to determine the level and relationship between emotional intelligence and leadership style of nurse managers	Positive relationships found between emotional intelligence and transformational leadership outcomes	Not described
(Valiga, 2019) [91]	Descriptive	Article detailing characteristics of effective leaders and followers, emphasizing leadership outside of managerial positions	Various ways to identify, develop, and strengthen leadership skills	Not described
(Verschuere et al., 2013) [92]	Review on leadership styles	Literature review conducted from January 2000 to September 2011, across multiple databases	A trend suggesting the importance of trust between head nurses and subordinates for positive patient outcomes	Not described
(Walker et al., 2011) [93]	Narrative review	Critical evaluation of selected articles on the influence of leadership on organizational learning and development and undergraduate clinical education	Core leadership factors identified include transformational principles and the role of the nursing unit/CEO	Not described
(Yañez et al., 2016) [94]	Delphi technique	Consensus study among 67 staff members from various hospital services, divided into four groups	Consensus on behaviors displayed by leaders that foster trustworthiness	Not described
(Yoon et al., 2023) [95]	Cross-sectional descriptive online survey design	Study on the mediating effect of patient participation culture between ethical leadership and performance in Korean hospitals	Ethical leadership directly affects performance; patient participation culture partially mediates this relationship	Bias from the self-reported survey and focus on Korean hospitals, limiting generalizability

quality assessment steps, and the use of a nurse manager competency model validated by a broad panel of experts [96].

We identified 339 characteristics of leadership competency, although this number was reduced to 38 after each characteristic was analyzed individually and grouped according to its meaning. In the scientific literature, only one study classifies the characteristics of competencies but differs in how it classifies the characteristics of leadership. For example, the “ethics” characteristic is not included within leadership but rather as

a separate dimension [97]. On the other hand, the analyzed works consistently specify certain specific attributes in the leadership of nurse managers, often not referring directly to leadership characteristics or discussing leadership in a general way without delving into the competence itself [58, 98].

When comparing some of the characteristics identified in this review with those of other studies that discuss competencies, we observed similarities with our findings. Li and Wivatvanit [66] also prioritized characteristics related to the personal domain in their research, such as self-

confidence, serving as a role model for staff, and being innovative and creative. The importance of innovation becomes even more crucial in constantly changing environments, such as healthcare [66].

Our research reveals leadership characteristics related to communication, such as “Being a communicator” and “Listening,” within the Individualized Consideration dimension. In this line of thought, Hopkinson et al. [56] also emphasize communication as a key characteristic in the leadership of nurse managers. Anderson et al. [39] demonstrated how the ability of nurse leaders contributes to creating collaborative environments, reducing costs associated with healthcare, and improving patient safety.

A particularly relevant characteristic that emerges from our research is “knowledgeable,” as it is the fourth most frequent and most frequently cited within the intellectual stimulation dimension. The importance of this characteristic was emphasized by Lehtonen et al. [64], who prioritized the

training of nurse managers in exercising leadership within work teams.

The literature reviewed in this research suggests that nursing leaders must focus on emotional intelligence as one of the fundamental pillars of the leadership of nursing teams, in addition to ensuring care efficiency and patient safety. Bikmoradi et al. [43] echoed this opinion by stating that emotional intelligence is the most relevant aspect that leaders must develop to achieve excellent performance in their work teams.

Furthermore, our research revealed that transformational leadership is predominant in the context of nursing management, with 69.57% of the findings focusing on transformational leadership. This result aligns with those reported by Ferreira et al. [99], Sammut and Scicluna [100], and Duggar [101], who identify transformational leadership as responsible for the best outcomes for nurses and patients, making it suitable for the development of nurse manager roles. Boamah et al. [102] added that transformational leadership exercised by nurse managers is key to nursing team satisfaction, work environment, achieved outcomes, and staff retention.

Regarding the impact of transformational leadership, our research shows that this leadership style is the most relevant for the work environment, the effectiveness of nursing care, conflict management, team commitment, and adaptation to change. Sahan and Terzioglu [103] and Jankeleova and Joniakova [104] point out how transformational leadership has a high impact on all organizational outcomes, especially on job satisfaction of nurses. Lappalainen et al. [63] evidenced a positive correlation between transformational leadership and patient safety.

TABLE 7: Mapping characteristics to transformational leadership dimensions.

Characteristics	Transformational leadership dimension
Care about nurses as individuals	IC
Being a communicator	IC

TABLE 8: Impact and applications of leadership in nursing.

Leadership style	Impact on job satisfaction	Efficiency in patient care	Conflict management	Team commitment	Adaptation to change
Transformational leadership	High	Significantly improved	Effective	Significantly improved	High
Transactional and task-oriented leadership	Moderate to high	Maintained or improved with incentives	Effective with clear structure	Moderate to high	Moderate to low
Contextual and adaptive leadership	Variable	Highly adaptable to changing situations	Variable	Highly adaptable	Very high
Participative and democratic leadership	High	Improved with inclusive decision-making	Very effective in collaborative environments	High	High

Source: own elaboration.

Additionally, Alise [105], in her thesis studies, identifies transformational leadership as responsible for the outcomes of conflict management. Likewise, Bagga et al. [106] show

how transformational leadership is significantly related to change management and organizational culture, aligning with Lewans [107], who points out transformational

leadership as key in the implementation of changes in organizations.

5. Conclusions

This scoping review identified and described the characteristics of the leadership competency required for nurse managers, which is key to advancing health management toward the Sustainable Development Goals (SDGs). A total of 339 characteristics were identified in the 62 articles analyzed, which were synthesized into 38 characteristics and categorized into four distinct dimensions, providing a comprehensive structure for understanding the leadership of the nurse manager.

Five characteristics were identified as the most cited in the literature included in the review: caring for nurses as individuals, being a visionary, knowledgeable, agent of change, and being a communicator. The two most frequently cited characteristics were caring for nurses as individuals and being visionary. This underscores the need for nurse managers to adopt a visionary and person-centered leadership style.

The leadership style mentioned most frequently in this review was transformational, focusing on its impact on the work environment, the effectiveness of nursing care, conflict management, team commitment, and change management. Characterized by being person-centered, motivating, and inspiring, transformational leadership appears to be the most appropriate style for nurse managers, oriented toward the SDGs and changing environments of healthcare systems.

Emotional intelligence in the leadership of nurse managers has emerged as a fundamental pillar for improving the efficiency of the nursing team and patient care, in addition to favoring the achievement of health objectives, reducing conflict, and improving the work environment.

Future research should focus on developing various scenarios in which to train leadership competency, as well as evaluating the development of these competencies. Practical applications include integrating these identified characteristics into training programs for nursing managers to enhance leadership effectiveness and organizational outcomes.

6. Limitations

One limitation of this scoping review is the potential variability arising from the diverse contexts represented in the analyzed articles. Although the research team implemented measures to mitigate this challenge and comprehensively capture the knowledge base, some context-specific nuances may affect generalizability.

Moreover, despite employing multiple databases and search strategies in both English and Spanish, relevant studies published in other languages or gray literature sources may have been inadvertently excluded. This could introduce a potential bias toward the general representation of leadership characteristics and styles in nursing management. However, the research team believes that this risk is minimal given the extensive number of sources consulted in the previous phase of the research. We believe that the

results presented bring us very close to knowledge saturation.

7. Implications for Nurse Managers

This research shows a series of characteristics relevant to the development of leadership competency that could be considered when developing training programs for nursing managers.

Undoubtedly, the identified characteristics constitute a body of knowledge necessary to develop the work of a nursing manager. Given the large number of characteristics and the difficulty involved in developing them, the characteristics identified as most cited represent the minimum characteristics that a nurse manager should develop. This body of knowledge leads to the operationalization of the competencies of person-centered, forward-looking leadership.

Data Availability

The datasets generated during and/or analyzed during the current study are available from the corresponding author upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest with respect to the publication of this article.

Introduction. The outbreak of COVID-19 has led to various challenges for healthcare workers, including nurses. Nurses play a critical role in the fight against this disease, and their communication of self-efficacy and job satisfaction has garnered significant attention. This study aimed to investigate the relationship between communication self-efficacy and job satisfaction of Iranian nurses during the COVID-19 pandemic. **Methods.** This study was conducted using a cross-sectional design. A total of 500 nurses working in hospitals in Iran were selected using a convenience sampling method. The communication self-efficacy scale and the job satisfaction scale were used to collect data. **Results.** The study found that nurses with higher communication self-efficacy exhibited better performance and job satisfaction in various work challenges ($r = 0.56, p < 0.001$). However, nurses holding a master's degree or higher reported the lowest average communication self-efficacy and job satisfaction scores during the COVID-19 epidemic. The study also explored the impact of shift work on job satisfaction among nurses and found that nurses working exclusively on the morning shift reported the highest average job satisfaction score. **Conclusion.** The findings of this study suggest that communication self-efficacy is an important factor in predicting job satisfaction among Iranian nurses during the COVID-19 pandemic. Therefore, it is recommended that healthcare organizations provide effective communication training sessions and mental health interventions to enhance nurses' communication self-efficacy and job satisfaction. This can ultimately lead to improved performance and better patient outcomes.

1. Background

With the outbreak of COVID-19 disease, various issues arose in the personal lives of nurses. Failure to fully follow preventive protocols in caring for COVID-19 patients could have turned the nurse into a carrier of the disease and endangered her family, and early onset of the disease led to feelings of fear and insecurity among nurses and their families [1, 2]. For a long time after the epidemic began, hospital staff neighbors always considered them carriers of the disease and avoided them, which led to more loneliness, fear, feelings of insecurity [3], and sometimes

discouragement and regretted their choice of nursing profession and reduced job satisfaction [1].

1.1. Communication Self-Efficacy in Healthcare. Different functional situations in healthcare centers are often stressful and unpredictable [4], and a person's belief in his ability to master the correct and timely response shows the degree of individual self-efficacy. Communication self-efficacy is defined as a person's belief in his ability to communicate effectively in certain situations and the regulation of the thought processes, motivation, and physiological states required for effective communication in a particular situation.

When assessing communication self-efficacy, people's communication skills are not measured but their confidence that they can successfully use any skill they have to communicate effectively in different communication environments [5, 6].

1.2. Nurse Job Satisfaction. Nurses have a great role to play in promoting global health, so it is necessary to plan and invest to improve their quality of life, which will definitely benefit society. By investing in the working conditions and quality of life of nurses, not only the job satisfaction of the nurse and the improvement of his performance will be provided but also the whole healthcare system and ultimately the whole society will benefit [7, 8].

1.3. Study Rationale. In light of the global COVID-19 pandemic, nurses have emerged as key and indispensable members in the fight against this disease [9]. Given their critical role in healthcare, the communication self-efficacy and job satisfaction of nurses have garnered significant attention [10]. Investigating the relationship between the communication self-efficacy and job satisfaction of nurses in the context of the COVID-19 pandemic can contribute to improving working conditions and enhancing nurses' performance in the fight against this disease [11]. Previous studies have demonstrated that nurses' self-efficacy and job satisfaction are closely linked to the quality of healthcare [12–14]. While context and certain social and physiological factors have the potential to influence the self-efficacy and job satisfaction of nurses, identifying these factors and implementing effective interventions can improve these two critical components. However, previous research has been limited by the use of conventional instruments to measure communication self-efficacy and job satisfaction, as well as a lack of consideration of critical situations like the COVID-19 pandemic. Furthermore, data on communication self-efficacy and job satisfaction among nurses during the COVID-19 pandemic are scarce. Therefore, the present study was conducted with the aim of investigating the relationship between communication self-efficacy and job satisfaction of nurses during the COVID-19 epidemic and the factors affecting these two components in this epidemic.

2. Materials and Methods

2.1. Design. All nurses deployed to Shiraz university hospitals to care for COVID-19 patients were eligible for this anonymous cross-sectional study.

2.2. Study Setting and Population. The research participations were the convenience population from the nursing staff of Shiraz public hospitals who had more than two years of work experience and were employed both before and after the COVID-19 era.

To calculate of sample size, we used the previous study [15], considering a 15% invalid questionnaire rate. Therefore, the final sample size was determined as 346.

2.3. Inclusion and Exclusion Criteria. Nursing staff working in hospitals, with more than two years of continuous work experience in the clinical wards of the hospital, no pregnancy, no long-term leave, and no specific diseases were among the inclusion criteria.

The exclusion criterion was the announcement of the nurse's withdrawal from continuing to participate in the study.

2.4. Instruments

2.4.1. Participants' Demographic Profiles. Participants' demographic profiles included questions about age, sex, marital status, number of children, education level, years of work, care history of COVID-19 patients, etc.

2.4.2. Communication Self-Efficacy during the COVID-19 Epidemic (CSE.C). Questionnaire developed by researchers to measure CSE.C was used. The questionnaire was investigator developed based on an extensive literature review. Issues such as the nurse's ability to motivate the patient to describe his problems and concerns, active listening, appropriate nonverbal behaviors, empathy with the patient, checking the patient's awareness of the given information, and creating a plan based on shared decisions with the patient, etc. are stated in the existing questionnaire [16]. On the other hand, several articles have pointed out the importance of the nurse's ability to manage stress in critical situations, the ability to perform tasks with team coordination in critical situations, the ability to make a correct assessment in unexpected events, etc. In the existing communication self-efficacy questionnaire, these dimensions are not mentioned [17–19]. For this reason, we decided to design special questions to measure the communication self-efficacy of nurses during the COVID-19 era. The CSE.C questionnaire was evaluated with 19 questions with a score of 1 from "not at all sure" with a score of 10 to "absolutely sure" with a score of 1, which assesses a person's perception of competence and ability to deal effectively with stressful situations such as COVID-19 era. The total score of this questionnaire is 19–190, and the higher the score, the higher the self-efficacy.

2.4.3. Job Satisfaction during the COVID-19 Epidemic (JS.C). Questionnaire developed by researchers to measure JS.C was used. The questionnaire was investigator developed based on an extensive literature review. It was necessary to select a questionnaire that would measure the different dimensions of job satisfaction among nurses during the COVID-19 era with the fewest questions. Therefore, based on the review of the literature, the existing questionnaires are either designed only for normal working conditions or for other dimensions of job satisfaction in crisis conditions, such as benefits commensurate with the volume and difficulty of the work, managers' understanding of the efforts and tolerance of the hardships of nursing work, and timely encouragement and appreciation, as well as satisfaction with their ability to

provide quality nursing care to patients with COVID-19, have mentioned a little. Therefore, the research team decided to design a questionnaire to measure the job satisfaction of nurses during the COVID-19 era. JS.C questionnaire was evaluated with 8 questions and six-point scoring from a score of one (strongly disagree) to six (strongly agree).

2.4.4. Reliability and Validity. Questionnaire's face and content validity were evaluated by 9 faculty members in the fields of nursing and health education and promotion. Then, based on their opinions, necessary changes were made in CSE.C questionnaire (CVR 0.78 and CVI 0.79) and JS.C questionnaire (CVR 0.76 and CVI 0.82). The reliability of the tool was evaluated through the retest method, which was completed on two occasions with an interval of two weeks by 21 nurses working in other hospitals. The reliability coefficient of the retest results after two weeks was 0.805 and 0.667, respectively, and Cronbach's alpha coefficient was 0.93 and 0.72 ($P < 0.001$).

2.5. Procedure. In order to collect information, while providing a complete description of the project, the questionnaires were provided to the target group online. At the beginning of the questionnaire, the consent form and the purpose of the project were mentioned that the individual's signature and completion of the information meant the individual's consent to participate in the research.

2.6. Statistical Analysis. The study data were analyzed using the SPSS statistical software, version 26. Data analysis and description of variables were performed using descriptive statistics including mean indices, standard deviation, and analytical statistics including independent *T*-test, ANOVA, and Pearson's correlation tests. $P < 0.05$ was considered as statistically significant.

2.7. Ethical Considerations. Ethical approval was obtained from Shiraz University of Medical Sciences and Shiraz Ministry of Education. Moreover, considering that the data collection was online, the participants were asked to read the full description of the study that we posted at the beginning of entering the site, and if they want to participate, select the option "consent to participate in the study."

Ethics Committee code: (IR.SUMS.SCHEANU-T.REC.1400-068).

3. Results

A total of 500 nurses participated in the study and all completed questionnaires were analyzed. Most participants were female (79.8%), married (61.2%), and had a bachelor's degree (86.8%). Their mean age was 33.74 ± 6.8 years, work experience was 9.49 ± 6.44 years, and 44.6% of them mentioned the history of caring for Covid patients in the hospital.

The results of univariate analysis showed that there is no statistically significant relationship between most of the

demographic and work characteristics of nurses (sex, age, education level, number of children, working years, work shift, and care history of COVID-19 patient) with their communication self-efficacy and job satisfaction. The only statistically significant relationship obtained in this study was between the marital status and communication self-efficacy of nurses. The highest mean score of the communication self-efficacy was obtained for the group of widowed/divorced nurses (164.58 ± 22.84). Despite the lack of significant results for average communication self-efficacy and job satisfaction scores, it should be noted that nurses holding a master's degree or higher reported the lowest average communication self-efficacy and job satisfaction scores during the epidemic, respectively (132.47 ± 32.88 and 27.31 ± 7.21).

The results derived from the job satisfaction scores obtained during the COVID-19 pandemic indicate that nurses working exclusively in the morning shift reported the highest average job satisfaction score (29.21 ± 5.22) (Table 1).

Mean and standard deviation of nurses' CSE.C questionnaire total scores were 142.75 ± 30.41 and JS.C scores of 28.11 ± 6.48 were obtained (Table 2).

Table 3 shows the maximum and minimum average score of the participants' answers to the CSE.C and JS.C questions.

The Pearson's correlation test showed positive and significant relationships between CSE.C and JS.C ($r = 0.254$, $P = 0.000$). Nurses who had higher communication self-efficacy in caring for the COVID-19 patient also reported almost higher job satisfaction during the COVID-19 epidemic. Also, a statistically significant correlation was found between age, work shift, and CSE.C (Table 4).

4. Discussion

This study investigated the relationship between communication self-efficacy and job satisfaction during the COVID-19 epidemic among hospital nurses who worked in Shiraz university hospitals.

4.1. Key Findings

4.1.1. Comparison between CSE.C and JS.C Scores among Participants' Demographic Characteristics. The results showed that CSE.C has a significant statistically relationship with the marital status. In Motahari et al.'s study, married students had higher clinical self-efficacy than unmarried students, which is not consistent with the results of the present study [20]. The findings of Asadpour and Sadat Hosseini's study showed that normal women and men have higher self-efficacy compared to divorced people [21], which is not consistent with the results of the present study. To date, research has not consistently shown that the self-efficacy of widowed and divorced nurses, or other widowed and divorced individuals, is higher than single and married people. However, studies that have implemented educational interventions for these groups have demonstrated positive outcomes in terms of mental health and empowerment [21–23]. It is possible that the high levels of

communication self-efficacy observed in nurses during the COVID-19 pandemic can be attributed to their participation in effective communication training sessions and mental health interventions. Further research is required to confirm this hypothesis.

Nurses holding a master's degree or higher reported the lowest average communication self-efficacy and job satisfaction scores during the COVID-19 epidemic. However, there are no specific studies that provide positive or negative

results regarding this finding. Nevertheless, there are several studies that have investigated factors affecting job satisfaction and burnout among nurses. For example, one study found that job satisfaction was positively related to professional commitment among nursing students during the COVID-19 lockdown [24]. Another study found that job satisfaction was negatively affected by toxic leadership practices among nurses [25]. In addition, a study found that burnout among nurses was related to their level of self-efficacy and job satisfaction [26]. It is important to consider factors such as job satisfaction, self-efficacy, and leadership practices when addressing the well-being of nurses during the COVID-19 pandemic [24–26].

The results indicate that nurses working exclusively in the morning shift reported the highest average JS.C score. Several studies have investigated the effect of shift work on the job satisfaction of nurses. One study conducted in Pakistan found that nurses working rotating shift duties reported lower job satisfaction than those working day shifts [27]. Another study conducted in Italy found that nurses working rotating night shifts reported the lowest mean score in job satisfaction compared to those working day shifts [28]. The available evidence suggests that shift work, particularly rotating night shifts, can have a negative impact on the job satisfaction of nurses. More research is needed to fully understand the relationship between shift work and job satisfaction among nurses during the COVID-19 pandemic.

The results indicated a statistically significant correlation between age and CSE.C. Lim et al. in their study indicated that significantly nurses aged 50 years or more have high self-efficacy [10]. Also, Mehralian et al. in their study on 312 nurses working in a COVID-19 hospital in the south of Iran; they also reached a similar conclusion [29]. Therefore, it can be concluded that age is one of the important factors in nurses' self-efficacy against COVID-19. Older nurses show greater self-efficacy against this disease. This issue can be considered as one of the important components in the planning and management of human resources in the field of nursing.

Finally, the relationship between sociodemographic characteristics of nurses and their self-efficacy and job satisfaction appears to be complex and multifactorial. It is important for nursing managers to consider these factors and construct a monitoring system to reduce negative outcomes and improve job satisfaction and self-efficacy among nurses.

4.1.2. Nurses' Communication Self-Efficacy during the COVID-19 Epidemic. The study findings revealed that the highest average response of the participants to the CSE.C questions was obtained in relation to the question "in any situation, especially critical situations such as caring for a COVID-19 patient, how confident are you in coordinating your duties with the team?" Based on the search results, there is limited information on the confidence of nurses in their ability to perform teamwork in critical situations such as taking care of a COVID-19 patient. However, there are studies that explore the influence of management modes on

TABLE 3: The maximum and minimum average response of the participants to the CSE.C and JS.C questions.

Instrument	Questions	Scores	Mean \pm SD
CSE.C	(i) In any situation, especially critical situations such as caring for a COVID-19 patient, how confident are you in coordinating your duties with the team	Maximum	7.96 \pm 1.93
	(ii) How sure are you that you are successful and capable in preparing a preprepared conversation plan with the patient of COVID-19?	Minimum	6.33 \pm 2.42
JS.C	(i) I am satisfied with my ability to influence quality nursing care of patients	Maximum	4.85 \pm 1.01
	(ii) The salary and benefits received are proportional to the volume and difficulty of my work	Minimum	1.80 \pm 1.33

TABLE 4: Correlation coefficients between research variables ($n = 500$).

Variables	CSE.C	
	r	P
(1) Age	0.094	0.036*
(2) Work shift	0.090	0.045*
(3) JS.C	0.254	0.000**

**Correlation is significant at the 0.01 level (2 tailed). *Correlation is significant at the 0.05 level (2 tailed).

the teamwork ability of nurses [30]. In addition, newly graduated registered nurses working in acute care hospital settings play a critical role in providing safe nursing care, and teamwork is essential in reducing preventable errors and improving safety outcomes [31]. While there is limited information on the confidence of nurses in their ability to perform teamwork in critical situations such as taking care of a COVID-19 patient, teamwork is essential in providing safe nursing care and reducing preventable errors.

The lowest average response of the participants to the communication CSE.C was obtained in relation to the question “how confident are you in your ability to successfully prepare and conduct a preprepared conversation plan with a COVID-19 patient?” There is limited evidence available on nurses’ confidence in developing a conversation plan for critical situations in general. However, some studies have explored the impact of the COVID-19 pandemic on communication in clinical settings and the use of communication strategies in online teaching and learning during the pandemic. Communication was slightly affected during the pandemic, especially nonverbal communication, with verbal communication maintained and, in some cases, strengthened [32]. In terms of end-of-life care planning, the use of the Supportive and Palliative Care Indicators Tool (SPICT) for hospital admissions and the application of education in topics related to end-of-life care resulted in a significant improvement in renal nurses’ perception of confidence in their ability to recognize end of life [33]. While there is limited information available on nurses’ confidence in developing a conversation plan for critical situations in general, studies have explored the impact of the COVID-19 pandemic on communication in clinical settings and the use of communication strategies in online teaching and learning during the pandemic. In addition, studies have explored the use of tools such as SPICT to improve nurses’ confidence in recognizing end-of-life care needs.

4.1.3. Nurses’ Job Satisfaction during the COVID-19 Epidemic. The highest average response of the participants to the JS.C questions was obtained in relation to the question “I am satisfied with my ability to influence quality nursing care of patients?” A study conducted in Quebec, Canada, found that nurses caring for COVID-19 patients reported high chronic fatigue, poor quality of care, lower work satisfaction, and higher intention to leave their organization [34]. However, another study found that nurse-led multidisciplinary team care, training, and development, appropriate skill mix, quality, and outcome of care can lead to improved nurse-patient relationships and increased satisfaction with the quality of care provided [35]. Effective communication and support for nurses are crucial in providing quality care to COVID-19 patients. It is also important to address concerns about nurse-led care and provide evidence regarding patient safety, clinical outcomes, cost, and patient satisfaction to reflect on the ability of nurses to provide high-quality care within the primary care setting [36].

The lowest average response of the nurses to the JS.C questions was obtained in relation to the question “the salary and benefits received are proportional to the volume and difficulty of my work during the COVID-19 pandemic.” One study found that financial factors, such as monthly salary or bonuses, had no or little impact on work motivation during the pandemic [37]. It appears that the impact of COVID-19 on nurse salaries and benefits is complex and multifaceted, with various factors affecting compensation and job satisfaction. This emphasizes the importance of nursing organizations playing an active role in advocating for the profession and ensuring that nurses’ voices are appreciated in the healthcare system.

4.1.4. Correlation Relationship between CSE.C and JS.C.

The correlation results showed a positive and significant relationship between CSE.C and JS.C in the nurses under study. The results of studies conducted on employees of different jobs showed that self-efficacy is one of the factors affecting job satisfaction [12, 38–40]. Similar results were obtained in the studies of Klassen et al. on 1430 Canadian teachers [41], and Darvish et al. on 100 Tabrizi-Iranian nurses [42]. People who believe in their abilities act well in the face of challenging situations, which will make them feel productive and increase their job satisfaction. Nurse self-efficacy is a key factor in how to care the patient and his job satisfaction. The nurse’s performance during stressful situations such as the COVID-19 epidemic may overshadow the

individual's self-efficacy. A reasonable understanding of the consequences of COVID-19 in nurses and anticipation of possible measures to deal with these consequences is important in their effective management [3].

4.2. Practical Implications. The results of this current study can furnish substantial evidence for nursing managers, decision-makers, and policymakers in the nursing field, augmenting their knowledge of the factors that influence nurses' communication self-efficacy and job satisfaction. Moreover, this study can serve as a commendable initial step towards designing and implementing programs aimed at enhancing nurses' communication self-efficacy and job satisfaction. In addition, as this study was conducted during the COVID-19 pandemic, its outcomes can provide a reliable benchmark for future research, both during and after critical situations and for studies conducted under normal and non-critical circumstances.

4.3. Limitations and Future Research. To increase the generalizability of the results, future research should be improved with a more balanced mix of male and female nurses. Also, the tool used in this study was a self-report questionnaire that could potentially impair data quality due to social desirability. Despite the limitations, in the present study, two questionnaires of self-efficacy and job satisfaction were developed during COVID-19 and, according to their validity and reliability, can be used in similar epidemics.

5. Conclusions

The relationship between sociodemographic factors and nurses' self-efficacy and job satisfaction is complex and multifactorial. Therefore, nursing managers need to take these factors into account and establish a monitoring system to improve job satisfaction and self-efficacy among nurses. In addition, factors such as widowhood, divorce, shift work, and communication strategies can affect nurses' job satisfaction and self-efficacy during the COVID-19 pandemic. Furthermore, nursing organizations need to advocate for the profession and ensure that nurses' voices are heard in the healthcare system. Finally, the age of nurses appears to be an important factor in their self-efficacy against COVID-19, with older nurses showing greater self-efficacy. This finding can be considered in the planning and management of human resources in the nursing field. Overall, an understanding of the complex factors affecting nurses' job satisfaction and self-efficacy is crucial for effective management and care during the COVID-19 pandemic.

Data Availability

The data used to support the findings of this study may be released upon application to the Department of Health Education and Health Promotion, who can be contacted at healthpromotion.sums@gmail.com.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

The authors thank the Vice Chancellor for Education of Shiraz University of Medical Sciences and all the nurses who participated in the study. Dr. Zahra Jamshidi from Shiraz University of Medical Sciences is also appreciated for her valuable cooperation in informing nurses to participate in the research. This study was financially supported by Shiraz University of Medical Sciences (no. 24434).

Background. Compared to nurses in other hospital departments, intensive care unit (ICU) nurses have more frequent exposure to patient deaths, potentially rendering them more susceptible to experiencing professional grief following patient fatalities. **Objective.** To explore the coping experiences of ICU nurses following their encounter with professional grief. **Methods.** This study utilized a qualitative research design based on Heideggerian phenomenology. A purposive sample of 18 ICU nurses was selected from six tertiary hospitals in Guangdong Province, China. Individual semistructured interviews were audio-recorded and transcribed verbatim. The transcribed texts were analyzed using interpretative phenomenological analysis. **Results.** Two main themes emerged: (1) short-term dual coping with professional grief and (2) long-term cumulative changes from professional grief. These themes reflect the dynamic coping processes experienced by ICU nurses amidst frequent encounters with loss and grief during their clinical work. **Conclusions.** ICU nurses employ both adaptive and maladaptive coping strategies to address professional grief, significantly impacting their personal and professional well-being. It is advisable to offer targeted education and organizational support systems for ICU nurses to promote positive cumulative growth when they repeatedly encounter patient deaths.

1. Introduction

Professional grief, within the healthcare context, refers to the emotional distress experienced by healthcare practitioners following patient deaths during clinical practice [1]. This distress often presents with symptoms such as sadness, self-blame, insomnia, decreased appetite, and intrusive thoughts about death [1]. Due to the unique nature of the relationship between healthcare professionals and patients, the professional grief they undergo, distinct from familial grief, is often characterized as disenfranchised grief—not widely recognized or accepted by the general public [2]. Data from the Societies of Intensive and Critical Care reveal that the

global average mortality rate for intensive care unit (ICU) inpatients falls within the range of 10% to 29% [3]. Compared to their counterparts in other hospital departments, ICU nurses are more frequently exposed to patient deaths, making them more susceptible to experiencing professional grief [4].

Existing research emphasizes the inevitability and prevalence of professional grief among healthcare professionals [1, 4]. For example, Papadatou et al. [5] conducted semistructured interviews with 63 oncology and ICU nurses caring for terminally ill children in Greece and Hong Kong, revealing that 93% of nurses had experienced grief following patient deaths. Faced with professional grief, many

healthcare professionals resort to maladaptive coping strategies, such as avoiding direct exposure to death and death-related environments [6, 7], evading communication with patients' families [6, 7], and turning to substance abuse to manage psychological stress [8]. While some studies investigate adaptive coping mechanisms employed by healthcare professionals in professional grief, such as openly expressing their emotions [9, 10], engaging in recreational activities [7, 10], or seeking support from family [7, 9, 10], these studies lack an in-depth exploration of the psychological coping mechanisms used by healthcare professionals in professional grief and the potential long-term impacts on their personal and professional lives.

To date, the majority of research on professional grief among nurses has been concentrated in Europe and North America, with relatively limited participation from non-Western regions [1]. In China, the nursing profession faces challenges such as low societal recognition, demanding workloads, and strained nurse-patient interactions [11]. Consequently, the professional grief experienced by nurses is often marginalized or inadequately addressed [10]. This study employed a phenomenological research approach with the aim of comprehensively analyzing the coping experiences of Chinese ICU nurses in the face of professional grief. The goal is to enhance the conceptual model of professional grief among healthcare professionals in a cross-cultural context and facilitate managers in devising intervention strategies to address professional grief.

2. Methods

2.1. Study Design. This phenomenological study was conducted within the hermeneutic paradigm proposed by the German philosopher Martin Heidegger (1889–1976) [12]. Heidegger's perspectives primarily focus on elucidating the essence of existence, emphasizing an understanding of the modes of existence and the intrinsic meaning of existence itself, rather than solely concentrating on the surface phenomena of objects [13]. To facilitate operational procedures, we employed Jonathan A. Smith's developed method known as the Interpretative Phenomenological Analysis (IPA) framework [14]. The reporting of this study adhered to the Consolidated Criteria for Reporting Qualitative Research (COREQ) checklist [15].

2.2. Study Participants. From October 2020 to May 2021, ICU nurses were recruited through purposive sampling from six tertiary hospitals in Guangdong Province, China. Inclusion criteria comprised possessing a valid nursing license, a minimum of 6 months of ICU experience, and previous exposure to patient deaths. Exclusion criteria included refusal to participate in the study, being on vacation, and the presence of severe physical or mental illnesses. IPA research involves a meticulous analysis of cases, typically conducted within a small sample size of around 10 cases [14]. Smith et al. also suggested that determining the sample size should be pragmatic, considering the depth and breadth of the study, rather than adhering to fixed standards [16].

Following the fundamental principle of "data saturation" [17], researchers conducted in-depth interviews with 12 ICU nurses from a single hospital. Subsequently, interviews were extended to include 6 ICU nurses from five additional hospitals, concluding recruitment upon confirmation that no new themes or codes emerged.

2.3. Data Collection. The first and second authors conducted individual face-to-face interviews with participants in a quiet lounge after their work hours. The interview guide, developed through a literature review, expert consultation, and pilot interviews with four ICU nurses, included the following questions: (1) Could you share your most memorable experience involving a deceased patient during your ICU work? (2) What internal feelings arise when confronted with patient deaths? (3) Have you employed strategies to alleviate these feelings, and how effective were they? (4) When saddened by a patient's passing, what support mechanisms are available to you? (5) How have your reactions and coping strategies evolved since your initial encounter with patient deaths? The interviews varied in duration from 42 to 96 minutes, with an average interview time of 58 minutes. All interviews were recorded and transcribed verbatim. Both interviewers meticulously reviewed the transcripts for accuracy, providing interviewees with the opportunity to verify and validate their statements.

2.4. Data Analysis. The analytical process was subjected to IPA, wherein a meticulous idiographic analysis was prioritized on a case-by-case basis, followed by the exploration of patterns across cases [16]. Following the six-stage process outlined in the IPA research guidelines [14], each complete transcript was thoroughly and repeatedly read line-by-line, annotated to develop emergent themes and explore connections between emerging themes. This process was iteratively applied to review all remaining cases, identifying patterns across cases and determining themes and sub-themes reflecting the experiences of all participants. The first author led the analysis, with each step reviewed and verified by the corresponding authors. The final analysis underwent scrutiny by all other team members, ensuring consensus on the overall interpretation of interviews and contributing to the ultimate findings. NVivo version 12.0 was utilized for data management and analysis assistance.

2.5. Trustworthiness/Credibility. The first author, who has previously interned in the ICU, established positive relationships with participants, facilitating the sharing of sensitive experiences related to professional grief. Before formal interviews, researchers extensively practiced using the interview guide and conducted pilot interviews to refine their interview skills. Both the first author and corresponding authors received standardized training, possessed rich qualitative research experience, and employed a systematic approach to iteratively analyze transcripts. Throughout the analysis process, researchers engaged in continuous self-reflection, questioning data, and existing

knowledge to ensure the validity of interpretations without undue stretching or overinterpretation. In addition, they actively sought review and validation from team members and participants to ensure the accuracy and reliability of the study results.

2.6. Ethical Considerations. The study received ethical approval from the Southern Medical University Ethics Committee (No. 2020–16). Participants were informed about the study's purpose and gave written informed consent. Participant identities are anonymized using numerical codes. Audio recordings and transcribed data are securely stored in password-protected files, accessible only to research team members.

3. Results

3.1. Participant Characteristics. A total of 18 ICU nurses, comprising nine males and nine females, participated in this study. The participants' ages ranged from 23.0 to 37.0 years (mean age of 30.0 years), and their average tenure in ICU nursing was 7.3 years. Among the participants, 4 were supervisor nurses, and 1 held a master's degree. None of the participants reported having any religious beliefs, and none had received professional training related to grief adjustment. The characteristics of the participants are presented in Table 1.

3.2. Emerging Themes and Subthemes. The coping experiences of ICU nurses with professional grief were identified as two themes, comprising six subthemes and 42 codes. The results are presented in Table 2.

3.2.1. Short-Term Dual Coping with Professional Grief

(1) Avoidance of Death and Confrontation with Death. For the majority of ICU nurses, the experience of encountering patient deaths was a significantly stressful event. Consequently, they often chose to avoid direct contact with dying or deceased patients, refrained from interacting with patient families during mourning scenes and sidestepped discussions regarding patient death.

N4: "My main focus was on the medical condition, and I preferred not to delve into discussions about information connected to patient death."

N8: "I didn't want patients to pass away while I was on duty. If I could hand over the shift to someone else, it was a relief."

N15: "I chose to avoid, trying not to hear the cries of the family members."

In contrast, some nurses attempted to derive meaning from patient deaths by rationalizing them as liberation, finding solace in destiny-based explanations for death, or believing themselves to have fulfilled their caregiving

responsibilities. Moreover, a few nurses chose to bid farewell to deceased patients, accompanying them through their final moments as a means of completing the mourning process.

N1: "He's finally at peace, no more suffering."

N7: "I just stood there silently, watching her, accompanying her through the final moments of her life..."

N13: "Everyone has their own fate; you have to believe in it."

N18: "I feel like I have a clear conscience; I've provided the best care to the patient."

(2) Psychological Detachment and Psychological Adjustment. Three nurses reported proactively disengaging from their duties and taking a break in the relaxation area after completing postmortem care. Simultaneously, the majority of ICU nurses actively disengaged from work after their shifts, deliberately avoiding contemplation of work-related matters to prevent further interference with feelings of grief.

N3: "when I'm off duty, I don't want to bring these emotions home."

N16: "As I left the ward environment and entered the living area, I gradually underwent a process of detachment."

Nevertheless, participants also recognized that, at times, they faced challenges in completely disengaging from the negative emotions associated with patient deaths. In these instances, they made efforts to mitigate their grief through distraction techniques, including engaging in conversations, participating in leisure activities, or indulging in retail therapy.

N12: "I tried chatting with colleagues or doing something else, just to quickly divert my attention."

N13: "I went for walks, watched movies, and did some shopping, all just to forget about these things."

(3) Social Withdrawal and Support Seeking. After experiencing the death of a patient, some ICU nurses exhibited a strong desire for solitude. They temporarily withdrew from social and recreational activities, declined unnecessary interactions with others, and lost interest in the external world.

N2: "The entire world seemed gray; I became quieter. Even when I walked on the street after work, I didn't want to look around."

N6: "I didn't feel like talking; I just wanted to find a quiet place to be alone, and it was better if others didn't bother me."

ICU nurses had often attempted to seek support from colleagues and family members to express or release their own grief. However, this support sometimes remained on

TABLE 1: Characteristics of study participants ($n = 18$).

Number	Gender	Age, years	Employment duration in the ICU, years	Positional title	Educational background	Marital status	Psychological acceptance of patient deaths
N1	Female	31	5	Senior nurse	College degree	Unmarried	Moderate
N2	Female	24	2	Registered nurse	College degree	Unmarried	Moderate
N3	Male	30	8	Senior nurse	Bachelor's degree	Married	Unacceptable
N4	Male	32	8	Senior nurse	College degree	Married	Somewhat acceptable
N5	Female	25	4	Registered nurse	College degree	Unmarried	Somewhat acceptable
N6	Female	36	16	Senior nurse	Bachelor's degree	Married	Moderate
N7	Male	37	14	Nurse supervisor	College degree	Unmarried	Moderate
N8	Female	28	8	Supervisor nurse	Bachelor's degree	Married	Moderate
N9	Female	27	1	Senior nurse	College degree	Married	Moderate
N10	Female	37	13	Senior nurse	College degree	Married	Somewhat acceptable
N11	Male	32	11	Senior nurse	Bachelor's degree	Married	Somewhat acceptable
N12	Female	35	14	Supervisor nurse	Bachelor's degree	Married	Moderate
N13	Male	23	3	Registered nurse	College degree	Unmarried	Somewhat acceptable
N14	Male	25	3	Registered nurse	College degree	Unmarried	Moderate
N15	Male	28	4	Registered nurse	Bachelor's degree	Unmarried	Moderate
N16	Female	34	10	Supervisor nurse	Master's degree	Married	Moderate
N17	Male	27	2	Registered nurse	Bachelor's degree	Unmarried	Somewhat acceptable
N18	Male	29	6	Senior nurse	Bachelor's degree	Unmarried	Moderate

TABLE 2: Themes, subthemes, and codes.

Themes	Subthemes	Codes
Short-term dual coping with professional grief	Avoidance of death and confrontation with death	(i) Avoidance of deceased patients/avoidance of dying patients/avoidance of patient families/avoidance of mourning scenes/avoidance of discussions on death (ii) Patient's relief from suffering/family's relief from distress (iii) Fate's interpretation (iv) Clear conscience/voluntary farewell/voluntary mourning
	Psychological detachment and psychological adjustment	(i) Maintaining distance from work/forgetting work-related matters/taking a short break (ii) Relaxing oneself/shifting attention
	Social withdrawal and support seeking	(i) Self-isolation/diminished interest (ii) Family support/friend support/colleague support/leadership support
	Cherishing life and existential meaningfulness	(i) Valuing health/valuing quality of life/changing priorities/enjoying the present/spending time with family (ii) Worthlessness of life/meaninglessness of life/lack of life goals
Long-term cumulative changes from professional grief	Emotional resilience and emotional exhaustion	(i) Familiar situation/inner calmness/rapid adjustment (ii) Emotional numbness/empathic fatigue/emotional absence
	Professional development and occupational burnout	(i) Medical knowledge and skills/end-of-life care/grief counseling (ii) Depersonalization/reduced accomplishment/intentions to leave

the surface, and inappropriate consolation or less-than-ideal reactions left ICU nurses feeling isolated.

N6: *"I used to talk to my mom when I first started working, but later she said, 'Why is your department so scary?' so I stopped talking to her about it."*

N11: *"I talked to the head nurse about my fears, and she said, 'You'll get used to it after seeing it more.'"*

3.2.2. Long-Term Cumulative Changes from Professional Grief

(1) *Cherishing Life and Existential Meaninglessness.* ICU nurses transitioned from initial anxiety about death to valuing health, embracing the present moment, and cherishing relationships with loved ones. This transformation reflects an awakening derived from their experiences of grief. They also contemplated their own death, desiring to make rational end-of-life arrangements for the future, leading towards a death with a high quality of life.

N1: *"Having witnessed patient deaths, I now understand the importance of being there for family."*

N9: *"Taking care of my health, living each day to the fullest; who knows what the future holds? If I have a choice, I hope not to experience too much pain at the end of life."*

Some nurses had witnessed numerous patients teetering on the edge of life and death, eventually succumbing to their fate, leading to nurses feeling a profound sense of helplessness. Faced with the fragility and unpredictability of life, these nurses engaged in deep reflections on the meaning and value of existence. This contemplation led these nurses to adopt the conviction that life is transient, potentially causing them to lose sight of life goals and perhaps slipping into a sense of existential nihilism.

N8: *"Life is so difficult, and I don't even know what people are living for."*

N10: *"I feel like there are not many joyful things in life, and I don't want to strive for a lot of things; it doesn't seem meaningful."*

(2) *Emotional Resilience and Emotional Exhaustion.* Most ICU nurses indicated that, after repeatedly experiencing patient deaths in their work, their emotions were not as profoundly affected as when they first started. They were able to quickly adjust their emotions within a short period.

N3: *"After putting in years on the job, I've gotten pretty good at handling my emotions on my own. It's been working out quite well."*

N18: *"Back in the day, it used to take me over two weeks to shake off a bad mood, but these days, I can bounce back right after wrapping up my shift."*

Moreover, several interviewees mentioned encountering emotional fatigue in the face of patient deaths. They exhibited a reduced sense of empathy towards the families of patients, experienced a decline in the intensity of professional grief, or even reported a complete absence of such feelings.

N5: *"The deaths of patients don't affect me as much anymore; I recognize that they're reaching the end, and I don't experience strong emotions about it."*

N9: *"Having witnessed numerous resuscitations and gone through so many, I've developed emotional numbness."*

(3) *Professional Development and Occupational Burnout.* Most ICU nurses drew lessons from cases of patient deaths, focusing on enhancing their professional skills to effectively handle similar medical situations. They also reflected on their inadequate abilities in end-of-life care and grief counseling but strove to maintain the dignity of patients and fulfill the requests of grieving families to the best of their ability.

N8: *"In most cases, we find ourselves at a loss for words when facing family members... striving to fulfill their wishes to the best of our ability."*

N17: *"(Reflecting on a patient's death) The challenges in these situations force me to grow up fast; I become more careful and detailed in observing the medical condition."*

In the busy environment of the ICU, nurses often found themselves too occupied to attend to their own grief. As a result, they intentionally maintained emotional distance from patients, mechanically adhering to established caregiving procedures. In addition, nurses expressed an inclination to transition to departments with reduced exposure to patient deaths or to consider leaving the nursing profession altogether.

N1: *"I feel like I'm being a robot, going through the same process day after day, taking care of one patient, and then the next, in a repetitive cycle."*

N10: *"After working in the ICU for a long time, I want to change the work environment, dealing with patients who can move and speak."*

4. Discussion

4.1. *Main Findings.* To the best of our knowledge, this is the first qualitative research conducted in mainland China that specifically investigates the professional grief experienced by ICU nurses. Our research synthesizes the dual coping strategies employed by ICU nurses within the Chinese cultural context, focusing on dealing with death, psychological adjustment, and external support. In addition, our findings highlight the cumulative impact of professional grief on both the personal and professional

lives of ICU nurses, addressing the scarcity of evidence regarding ICU nurse professional grief in non-Western regions [1].

4.2. Comparing Study Findings with Relevant Professional Grief Models. In this study, ICU nurses commonly experienced grief due to patient deaths and employed various adaptive coping mechanisms, such as rationalizing death, bidding farewell proactively, and psychological detachment. Some nurses, however, tended to adopt maladaptive coping strategies, including death avoidance and social withdrawal, in response to professional grief, aligning with the Model of Health Professionals' Grieving Process proposed by Papadatou [18]. Nevertheless, in contrast to this model, we argue that the construction of meaning around patient death and behaviors like self-adjustment and seeking support are coping strategies for professional grief, rather than outcomes of the grieving process or consciously completed tasks. Furthermore, the cumulative effects of repeated encounters with professional grief, whether positive or negative, align with the Professional Grief Integration Model by Chen et al. [1], where the cumulative experiences of multiple patient deaths eventually have long-term personal and professional consequences for healthcare providers. In our study, while discerning shifts in the perspectives of ICU nurses on life and death, there is minimal discourse regarding transformations linked to religious beliefs. In contrast to Western nations, the religious ambiance in Chinese society is relatively subdued [10]. Embedded within traditional Chinese culture is the notion that "life and death are predestined, and wealth and poverty are heaven's arrangement," significantly influencing individuals' attitudes towards life and death [10]. This inclination tends to foster a preference for embracing reality over seeking solace through religious faith.

4.3. ICU Nurses Lacking Support to Cope with Professional Grief. After experiencing patient deaths, ICU nurses frequently found themselves confronted with a shortage of adequate professional resources to cope with their grief—a situation pervasive in many healthcare systems [6, 19]. In response, they often resorted to employing self-distraction strategies, suppressing their grief and emotions to fulfill their professional duties [20]. While this self-protective mechanism may offer some short-term relief, the accumulation of unaddressed grief over time poses the risk of leading to professional grief overload among ICU nurses [21]. Despite their attempts to confide in colleagues or family members for support, the cultural taboo surrounding death often stigmatizes discussions about mortality and grief, deeming them as inauspicious or inappropriate topics [10]. This, in turn, leaves nurses feeling isolated and helpless, deprived of the emotional support they urgently require [10]. In light of these challenges, it becomes imperative for healthcare institutions to prioritize the monitoring of the emotional well-being and psychological state of ICU nurses and to provide resources and channels that facilitate professional grief relief for them [21].

4.4. ICU Nurses Undergoing Negative Cumulative Changes from Professional Grief. This study revealed that ICU nurses, when exposed to prolonged instances of patient deaths, tended to experience emotional exhaustion and a decline in empathy towards both patients and their families. Some ICU nurses adopted a strategy of limiting emotional involvement, delivering care in a more mechanical manner to alleviate professional grief. While this approach can mitigate professional grief to some extent, it may lead to an insufficient provision of humanistic care for patients and their families, a decrease in nursing quality, and diminished job satisfaction among ICU nurses, ultimately resulting in a loss of nursing talent [22]. Our research found that these adverse cumulative changes were notably influenced by maladaptive coping strategies employed by ICU nurses in the face of patient deaths. Conversely, adaptive coping strategies resulted in a positive perspective on life and death, improved interpersonal relationships, and significantly enhanced self-emotional regulation abilities. Therefore, it is crucial to acknowledge the emotional shifts and psychological states experienced by ICU nurses, especially those with limited experience [23], and guide them in redefining the meaning of life and death through their losses and fostering personal reflection and growth.

4.5. Study Limitations. This study has several limitations. First, being a phenomenological study, our objective is exploratory rather than confirmatory, delving into the in-depth examination of grief coping experiences among ICU nurses—experiences that often go unnoticed. To ascertain variations in their professional grief coping and its evolutionary processes, further investigation with a larger sample of ICU nurses is imperative. Second, the researchers, serving as the investigative tool, may introduce interviewer bias. To ensure credibility, we engaged in self-reflection, avoiding the impact of a priori assumptions, and employed the triangulation method for data collection and analysis [24]. Third, although interviews were conducted in 2021, data analysis was not completed until 2023, potentially resulting in a lag in data information. Fourth, our interviews took place during the COVID-19 pandemic. During this unique period, strict infection control measures were in place, and healthcare professionals experienced increased workloads. These factors may have affected participants' availability and psychological resilience, potentially making them feel more stressed or fatigued during the study. Finally, our study was conducted exclusively in Guangdong Province, China. While our findings align closely with research on healthcare professionals' professional grief in other regions, caution should be exercised when generalizing the results.

5. Conclusion

In summary, ICU nurses employ adaptive or maladaptive strategies to navigate professional grief, resulting in subsequent positive or negative cumulative changes in both their personal and professional lives. It is imperative to guide ICU nurses in recognizing and expressing their professional

grief, provide formal organizational support, and offer professional psychological counseling to promote their adaptive coping and personal growth. Further research with larger sample sizes and across multiple regions is recommended to develop and evaluate interventions facilitating ICU nurses' coping with grief when confronted with patient death.

Data Availability

The datasets analyzed during the current study are not publicly available due to privacy issues of participants but are available from the corresponding author on reasonable request.

Disclosure

The funders had no involvement in the study design, data collection and analysis, manuscript preparation, or decision to publish.

Conflicts of Interest

The authors declare that there are no conflicts of interest regarding the publication of this paper.

Authors' Contributions

Zhengmin Zhang conceptualized the study, performed data curation, proposed the methodology, conducted interview data acquisition, analyzed the study, wrote the original draft, and reviewed and edited the manuscript. Manyi Gao was responsible for interview data acquisition, proposed the methodology, analyzed the study, and reviewed and edited the manuscript. Zejian Fang and Xin Chen analyzed the study and reviewed and edited the manuscript. Qiaoqiao Shen conceptualized the study, proposed the methodology, analyzed the study, wrote the original draft, and reviewed and edited the manuscript. Yulin Gao performed project administration, provided resources, proposed the methodology, analyzed the study, and reviewed and edited the manuscript. Zhengmin Zhang and Manyi Gao contributed equally to the work and should be recognized as co-first authors. Likewise, Yulin Gao and Qiaoqiao Shen contributed equally to the work and should be regarded as co-corresponding authors.

Acknowledgments

The authors express our gratitude to all interviewed nurses. This work was supported by the China Academic Degrees and Graduate Education Development Center (No. 2020MSA385) and the College Students' Innovation and Entrepreneurship Training Program (No. S202212121148).

Background. The study investigates critical care nurses' perceptions of medication administration errors (MAEs) in a tertiary hospital in Kelantan, Malaysia, within the unique sociocultural context of East-Coast Malaysia. The research aims to understand the causes and underreporting of MAEs and assess the proportion of reported incidents according to MAE types. **Methods.** A cross-sectional study involving 424 critical care nurses from Hospital Raja Perempuan Zainab II (HRPZII), Hospital Sultan Ismail Petra (HSIP), and Hospital Tanah Merah (HTM) was conducted. Nurses in administrative roles or unavailable during the survey period were excluded. The study utilized a validated Medication Administration Errors Survey questionnaire to gauge nurses' perceptions on the causes of MAEs, reasons for underreporting, and the percentage of reported incidents based on MAE types. **Results.** Results indicate that illegible medication orders from doctors were identified as the primary cause of MAEs, while a lack of 24-hour pharmacist availability received the lowest score. The most common reason for not reporting MAEs was identified as the nursing administration's focus on individuals rather than systemic issues when errors occur. The majority of MAEs were non-intravenous, with incorrect timing of administration being the leading cause. **Conclusion.** The study sheds light on critical care nurses' perspectives on MAEs in a Malaysian hospital setting, highlighting key factors contributing to these errors and barriers to their reporting. Understanding these perceptions is crucial for developing strategies to mitigate MAEs and enhance patient safety in critical care environments.

1. Background

Medication administration errors (MAEs) are defined as “a deviation from the prescriber's medication order as written on the patient's chart, manufacturers' preparation/administration instructions, or relevant institutional policies” [1]. MAEs are a major concern in the nursing sector, resulting from inconsistencies between the medication delivered to patients and the intended medical therapy prescribed by healthcare practitioners [2]. In the United States alone, drug-related incidents kill between 7,000 and 9,000 people each year [3]. Medication errors can have serious consequences, such as increased patient mortality, extended hospitalization times, and increased medical costs [4–6]. Medication errors are predicted to cost the world USD 42 billion per year [7].

The major reason for reporting such errors was concern about patient safety [8]. The goals of World Patient Safety Day are to educate the public, motivate action, and encourage governments to prioritize patient safety in health-care systems worldwide. On September 17, 2022, World Patient Safety Day was honored with the theme “Medication Safety,” highlighting the necessity of ensuring that medications are safe for patients to use [9]. The program aimed to eliminate unnecessary adverse drug reactions by consolidating the World Health Organization's Global Patient Safety Challenge: Medication without Harm [10].

The five “rights” linked with the safe and effective administration of medicines are the “right patient,” “right medication,” “right time,” “right dose,” and “right route.” Errors when delivering medications to patients often violate

one or more of these rights [11]. The five “rights” have been firmly established in nursing education as standard guidelines for ensuring safe and effective medication delivery. However, new study has highlighted the concept that medication administration is merely one component of a larger and more complex pharmaceutical utilization process [3, 12]. As a result, four new “rights” were proposed: right documentation, right action/reason, right form, and right reaction [13]. Medication errors are more common in high-volume care settings including emergency rooms and intensive care units [14].

The fear of experiencing negative consequences associated with reporting and undergoing disciplinary actions, the fear of being held accountable, the fear of the response from nurse management and colleagues, and the fear of job loss all influence nurses’ attitudes toward reporting medication errors [15]. The act of reporting medication errors is critical to properly resolving these situations because it facilitates knowledge learning among healthcare personnel and raises medication safety awareness [16]. Multiple factors, including insufficient professional experience, participation in night shifts, poor on-the-job training, the absence of preestablished protocols for medicine administration, and interruptions during administration procedures, have shown statistically significant relationships with medication administration errors [17]. Medication errors are more likely in the context of intravenous therapy [18].

Nurses spend 40% of their time on medication administration, making them crucial in the healthcare system as the last checkpoint before giving medications. Nurses need to detect and correct errors in keeping with their professional, legal, and ethical responsibilities [19]. The ongoing concern about medical delivery errors remains a significant feature in the goal of patient safety [13]. Identifying a persistent root cause of errors and subsequently devising a good solution that significantly minimizes the likelihood of their recurrence is a substantial and tough challenge [3].

Nurses play an important role in facilitating medication administration to patients in the hospital setting [20]. The study setting still relies on conventional paper-based methods for prescription of the medications. Nurses in critical care units at a tertiary hospital in East-Coast Malaysia are likely to speak Malay at home and at work [21]; this study aims to learn their perspectives on the factors that lead to MAEs and why some of them choose not to report them. In order to fulfil healthcare needs, Malaysia uses both locally branded medications and medications imported from other nations, such as Pfizer, as per the National Pharmaceutical Regulatory Agency (NPRA) [22]. Because of the scarcity of local study on MAEs among nurses, the current study takes advantage of this information gap. As a result, the study’s objectives are to assess critical care nurses’ perceptions of the causes of MAEs and the reasons for not reporting MAEs, as well as the percentage of reported non-intravenous and intravenous-related MAEs.

2. Materials and Methods

2.1. Study Design and Participants. Over a period of two months beginning in February 2023, a cross-sectional survey was undertaken among critical care nurses registered and employed at tertiary institutions in Kelantan, Malaysia. The study involved three tertiary hospitals: Hospital Raja Perempuan Zainab 2 (HRPZII), Hospital Sultan Ismail Petra (HSIP), and Hospital Tanah Merah (HTM).

The sample size was calculated using a single mean calculation according to study conducted by You et al. [23]. The lists of critical care nurses were obtained from the nursing units of each hospital. The participants were chosen at random in proportion to the quantity of nurses available during the study. There were 424 critical care nurses in all, including 276 from HRPZII, 121 from HSIP, and 27 from HTM. The inclusion criteria for this study consisted of registered nurses who were directly involved in providing patient care and had a minimum employment duration of six months at each unit. Additionally, in order to keep our emphasis on evaluating staff who interact directly with patient care, we purposefully eliminated administrative roles, nurses who were not present during the survey, and nurses who did not provide direct patient care from our consideration.

2.2. Measuring Tool. The Medication Administration Errors Survey, a self-reported questionnaire created by Wakefield et al., was used to assess nurses’ perceptions of MAEs [24]. The questionnaire was approved for use prior to the study’s conduct. It was confirmed, and Cronbach’s alpha value was 0.78. The surveys were divided into three sections: 28 questions on the causes of MAEs; 16 items on why MAEs are not reported; and 20 items on the reported non-intravenous (Brabcová et al.) and IV-related MAEs (9 and 11 items, respectively). Each question in the first two parts was scored on a 6-point Likert scale (1 = strongly disagree and 6 = strongly agree). The result was presented as mean and standard deviation for each item. The third domain was presented as frequency and percentage of type of MAEs, which include non-intravenous and intravenous-related MAEs. They used a 10-point Likert scale. The participants required 10 to 20 minutes to complete the survey.

2.3. Data Collection. The permission to conduct the study was granted by the State Health Director and the director of each of the hospitals. The data collecting method was facilitated by the nursing units. The survey was in English format, but the participants were able to comprehend and respond appropriately. We made sure to get the informed consent of those who were chosen and willing to participate. The questionnaires were collected as soon as the participants completed the survey. Their decisions were not affected by the superior since the procedure occurred in an isolated hall for each hospital involved.

2.4. Data Analysis. The data were entered and analyzed using SPSS ver. 26. Descriptive statistics were used to summarize the result. The mean and standard deviation were used to portray numerical data, considering their normal distribution. Categorical data were reported as frequency and percentage. Multiple logistic regression was used to analyze the variables of age, gender, education level, and job duration, as detailed in the following.

2.5. Ethical Consideration. Ethical approval was obtained from the relevant committees, including Jawatankuasa Etika Penyelidikan Manusia Universiti Sains Malaysia (JEPeM-USM) dated 28th December 2022, bearing the JEPeM Code: USM/JEPeM/22110733, and the National Medical Research Register (NMRR) dated 13th January 2023, with the reference number NMRR ID-22-02882-R29. Strict confidentiality measures were adhered to, and the data analysis and reporting were conducted without revealing participants' identities.

3. Results

3.1. Sociodemographic Characteristics and Job Experience of the Participants. The study involved 424 critical care nurses. Table 1 summarizes the sociodemographic characteristics and job characteristics of the participants in a comparable study by You et al. [23] and Biftu et al. [25]. The mean age was 40.90 ± 6.13 years. Most of the participants are married. The mean work time was 16.83 ± 5.90 years. Most of them worked at Intensive Care Unit (ICU; 39.2%), followed by Neonatal Intensive Care Unit (NICU; 16.3%), Operation Theatre (OT; 15.3%), Emergency Department (ED; 8.3%), Cardiac Care Unit (CCU; 8.0%), High Dependency Ward (HDW; 7.3%), and Paediatric Intensive Care Unit (PICU; 5.7%). Majority of them (79.5%) worked at least 50 hours per week. In their clinical context, 84.9% of the participants reported a nurse-patient ratio of 1:1 to 1:6. Patient safety training was attended by 61.3% of participants. 86.8% of participants were instructed how to administer medications. In contrast, 84.7% and 65.6% of people, respectively, had no prior experience with MAEs, either directly or via observation. The outcome under consideration is critical care nurses' readiness to report MAEs to authorities. Most nurses (60.1%) did not believe errors should be revealed.

3.2. Critical Care Nurses' Perception regarding the Causes of MAEs. Table 2 shows the perception of MAE causes by the critical care nurses. According to the finding, illegible medicine orders from physicians scored the highest items (4.39 ± 1.35) followed by look-alike drugs (4.38 ± 1.47), and package similarity (4.31 ± 1.46) was the third most recognized cause of MAEs. The least cause of MAEs was pharmacists being unavailable for over 24 hours, with a mean value of (1.94 ± 1.20). The remaining items' score ranged from 2.29 to 4.27.

TABLE 1: Sociodemographic characteristics of the participants ($n = 424$).

Variables	<i>n</i> (%)	Mean \pm SD
Age (years)		40.90 \pm 6.13

TABLE 3: The perception of the reasons for not reporting MAEs among critical care nurses in tertiary hospitals, Kelantan (n = 424).

Items	Strongly disagree, n (%)	Moderately disagree, n (%)	Slightly disagree, n (%)	Slightly agree, n (%)	Moderately agree, n (%)	Strongly agree, n (%)	Mean ± SD*
(1) Nurses do not agree with the hospital's definition of a medication error	109 (25.7)	88 (20.8)	106 (25.0)	80 (18.9)	27 (6.4)	14 (3.3)	2.69 ± 1.37
(2) Nurses do not recognize an error occurred	134 (31.6)	87 (20.5)	80 (18.9)	77 (18.2)	33 (7.8)	13 (3.1)	2.59 ± 1.44
(3) Filling out an incident report for a medication error takes too much time	126 (29.7)	90 (21.2)	87 (20.5)	72 (17.0)	35 (8.3)	14 (3.3)	2.63 ± 1.44
(4) Contacting the physician about a medication error takes too much time	154 (36.3)	104 (24.5)	80 (18.9)	55 (13.0)	20 (4.7)	11 (2.6)	2.33 ± 1.34
(5) Medication error is not clearly defined	111 (26.2)	86 (20.3)	97 (22.9)	83 (19.6)	34 (8.0)	13 (3.1)	2.72 ± 1.40
(6) Nurses may not think the error is important enough to be reported	256 (60.4)	72 (17.0)	54 (12.7)	26 (6.1)	10 (2.4)	6 (1.4)	1.77 ± 1.17
(7) Nurses believe that other nurses will think they are incompetent if they make medication errors	161 (38.0)	100 (23.6)	64 (13.4)	57 (13.4)	29 (6.8)	13 (3.1)	2.37 ± 1.43
(8) The patient or family might develop a negative attitude toward the nurse or may sue the nurse if a medication error is reported	97 (22.9)	76 (17.9)	81 (19.1)	82 (19.3)	51 (12.0)	37 (8.7)	3.06 ± 1.60
(9) The expectation that medications be given exactly as ordered is unrealistic	208 (49.1)	87 (20.5)	69 (16.3)	38 (9.0)	18 (4.2)	4 (0.9)	2.02 ± 1.24
(10) Nurses are afraid the physician will reprimand them for the medication error	165 (38.9)	97 (22.9)	77 (18.2)	44 (10.4)	24 (5.7)	17 (4.0)	2.33 ± 1.43
(11) Nurses fear adverse consequences from reporting medication errors	144 (34.0)	79 (18.6)	67 (15.8)	56 (13.2)	51 (12.0)	27 (6.4)	2.70 ± 1.63
(12) The response by the nursing administration does not match the severity of the error	133 (31.4)	75 (17.7)	71 (16.7)	67 (15.8)	52 (12.3)	26 (6.1)	2.78 ± 1.61
(13) Nurses could be blamed if something happens to the patient as a result of the medication error	70 (16.5)	47 (11.1)	62 (14.6)	83 (19.6)	88 (20.8)	74 (17.5)	3.69 ± 1.70
(14) No positive feedback is given for passing medications correctly	103 (24.3)	71 (16.7)	103 (24.3)	75 (17.7)	47 (11.1)	25 (5.9)	2.92 ± 1.51
(15) Too much emphasis is placed on med errors as a measure of the quality of nursing care provided	97 (22.9)	76 (17.9)	90 (21.2)	85 (20.0)	49 (11.6)	27 (6.4)	2.99 ± 1.53
(16) When med errors occur, nursing administration focuses on the individual rather than looking at the systems as a potential cause of the error	54 (12.7)	50 (11.8)	65 (15.3)	91 (21.5)	86 (20.3)	78 (18.4)	3.80 ± 1.64

* Min (1), max (6).

rather than looking at the systems as a potential cause of the error (3.80 ± 1.64). The second higher mean score was when nurses could be blamed if something happens to the patient as a result of the medication error (3.69 ± 1.70), and the third reason was when the patient or family might develop a negative attitude toward the nurse or may sue the nurse if a medication error is reported (3.06 ± 1.60).

3.4. Perceived Reported Medication Administration Errors (MAEs) by Intravenous and Non-Intravenous (Non-IV) Routes among Critical Care Nurses. Table 4 shows the percentage of perceived MAEs for each item in Kelantan government hospitals with specialists. The data show that the MAEs with the greatest perceived intravenous drug error rates were incorrect timing (16.5%), wrong dosage (16.3%), and wrong route (16.1%). The least perceived medication error was IV fluid mismatch (14.9%). The highest percentages for non-intravenous MAEs were 18.9% for medication given at the inappropriate time, 18.6% for method, and 18.2% for dosage.

4. Discussion

MAE prevention is a main focus of hospital quality improvement and risk management initiatives. Medication administration is generally entrusted to nurses and is an important component of nursing practice, having a substantial impact on patient safety and the provision of high-quality healthcare services. Nurses receive medication administration training in order to reduce drug-related incidents in hospital settings, as they play a critical role in preventing such errors prior to medication administration to patients.

According to the findings of the current study, 61.3% of participants had attended patient safety courses, showing that they had received enough training on safe and effective patient care. In comparison to a survey conducted in Seoul, just 47.8% of participants had received patient safety education [26]. However, in an Ethiopian study, 84.5% of participants did not get patient safety training [27]. This is concerning because healthcare providers require adequate patient safety training to avoid making errors that endanger patients. It emphasizes the need of healthcare organizations stressing patient safety education and training for their employees [28]. Medication administration instructions were given to more than 80% of study participants. This demonstrates the importance of critical care hospitals prioritizing employee training on medication administration practices. But, only 55.7% of Ethiopian study participants obtained medical administration instruction [6].

The present study's results indicated that 84.7% of critical care nurses had no MAE experience, compared to a previous study in Turkey, where 73.9% of nurses had no MAE experience, showing that the current study had improved better in terms of practicing patient safety culture [29, 30]. However, prior MAE experience was reported by 69.6% of nurses in South Korea, demonstrating that MAE prevalence differs among healthcare systems and settings

[31]. These disparities in prevalence could be attributed by differences in reporting standards or medication administration practices [32]. These findings emphasize the significance of continuing education for healthcare personnel especially critical care nurses in ensuring patient safety. According to the results of this survey, 65.6% of respondents have seen MAEs performed by others. This shows that MAEs are common in clinical settings and can risk patient safety. According to a recent Turkish study, 55.8% of respondents reported witnessing MAEs [29]. It emphasizes the significance of encouraging nurses to report and treat MAEs to improve patient safety. Having healthcare personnel report MAEs helps organizations discover areas for improvement and take preventive measures.

MAEs are causing worry in healthcare settings since they may endanger patients. MAEs can arise as a result of problems with drug ordering, dispensing, administration, and monitoring. According to critical care nurses, unclear physician prescription instructions induced MAEs. A similar finding was found in a South Korean study [31], where nurses assessed the unreadable physician's medication order as extremely crucial in contributing to MAEs. Both studies emphasize the need of legible medication instructions in avoiding MAEs. Clear and easy-to-read prescription instructions are important to avoid medication errors, and this can be achieved through standardized templates, electronic prescribing, or better physician training [33]. According to a South African study, MAEs may be caused by illegible handwriting. Prescription interpretation was performed by pharmacists 75% of the time and nurses 81.8% of the time [34]. This study highlights the significance of healthcare providers giving legible and explicit prescription instructions during medication administration [12]. The introduction of comparable drugs was the second most common cause of MAEs. It is worth noting that nurses in the United States reported this difficulty more frequently, implying that it is a more general issue [35]. When many prescriptions have identical colors or formats, it can be confusing. Critical care nurses identified this issue as the second most common cause of MAEs in this study, emphasizing its importance in medication use. Drug packaging, labelling requirements, and cultural variances may all contribute to this impression mismatch [3, 36, 37].

Nursing administration attributes prescription errors to individual acts or oversights rather than systemic issues. According to the majority of critical care nurses, nursing administration prioritized the individual over the system, which is consistent with previous study and conclusions [3, 31, 35]. Nursing administration, according to these studies, blames nurses for prescription errors rather than addressing systemic issues. This limited view of human responsibility may make it more difficult to explain drug mishaps. As a result, addressing the contextual factors driving medication errors requires a thorough strategy. Healthcare medicine administration must change for the sake of safety and efficiency [38, 39]. Another MAE myth that critical care nurses in this study perceived was that nurses may be held accountable for patient damage caused by prescription errors. According to a Saudi Arabian study,

TABLE 4: The percentage of perceived medication administration errors reported for each type by the critical care nurses in tertiary hospitals, Kelantan ($n = 424$).

Type of medication errors	Percentage of each type of medication error reported (%) [*]	
	IV-related MAEs	Non-IV-related MAEs
(1) Wrong route of administration	16.1	18.6
(2) Wrong time of administration	16.5	18.9
(3) Wrong patient	15.4	16.5
(4) Wrong dose	16.3	18.2
(5) Wrong drug	15.6	16.7
(6) Medication is omitted	24.2	26.5
(7) Medication is given but has not been ordered by the physician	15.0	14.7
(8) Medication is administered after the order to discontinue has been written	15.6	15.2
(9) Given to patients with a known allergy	15.3	15.1
(10) Wrong fluid	14.9	
(11) Wrong rate of administration	15.5	

*Min (0); max (100).

nurses were unwilling to report medication mistakes for fear of being implicated [40]. According to this study, nurses may be hesitant to disclose prescription errors for fear of disciplinary or legal penalties. This emphasizes the need of building a safety culture in healthcare companies that encourages reporting and learning from errors rather than condemning nurses [41]. Such an approach may improve patient safety and service quality by encouraging openness and responsibility [41, 42].

In this study, non-intravenous and intravenous MAEs included medication administration at the inappropriate time, route, and dose. In non-IV and IV-related MAEs, medication was rarely given without a doctor's order. Medication distribution at an inconvenient time was the most common IV-related MAE in Saudi Arabia [40]. South Korean studies produced a range of results. Giving medicine to the wrong patient was the most common non-intravenous MAE, while improper drug infusion rate was the most common IV-related MAE [31]. Effective communication among the healthcare team and adherence to medication order protocols may help decrease MAEs. Ongoing education, training, and monitoring are essential for ensuring medication safety [6].

This study does have a few limitations. It is based on data that participants reported themselves, which could be influenced by biases. These biases could include misremembering past events, wanting to appear in a positive light, and interpreting questions differently. Most of the people who took part in the study are critical care nurses who are 40 years old. It is possible that the responses are biased because people who have made or seen medication errors might be more willing to admit them. Using questionnaires to collect self-reported data can limit the amount of detailed information about how often medication errors happen or how serious they are.

5. Conclusion

In conclusion, the study looked into the perceptions of critical care nurses on the causes of MAEs in public hospitals with specialists in Kelantan, as well as the reasons for not reporting these MAEs. According to the findings of this study, illegible

medication orders from physicians, drug similarity, and medication package similarity are the top contributors to MAEs in the eyes of nurses. In contrast, the key reasons why MAEs are not reported are that nursing administration focuses on persons rather than systems, nurses may be held accountable, and patients and their families may file legal action against them. The findings highlight the importance of developing comprehensive strategies to address the highlighted reasons, improve communication and training, decrease strain and time pressure, and create a safety culture that fosters error reporting and learning. Further study is required to investigate the efficacy of these approaches in reducing MAEs.

Data Availability

The data are not publicly available due to privacy and confidentiality. However, restrictions apply to the availability of hospital data, which are available from the authors with the organization's permission.

Conflicts of Interest

The authors declare that there are no conflicts of interest regarding the publication of this paper.

Authors' Contributions

MII conceptualized the study, contributed to literature review, led the project, reviewed the article, and edited the article. MSI performed analysis, wrote the article, and provided references. All authors have read and agreed to the published version of the article.

Acknowledgments

The authors would like to express gratitude to the Kelantan State Health Department for the permission to conduct this study. Special thanks go to the nursing unit of all three hospitals. Massive thanks go to the respondents, whose involvement is very much appreciated.

Aims. To adapt the Authentic Nurse Leadership Questionnaire (ANLQ) to the Chinese cultural context and evaluate its psychometric properties. **Background.** Authenticity serves as a pivotal factor in the dynamic interaction between nurse leaders and nurse staff, exerting a profound influence on the growth of nurse individuals, healthcare teams, and organizations. However, there is still a dearth of research instruments to assess nurses' perception of authentic leadership in China. **Methods.** After authorization from the original author and technical support had been secured, a systematic process of initial translation, back translation, expert panel review, and pretesting was employed to ensure cross-cultural adaptation in accordance with established guidelines. A two-stage study design was implemented. In stage 1, 189 nurses were sampled for psychometric validation, during which the internal consistency reliability, split-half reliability, and test-retest reliability were tested and exploratory factor analysis was performed. In stage 2, 255 nurses were sampled for confirmatory factor analysis and assessment of convergent and discriminant validity, to further validate the constructs. **Results.** In stage 1, the validated instrument showed a Cronbach's alpha value of 0.973, a split-half coefficient of 0.888, and a test-retest reliability coefficient of 0.912. The exploratory factor analysis extracted five dimensions that accounted for 82.629% of the overall variance. The findings in stage 2 showed that the observed data were well fitted to the five-factor theoretical model, with acceptable levels of convergent and discriminant validity. **Conclusions.** The Chinese version of the ANLQ demonstrated appropriate psychometric properties, as evidenced by its good reliability and validity. **Implications for Nursing Management.** This study offers nurse administrators and executives a valuable instrument, enabling them to establish leadership evaluation criteria, conduct nurse leader performance appraisals, and assist in selecting new nurse leaders. Ultimately, this contributes to the cultivation and development of exceptional managers capable of providing positive leadership to their followers.

1. Introduction

In the rapidly evolving contemporary healthcare setting, ethical dilemmas are frequently encountered [1]. Given the deep integration of nursing with intricate human relationships, these ethical dilemmas are amplified, resulting in undesirable outcomes such as moral distress, decreased job satisfaction, burnout, intrateam conflicts, and compromised patient care [2–4]. Consequently, there is a growing discourse surrounding the importance of values-based leadership and relational leadership as potential strategies to

address these dynamic changes [5–7]. Authentic leadership (AL), which is a common component of both aforementioned leadership styles [6, 8, 9], fosters a distinctive relationship between the leader and followers that is marked by high levels of trust, transparency, and integrity [10]. In addition, AL reflects the alignment between the core values of the leader and those demonstrated within the values-based leadership framework [8]. Many studies have emphasized the importance of AL as the foundational basis for various forms of positive leadership [11], highlighting its positive impacts on healthcare staff [6, 12]. These impacts

include improving job satisfaction [10], fostering optimism and trust, promoting engagement, and cultivating a supportive work environment [7, 13], ultimately leading to better patient care quality [14]. Furthermore, research has underscored the crucial role of AL in mitigating the emotional exhaustion of followers, reducing workplace stress, alleviating cynicism, preventing burnout, and reducing turnover intention [10, 15–17]. Thus, authenticity, recognized as the paramount aspect of human interaction, is of immense value in healthcare settings that prioritize interpersonal relationships [16] and communication that focuses on the needs and effectiveness of others. Authentic leaders, by exemplifying AL behaviour, not only inspire and motivate their followers while improving their work efficacy [17] but also provide a favourable pathway for their own personal growth and advancement [12].

The majority of existing instruments used to measure AL were developed based on earlier AL theories [11, 18] and showed similarities in terms of their structure, content, and measurement indices. One notable example is the Authentic Leadership Questionnaire (ALQ) developed by Walumbwa et al. [19] in 2008. Notwithstanding the widespread use of the ALQ in healthcare and its adoption in the Chinese nursing domain, it is essential to recognize that the instrument was originally tailored for the for-profit corporate setting. Consequently, the questionnaire may lack fundamental nursing concepts and exhibit limited relevance when applied in the context of nursing practice. In 2011, a group of researchers addressed criticisms of the ALQ and made modifications, resulting in the development of an instrument with four subscales, the 14-item Authentic Leadership Inventory (ALI) [20]. However, the validation process conducted by Davidson et al. [21] for the ALI specifically in the U.S. acute care setting confirmed only a single-factor structure, highlighting the need for further validation of the four-factor structure in the nursing context. Another instrument, the 13-item Authentic Leadership Self-Assessment Questionnaire (ALSAQ, Polish version) [22], demonstrated a favourable Cronbach's alpha of 0.84. However, two out of the three subscales did not meet the criterion of 0.7 for Cronbach's alpha and lacked convergent and discriminant validity [23]. Although the ALSAQ is intended for professional nurses, it assesses registered nurses' perceptions of their own AL, not the AL exhibited by nurse leaders. Moreover, the recruitment of nurses mainly from postgraduate education centres raises doubts about its applicability to clinical settings.

Giordano-Mulligan [24] developed the 29-item Authentic Nurse Leadership Questionnaire (ANLQ) to measure nurses' perception of the AL by nurse leaders, with a specific focus on the core attribute of caring in nursing. By integrating Jean Watson's theory of caring [25] with AL theory, the questionnaire addressed the limitations of existing measures in capturing essential nursing characteristics. The ANLQ has exhibited acceptable psychometric properties with a Cronbach's alpha value of 0.99 and 5 subscales ranging from 0.89 to 0.97. However, its applicability to Chinese nurses from socially and ethnically diverse backgrounds needs to be tested. Therefore, the objective of

this study was to report on the cross-cultural adaptation processes and psychometric properties of the ANLQ to prompt a better understanding of its psychological structure in the Chinese cultural context.

2. Methods

2.1. Translation and Cross-Cultural Adaptation. The ANLQ was translated with the consent and permission of Dr. Giordano-Mulligan. In accordance with Beaton's cross-cultural adaptation guidelines [26] and Brislin's back-translation model [27], several adaptation steps were followed.

2.1.1. Initial Translation with Synthesis. The translation was independently completed by two native Chinese translators, one of whom was a lecturer who had lived in the United States for six years and obtained her doctoral degree in nursing there and the other of whom had graduated with a master's degree and worked as a professional English translator for 14 years. Another professor, a Ph.D. in nursing management, compared the two independent translations word for word and synthesized them into one version.

2.1.2. Back Translation with Reconciliation. The translated version was back-translated to English by two other translators with bilingual backgrounds and no exposure to the original questionnaire, one of whom was a medical doctor who had studied and lived in the United States for 12 years and the other of whom was an American lecturer with no medical background who had worked as a teacher in China for 10 years. Subsequently, another medical doctor who was a visiting scholar at Duke University was invited to compare the two translations and then provided feedback to the original author for verification. Finally, the synthesized Chinese version was modified accordingly to ensure that the expressions retained their original connotation.

2.1.3. Expert Panel Review. Seven experts with master's degrees or above were invited to participate in an expert panel for the study. The panel consisted of a professor with experience in psychological nursing, a methodologist, a linguistics expert, two professors of nursing management, and two nursing administrators with 13 and 34 years of clinical experience. One of the experts, Dr. Sun, was a Chinese American invited by Dr. Giordano-Mulligan to review the translations of the various versions and provide technical support. The cross-cultural adaptation process involved using e-mail, face-to-face interactions, and Zoom videoconferencing, to engage experts in reviewing materials during both initial translation and back translation. The researcher synthesized expert opinions, and in cases of disagreement, the final decision was determined through a written ballot. Subsequently, six experts were invited to assess content validity, scoring each item on a scale from 1 (not relevant) to 4 (highly relevant). A validity threshold was set at an item-level content validity index (I-CVI) of 0.78 or higher and a scale-level average CVI (S-CVI/Ave) of 0.9 or above.

2.1.4. Pilot Testing and Reporting. To ensure that the language used in the questionnaire was both understandable and acceptable, a preliminary investigation was conducted by convenience sampling 30 nurses from various age groups, educational levels, and professional titles. Afterwards, each respondent participated in a 15–20-minute interview to discuss whether they understood each item correctly and if they had any incomprehensible details.

2.2. Study Design and Participants. A two-stage cross-sectional survey design employing convenience sampling was implemented in this study. In stage 1, participants were recruited from two tertiary comprehensive hospitals in Henan Province, China. Within each hospital, sample selection was based on the proportion of nurses in different departments to ensure sample diversity. The sample size for the exploratory factor analysis (EFA) adhered to the recommended item response ratio of 1:5 to 1:10 [28]. To accommodate a potential 20% questionnaire invalidity rate, a minimum sample size of 182 participants was determined. The inclusion criteria were registered nurses who (1) were employed and age 18 years or older, (2) had worked with their current nurse leader for ≥ 1 year, and (3) were under the direct leadership of the nurse leader. The exclusion criteria were nurses who were not at work (e.g., on further training, missions, or leave of absence) and those rotating within the department during the study period. For the test-retest reliability assessment, thirty respondents were selected and returned to complete the C-ANLQ after a two-week interval.

Moving to stage 2, participants were drawn from the other two tertiary comprehensive hospitals ensuring a distinct selection from those involved in stage 1. It is generally accepted that the sample size for confirmatory factor analysis (CFA) should not be less than 200 [29], with an additional 20% accounting for potential invalid responses, thus establishing a minimum sample size of 250 participants. Inclusion criteria mirrored those of stage 1 participants.

2.3. Instruments

2.3.1. General Information Questionnaire. The self-designed demographic questionnaire included 8 questions on the participant's age, gender, marital status, department affiliation, years of experience, years working with the current nurse leader, education, and professional title.

2.3.2. Authentic Nurse Leadership Questionnaire. The ANLQ is a 29-item instrument developed by Giordano-Mulligan [24] with five subscales: self-awareness, moral ethical courage, relational integrality, shared decision making, and caring. The instrument uses a 5-point Likert scale ranging from 0 (never) to 4 (all time), with an overall score ranging from 0 to 116. A higher score indicates a higher level of perceived authentic leadership by nurses. The instrument was validated by Hwang et al. in a group of Korean nurses [15], with a total Cronbach's alpha coefficient of 0.97, which indicated good psychometric properties.

2.3.3. Authentic Leadership Questionnaire. The 16-item ALQ was developed by Walumbwa et al. [19] and consists of four subscales: self-awareness, relational transparency, internalized moral perspective, and balanced processing. The items are measured on a 5-point Likert scale from 0 (highly disagree) to 4 (fully agree), with a total score ranging from 0 to 64. The Cronbach's alpha coefficient for the Chinese version [30] of ALQ was 0.95, and the one in this study was also 0.95.

2.4. Data Collection. Initial support was secured from the participating hospitals and nursing supervisors before commencing the field survey. The data for stage 1 were gathered between January and February 2023. Participants received printed questionnaires in sealed envelopes from the investigator and submitted them on the spot. To minimize bias, they completed the questionnaire in the absence of the nurse leader. Additionally, for those willing to participate in the follow-up survey, we recorded their contact details and assigned numbers for the assessment of test-retest reliability two weeks after the initial survey. Stage 2 data collection occurred between March and April 2023, following the same protocol as stage 1.

2.5. Data Analysis. The data analysis was conducted using IBM SPSS software (version 26.0) and AMOS software (version 24.0) for Windows. Descriptive statistics were used to analyse participant characteristics as necessary. In stage 1, the internal reliability of the scale was assessed using both Cronbach's alpha coefficient and the split-half reliability coefficient. A Cronbach's alpha coefficient of ≥ 0.9 was considered excellent, ≥ 0.8 indicated high reliability, and ≥ 0.7 was considered acceptable. The Spearman–Brown coefficient was used to correct the number of items in which the two subscales were not equal [28]. Test-retest reliability was used to capture external reliability, and a value greater than 0.7 indicated a high degree of stability of the scale. Item analysis was conducted with the critical ratio (CR) method (a sample *t*-test to compare the differences between the upper 27% and lower 27% of the subgroups), and homogeneity tests were used as screening indicators for each of the individual items. Items with a CR value < 3.0 , item-total correlation coefficient < 0.4 , or an increase of 0.5 or more in Cronbach's alpha after the deletion of the item were removed.

Construct validity was verified by a joint evaluation of EFA and CFA. The Kaiser–Meyer–Olkin (KMO) test and Bartlett's test of sphericity were initially performed to determine the sample fit to confirm that EFA was appropriate. Factors were extracted based on an eigenvalue > 1.0 , scree plot, and factor loading ≥ 0.5 . In stage 2, the CFA further validated the default model from stage 1, in which the parameters were estimated using the maximum likelihood method. Convergent validity was considered appropriate with an average variance extracted (AVE) > 0.5 , standardized factor loading > 0.5 , and composite reliability > 0.7 [31]. Determining discriminant validity, we ensured that the square root of the AVE was greater than the correlation coefficient between each factor and the other factors.

Pearson correlation analysis was used to determine the association between the C-ANLQ and the ALQ to evaluate criterion validity.

3. Results

3.1. Translation and Cross-Cultural Adaptation. In the cross-cultural adaptation phase, considering the potential difficulty of Chinese nurses comprehending the term “visible” in item 4, the word was replaced to convey a meaning understandable in the Chinese healthcare context. Following two rounds of expert discussions, “visible” was translated as “appearing frequently in front of nurses and actively interacting with them.” Additionally, after consulting with the original author and expert panel, item 22 was modified to read “My nurse leader participates in organizations or activities associated with the nursing profession,” providing a more detailed explanation for nurses. This phase involved revising a total of 12 items and adjusting the labels for both dimensions and the questionnaire title.

During the pilot testing phase, nurses took approximately 3–5 minutes to complete the questionnaire. In response to nurses’ misunderstandings of “group pressure,” the wording was amended, and supplementary instructions were included based on integrated group feedback. Consequently, item 9, “My nurse leader would not be influenced by negative group pressure,” was revised to “My nurse leader would not be influenced by negative group pressure (e.g., the influence of doctors, nurses, supervisors, medical techniques and colleagues in clinical support departments).” Item 28, “My nurse leader pampers the personal growth of followers,” was adjusted to “My nurse leader fosters followers and promotes their personal growth.” This change was made because several nurses noted that “pampering followers” behaviour was slightly exaggerated and that it was more appropriate to use the language of fostering between leaders and followers. Additionally, four redundant statements were streamlined during the pretest. Throughout the research process leading to this stage, the Chinese version of the ANLQ was formed, proving relevant to clinical nursing work and easily comprehensible.

3.2. Participant Characteristics. In stage 1, all 200 participants who met the criteria responded and returned the questionnaires. However, 11 questionnaires were found to be spurious, as all the items were filled in with the same answer. Consequently, 189 questionnaires (94.50%, 189/200) were deemed valid. Moving to stage 2, the survey involved 280 registered nurses, 278 of whom returned the questionnaires, yielding a response rate of 99.29%. After excluding incomplete questionnaires and spurious responses, a total of 255 questionnaires (91.07%, 255/280) were considered valid. The characteristics and demographics of the participants in the two stages are shown in Table 1.

3.3. Reliability and Item Analysis. The item-total correlations for the 29-item C-ANLQ ranged from 0.600 to 0.875, indicating that item-total correlations not only achieved

significance ($p < 0.001$) but also showed a mid-high correlation ($r > 0.40$). The independent t -test showed that the CR value for each item significantly differed ($p < 0.001$) in the high subgroup (>73%, score = 92) and the low subgroup (<27%, score = 68). Consequently, there was no need to delete any items, since they were sufficiently distinct from one another, and there was a good homogeneity from the items to the total scale.

Cronbach’s alpha coefficient and the split-half reliability were used to validate the internal consistency of the C-ANLQ. The Cronbach’s alpha value was 0.973 for the total scale and ranged from 0.921 to 0.972 for the subscales, with a split-half reliability of 0.888. The alpha coefficients ranged from 0.971 to 0.973 if an item was deleted, indicating that no item needed to be considered for deletion. Moreover, there was a statistically significant correlation between the test and retest for “self-awareness” ($r = 0.769$, $p < 0.001$), “moral ethical courage” ($r = 0.818$, $p < 0.001$), “relational integrity” ($r = 0.850$, $p < 0.001$), “shared decision making” ($r = 0.814$, $p < 0.001$), “caring” ($r = 0.878$, $p < 0.001$), and the C-ANLQ total score ($r = 0.912$, $p < 0.001$).

3.4. Content Validity and Criterion Validity. Six experts were invited to rate the content validity two weeks after the expert panel review. The results showed that the I-CVI ranged from 0.83 to 1.00 (greater than 0.78), and the S-CVI/Ave was 0.97 (greater than 0.9), indicating good content validity. The Pearson’s correlation results (see Table 2) showed positive correlations of the C-ANLQ (and subscales) with both the C-ALQ (and subscales), from 0.586 to 0.783, and all correlations were significant ($p < 0.001$).

3.5. Construct Validity. The KMO coefficient was 0.954, and Bartlett’s test was significant (chi-square = 6450.072, $p < 0.001$), which supported the feasibility of EFA (with a sample of 189 nurses, stage 1). Five factors were extracted (see Figure 1) by using principal component analysis (PCA) with varimax rotation; these factors explained 82.629% of the total variance. Table 3 details the results of descriptive statistical analysis and EFA for the C-ANLQ. The factor loadings on each item exceeded the acceptable level in the range of 0.697 to 0.863, and no cross-loading was observed, with the communality of each item over 0.4; thus, all items were retained.

The five-factor structure was then validated using CFA on a sample of 255 nurses in stage 2. The initial model fit indices showed an inadequate model fit, which was corrected by adding four residual paths based on the principle of maximizing the modification index [32], which ultimately improved the model fit and formed the CFA-modified model (see Figure 2). The initial and modified model fit indices are shown in Table 4.

3.6. Convergent and Discriminant Validity. The standardized factor loadings of all items in the C-ANLQ were statistically significant ($p < 0.001$) and higher than 0.5, ranging from 0.637 to 0.891. In addition, the AVE estimates ranged from

TABLE 1: Social and demographic information of the participants (stage 1, $n = 189$; stage 2, $n = 255$).

Descriptive characteristics	Stage 1		Stage 2	
	Frequency (n)	Percentage (%)	Frequency (n)	Percentage (%)
Gender				
Male	18	9.5	17	6.7
Female	171	90.5	238	93.3
Age, years ($M \pm SD$)	32.40	6.415	31.47	6.526
Education				
High school	4	2.1	5	2.0
Junior college	39	20.6	40	15.7
Undergraduate	145	76.7	201	78.8
Postgraduate or above	1	0.5	9	3.5
Marital status				
Unmarried	45	23.8	93	36.5
Married	141	74.6	159	62.4
Divorced or widowed	3	1.6	3	1.2

Nurse-in-charge	83	43.9	99	38.8
Deputy director nurse	1	0.5	4	1.6

$M \pm SD$: mean \pm standard deviation.

TABLE 2: Pearson's correlations between C-ANLQ and ALQ ($n = 40$).

	ALQ (total)	Self-awareness	Internalized moral perspective	Relational transparency	Balanced processing
C-ANLQ (total)	0.783	0.733	0.740	0.697	0.705
Self-awareness	0.774	0.755	0.727	0.675	0.689
Moral ethical courage	0.690	0.620	0.673	0.650	0.591
Relational integrity	0.778	0.728	0.725	0.735	0.676
Shared decision making	0.740	0.684	0.688	0.633	0.708
Caring	0.696	0.661	0.663	0.586	0.641

All $p < 0.001$.

0.560 to 0.608, all of which were higher than 0.5, while the composite reliability estimates ranged from 0.884 to 0.914, with all above 0.7. As shown in Table 5, the square roots of the AVE of all five dimensions were greater than their correlation coefficients, indicating that the dimensions were discriminated.

4. Discussion

An integral part of nursing practice is the nurse leader's ability to build authentic relationships with nurse staff through his or her authentic leadership. This ability generates positive attitudes among nurse staff, which, in turn, improves the quality of care. This study describes the first verified study of the C-ANLQ in China, which was validated

by a two-stage survey. The adapting process of the instrument followed Beaton's cross-cultural adaptation guidelines [26] and Brislin's back-translation model [27]. These guidelines suggest that in cross-cultural research, it is crucial to not only maintain semantic and conceptual equivalence with the original scale but also paraphrase one's own culture-specific experiences or behaviours. This ensures the relevance and applicability of the instrument in the specific cultural context. Moreover, continuous communication with the original author was pivotal to ensure that the instrument was suitable for the Chinese cultural context while preserving the integrity of the original version.

The C-ANLQ demonstrated good psychometric properties in the sample of registered nurses in this study. For item analysis, the item-total correlations were acceptable, as

FIGURE 1: Scree plot.

TABLE 3: Results of descriptive statistics and exploratory factor analysis ($n = 189$).

Items	Mean	SD	Factor					C^2

all were over 0.4, indicating that all items in the instrument measured the same constructs. In addition, all 29 items had CR values in excess of 3 and at the 0.05 level of significance, showing that all items were able to discriminate between the levels of variance reflected by different respondents. In the study, Cronbach's α coefficient for the total scale and each

subscale exceeded 0.9, representing a favourable level of internal consistency reliability, which is compatible with the results of other studies [15, 33]. The Cronbach's α coefficient derived after deleting each item separately never surpassed the overall Cronbach's α coefficient of the questionnaire, indicating that the psychological traits to be measured by

TABLE 4: Model fit indices of the five-factor model in confirmatory factor analysis.

	χ^2/df	GFI	AGFI	RMSEA	NFI	TLI	CFI	PGFI
Initial model	1.423	0.879	0.857	0.041	0.889	0.960	0.964	0.742
Modified model	1.104	0.905	0.887	0.020	0.915	0.990	0.991	0.756
Target value	<2.0	>0.90	>0.90	<0.05	>0.90	>0.90	>0.90	>0.50

GFI: goodness-of-fit index; AGFI: adjusted goodness-of-fit index; RMSEA: root mean square error of approximation; NFI: normed fit index; TLI: Tucker-Lewis index; CFI: comparative fit index; and PGFI: parsimony goodness-of-fit index.

Caring	0.641*	0.616*	0.513*	0.478*	0.750
AVE	0.564	0.608	0.604	0.560	0.563

* $p < 0.001$; AVE, average variance extracted; SA: self-awareness; MEC: moral ethical courage; RI: relational integrity; SDM: shared decisionmaking. Bold values show the AVE square root in each of the five dimensions.

each item in the questionnaire were consistent. In the retest after a two-week interval, the test-retest reliability of the five factors was between 0.769 and 0.878, which was consistent with the Giordano-Mulligan results [24] between 0.780 and 0.880, showing good measurement stability.

This study carried out seven iterations of EFA, resulting in the extraction of five factors: self-awareness, moral ethical courage, relational integrity, shared decision making, and caring. These factors collectively accounted for 82.629% of the total variance of the questionnaire, and the factor loading of each item exceeded 0.4, indicating consistency with the original instrument structure. However, the initial predefined model did not achieve the desired fit during CFA, possibly due to correlations between items [34]. Consequently, the model underwent a progressive revision based on correction index suggestions, including the addition of four residual paths to improve statistical fitness. The four residual paths added indicate that certain items could not be fully explained by their respective latent variables. For example, the residual paths between item 23 and item 19 and between item 23 and item 22 indicate associations beyond the latent variables of “shared decision making” in the work, possibly involving other factors. This variation may be attributed to cultural differences in the interpretation of the questionnaire items. In individualistic cultures such as the United States, personal viewpoints and active participation in management decision making are valued, whereas collectivistic cultures such as China emphasize deference to leadership decisions [35, 36]. Additionally, the presence of residual paths between item 12 and item 13 and between item 15 and item 16 suggested the involvement of additional shared factors beyond “relational integrity.” This may be due to the proficiency of Chinese nurse staff in building relationships, as they are adept at quickly establishing strong personal connections with leaders and cultivating common interests [37], thus experiencing greater influence from nurse leaders. The modified model incorporates these residual paths, offering a more accurate representation of the structure of the sample data. The

modified chi-square degrees-of-freedom ratio of 1.131 meets the stricter fit criterion of less than 2 and surpasses the Giordano-Mulligan index results [24]. Although the adjusted goodness-of-fit index (AGFI) did not reach the optimal fit index, probably due to the limitation of the sample size, it was close to 0.9, which remained acceptable. AGFI is calculated from the goodness-of-fit index (GFI) and is generally less than the estimate of GFI [34]. In this study, the GFI met the criteria, and the other fit indicators met the needed standard. Therefore, in general, the modified five-factor model was in good fit with the sample data and matched the theoretical design of the original instrument.

In terms of content validity, the expert base information, qualification, and consultation process ensured the validity of the CVI evaluation. Following a single round of expert consultation, the C-ANLQ met the criteria of S-CVI/Ave > 0.90 and I-CVI > 0.78 , demonstrating its good content validity. The scores between the four dimensions of the C-ANLQ and the four dimensions of the ALQ showed a significant positive correlation, aligning with the findings of Giordano-Mulligan [24]. Furthermore, a newly identified factor, “caring,” pertains to authentic leaders’ willingness to serve others and demonstrate concern for the well-being of their followers [38]. Such leaders possess self-transcendent values and exhibit heightened levels of compassion. In this study, caring exhibited significant positive correlations with the total ALQ score and its four dimensions, with correlation coefficients of 0.696, 0.661, 0.663, 0.586, and 0.641 (all $p < 0.001$). This may be attributed to the fact that nursing, as a caring profession, plays a crucial role in the perception of AL from nurse leaders. This statement is in line with the ANLQ conceptual framework [38] in which caring is a natural attribute. Therefore, these results showed a promising correlation between the C-ANLQ and ALQ, with good criterion validity.

Regarding convergent validity, all five latent variables exhibited a composite reliability greater than 0.7, which determined the good inherent quality of the model. The AVE

exceeded 0.5, suggesting that the latent construct accounted for at least 50% of the indicator variance [34]. Additionally, the standardized factor loading of each item surpassed 0.5, indicating a good model fit [31]. Collectively, these findings support the strong convergent validity of the latent construct. For discriminant validity, the square root of the AVE for each of the five dimensions exceeded the correlation coefficient between that dimension and the others. This observation indicates good discriminability among the five dimensions and validates the presence of distinct constructs within the C-ANLQ. Therefore, the C-ANLQ can be deemed to possess five dimensions with reasonable discriminant validity.

4.1. Limitations. The survey conducted in this study was limited to tertiary comprehensive hospitals in Henan Province, China, using a convenience sampling method, which might restrict the generalizability of the findings. Future research could encompass a broader range of participants, such as outpatient nurses and those working in sterilization supply centres, and validate the instrument in diverse geographic regions across China. While the C-ANLQ was administered by the researcher in person to minimize the influence of nurse leaders, response bias might still exist due to social expectations, potentially inflating the response scores compared to actual internal scores.

5. Conclusion

This study adhered to systematic guidelines to translate the English version of the ANLQ into Chinese, establishing an expert panel to conduct cross-cultural adaptation and language validation within a Chinese nursing context. The C-ANLQ was subsequently verified as a valid instrument, exhibiting satisfactory reliability and validity through a two-stage survey involving registered nurses.

5.1. Implications for Nursing Management. Nurse leaders hold pivotal roles as primary managers and direct supervisors of nurse staff, exerting a significant influence on work attitudes and behaviours. This study offers nursing administrators a novel and contextually appropriate assessment instrument, the C-ANLQ, to measure nurses' perception of AL, with far-reaching implications for healthcare organizations aiming to foster AL development among nurse leaders. The C-ANLQ serves as a benchmark for nurse administrators and executives when establishing leadership evaluation criteria, designing training programs, selecting new nurse leaders, and conducting performance appraisals. Furthermore, a longitudinal perspective on the enduring impact and growth trajectory of nurse leaders' AL in practice provides valuable insights into the evolution of AL behaviours over time.

The data supporting the results of this study are available from the corresponding author upon reasonable request.

Ethical Approval

The Zhengzhou University Ethics Committee reviewed and approved the study, number ZZUIRB2023-072.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

We express our sincere gratitude to the members of the translation team and expert panel, along with the interview participants, for their invaluable support and insightful suggestions. Additionally, we would like to extend our thanks to AJE for their English language editing. Special acknowledgment goes to Dr. Giordano-Mulligan for kindly granting permission to use the original instrument and for providing constant assistance throughout the research process. Furthermore, we would like to acknowledge Dr. Sun for sharing expertise and making special contributions to the field of cross-cultural research.

Nursing staff turnover is an increasing problem for healthcare globally. In Sweden, the shortage of nurses in primary healthcare has increased significantly in recent years. This development is alarming because primary healthcare, both in Sweden and internationally, is responsible for a large part of healthcare. The aim of this study was to explore working conditions (change fatigue, leadership climate, and social support from colleagues) and characteristics of primary care nurses who are discontent with their current job, i.e., those with high turnover intentions and poor job satisfaction in Sweden. This was a cross-sectional survey of 466 registered nurses working in Swedish primary healthcare. Data were analyzed using descriptive statistics and logistic regression. The results demonstrate that 21.1% of the responding nurses are discontent with their current job and have considered quitting. Being discontent had significant associations with poor leadership climate ($p < 0.001$), lack of social support from colleagues ($p < 0.001$), change fatigue ($p < 0.001$), poor health ($p < 0.001$), and working more than 40 h per week ($p = 0.02$). The results have implications for how healthcare organizations structure the work of nurses in primary healthcare and how they can attract and retain future staff to these workplaces.

Keywords: change fatigue; job satisfaction; leadership; social support; turnover intentions; work environment; working conditions

1. Introduction

Nursing staff turnover is an increasing problem for healthcare globally. The World Health Organization estimates that there is a global shortage of 5.9 million nurses [1]. In Sweden, the National Board of Health and Welfare has identified a severe national nursing shortage [2, 3], and the demand for nurses in the healthcare system has increased sharply in recent years [4]. The proportion of primary healthcare nurses per 1000 population in Sweden has

decreased since the early 2000s [5]. There are reports that the availability of nurses in primary healthcare does not reach actual needs [6]. This development is particularly alarming as primary healthcare is responsible for a large part of healthcare. Furthermore, primary healthcare in Sweden is expected to take on an important role in the development of an integrated care model to achieve a more holistic form of care to prevent disease, manage chronic conditions, bring care closer to home, and educate the population on better self-care [7].

Nurses leave healthcare for numerous reasons, including dissatisfaction with psychosocial working conditions such as staffing, heavy workload, low wages, poor leadership, lack of recognition, and inadequate authority [8, 9]. Turnover intention is an employee's willingness to voluntarily quit their job [10], and it has been found to correlate with the actual turnover [11]. Studies have shown that the turnover intention is associated with sickness absenteeism, reduced job performance, low work commitment [12], and low job satisfaction [13, 14]. Job satisfaction—i.e., the degree to which an employee enjoys their job or various aspects of their job [15]—correlates with nurses' self-confidence, communication, and mental health [16], as well as with patient care quality [17]. In addition, high job satisfaction is a major contributory factor to the intention to stay in the nursing profession [18, 19].

While nurses can have the intention to leave their jobs, they may still be satisfied with working as a nurse. Thus, they may express a desire to quit their job to look for other employment that can facilitate their personal development and provide better career opportunities. There may also be practical reasons, such as commuting distance or family circumstances. Still, there is a well-established negative relationship between turnover intention and job satisfaction; the more job satisfaction decreases, the more turnover intention increases [20, 21]. Turnover intention is also correlated with numerous factors besides job satisfaction, e.g., sickness absenteeism and reduced job performance [12]. However, the combined measure ascertains that low job satisfaction is a contributing factor to high turnover intention, which is important because job satisfaction plays a crucial role in attracting and retaining quality nurses and preventing the departure of discontent nurses.

Nurses' turnover and job satisfaction may also be adversely affected by many organizational changes that primary care has undergone in recent decades that have made nursing an increasingly complex profession [9]. Aging populations, changing disease patterns, new treatments for diseases, technological advancements (including telemedicine), an increased emphasis on patient/provider relationships based on partnership and mutual empowerment, political reforms, and policy initiatives all place strong demands on primary care organizations and health professionals' capacity to implement change [22–26]. Research has shown that organizational changes are often associated with employees' psychological uncertainty about how the changes will affect them [27–29]. Studies on nurses [30, 31] have shown that workplace changes can lead to change fatigue, which is the overwhelming feeling of stress, exhaustion, and burnout associated with rapid and continuous change in the workplace [30]. It is therefore useful to explore whether change fatigue is more common among nurses who are discontent.

Social support received at the workplace, as well as the level of leadership, are important factors in the work environment that may act as buffers for some of the negative aspects previously described. For example, social support from colleagues in a workplace is an important predictor of increased intention to stay in an organization and in

improved job satisfaction [32]. Other studies on the social support of nurses in primary healthcare demonstrate that an unsupportive clinical environment is associated with lower ratings in quality of care [33]. Social support can be broadly defined as the assistance and protection given by others [34]. Studies have shown that there is a positive relationship between nurses' social support in the workplace and the quality of patient care [35–38]. Similarly, leadership is positively associated with an intention to stay and job satisfaction, respectively [39, 40]. Leadership is defined as the art of influencing others to achieve their maximum potential to accomplish any task, objective, or project [41, 42]. Leadership climate refers to the way employees perceive leadership in terms of the manager's ability to create mutual trust and the emotional tone that characterizes the workplace [43].

Despite their obvious relevance for nursing retention and recruitment, there is limited research on primary care nurses' psychosocial working conditions in terms of turnover intention, job satisfaction, change fatigue, social support, and leadership climate. These issues have been studied primarily in hospital care settings [44]. Turnover intention and job satisfaction have been examined in primary healthcare nurses in Ireland [45], the United States [46], and South Africa [47]; job satisfaction has been studied among Canadian primary healthcare nurses [48]; and turnover intention and professional support have been investigated among primary healthcare nurses in Scotland [49]. No previous study has explored the working conditions and characteristics of primary care nurses who are discontent with their current job. This study combines high turnover with poor job satisfaction in order to examine nurses' discontent with their current job.

This study was developed to address numerous knowledge gaps. The aim was to explore working conditions (change fatigue, leadership climate, and social support from colleagues) and characteristics of primary care nurses who are discontent with their current job, i.e., those with high turnover intentions and poor job satisfaction in Sweden. Two research questions were addressed: (1) What characterize nurses who are discontent with their current job? and (2) How are nurses' discontent with their job associated with background and organizational workplace factors?

The knowledge contribution relates to the combination of variables and the associations between them. Furthermore, this study contributes knowledge about nurses' psychosocial working conditions in primary healthcare. These issues are important, considering that primary healthcare in Sweden and internationally is facing nursing shortages. Knowledge of these issues will be valuable for developing nursing retention and recruitment strategies.

2. Materials and Methods

2.1. Study Setting. This is a cross-sectional questionnaire study of registered nurses working in primary healthcare in Sweden. The Swedish primary healthcare system is divided into 21 different regions (previously known as "county councils") and provides universal coverage for all citizens.

Primary healthcare, often referred to as the “first line” of healthcare, manages a broad range of conditions that do not require specialist healthcare in hospitals or other specialized units, commonly including access to different professionals such as physicians, nurses, occupational therapists, and physiotherapists. In Sweden, primary healthcare consists of both public and private professionals; private professionals can include those with a contract with the region (which provides healthcare at the same costs as public healthcare) or those without regional contracts (which patients pay for themselves) [50].

Primary healthcare in Sweden employs about 25,000 people, and registered nurses make up 43% of the workforce [51]. Nurses are predominantly female. The role of the registered nurse in primary healthcare typically involves tasks such as handling medication, performing different tests on patients, documenting patient records, telephone counseling, and assessing and prioritizing a patient’s need for healthcare. They also have a leading role in structuring nursing work in collaboration with other team members such as assistant nurses.

2.2. Data Collection. An invitation to participate in this study, along with an information letter and a questionnaire, were sent in March 2022 by Statistics Sweden (SCB) to a representative selection of registered nurses working in Sweden. This selection was made in consideration of geographic spread, and the population was identified through the 2020-2021 occupational registry and the national educational registry. The total population consisted of 109,475 registered nurses, and SCB randomly selected a sample of 8000 registered nurses who were invited to answer the survey. The information letter addressed ethical aspects, such as assuring confidentiality and that the respondents accepted participation in the study by answering the questionnaire. The letter also provided information about the study’s aims, and that data collection included both the questionnaire and registry data. Respondents were informed that they could answer the questionnaire either online or by filling out the paper form sent with the invitational letter.

Three reminders were sent by post, and data collection closed in June 2022. In total, 2903 nurses answered the questionnaire, giving a 37.2% response rate. Of the respondents, 75.2% chose to answer the questionnaire online. Most of the nurses responded to the first invitation (33.4% of the total population).

A nonresponse analysis was performed by SCB, revealing that 48 of the nurses lacked a valid postal address or had protected identities, 21 declined participation with no reason given, 1 was prevented from participating (because of either language difficulties or disability), and 3 were labeled as “others” (because the returned questionnaire was unusable for some reason). The remainder of the nurses did not respond, and no reasons were provided.

In this study, we were particularly interested in the working conditions for nurses in primary healthcare; therefore, nurses who stated that they worked in a primary healthcare setting ($n = 466$) were selected. Inclusion criteria

included working in Sweden, being a registered nurse, and stating currently working in primary healthcare.

2.3. The Questionnaire. The questionnaire was developed together with researchers at the Karolinska Institute in Sweden. This questionnaire has been used previously by Hagqvist et al. [52] and the 2022 version included 78 variables focusing on work environment issues. The questionnaire was developed for physicians, registered nurses, and assistant nurses working in various healthcare settings in Sweden. For this specific study, we restricted the analyses to nurses working in primary healthcare settings and chose to include a limited number of variables relating to socio-demographic characteristics, background factors, health-related variables (sickness presenteeism and perceived health), psychosocial working conditions (change fatigue, leadership climate, and social support from colleagues), and work-related outcomes (turnover intentions and job satisfaction).

The questionnaire data were linked to registry data collected from the national population registry for demographic information (age and sex).

2.4. Measures. This study investigated discontent with one’s job. To this end, we created a new variable indicating discontent by combining respondents’ ratings on turnover intentions and job satisfaction. Nurses who both had high rates of turnover intentions and low rates on job satisfaction were included.

We chose to include whether the nurses had a specialist degree, whether they had changed their job in the last 12 months from a region to a staffing agency, their main employer, work experience, whether they were working full or part time, their estimated working hours per week, whether they had a partner, and whether they had children living at home.

Age was categorized into four fairly evenly sized groups, and sex was categorized as male or female. For educational level, we chose to categorize the nurses as either registered nurses or specialist nurses (in which we also included midwives and radiology nurses).

The response options for their main employer were as follows: municipality, region, private employer with public funding, private employer with private funding, public employer, staffing agency, self-employed, or none of these, which included an open text response. These responses were categorized into five categories for this study: municipality, region, private employer with public funding, private employer with private funding, and others (which included the responses with the lowest number of respondents, i.e., those publicly employed, in staffing agencies, those self-employed, and those who answered that none of the response options applied to them). Swedish primary healthcare consists of public actors and two types of private actors: those having a contract with the region which provides healthcare at the same cost for citizens as public healthcare, and those without regional contracts, where the patients pay for the visits themselves [50]. In Sweden, the regions are the largest

employers of healthcare staff, and this was the reference group in our analyses of main employer.

The options for estimated working hours per week were <30 h, 30–35 h, 36–40 h, 41–45 h, 46–50 h, 51–60, or >60 h per week. For this study, we chose to dichotomize at 40 h, dividing the respondent's answers into two groups: ≤ 40 h per week or >40 h per week (as 40 h of work per week is the standard for working full-time in Sweden).

2.4.1. Turnover Intentions. Turnover intentions refer to an employee's willingness or intention to voluntarily quit their job [11]. The turnover intentions among the respondents were measured with one question: How often during the past 12 months have you considered applying for a new job? Five response options were provided on a Likert scale, ranging from *every day* to *never*.

2.4.2. Job Satisfaction. Job satisfaction is defined as the extent to which a person reports overall satisfaction with their work [53]. For this study, job satisfaction was measured with one question: How satisfied or dissatisfied are you with your job? The five response options ranged from very satisfied to very dissatisfied.

2.4.3. Discontent With Current Job. Based on the responses pertaining to turnover intentions and job satisfaction, we created a combined measure in order to investigate the characteristics of the respondents with high turnover intentions and low job satisfaction. The rationale for combining the two variables was to identify nurses who expressed high turnover intentions and low job satisfaction simultaneously, which potentially suggests a stronger predictor of being discontent with their job.

Specifically, we created a category consisting of those who rated their job satisfaction as very dissatisfied, fairly dissatisfied, or neither satisfied nor dissatisfied and rated their turnover intentions as having considered leaving their current work every day, a couple of times a week, or a couple of times a month. This newly created combination variable is referred to as "discontent with current job." From this variable, we aimed to gain an improved understanding of the factors contributing to nurses' turnover and identify potential strategies to address these issues.

2.4.4. General Health. In the questionnaire, the respondents were also asked how they perceived their health in general, rating on a five-point Likert scale ranging from *excellent* to *poor*.

2.4.5. Sickness Presenteeism. Sickness presenteeism is described as "the first cousin of absenteeism that occurs when employees show up for work but because of mental or medical illness do not function productively or perform at 100%" ([54] p. 1).

One question in the questionnaire was used to investigate potential sickness presenteeism: "During the past

6 months, how many days in total have you gone to work when you should have called in sick?" We used three categories: those who stated they had no such days, those reporting 1–5 days of sickness presence, and those with more than 5 days for the past 6 months.

2.4.6. Change Fatigue. Change fatigue is the perception that there are too many organizational changes taking place simultaneously, which may lead to exhaustion and the incapacity to support and adapt to further changes, regardless of whether they may be favorable [30]. The change fatigue scale by Bernerth et al. [27] is a validated measure originally developed to explore the impact of multiple organizational changes on employee's well-being, organizational commitment, and turnover intentions [27]. The scale contains items such as "the number of changes that are carried out in my workplace is overwhelming," "I am sick of all the changes at work," and "I would prefer a period of stability before another change is carried out in the organization."

For this study, the measure was translated into Swedish and subsequently reviewed by bilingual colleagues and validated through a cognitive pretest inspired by cognitive interviewing [55]. This was performed by HF and JS, who tested the translated measure linguistically and semantically on four physicians and two nurses, respectively, who were asked to answer the translated measure while expressing their thoughts and interpretations of the questions out loud. After this, JS and HF discussed the findings together with PN and IS, which resulted in minor revisions and clarifications of a few terms in some of the questions.

The original change fatigue scale uses six items that are measured using a seven-point Likert-like scale ranging from 1 ("strongly disagree") to 7 ("strongly agree") [27]. In this study, the same six items were measured using a five-point Likert scale upon the advice of SCB after scrutinization of the questionnaire and the responses are as follows: (1) "strongly disagree," (2) "disagree," (3) "neutral," (4) "agree," and (5) "strongly agree." Change fatigue scale was calculated as the sum of different items. Cronbach's alpha for change fatigue was 0.96, indicating the internal consistency of the scale.

2.4.7. Leadership Climate. Leadership climate is described as how managers set an emotional tone and create mutual trust within the work environment [43]. Rather than rating one's managers' individual skills as a boss, leadership climate captures one aspect of the psychosocial work environment, thus referring to an organizational level rather than an individual level. This climate was measured with a ten-item instrument [56, 57], including statements such as: "I am clear about what my boss expects of me," "I have sufficient authorization in relation to the responsibility I have," and "my boss encourages me to participate in the arrangement of my work," with five response options ranging from "yes, often" to "no, never" and including the option "not relevant." The leadership climate scale was calculated as the sum of the items of the scale. Cronbach's alpha for leadership climate was 0.88.

2.4.8. Social Support From Colleagues. The respondents rated perceived social support from colleagues with two questions from the Copenhagen Psychosocial Questionnaire, third version (COPSOQIII) measure: If you need it, do you get help and support from your colleagues? A five-point Likert scale was used, ranging from “always” to “never.” Cronbach’s alpha for social support from colleagues was 0.77.

2.5. Data Analysis. When variables in a psychosocial scale (leadership climate, social support from colleagues, and change fatigue) were missing, a total score was calculated for that person if at least half of the questions of the scale were answered, and the missing variables were given the average score of the other variables in the scale [58]. The reliability of the psychosocial scales (leadership climate, social support from colleagues, and change fatigue) was estimated using Cronbach’s alpha internal consistency coefficient.

The distribution of sample characteristics and discontent was estimated for all respondents. Descriptive statistics are presented as frequencies for categorical variables or mean values and standard deviations (SDs) for continuous variables. General health was dichotomized prior to the regression analysis (1 = *good health*, being either “excellent health,” “very good health,” or “good health” vs. 2 = *poor health*, being either “fairly good health” or “bad health”). The psychosocial scales (leadership climate, social support from colleagues, and change fatigue) were standardized with mean zero and SD one and were used as continuous variables prior to the regression analysis.

Logistic regression was used to identify the characteristics of those who had a high level of discontent with their current job. The logistic regression analysis was unadjusted in Model I and was adjusted for all confounders in Model II (sex, age, main employer, working time, general health, change fatigue, leadership climate, and social support from colleagues). Odds ratios (ORs) for high discontent were estimated with 95% confidence intervals. The ORs for discontent with one’s current job are expressed per one SD increase for the psychosocial scales (mean, 0; SD, 1).

Results were considered statistically significant at $p < 0.05$ using two-tailed tests. Statistical analyses were performed using SPSS version 28.

2.6. Ethical Considerations. Study procedures and data collection were performed in accordance with the Helsinki Declaration [59]. Respondents were informed in the letter that participation was voluntary and confidential and that they had the right to withdraw their participation at any time. This study was approved by the Swedish Ethical Review Authority (Dnr 2022-03275-01; 2022-00310-02).

3. Results

3.1. Sample Characteristics. The characteristics of the respondents are presented in Table 1. This study included 466 respondents, mostly female nurses ($n = 447$; 95.9%). About half of the respondents were 50 years or older ($n = 235$;

50.4%). Of those who answered the questionnaire, 71.4% had an additional specialist education. Most respondents were employed in regions ($n = 317$; 68.3%), and 26% were employed in the private sector.

Although 51.6% of all respondents worked part time, 30.8% stated that they worked more than 40 h per week. In terms of general health, the nurses reported adequate health overall; 77.1% reported good, very good, or excellent health. However, regarding sickness presenteeism, 33.7% of the nurses reported being sick at work to some extent over the past 12 months.

The mean score for leadership climate was 30.3 on a scale ranging from 10 to 40, indicating that most of the nurses were fairly content in this regard. The perception of social support from colleagues was rated at a mean of 9.1 on a scale ranging from 2 to 10, which implies a high level of social support from colleagues. The mean score for change fatigue was 17.3 on a scale ranging from 6 to 30. This indicates that change fatigue is a feature experienced by nurses in primary healthcare.

3.2. Discontent With Current Job, Job Satisfaction, and Turnover Intentions. The results for discontent with one’s current job, job satisfaction, and turnover intentions are presented in Table 2. For the primary outcome variable, discontent, 21.1% of the respondents were dissatisfied with their current job and had considered looking for a new job. The characteristics of these nurses and the associations with other variables were explored further through a regression analysis, as shown in Table 3.

3.3. Characteristics of Primary Care Nurses Who Are Discontent With Their Current Job. Crude and multivariable logistic regression models are presented in Table 3. In Model II, ORs are adjusted for all other variables in the table (sex, age, main employer, working time, general health, change fatigue, leadership climate, and social support from colleagues). Significant associations between discontent with one’s current job and the leadership climate were demonstrated, with a positive leadership climate reducing nurses’ discontent (OR = 0.39; 95% CI 0.28–0.55). Similarly, higher ratings for social support from colleagues were significantly associated with a lower score for discontent (OR = 0.52; 95% CI 0.38–0.72) and change fatigue was associated with higher discontent (OR = 2.18; 95% CI = 1.54–3.10). Those who reported working more than 40 h per week were more than twice as likely to be dissatisfied with their current job compared to those who reported working less than 40 h per week (OR = 2.13; 95% CI 1.14–3.98). Furthermore, respondents who reported poor health were almost four times as likely to experience discontent compared to those who reported good health (OR = 3.90; 95% CI 2.03–7.50).

4. Discussion

This study aimed to investigate working conditions (change fatigue, leadership climate, and social support from colleagues) and characteristics of primary care nurses who are

Social support from colleagues	458	9.1 ± 1.3	

Note: When data are missing, the numbers do not sum up to 466 due to internal dropout.

discontent with their current job, i.e., they have both high turnover intentions and low job satisfaction. One in four nurses in primary care in Sweden is discontent with their current job. In terms of turnover intentions, 69.8% of nurses reported that they, to some extent over the past 12 months, had considered getting a new job and 13.8% rated their job satisfaction as being “fairly dissatisfied” or “very dissatisfied.” Nurses who were discontent with their job to a larger

extent reported a poor leadership climate, less social support, more change fatigue, and poorer general health. Our finding suggests the importance of improving working conditions for nurses in primary healthcare in Sweden to increase their job satisfaction and willingness to stay at their current job. While turnover intentions are a proxy measure used to capture the feelings that lead to leaving a job, research shows that turnover intentions are related to an increased

TABLE 2: Descriptive statistics of job satisfaction, turnover intention, and the primary outcome—discontent with current job, among primary healthcare nurses.

Study variables	Number	Frequency (%)

probability of actual resignation [11, 60]. In fact, the proportion of permanent staff on the team predicts the likelihood of leave rates [60]. Thus, creating attractive workplaces for nurses is essential to prevent continuous employee turnover that may strain both those who leave and those who remain. Limitations in the working environment for nurses have been increasingly highlighted, with reports of high workloads and excessive administrative work unrelated to patient care [61, 62].

We found that a positive leadership climate was associated with reduced discontent among nurses with their current job. Similar associations have been found in other studies of nurses in primary healthcare [63, 64]. These findings can be related to previous research on managerial leadership and its influence on employees' health and well-being (e.g., [65, 66]). For example, studies show that a supportive and relationship-oriented leadership (e.g., managers who express concern, support, and empathy for their staff) is important for employees' well-being at work, including job satisfaction and work engagement [67]. Nursing management can have a significant impact on the work climate, including improving job satisfaction, employee engagement, retention rates and overall staff well-being. Studies show that transformational leadership in nursing management is linked to higher job satisfaction and lower burnout rates among nurses [68]. Nursing managers who provide support, recognition, and feedback to their staff can boost morale and job satisfaction, thus creating a positive work climate and improving nurse well-being and job performance [69].

Experiencing social support from colleagues was another aspect that our study highlighted as an important factor for lower scores for discontent with one's current job. This finding is also in line with previous research [70–73]. It has been shown that supportive colleagues who respect and trust each other, facilitate work motivation, thus encouraging nurses to remain at work [72, 73]. Other positive work environmental aspects, such as recognition for the work that

the nurses perform and autonomy and flexibility to find creative solutions for patients, can contribute to increased job satisfaction [70] and help prevent burnout [74].

Our study demonstrated that change fatigue and poor health were significantly associated with nurse dissatisfaction with their current job. Research demonstrates that change fatigue is associated with decreased job satisfaction [30, 75], as well as increased turnover and absenteeism among nurses [75]. Thus, perceptions that there have been too many organizational changes are one aspect that may negatively influence the possibility of sustainable nurse retention.

There was a trend in our study toward nurses working in regions being more dissatisfied with their current job compared with those working in municipalities or private practices with public funding. A Swedish report highlighted the difficulty in recruiting experienced professionals and professionals willing to work in the regions [2]. Notably, we found that almost one-third of the nurses in our study reported working more than 40 h per week (the Swedish full-time norm), which was another aspect related to dissatisfaction. More than half of the nurses were supposed to work part-time according to their responses as to whether they worked full-time or part-time. Other studies have demonstrated that overtime work is associated with poor nursing performance and decreased patient safety [61], low job satisfaction [60], and an increased risk that the nurse will be afflicted with occupational hazards and injuries [76].

The findings from this study have policy implications for how healthcare organizations and nursing management structure the work of nurses in primary healthcare, how they can attract staff to these workplaces, and how to facilitate nursing retention. High turnover rates may be harmful to healthcare quality if skilled nurses often leave, and nursing staff includes a high proportion of novices. Nurses' working environment affects the quality of care that they provide to their patients [77]; thus, the quality of their work environment may also affect patient safety. Ensuring that nurses

are willing to remain at their workplace and their profession is essential for patient safety and to meet healthcare needs [78]. This is a pressing issue and a challenging task for healthcare organizations and decision-makers. What we do not know, and thus could be of interest to explore further, is what “solutions” for the sustainable retention of nurses are used in practice and considered beneficial for improving their psychosocial working conditions. Specifically, future research is needed on organizational key achievements rather than interventions at the individual level.

There are several methodological issues to consider when interpreting the findings. We used a quantitative research method for this study. The aim was to investigate a population of nurses at one particular point in time, which made a cross-sectional survey appropriate. This type of research makes it possible to reach many individuals in a short time in an inexpensive manner. However, it does not allow for causal inference, as cross-sectional studies can only point to statistical associations between variables [79]. Another limitation was the relatively low response rate and the inability to analyze nurses' reasons for not participating. This means that the generalizability of the findings is somewhat restricted. SCB distributed the questionnaires and provided the researchers with a technical report, including a dropout analysis for the full sample, including nurses in all types of settings—not solely primary healthcare. The response rate for the questionnaire among these nurses was 37.3% (2903 participating respondents). A comparison to the target population showed that there were relatively more nurses born in Nordic countries or with a Swedish background among the survey respondents and that respondents tended to be a little older than the target population and were less likely to be newly graduated nurses.

We lack information about how many primary healthcare nurses were included in the total population. Therefore, we do not know the response rate for this group. However, there are no indications that nurses in primary healthcare would be either more or less likely to answer a questionnaire on psychosocial working conditions than nurses in other settings. As in most research, there is a risk that those who participate are the ones most interested in the topic or most capable of responding. Research has established that more motivated and opinionated people are more likely to respond to surveys [80] and that a lack of motivation, high workload, bad timing, and inaccurate addresses may cause dropouts and nonresponses [81]. Hence, it is plausible that the respondents in this study were either more positive or more negative to the issues we investigated.

Furthermore, the sex distribution in this study is overrepresented by female respondents. However, this is not surprising because the healthcare sector, and nursing in particular, is heavily dominated by females [82]. In 2022, 87% of the nursing population in Sweden were women [82]. Other sampling strategies and analytical methods are required to obtain a clearer gender perspective and to compare the perceptions of male and female nurses. This was not the purpose of the current study but might be of interest in future studies.

In terms of generalizability, we can conclude that the findings of this study are in line with previous research within this area. However, the Swedish healthcare system is part of a comprehensive welfare system with universal coverage for all citizens, i.e., it provides care to anyone in need of it. This might lead to other types of demands on nurses as citizens in Sweden might be more prone to seeking care. Thus, our findings may to some extent be less generalizable to countries with other types of welfare systems, such as the American liberal system in which the state emphasizes the individuals' responsibilities and the need for private health insurance is greater. Although this was not a comparative study between systems or countries, nurses' working conditions may differ depending on which system they work in, and the generalizability of our study's findings, therefore, is mainly related to similar comprehensive healthcare systems.

5. Conclusions

In conclusion, this study found that nurses' discontent with their current job (i.e., high turnover intentions combined with low job satisfaction) is associated with the leadership climate, social support from colleagues, working more than 40 h per week, change fatigue, and poor health. Specifically, experiencing poor health, change fatigue, or working more than 40 h per week were associated with being more discontent, while the perception of a good leadership climate and supportive colleagues were associated with decreased rates of discontent. The retention and recruitment of nurses in primary healthcare are essential to ensure stability in the movement of personnel and to prevent the need for nurses to work more than 40 h per week, which in this study turned out to be associated with discontent.

This knowledge may facilitate the identification of potential problems in need of solutions that could benefit nurses in terms of improved working conditions, patients in terms of potentially increased quality of care, and organizations who are interested in strategies for retaining their staff at work.

Data Availability Statement

The questionnaire data used in this study are restricted by the Swedish Ethical Review Authority in order to protect patient privacy. Furthermore, the respondents have consented to participate in studies conducted by this research group, and we thus lack their consent to share the data.

Aim. To analyze the literature on nursing administrative actions related to patient education to inform healthcare organizations for the development of patient education and identify the knowledge gaps for future research. *Background.* Patient education is a patient's right, yet numerous organizational factors can hinder the effective delivery of patient education. Nursing administrative actions can mediate these factors, but little is known about nursing administration in patient education. *Evaluation.* A systematic integrative review was conducted in October 2022 on five databases (CINAHL (Ebsco), PubMed, Web of Science, ABI/Inform, and Business Source Complete). No time limitations were set. Empirical research articles reporting nursing administrative actions related to educational actions as a main topic were screened and evaluated. The data analysis was based on a constant comparison method. *Key Issues.* There were 3,110 studies identified, of which five quantitative and four qualitative studies were included. Three main themes were generated from the data describing nursing administrative actions related to patient education: (1) strengthen the commitment to patient education, (2) ensure the necessary resources for patient education, and (3) enhance patient education policies. *Conclusion.* This review provides insights into nursing administration in patient education, focusing on commitment, resources, and policies. It not only highlights the critical role of nurse administrators but also calls for further research to assess the impact of these actions. *Implications for Nursing Management.* The findings of this review will be useful for nurse administrators by providing knowledge about nursing administrative actions in patient education and underlining the need for them to pay more attention to it. The implications for nursing management also include supporting further research in the field.

1. Introduction

Patient education is a patient's right [1] and is essential for supporting the empowerment of people in promoting their health and managing their health problems. Patient education is both an "art" and a "science," meaning it is nuanced and evidence-based, and a component of high-quality care [2]. Even though education is considered a core activity of nursing, executing excellent patient education may be demanding due to the need for a comprehensive and patient-centered approach, incorporating both the "art" and "science" aspects [2]. Patient education is described as a process

focusing on both teaching and learning [3]. Terms related to patient education have been identified in the nursing literature despite some differences in these terms, for example, patient teaching, health education [3], health information, counseling, and health promotion [4]. On this basis, we use the term patient education in this review, but the study also considered other terms in the literature search phase, recognizing their interchangeable use with patient education.

A variety of organizational factors have been identified that should be improved in the delivery of patient education [5, 6]. For example, nurses have reported inadequate organizational support, unclear job descriptions [6], and a lack

of resources and time [5]. These studies discuss the important role of the nursing manager in supporting patient education. Recently, practice standards have been developed for patient education in nurse-led clinics, and several of these statements address management's role in patient education [7]. Despite the importance of organizational factors and managerial support for patient education, little is known about nursing management in this core activity of nursing.

Administrator refers to a person who is responsible for carrying out the administration of an organization [8]. In the context of healthcare, the American Nurses Association (ANA) [9], for example, defines a nurse administrator as a person "who orchestrates and influences the work of others in a defined environment, most often healthcare-focused, to enhance the shared vision of an organization or institution" (p.3). Administrators can work at different administration levels of the organization [10]. Administrators at the first and middle levels oversee clinical units at the microlevel, while administrators at the executive level handle top-level patient care administration [11]. There is variation in the international literature on the titles of nurse administrators because of differences in healthcare systems. These titles include nurse manager, ward manager, charge nurse, head nurse, nurse director, supervisor, and nursing officer [12]. In this review, we use the term nurse administrator to cover all these different level administrators in the organizations, assuming their importance for patient education.

Nurse administrators' responsibilities include aspects of both leadership and management which often overlap, such as human resource management, collaboration, nursing development, financial management, and planning and evaluation of actions [13]. Several different leadership styles can also be identified in the work of nurse administrators [14]. In this review, we use the term nursing administration to include both leadership and management. The role of the nurse administrator is important for patient safety and quality of care [15]. It also influences missed nursing care [16]. The work of nurse administrators has an impact on the whole nursing process. Nurse administrators play a crucial role in patient education, and systematic research is required to identify the administrative actions relating to patient education.

2. Aim

The aim of the study was to analyze the literature on nursing administrative actions related to patient education to inform healthcare organizations about the development of patient education and identify the knowledge gaps for future research.

The research questions were as follows:

- (1) What are the nursing administrative actions related to patient education?
- (2) What is the quality of the studies on the nursing administrative actions related to patient education?

3. Methods

3.1. Design. The study design is a systematic integrative review. A guideline by Whittemore and Knafl [17] for the integrative review was followed and complemented by the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines [18] according to the protocol [19].

3.2. Literature Search. The search was guided by the aim and research questions. Predefined inclusion and exclusion criteria related to the topic of interest, research design, and language were followed throughout the literature search process (see Table 1).

The search was completed on 17 October 2022 on five databases: CINAHL (Ebsco), PubMed, Web of Science, ABI/Inform, and Business Source Complete. Furthermore, the reference lists of the included reports were examined by two researchers. The search terms were formulated based on the PICO framework: the population was administrators, the interest was patient education, and the context was nursing. A wide range of related keywords were used to obtain comprehensive information on the topic. The search strategy was based on the eligibility criteria and revised for each database (Table 2). The search was limited to the English language in all databases. Where possible, only peer-reviewed reports were included (i.e., in CINAHL, ABI/Inform, and Business Source Complete). There was no time limit for the inclusion studies. Prior to the systematic search, the research team repeatedly tested and revised the search strategy in close collaboration with an information specialist at the University of Turku.

The reports were transferred, and the duplicates were removed in the reference management software Zotero, Corporation for Digital Scholarship (version v6.0.15). Two researchers screened each record independently (title, abstract, and the full text). Any disagreements between screeners were resolved in discussions with the research team.

3.3. Data Analysis. The data analysis was based on a constant comparison method consisting of four steps as reported by Whittemore and Knafl [17]. The analysis was performed using the Methods and the Results sections of the studies. First, in the data reduction, one researcher collected the data from the included reports in a data extraction table, which included information about the author(s), year of publication, title, location, study design, the purpose of study, sample, context, data analysis, and results. Next, each study was examined for sentences and phrases describing the administrative actions in patient education in the context of nursing from the perspectives of different data sources, such as head nurses, supervisors, and nurses. Administrative actions related to patient education delivered by physicians were not included. The actions identified were extracted

TABLE 1: Inclusion and exclusion criteria.

Inclusion criteria	Exclusion criteria
The main topic of the report is nursing administrative actions related to educational actions	The main topic of the report is nurse administrator-developed or researched patient education (but not nursing administrative activities)
Educational actions are connected to health individual or group health education or promotion	Health promotion at the population/community level
An international scientific peer-reviewed report	Not scientific peer-reviewed report, e.g., conference abstracts, theses/dissertations, editorials, and letters
Empirical research report	Discussion/theoretical papers and literature review
The full text is available	
English language	

TABLE 2: An example of the search strategy (PubMed).

(“Health Education” [Mesh] OR “Health Promotion” [Mesh] OR “Consumer Health Information” [Mesh] OR “Patient Education as Topic” [Mesh] OR “Counseling” [Mesh] OR “health education” [tw] OR “patient education*” [tw] OR “patient-educat*” [tw] OR counseling [tw] OR counseling [tw] OR “health information*” [tw] OR “health promoti*” [tw] OR “patient guidance” [tw] OR “patient information” [tw] OR “patient teach*” [tw] OR “treatment information” [tw] OR “health advice” [tw]) AND (“Nurse Administrators” [Mesh] OR “Nursing Administration Research” [Mesh] OR “Nursing, Supervisory” [Mesh] OR “nurse leader*” [tw] OR “nursing leader*” [tw] OR “nurse manager*” [tw] OR “nurse management*” [tw] OR “nursing management*” [tw] OR “nurse executive*” [tw] OR “nurse administrator*” [tw] OR “nursing administrator*” [tw] OR “head nurse*” [tw] OR “nurse supervision” [tw] OR “nursing supervision” [tw])

verbatim from each of the studies. The collection process was guided and monitored by the research team. Subsequently, data were organized and coded into a data display matrix. Data comparison was conducted by comparing and grouping coded phrases of nursing administrative actions related to patient education based on similarities of actions. The codes were gradually clustered into subthemes and finally merged into overall main themes [17].

Data quality was assessed independently by two researchers using the Joanna Briggs Institute Critical Appraisal Tools [20, 21]. The appropriate tool was chosen based on the study design of each report (Checklist for Analytical Cross-Sectional Studies or Qualitative Research). Any disagreements in data evaluation were resolved by the research team. No report was excluded based on the data evaluation.

4. Results

There were 3,110 studies identified from five databases and 408 studies from citation searches. After the removal of duplicates, 2,424 studies were screened for eligibility. The title screening process excluded 2,133 studies, 295 studies were retrieved first at the abstract level, and 55 studies were retrieved in full text. Finally, nine studies focusing directly on nursing administrative actions related to patient education met the inclusion criteria (Figure 1).

4.1. Characteristics of the Included Studies. The nine selected studies were published between the years 2001–2019. Five studies used a descriptive cross-sectional design [22–26], and four used qualitative designs [27–30]. The study’s characteristics are presented in Table 3.

The studies were conducted in five different countries: Four in Iran [22–25, 27], two in Sweden [24, 28], one in Finland [26], one in the Netherlands [28], and one in the United States [29]. Most of the studies ($n = 7$) had a hospital environment as the study setting [22–25, 27, 28, 30]. Other study settings were adult acute psychiatric hospitals [26] and telephone advice nursing services [29], and one study was set in primary and municipal care, in addition to hospitals [24].

Nursing administrative actions related to patient education were identified from different perspectives. In most of the studies ($n = 8$), the respondents were administrators: nursing managers, head nurses or supervisors [22, 23, 25, 26, 28, 29], or patient education officers [30]. Four of these studies also included other respondents, such as nurses ($n = 3$) [25, 27, 29], documents, and websites [30]. One study reported exclusively nurses

as respondents [24]. In some of these studies, the respondents also included patients [25] and physicians [25, 29]. However, the patients’ and physicians’ perspectives did not directly describe the relation between nursing administrative actions and patient education by nurses, and their perspectives have, therefore, not been taken into account in the final analysis of this review.

Information on nursing administrative actions related to patient education was collected through questionnaires [22–26, 29], interviews [25, 27–30], and observations [27] of respondents. In addition, websites and documents were analyzed [30].

4.2. Quality of the Selected Studies. Based on our quality assessment [20, 21], the quality varied among both cross-sectional and qualitative study designs (Table 3). Most commonly, there were disparities in reporting in terms of strategies to deal with confounding factors [22, 23, 25, 26] and criteria for inclusion in the sample [23, 25, 26]. All qualitative studies lacked a statement of the researcher’s cultural or theoretical location [27–30]. One qualitative study clearly reported a philosophical perspective [28].

4.3. Nursing Administrative Actions Related to Patient Education. As a result of the analysis, three main themes describing nursing administrative actions related to patient education were identified: (1) strengthen the commitment to patient education, (2) ensure the necessary resources, and (3) enhance patient education policies. Each main theme includes several subthemes, identified from three different perspectives: nurse administrators, nurses, and policy papers. Main themes, subthemes, codes, and original phrases describing nursing administrative actions related to patient education are presented in Table 4.

The main themes ($n = 3$), subthemes ($n = 9$), and different perspectives are described below in detail. For each theme, the different perspectives are presented in order: first, the nurse administrators’ perspectives, followed by the perspectives of other respondents such as nurses, or if the respondents were not specified in the study, as a common opinion.

4.3.1. Theme 1: Strengthen the Commitment to Patient Education. The first theme describes nursing administrative actions to strengthen the commitment to patient education including three subthemes: enhancing motivation for patient education [22, 27, 29], prioritizing patient education

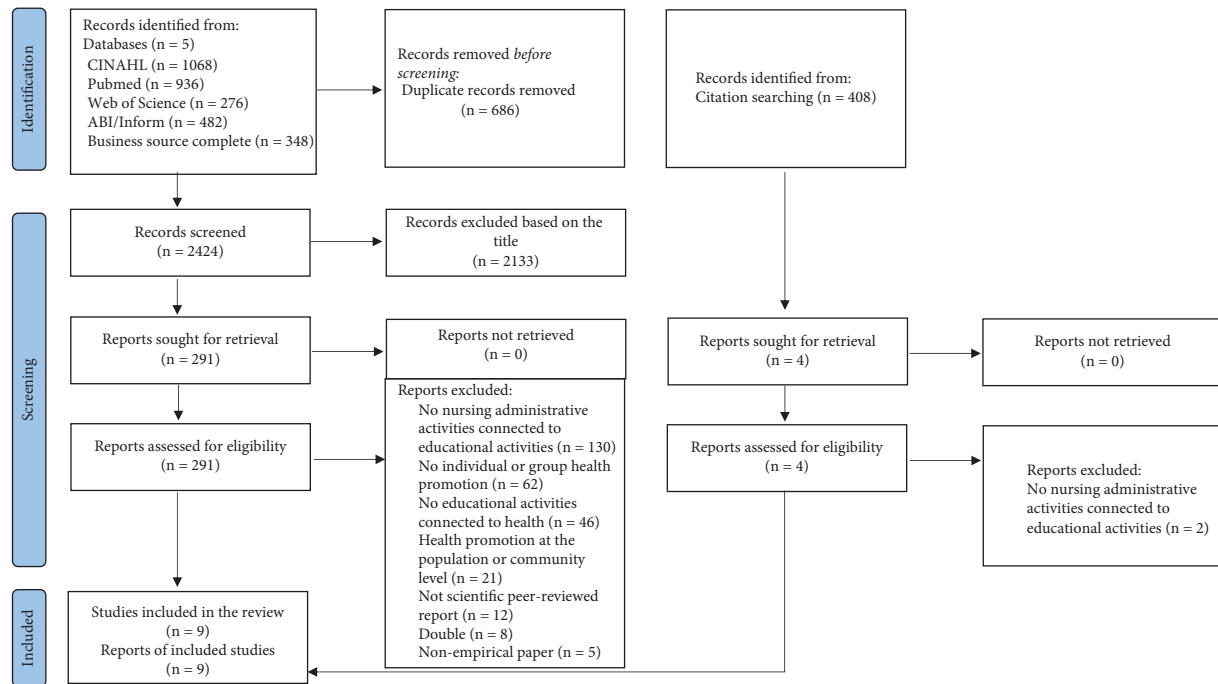

FIGURE 1: PRISMA flow diagram [18].

[25, 27], and providing support [24, 28, 29]. These sub-themes describe the strengthening of nursing, administrative, and organizational commitment to patient education in terms of reported development targets, lacking issues, and important aspects.

(1) *Enhancing Motivation for Patient Education.* Nurse administrators should develop factors that motivate nurses to overcome the obstacles of patient education [27]. Nurse administrators assessed that the most important factor in forming motivation was to improve nurses' mentality and motivation [22]. When asked about educational barriers, nurses reported that managers should appreciate nurses' efforts in patient education [27] and provide feedback [27, 29].

(2) *Prioritizing Patient Education.* Patient education was not given enough attention by nurse administrators. However, both nurses and managers stated that everyone within an organization needs to actively participate in patient education and that patient education should be a priority [27]. Some nurses agreed that if managers did not value patient education, nurses should not be so concerned about it either [25].

(3) *Providing Support.* Nurse administrators reported the importance of helping new nurses with patient education [28]. According to nurse administrators, the most important factor in engaging nurses in patient education was utilizing nurses' suggestions for patient education [22]. Nurses' perceptions of managerial support for patient education include managerial consultation, valuing and supporting the nurses' advisory role [29], and interested and involved managers [24].

4.3.2. *Theme 2: Ensure the Necessary Resources for Patient Education.* This theme describes nursing administrative actions to ensure all the necessary resources in patient education in three sub-themes: creating facilities for patient education [22, 27, 28, 30], managing human resources [22, 25, 26, 28], and educating and training [26, 27]. In the next paragraphs, these sub-themes will be described in detail: first, how nurse administrators saw themselves, second, highlighting the problems related to patient education, and third, what was seen as important for nurses.

(1) *Creating Facilities for Patient Education.* Nurse administrators saw their responsibility as creating facilities for nurses to provide patient education, such as providing space for education and access to the Internet [22, 28], and introducing standard forms for patient education [22]. Designing appropriate forms was seen as improving patient education [27]. Creating facilities for patient education also includes budgeting, where nurse administrators experience powerlessness in explaining deficits to their superiors [28]. Also, nurses reported that having designated facilities and rooms for patient education would enhance its effectiveness [27].

(2) *Managing Human Resources.* Human resource management was highlighted as a problem related to patient education by nurse administrators. They described situations of understaffing and tight work schedules that they had to manage [26–28]. Most of the nurse administrators still assessed that requesting nurses to provide patient education is realistic [25]. Establishing coordination in relationships and coordination of educators was assessed as an important task of the nurse administrators' role in patient education

TABLE 3: A summary of the selected studies ($n = 9$).

Author(s), year of publication, and location	Purpose of the study	Sample, sample size, and sampling method	Study design and data collection	Context	Data analysis	Quality scores (JBI 2020, critical appraisal tools)
Fereidouni et al. 2019, Iran [27]	"To document the perspectives and recommendations of nurses with regard to patient education" p.2	Head nurses, $n = 8$, clinical nurses, $n = 16$, and purposive sampling	A qualitative exploratory design semistructured in-depth interviews focus group observation	Medical, surgical, emergency, and pediatric departments	Conventional content analysis (Graneheim and Lundman 2004)	7/10
Ghorbani et al. 2019, Iran [22]	"To determine the mechanisms for attracting nurses" for attracting nurses" engagement in patient education from the viewpoint of nursing managers" p.164	Nursing managers (ward head, supervisor), $n = 91$, convenience sampling	A cross-sectional descriptive-analytic study A two-part questionnaire (developed for this study) (40 questions)	Educational hospitals	Descriptive statistics methods	7/8
Bergh et al. 2015, Sweden [28]	"To explore the conditions for nurses' daily patient education work by focusing on managers' way of speaking about the patient education provided by nurses in hospital care" p.192	Managers, $n = 10$	A qualitative exploratory design (i) A social constructionist perspective 3 focus group interviews	Not specified, patient education in hospital care	Critical discourse analysis	9/10
Seyedin et al. 2015, Iran [23]	"To investigate the dimensions of patient education process including need assessment, planning, implementation, and evaluation" p.2	Head nurses, $n = 187$, convenience sampling	A descriptive cross-sectional study A questionnaire (developed for this study) (i) 1 part: demographics, (ii) 2 part (31 items) a five-point Likert scale (1 = never and 5 = always)	Teaching hospitals	Descriptive statistics methods	4/8
Bergh et al. 2012, Sweden [24]	"To describe nurses' perceptions of conditions for patient education, focusing on organizational, environmental and professional cooperation aspects" p.759	Nurses, $n = 701$, stratified random sample	A cross-sectional survey A questionnaire (developed for this study) (60 items) with fixed response categories (1-5) dichotomous response options (yes or no) open-ended answers	Primary care, municipal care, and hospital care	Quantitative data: statistics methods Qualitative data: a content analysis	8/8
Vafae-Najar et al. 2012, Iran [25]	"Studying what patient education services were offered and which organizational factors in the hospitals affected the provision of these services" p.231	Patients, $n = 441$, physicians, $n = 200$, nurses, $n = 185$, supervisors, and managers, $n = 70$, stratified and simple sampling	A descriptive cross-sectional study of four self-administered questionnaires Three answer choices (agree, disagree, and neutral) open-ended questions and closed questions interviews	Teaching hospitals	Quantitative data: statistics methods Qualitative data: a content analysis	2/8

TABLE 4: Main themes, subthemes, codes, and original phrases describing nursing administrative actions related to patient education.

Subtheme	Code	Original phrase	Study
<i>Main theme 1: Strengthen the commitment to patient education</i>			
Enhancing motivation for patient education	Developing factors that motivate nurses	<p>“To overcome the obstacles of patient education, total commitment is necessary. Nurses must be fully willing to devote the necessary time and energy to patient education and believe in it. Thus, administrators should strengthen institutional commitment by developing motivational factors and facilitating change by every impetus to achieve this milestone.” p.4</p> <p>“Regarding motivation, the most important factor from the viewpoint of head nurses was forming motivation to follow the policy and teaching methods to the patient.” p.166</p> <p>“Regarding motivation, the most important factor from the viewpoint of supervisors was Improving the mentality and motivation of nurses.” p.166</p>	Fereidouni et al. 2019
	Motivating nurses	<p>“In another case, a participant stated that ignoring the nurses who enroll eagerly in patient education is not reasonable. Managers should appreciate their efforts, even with a smile or other acknowledgment.” p.4</p>	Ghorbani et al. 2019
	Improving nurses' motivation	<p>“Nurses indicated they did not receive feedback on advice appropriateness and that feedback on caller outcomes would be more helpful than the monitored service indicators.” p.220</p>	Ghorbani et al. 2019
	Appreciating nurses' efforts in patient education	<p>“12.2% of the nurses agreed with the viewpoint that if the managers did not consider patient education to be an important factor they should also not be so concerned about it.” p.234</p> <p>“The participants stated that all stakeholders should consider patient education a priority and take measures toward improving education. One participant mentioned: “A lasting change requires a general determination. All people in the organization from the top of pyramid to its base should actively participate.” p.4</p>	Fereidouni et al. 2019
	Improving patient education motivation and performance	<p>“The observations also revealed that these supervisors did not pay attention to patient education in their rounds and did not consider this domain to be a priority. The following field note showed that practical involvement of the supervisors was not sufficient.” p.4</p>	Fereidouni et al. 2019
Prioritizing patient education	Focusing on patient education	<p>“71.4% believed that due to the nurses' workload in each division, patient training would only be possible if special staff were dedicated to it.” p.234</p>	Vafaee-Najar et al. 2012
	Dedicating special staff to patient education	<p>“It's important that managers have an opportunity to help young nurses instead of being overwhelmed by administrative tasks—we're the ones who should help them. Patient teaching takes time, thus it's a question of where we're going to find the time.” p.194</p>	Bergh et al. 2015

TABLE 4: Continued.

Subtheme	Code	Original phrase	Study
Supporting patient education	Leveraging nurses suggestions for patient education	<p>“Using nurses’ constructive and effective suggestions for patient education, from the viewpoint of supervisors” p.166</p> <p>“Nursing personnel complained about their authority and decision making in hospitals. “Favoritism is corrosive. Desecration, discrimination, lack of authority, and professionalism are disappointing in our hospital. First of all, we should strengthen our profession and define our territory by choosing a qualified matron, supervisors, and nursing personnel.” p.4</p>	Ghorbani et al. 2019
	Getting interested and involved in supporting patient education	<p>“A total of 214 nurses responded to the supplementary open-ended item regarding perceptions of managerial support in nurses’ PE. Five categories emerged: offer of professional competence development, allocated time, available room for teaching, available working tools and interested and involved managers.” p.761</p>	Bergh et al. 2012
Supporting patient education	Providing consulting options for nurses executing patient education	<p>“One nurse observed that “I am not trained to deal with suicidal patients and yet, after hours, I am the only one available in the system to deal with this member.” Although she did have access to the on-call physician or could refer the patient to outside services, she still felt unsupported. In the medical offices, nurses could consult with an on-site physician, pharmacist, or supervisor.” p.220</p>	Valanis et al. 2003
	Valuing and supporting the nursing advice role	<p>“Nurses expressed varying perceptions of the extent to which the healthcare system valued and supported the nursing advice role. One medical office nurse stated: “I wonder how much advice nurses are actually valued. If there is a staff shortage in the clinic, we are always the first ones pulled.” p.221</p>	Valanis et al. 2003

TABLE 4: Continued.

Subtheme	Code	Original phrase	Study
<i>Main theme 2: Ensure the necessary resources for patient education</i>	Ensuring adequate working conditions	“Managers regarded themselves as responsible for creating the necessary conditions for nurses to conduct their daily work.” p.194	Bergh et al. 2015
	Creating room and facilities	“The importance of barriers to patients’ education, the most important factor from the perspective of head nurses was the creation of facilities and classes for patient education (video-internet-lag).” p.166	Ghorbani et al. 2019
	Facilitating patient education work	“There was a desire for external parties to study the managers’ work situation to help them facilitate nurses’ patient education work: “We’re running around and an outsider would surely ask: Why are you doing that?”” p.196	Bergh et al. 2015
	Providing room to conduct patient education	“We need a quiet room in our wards for patient education to enhance its effectiveness. Concentration in a noisy environment is impossible for patients.” p.5	Fereidouni et al. 2019
	Providing facilities to conduct patient education	“We need some facilities (such as video, TV, video software, and so on) to show various educational films on patient diets and medications while patients are in beds in their own rooms.” p.5	Fereidouni et al. 2019
	Budgeting	“The managers were powerless as professionals in relation to their superiors when budgeting was discussed: “We’re virtually up against the wall when we have to explain our deficits.”” p.196	Bergh et al. 2015
	Implementing standardized patient education forms	“From the viewpoint of head nurses, included introducing standard forms of education to the patient provided by health Ministry (3.88 ± 0.97), while it was being aware of the actual and potential capabilities of nurses (3.91 ± 0.79).” p. 166	Ghorbani et al. 2019
	Designing forms for patient education	“The participants stated that having a specific form for patient education was necessary. They mostly mentioned that the current forms that were used in the hospital were obligatory for patients and quite time-consuming to complete. Thus, they recommended designing appropriate forms to improve patient education.” p.4	Fereidouni et al. 2019
	Developing patient education leaflets	“In Dutch hospitals on the program level of patient education, there are specialized nurses with important roles in patient education for several patient groups. Dutch hospitals have a large number of patient leaflets on treatments that are developed within the hospital.” p.6	Albada et al. 2001
	Managing patient education materials	“Most Flemish hospitals have little organization of patient education on the organizational level. The editing of patient information leaflet is an important activity on the organizational level. This task is generally among the responsibilities of a general communications officer.” p.7	Albada et al. 2001
Developing patient education leaflets	“The hospital developed patient education leaflets for diabetes and cataract patients. Policy on when to give face-to-face information and leaflets is present for education with diabetes patients.” p.7	Albada et al. 2001	

TABLE 4: Continued.

Subtheme	Code	Original phrase	Study
		<p>“Altogether 50 respondents described problems related to patient education on their wards. First, patients’ poor condition in terms of lack of insight and poor motivation was perceived most frequently ($n = 33$) to hinder the patient education. Second, a lack of staff resources ($n = 25$) meant that there was not sufficient staff on the wards and they were not motivated or competent to carry out patient education. Third, the discrepancy in the procedures ($n = 17$) concerned the unplanned and short treatment periods and lack of patient education instructions. Fourth, poor operational conditions ($n = 9$) were described.” p.337</p>	Hätönen et al. 2010
Managing resources and environmental conditions		<p>“A typical description of the connection between available resources and nurses’ patient education work is provided in the following quotation: “It mustn’t cost anything. We struggle with the tight nursing turnarounds where everything has to be done incredibly quickly. We might have to discharge 6-7 patients every day and it’s almost like a conveyor belt, but what kind of information do they get? There used to be a discharge meeting, at which the patient could ask the physician and the nurse questions but that rarely happens today. When the patient asks questions in connection with discharge, the nurse often says—yes but you saw the physician” [in the nurse’s opinion the patient should have asked the physician at the discharge meeting].” p.196</p>	Bergh et al. 2015
Managing human resources	Coping with tight nursing schedules	<p>“17.6% of the managers also believed that “Due to the high volume of responsibilities expected from nurses, requesting them to provide a patient education service is unrealistic.” p.234</p>	Vafae-Najar et al. 2012
Requesting nurses to provide patient education		<p>“Considering the position of participatory management, the most important factor from the perspective of head nurses was the coordination in relationship and coordination of trainers in different shifts.” p.166</p>	Ghorbani et al. 2019
Managing available resources		<p>“Other obstacles to the development of patient education were that nurses often changed workplaces and that available healthcare resources were reallocated and used for training.” p.196</p>	Bergh et al. 2015
Coping with a shortage of nurses		<p>“I think that patient education falls through the cracks due to the high workload in the hospital. The nursing shortage is really a crisis. When I have seven patients in each shift, there is no chance left for patient education.” p.5</p>	Fereidouni et al. 2019

TABLE 4: Continued.

Subtheme	Code	Original phrase	Study
Educating and training new nurses		“Participants stated that newly graduated students were novices and that they started working in hospitals without experience. Thus, these new nurses needed to understand the importance of patient education and be thoroughly trained in this regard. One participant stated, “Frequent in-service education is recommended for nurses to improve their knowledge to educate patients efficiently.” p.5	Fereidouni et al. 2019
		“Less than half of the (45%) respondents reported that the nurses had sufficient professional education to deliver patient education interventions, whereas sufficient on-the-job training for staff had been poorly realized.” p 337	Hätönen et al. 2010
Improving training for staff		“Previously, nurse educators participated in students’ caring activities. Caring conversations created conditions for nurses to reflect over their own care and patient education, thus helping them grow in their profession. The managers stated that it was necessary for nurses to have time for reflection: “to advance from novice to expert” (FG, 2), something that was missing today.” p.196	Bergh et al. 2015
		“Primary care managers offered professional competence development in PE significantly more frequently than in MC/HC.” P. 761	Bergh et al. 2012
Providing opportunities for professional growth			
Offering professional competence development in patient education			

TABLE 4: Continued.

Subtheme	Code	Original phrase	Study
<i>Main theme 3: Enhance patient education policies</i>			
Monitoring and supervising patient education	Giving positive and negative reinforcement	“A head nurse said, “Managers should use carrots and sticks at the same times. Frequent punishment will not work.” p.4	Fereidouni et al. 2019
	Monitoring nursing tasks	“After repeated prompts to provide a more detailed description of the prerequisites for patient education, the managers quickly moved to general descriptions of nursing tasks that have to be monitored, such as documentation and liaison.” p.197	Bergh et al. 2015
	Supervising the process of patient education	“On the other hand, they are the line managers in hospitals who directly supervise the processes; therefore, they know and can judge the process of patient education in their wards.” p.2	Seyedin et al. 2015
	Ensuring quality	“The managers have control over routine matters as well as the power to decide the content, which implies quality assurance.” p.197	Bergh et al. 2015
Monitoring the implementation of patient education	Documenting	“The juridical discourse contained several controlling factors that restricted the nurses’ time available for patient education. By referring to the public regulations in health care, the managers expressed that nurses must exercise control and be controlled. The regulations require documentation. “I’m not exactly terrified but “I have to document everything to cover my back” is frequently heard.” p.197	Bergh et al. 2015
		“The participants acknowledged that including the implementation of patient education in annual personnel evaluations would be effective. Another participant also mentioned that “annual supervision at a specific time is not effective. Supervision should be intrusive and frequent” . p.4	Fereidouni et al. 2019
	Paying attention to how patient education is monitored	“Nurses reported aspects of the practice environment that limited their professional practice, impaired their optimal functioning, and contributed to low morale. These included the extent to which they were required to adhere to protocols, supervisor emphasis on time targets (eg, call time, talk time, and documentation time), and monitoring to ascertain that required questions were asked of all callers.” p.221	Valanis et al. 2003
	Managing operations	“Hence, they expressed a desire to have power to manage operations.” p.196	Bergh et al. 2015

TABLE 4: Continued.

Subtheme	Code	Original phrase	Study
		<p>“Constant changes constituted an obstacle to the development of the patient education provided by nurses, and all professional categories had tasks that were beyond their professional competence. The managers had no time. Only the most important administrative tasks were performed, and the rest were ignored: “It depends on how you sell it and your own opinions. I really resist any change. we’re fire fighters, we only have time to man the ward. We can’t reorganise things and think afresh. We have done that; now we have to reduce the number of tasks” . p.196</p>	Bergh et al. 2015
Reducing the number of tasks of managers		<p>“All of the head nurses mentioned that their job description needed to be revised by their hospitals based on new accreditation criteria. They stated that they were currently busy with the new accreditation criteria and standards, which led to their unintentional neglect of nursing care obligations such as patient education.” p.4-5</p>	Fereidouni et al. 2019
Revising job description	Updating the description of head nurses’ tasks and responsibilities	<p>“Managers commented that patient criticism about not receiving or understanding information would decrease if nurses devoted more time to patient teaching: “They do a whole lot of the physicians” tasks these days. Many physicians don’t prescribe tests—the nurse has to do it in our computer system and decides which tests should be performed. A lot of time is spent changing prescriptions for medications that are completely off the wall. if the nurse didn’t have to do these medical tasks she’d have more time for patient education.”</p>	Bergh et al. 2015
Clarifying nurses’ job descriptions		<p>“Managers commented that patient criticism about not receiving or understanding information would decrease if nurses devoted more time to patient teaching: “They do a whole lot of the physicians” tasks these days. Many physicians don’t prescribe tests—the nurse has to do it in our computer system and decides which tests should be performed. A lot of time is spent changing prescriptions for medications that are completely off the wall. if the nurse didn’t have to do these medical tasks she’d have more time for patient education.”</p>	Bergh et al. 2015

	Promoting patient education through international organizations	“The World Health Organization (WHO) promotes patient education through the Health Promoting Hospitals project.” “The European Association for Communication in Healthcare (EACH) aims to stimulate research and education on communication in healthcare.” “The European Association for the Study of Diabetes (DESG) provides advice and best practices on patient education in diabetes.” p.8	Albada et al. 2001

[22]. Nurses also reported factors relating to managing resources, and the lack of these was seen as a problem [27].

(3) *Educating and Training for Staff*. Educating and training new nurses was considered vital to improve their knowledge for effective patient education [27]. Nurse administrators reported that on-the-job staff training had been poorly realized [26]. Reflection was also an important part of education: one nurse administrator reported the importance of creating opportunities for nurses to reflect on their own care and patient education to support them grow as professionals [28].

4.3.3. *Theme 3: Enhance Patient Education Policies*. The third main theme was enhancing patient education policies. Patient education policies were divided into international, national, organizational, and program levels [30]. These policies influence nursing administrative actions within an organization. The nursing administrative actions related to this main theme include three subthemes: monitoring and supervising patient education [23, 27–29], revising job descriptions [27, 28], and developing and implementing policies and procedures [22, 30]. In the next paragraphs, these subthemes will be described in detail; first, how nurse administrators supervise patient education, second, what nurse administrators mentioned should be revised, and third, what are the nursing administrative actions at different levels relating to developing and implementing policies and procedures.

(1) *Monitoring and Supervising Patient Education*. Nurse administrators supervise and monitor the patient education process [23, 27–29]. This also includes documentation to meet legal requirements and quality assurance, for which managers are responsible for supervising routine tasks and deciding on content [28]. Nurses reported that patient education requires constant supervision [27], although too much control was also perceived as limiting professional work [29].

(2) *Revising Job Descriptions*. Nurse administrators reported that their job descriptions need revision [27], e.g., by reducing the number of tasks [28], because they did not have sufficient time resources to fulfill their responsibilities [27, 28]. The nurse administrators also described situations where nurses' job descriptions need to be revised. Nurse administrators commented that if nurses had more time for education, the number of patient complaints about patient education would decrease [28].

(3) *Development and Implementation of Policies and Procedures*. Nursing administrative actions at different levels include developing policies for patient education programs and coordinating quality projects in patient education [30]. They also considered providing legal and professional information on patient education as an essential factor [22]. Furthermore, nursing administrative actions include implementing patient education policies, e.g., focusing on

informed consent and promoting patient education through international organizations. At the national level, national laws, policies, and guidelines influence patient education. Centers of expertise and patient organizations influence patient education through quality projects. At the international level, the World Health Organization (WHO) promotes patient education through various projects [30].

5. Discussion

This integrative literature review examined the nursing administrative actions related to patient education, as there is a dearth of research in this area although it is a core nursing activity. The objective was reached, and the review produced information for both purposes: to inform healthcare organizations about the identified nursing administrative actions connected to patient education and to identify knowledge gaps for future research.

Different nursing administrative actions were identified from different perspectives, even though the number of analyzed studies was not very high (nine studies). Three main themes were formed: (1) strengthen the commitment to patient education, (2) ensure the necessary resources for patient education, and (3) enhance patient education policies. These themes highlight the actions corresponding to previous research on the standards developed for patient education [7] and nurse administrators' work content [13]. Additional research is needed on nursing administrative actions of patient education and to explore the connections and outcomes of these administrative actions to support high-quality and sustainable patient education.

Most of the studies focused specifically on the perspective of nurse administrators [22, 23, 25–29] working at the first and middle levels of their organizations; therefore, the identified actions do not necessarily represent all nursing administrative actions of patient education. First- and middle-level nurse administrators provided only a microview of detailed information on administrative actions related to patient education in the organizations. Moreover, the two qualitative studies included in this review showed that these nurse administrators did not always recognize the importance of their role in improving patient education [27, 28] which highlights the need to explore in more detail nurse administrators' experiences of their professional responsibilities concerning patient education. In previous research, nurse managers also find it difficult to express how to support nurses in undertaking fundamental care, possibly because it is overlooked in priorities [31]. The research area, therefore, still has gaps, and further research is needed in the future to synthesize these findings and explore reasons in depth. High-level administrators' actions on patient education need to be explored more, especially as there is a demand for nurses in high-level administration [32, 33]. Future research should take these different levels into account to provide a shared understanding of nursing administrative actions related to patient education. It would also be useful to analyze these different levels of administration actions separately to obtain more detailed practical information on patient

education-related nursing administrative activities in organizations.

In the literature, the nursing administrative actions were not related to patients. For patients, the ethical and often legal basis for patient education is their right to be knowledgeable about their health and care [34], and therefore, for the administration of patient education, patient outcomes should be the main interest in nursing administrative actions and should not be disregarded in future research. In the future, research is needed to explore the connections between nursing administrative actions and patient outcomes. Also, the perspectives of patients about nursing administrative actions on patient education were lacking in the included studies. This may be due to the fact that administrative actions might not be directly visible to patients, although they may have useful views that can be relevant to nursing administration [35]. The importance of the patient's perspective is emphasized especially due to the growing interest in patient and public involvement [36] and administrators' efforts aimed at sustainable and transparent healthcare [37]. Including patients' views could potentially provide information on the outcomes of nursing administrative actions for patients.

Our aim to analyze the nursing administrative actions of patient education also deserves a critical comment. A challenge in the analysis was that the nursing administrative actions of patient education were not always clearly described, but the studies described problems relating to patient education. This was the assumption, and therefore, a broad selection of keywords was used. We tried to reach as wide a range of studies as possible but still did not reach very specific studies on nursing administrative actions related to patient education. Both nurses and nurse administrators describe similar organizational barriers that hinder patient education [22, 24–29]. A common barrier was lack of time [24, 25, 27–29] which has also led to missed nursing care in other studies as tasks with direct patient care have been prioritized over patient education [5, 38]. It is worth noting that nurse administrators experienced the same problems on which they should provide support for their nursing staff. Nurse administrators indicated that there was a lack of time for nurses to provide patient education due to tight work schedules [25, 28]. However, lack of time and constant changes also hinder administrators' work to support patient education [28]. These findings highlight the need for improvement in these areas. Nurse administrators should also be offered support in their work to enable them to act on patient education. The studies identified some actions by nurse administrators to address these issues, e.g., revising job descriptions, but there is still a lack of knowledge on how to solve these issues in more detail.

This integrative review explored comprehensively nursing administrative actions related to patient education. The number of studies on the topic was quite low, which may indicate that patient education has not been identified as an area of nursing administration. Despite the low number of studies, these different designs provide rich information about nursing administration related to patient education. In the future, it would be relevant to explore the actions

identified in this review individually, targeting a specific activity, such as human resource management. It would also be beneficial to explore the connection between administration styles and patient education as it is known that there is a significant correlation between positive leadership styles and nurses' commitment to their work [16]. This could provide information on how to tackle the barriers to strengthening commitment to and ensuring the necessary resources for patient education.

5.1. Limitations. There are some limitations in this review, related to the sample/respondents, analysis of the result, and literature search. Respondents were first- and middle-level nurse administrators in their organizations, which may bias the generalizability of the results. Furthermore, the nursing administrative activities related to patient education were not always clearly described, which may have led to omissions in the analysis. However, this was controlled by monitoring the collection process and by frequent discussions within the research team. In addition, the quality of the included studies varied, and no report was excluded based on the data evaluation. In the literature search, the search terms "management" and "supervisor" generated a considerable number of studies of disease or patient management and supervising students, respectively. However, these were excluded at the latest in the full-text screening phase because they were out of the administrative scope of this review. In screening for the studies, the research team had constant discussions on differentiating the studies that focused directly on the nursing administrative action of patient education from those that reported administration actions in a limited section of the report.

6. Conclusion

This review provided new insight and a better understanding of nursing administration in patient education. Different nursing administrative actions related to patient education were identified relating to strengthening the commitment to patient education, ensuring that the necessary resources are available, and improving the policies for patient education. These actions highlight the important role of nurse administrators in patient education and should be made more visible. However, further research is needed to assess what are the outcomes of these nursing administrative actions on patient education. The results also revealed various obstacles related to these administrative actions, and these should be explored in the future.

7. Implications for Nursing Management

Based on the results of this review, nurse administrators tend to deprioritize patient education as their administrative action, or they do not have optimal conditions to act upon it. This review can raise awareness among nurse administrators on how to administer one of the central nursing actions and improve its quality. Nursing administrative actions vary, including strengthening the commitment to patient education, ensuring the necessary resources, and enhancing

patient education policies. All these activities should be given high consideration when developing patient education in organizations. The implications for nursing management also include supporting future research in this area: the development of patient education and its management requires more scientific evidence.

Data Availability

The data supporting this integrative review are from previously reported studies and datasets, which have been cited.

Ethical Approval

Good scientific practice was followed throughout the whole review process [39].

Conflicts of Interest

The authors declare that there are no conflicts of interest.

Nurses in South Korea experience high work intensity and poor working environments, which worsened during the COVID-19 pandemic. This study aimed to evaluate the work changes and grievances of nurses who provided direct care for patients at tertiary hospitals during the pandemic. The nurses' perceptions of their organizational culture and its impact on nurses' health were also explored. A three-round Delphi study was conducted with 36 expert group participants from six South Korean tertiary hospitals. Overall, 36, 35, and 33 participants responded in the first, second, and third rounds, respectively. Nursing work was divided into three categories: "work related to COVID-19-positive and close contacts," "work related to COVID-19 negative patients," and "work related to common nursing tasks." Organizational culture had the highest average for "increased compliance," followed by "increased conflict," "decreased collegiality," and "growing sense of community." The identified health problems of nurses during the pandemic were the highest for physical health, followed by mental and social health. These results showed that the workload and work intensity of hospital nurses increased significantly, and their physical, mental, and social health deteriorated during the pandemic. To overcome the crisis, the nursing organizational culture had a strong inclination to comply with the COVID-19-related guidelines with an increased sense of community. As conflicts between employees and departments grew, these were able to be overcome through trust and communication between departments, in which the nursing leadership played an important role. To protect the health and lives of people, it is important to secure skilled nurses in preparation for future disasters. In addition, support is needed to protect the safety and health of nurses and to cultivate effective nursing leadership.

1. Introduction

The World Health Organization declared the coronavirus disease 2019 (COVID-19) outbreak a global pandemic in March 2020 (WHO, 2020) [1]. The pandemic had significantly impacted politics, economy, society, culture, and healthcare worldwide, with diverse quarantine policies reflecting the community characteristics of each country [2, 3], as the COVID-19 continued in a rapid mass-spread pattern [4]. Nurses were at the forefront of this crisis, facing numerous challenges (i.e., insufficient resources, lack of

personal protective equipment, mandated long working hours, and lack of manpower) [5–7].

South Korea's COVID-19 pandemic management received much attention globally as a relatively successful quarantine effort compared to that of other overseas countries, where the number of confirmed cases and deaths increased rapidly [8, 9]. South Korean health authorities quickly established specialized COVID-19 hospitals and recruited medical personnel to treat patients with COVID-19. However, as the pandemic continued and the specialized hospitals ran out of beds, the role of tertiary hospitals

expanded to include tracking, isolating, and treating the COVID-19 patients [10].

Therefore, during this period, the work of tertiary hospital nurses became challenging by the direct care of patients with COVID-19, and complex and burdensome indirect care tasks (such as monitoring to prevent patients and their caregivers becoming infected, environmental management according to the quarantine guidelines, and adaptation/implementation of frequently changing COVID-19 guidelines), in addition to the general tasks previously performed. In most South Korean medical institutions, nurses experienced various unexpectedly complex and difficult situations in preventing the spread of infectious diseases [11, 12]. South Korean nurses were called “heroes” during the pandemic and recognized as the main players of the “K-quarantine.” However, meaningful and realistic support was lacking regarding the nurses’ grievances and the nurses could not adequately solve their grievances [13, 14].

Before the pandemic, South Korean hospitals were notorious for poor working conditions due to the high job demands and lack of resources for nurses [15]. The COVID-19 pandemic has placed huge physical and psychological burdens on nurses who already have enough on their plates, leading to various health problems. The deterioration of nurses’ working environment has raised concerns about worsening occupational health and safety, physical and mental exhaustion, and other complaints such as physical symptoms (i.e., musculoskeletal strains and pain) during the pandemic [16]. In addition, nurses’ psychological distress was extremely increased as they were dealing with fears of self-infection and concerns about possible viral transmission to their own families, as well as the soaring work demands while witnessing patient suffering and death [17, 18].

While coping with these unprecedented challenging situations in medical institutions, organizational culture also changed rapidly [19]. Organizational culture significantly influences the working environment and therefore substantially affects the behavior and well-being of medical professionals. However, it is difficult in uniformly evaluating the responses of medical institutions and their impact on nurses because the medical organization environments and policies varied worldwide, and the responses to COVID-19 also differed [20]. As nurses struggled to cope with an unprecedented pandemic, changes in their work and organizational culture and in-depth understanding of their health concerns are essential for allocating manpower and resources and for preparing systems for future disasters. However, few studies have focused on the work of nurses in Korean healthcare settings.

Therefore, using the viewpoints of nurses who provided direct care during the pandemic, this study was conducted to identify changes and related grievances in their work role and organizational culture and identify their health issues. We hope to provide some beneficial data for establishing efficient strategies, such as efficient allocation of manpower and resources and system overhaul, to help stakeholders prepare for future disaster situations.

2. Materials and Methods

2.1. Research Design. This survey study derived its results by applying the expert group Delphi technique to understand the COVID-19-related changes in work, organizational culture, and health effects as experienced by nurses who worked at tertiary hospitals in South Korea. The Delphi technique is based on the principle of quantitative objectivity that “opinions of two people are more accurate than that of one person” and the principle of democratic decision-making that “many judgments are more accurate than a few,” when accurate information is lacking on the problem to be estimated [10]. The Delphi technique is a method used to investigate the opinions or judgments of experts in the fields of decision-making, prioritization, and prediction [21].

2.2. Participants. The number of experts can vary from study to study [22], but the majority of Delphi studies have used between 15 and 20 respondents [23]. However, this study aimed to recruit a total of 40 participants, considering the similarities and differences related to the characteristics of the region and hospital size. The participants were nurses from six tertiary hospitals: three in Seoul, the largest city in South Korea, and three in Daejeon City, a medium-sized metropolitan area. The selected hospitals were representative tertiary hospitals in each region, each with more than 20 clinical departments.

The inclusion criteria for participants were head nurses, senior nurses, or general nurses with preferably at least five years of experience or those with a master’s degree or higher, even if their experience was slightly shorter. Nurses working in COVID-19 dedicated wards, intensive care units, operating rooms, outpatient departments, or those in managerial positions not involved in direct patient care were excluded.

Participants were recruited using the snowball sampling technique, and 36 participants agreed to participate after being individually contacted by the researchers. Among the 36 participants, one had less than five years of experience but was included due to holding a master’s degree and serving as a senior nurse in the ward.

The response period for each round was set to two weeks. After sending out the questionnaire, responses were awaited for one week, followed by a reminder message to non-respondents. Another reminder was sent two days before the deadline to encourage responses. Despite these efforts, there were four nonrespondents in the first round, one in the second, and two in the third, resulting in final responses from 36 participants in the first round, 35 in the second, and 33 in the third. All the participants were women with an average age of 35.3 ± 7.9 years. The average nurse experience was 12.7 ± 8.1 years and included staff nurses (44.4%), charge nurses (41.7%), and unit managers (13.9%) in the medical (38.9%) and surgical (61.1%) wards. The levels of education included bachelor’s degrees (38.9%), master’s (or currently attending) degrees (52.8%), and doctorate (or currently attending) degrees (8.3%) (Table 1).

TABLE 1: General characteristics of the expert panel (N = 36).

Variables	Categories	n (%) or M ± SD
Sex	Female	36 (100.0)
Age (years)	<30	11 (30.6)
	30–39	16 (44.4)
	40–49	6 (16.7)
	50≤	3 (8.3)
	M ± SD	35.3 ± 7.9
Experience (years)	<5	1 (2.7)
	5–9	15 (41.7)
	10–19	15 (41.7)
	20≤	5 (13.9)
	M ± SD	12.68 ± 8.1
Position	Staff nurse	16 (44.4)
	Charge nurse	15 (41.7)
	Unit manager	5 (13.9)
Department	Medical ward	14 (38.9)
	Surgical ward	22 (61.1)
Education	Bachelor's degree	14 (38.9)
	Master's degree	19 (52.8)
	Ph.D. degree	3 (8.3)

2.3. Data Collection. The research procedures to identify the COVID-19-related changes in nurses' work, organizational culture, and nurses' health in tertiary hospitals were largely divided into draft development and preliminary survey, first Delphi survey and focus group interviews, structured questionnaire development, and main survey.

2.4. Draft Development. The researchers reviewed various literature and available data on the work and organizational culture of medical hospital personnel using keywords, such as "inpatient ward," "work role," "nurse," "organizational culture," and "COVID-19." The questionnaire was largely composed of three categories: changes in nurses' work, changes in organizational culture, and COVID-19-related effects on health.

Under the category of "changes in nurses' work," the following open question was asked, "What nursing tasks have changed (in the amount or intensity of work) due to COVID-19?" For the category of "changes in organizational culture," the following open question was asked, "What has improved and worsened?" The participants were asked to describe perceived changes in detail. Then, they were asked about their health while coping with the COVID-19 at work.

2.5. Preliminary Investigation. The preliminary survey was conducted on June 25, 2022, to develop questions, and five participants were selected to conduct the survey. The answers were reviewed to determine if the questions seemed ambiguous, if there were any duplicate questions, or if any items seemed inconsistent with the study purpose. Based on the results of the preliminary survey, the researchers revised the questions.

For example, the questions under "changes in nurse's work" were divided into nursing work prior to and during the COVID-19. The questions about "changes in organizational culture" were restructured as the atmosphere within the

organization, communication methods, and efforts to resolve conflicts. Finally, the health questions were reorganized by addressing emotional, physical, and social health aspects.

2.6. Delphi Investigation. The first survey was sent via SNS or text message to 40 consenting participants who provided answers within two weeks. In efforts to better understand the results of the first survey, the researchers conducted a focus group interview with three participants who responded to the first round.

After the focus group, the questions were then refined to form a structured questionnaire.

For example, "changes in nursing work" was largely divided into *work related to COVID-19-negative patients*, *work related to COVID-19-positive patients (and other close contact cases)*, and *work related to common nursing tasks*. As the South Korean government's COVID-19 quarantine policy changed periodically, the time period pertaining to nursing work was limited from 2021 to the time of data collection (the third Delphi survey was completed on September 30, 2022).

To assess changes in organizational culture, the questions were divided into nursing floor (ward) atmosphere, communication, and conflict resolution, and the COVID-19-related health effect was divided into physical health, mental health, and social health.

An objective tool was developed to evaluate the frequency and degree of demand for each configured category on a five-point scale. For example, specific items under "changes in nursing work" were rated on a five-point Likert scale (1 = almost none, 2 = occasional implementation, 3 = normal, 4 = do it often, 5 = do it very often). The frequency of work performance and task difficulty were evaluated (1 = very easy, 2 = easy, 3 = normal, 4 = difficult, and 5 = very difficult). The changes in organizational culture and COVID-19-related health effect were also rated (1 = very disagreeable, 2 = disagreeable, 3 = normal, 4 = agree, and 5 = agree very much).

2.7. Ethical Considerations. This study was conducted after receiving approval from the Bioethics Committee of E University (IRB no. EU22-29). The participants were informed of the study purpose and procedures and provided written informed consent. In addition, the researchers explained that the survey data would be used only for research purposes and that anonymity and confidentiality would be guaranteed. Participants were informed of their right to refuse and withdraw from the study at any time without any consequences. For each Delphi survey conducted, sufficient time was provided to respond to the survey. A small gift was provided to the participants.

2.8. Data Analysis. In principle, the Delphi investigation process is conducted until experts reach an agreement [24] and up to third rounds were performed in this study. The mean and variation coefficients were determined for performance frequency, task difficulty, and degree of consent for each question. The coefficient of variation (CV) is used to evaluate the stability of the question, in which the experts' consensus is high for values <0.5 , while values of $0.5-0.8$ and ≥ 0.8 mean that further Delphi investigations are needed because of low agreement [25]. In this step, investigation after the second step was meaningless if an expert consensus is reached [23]. The present study investigated the opinions of the expert panel of nurses using structured questions until there was a consensus reached. The survey was conducted by delivering the questionnaire online to the experts, who responded within 14 days. Open questions were used in the preliminary survey to indicate specific opinions or items to include in the second and third rounds of the survey. Data were analyzed using IBM SPSS Statistics for Windows, version 26.0.

3. Results

3.1. Frequency and Difficulty of Nursing Work Related to COVID-19. The nursing work related to COVID-19 was largely classified into three categories: *work related to COVID-19-positive patients (and other close contact cases)*, *work related to COVID-19-negative patients*, and *work related to common nursing tasks* (Table 2).

3.2. Work Related to Patients Positive for COVID-19 and Close Contact Patients. The nursing work related to COVID-19-positive patients (and other close contact cases) pertains to performing specific tasks for those patients with confirmed COVID-19 or classified as close contact cases in the ward. In this category, "direct nursing work" rather than "indirect nursing work" increased overall. "Environmental and commodity management," such as cleaning and disinfecting rooms, also increased significantly.

The most frequently performed task related to "direct nursing work" was following the quarantine guidelines including retrieving the COVID-19 results for the patients and guardians ($M = 4.79$, $CV = 0.10$), which was identified as the second highest degree of difficulty ($M = 4.52$, $CV = 0.13$). The most difficult task was wearing protective gear when dealing

with isolated patients or responding to call bells ($M = 4.67$, $CV = 0.12$), indicating that the frequent donning and removing of level D protective gear during each patient encounter was very demanding. The added-on tasks of collecting blood and other specimens directly ($M = 4.00$, $CV = 0.25$; $M = 4.36$, $CV = 0.21$) and serving/assisting with meals ($M = 4.15$, $CV = 0.18$; $M = 4.03$, $CV = 0.22$) had to be performed by nurses themselves.

The most demanding task in indirect nursing was responding to complaints from patients and guardians following their COVID-19 confirmation after hospitalization ($M = 4.61$, $CV = 0.12$). As they were often asymptomatic and became positive while in the hospital, addressing complaints, providing explanation in the event of the confirmation or close contact case designation ($M = 4.55$, $CV = 0.11$), and confirming the change of guidelines for the patients with close contact designation ($M = 4.21$, $CV = 0.19$) were often difficult and time-consuming.

Environmental and product management work also increased significantly and was noted as difficult. The frequency of performance ($M = 4.58$, $CV = 0.12$) and difficulty ($M = 4.52$, $CV = 0.13$) were high for all related procedures, such as securing transport routes for inspection and isolation room. Managing the hospital room was also to be performed frequently and was a demanding task, including transporting confirmed patients and cleaning the hospital room ($M = 4.36$, $CV = 0.18$; $M = 4.42$, $CV = 0.14$), room ventilation, disinfection, linen, and curtain management ($M = 4.48$, $CV = 0.17$; $M = 4.15$, $CV = 0.19$). In addition, product/item procurement and room management for patients and guardians occurred frequently and were time-consuming. This included the direct procurement of drinking water and ice packs/hot packs for quarantined patients ($M = 4.15$, $CV = 0.25$; $M = 4.24$, $CV = 0.17$), room organization and arrangement of personal items as per patients' request ($M = 4.33$, $CV = 0.21$; $M = 4.21$, $CV = 0.18$), and management of resident guardian/couriers and food ($M = 4.33$, $CV = 0.19$; $M = 4.00$, $CV = 0.21$). In addition, the task of medical and general waste management was also performed frequently ($M = 4.52$, $CV = 0.16$) and was physically intensive work ($M = 4.21$, $CV = 0.17$) as some hospitals required nurses to handle medical and general waste due to access restrictions of janitorial staff.

3.3. Work Related to COVID-19-Negative Patients. Work related to COVID-19-negative patients refers to work that was increased or added on due to the pandemic. In this category, "indirect nursing work" increased more than "direct nursing work," and the degree of demand was much higher. Among indirect tasks, the highest degree of demand was an increase in patient status inquiries due to the prohibition of visitors ($M = 4.64$, $CV = 0.12$) and the frequency of this task performance was also high ($M = 4.73$, $CV = 0.10$).

There were increased frequencies of reporting on patients and resident guardians' COVID-19 symptom status ($M = 4.85$, $CV = 0.09$), and the degree of demand was also high ($M = 4.33$, $CV = 0.17$). This increase in reporting was linked to the increasing number of vital sign measurements

TABLE 2: Frequency and difficulty in performing nursing work related to coronavirus disease 2019 (COVID-19).

Category	Item	Frequency		Difficulty	
		Mean	CV	Mean	CV
Direct nursing work	(1) Use protective gear to treat quarantined patients or respond to call bells	4.67	0.12	4.58	0.12
	(2) Multistep nursing activities required according to isolation guidelines until COVID-19 results of patients and guardians are released	4.79	0.10	4.52	0.13
	(3) Direct blood specimen collection by nurses due to access restrictions	4.00	0.25	4.15	0.18
	(4) Serving meals/assisting with meals due to access restrictions	4.36	0.21	4.03	0.22
	(5) Check whether periodic PCR tests are performed and observe symptoms	4.70	0.10	4.33	0.15
Indirect nursing work	(1) Responding to complaints from patients and guardians	4.61	0.11	4.61	0.12
	(2) Explaining the situation in the event of confirmation or close contact	4.27	0.23	4.55	0.11
	(3) Confirmation of changed guidelines during the examination of patients with close contacts	4.36	0.18	4.21	0.19
Work related to COVID-19-positive and close contacts	(1) All procedures, such as securing a transport route for inspection and isolation room	4.58	0.12	4.52	0.13
	(2) Clean the hospital room after quarantine of confirmed patients	4.36	0.18	4.42	0.14
Environmental and commodity management	(3) Direct procurement of drinking water, ice packs, and hot packs for quarantined patients	4.15	0.25	4.24	0.17
	(4) Management of medical and general waste	4.52	0.16	4.21	0.17
	(5) Organize or manage items that are not managed by a single patient	4.33	0.21	4.21	0.18
	(6) Securing beds to move to the hospital room after the quarantine period ends	3.97	0.29	4.15	0.18
	(7) Ventilation, disinfection, linen, and curtain management in the hospital room	4.48	0.17	4.15	0.19
	(8) Assisting guardians (i.e., food and other related management)	4.33	0.19	4.00	0.21

TABLE 2: Continued.

Category	Item	Frequency		Difficulty	
		Mean	CV	Mean	CV
Work related to COVID-19-negative patients	(1) Increased COVID-19 inpatient infections and related discharge education	4.33	0.21	4.27	0.22
	(2) Increased hygiene management such as changing diapers and cleaning up urine/feces	4.15	0.25	4.12	0.31
	(3) Bringing syringes one at a time to each patient to prevent infection	4.27	0.20	4.09	0.19
	(4) Increased number of patients without guardians, increasing meal assistance	3.97	0.31	4.00	0.28
	(5) Increased frequency of checking vital sign measurements for patients/guardians	4.21	0.25	3.97	0.26
Indirect nursing work	(1) Increased calls for patient status due to prohibition of guardian visits	4.73	0.10	4.64	0.12
	(2) Increasing reporting of patients and guardians' COVID-19 symptoms	4.85	0.09	4.33	0.17
	(3) Increased ward tours for patient safety and fall management	4.36	0.15	4.30	0.18
	(4) Increased use of monitors and device rental due to increased patient severity	4.30	0.20	4.06	0.26
	(5) Regular PCR testing and confirmation of results to patients and caregivers, and confirmation of vaccination	4.79	0.11	4.06	0.25
	(6) Increased checklist for COVID-19 testing and infection in surgical patients	4.15	0.31	3.73	0.38
Work related to common nursing tasks	(1) Item delivery to patients due to discontinuation of guardian visits and increased purchases	4.03	0.31	3.91	0.27
	(2) Management of outings (outings of guardians or caregivers, and separation of movement from other outpatients)	4.39	0.21	4.24	0.21
	(3) Explaining the hospital policy (i.e., one guardian per patient, following the guidelines when visiting or going out)	4.70	0.10	4.21	0.15
	(4) Monitoring the application of resident guardians' masks and curtains, and announcing other relevant restrictions	4.91	0.06	4.12	0.19
	(5) Fever check and other related management with visitors	4.76	0.16	4.12	0.25
	(6) Identifying the number of caregivers or guardians	4.58	0.15	3.88	0.30
Environmental and commodity management	(1) Increased calls for patient status due to prohibition of guardian visits	4.73	0.10	4.64	0.12
	(2) Increasing reporting of patients and guardians' COVID-19 symptoms	4.85	0.09	4.33	0.17
	(3) Increased ward tours for patient safety and fall management	4.36	0.15	4.30	0.18
	(4) Increased use of monitors and device rental due to increased patient severity	4.30	0.20	4.06	0.26
	(5) Regular PCR testing and confirmation of results to patients and caregivers, and confirmation of vaccination	4.79	0.11	4.06	0.25
	(6) Increased checklist for COVID-19 testing and infection in surgical patients	4.15	0.31	3.73	0.38
Environmental and commodity management	(1) Item delivery to patients due to discontinuation of guardian visits and increased purchases	4.03	0.31	3.91	0.27
	(2) Management of outings (outings of guardians or caregivers, and separation of movement from other outpatients)	4.39	0.21	4.24	0.21
	(3) Explaining the hospital policy (i.e., one guardian per patient, following the guidelines when visiting or going out)	4.70	0.10	4.21	0.15
	(4) Monitoring the application of resident guardians' masks and curtains, and announcing other relevant restrictions	4.91	0.06	4.12	0.19
	(5) Fever check and other related management with visitors	4.76	0.16	4.12	0.25
	(6) Identifying the number of caregivers or guardians	4.58	0.15	3.88	0.30

for patients and their resident guardians ($M=4.21$, $CV=0.25$; $M=3.97$, $CV=0.26$) because nurses had to monitor not only the patients but also their resident guardians for symptoms and vital sign measurements. In addition, the frequency was high for increasing ward tours for patient safety and fall prevention ($M=4.36$, $CV=0.15$) and the degree of work demand for this task was high ($M=4.30$, $CV=0.18$).

The highest frequencies of direct nursing work were increased COVID-19-related infection and discharge education ($M=4.33$, $CV=0.21$), and the degree of arduousness was high ($M=4.27$, $CV=0.22$). This shows that checking quarantine guidelines, which changed frequently during the chaotic situation of the pandemic; accurately educating patients and guardians; and preventing confusion were the most frequent and arduous tasks.

As the number of patient cases without their resident guardians increased due to the quarantine guidelines, nurses had to perform sanitary management typically performed by the guardians, such as changing diapers and cleaning urine, and both the frequency ($M=4.15$, $CV=0.25$) and the degree of demand ($M=4.12$, $CV=0.31$) were high. In addition, the time per nursing task increased because nurses had to bring only one syringe or a single device at a time for each patient to prevent infection ($M=4.27$, $CV=0.20$), which was too time-consuming and demanding ($M=4.09$, $CV=0.28$).

3.4. Changes in Organizational Culture during the COVID-19 Pandemic

3.4.1. Changes in the Nursing Floor (Ward) Atmosphere. Changes in nursing organizational culture were largely divided into changes in the atmosphere of the ward, communication, and conflict resolution measures (Table 3). First, the change in ward atmosphere was classified into four topics, with the highest average observed for *increased rule compliance* ($M=4.25$), followed by *increased conflict* ($M=4.15$), *reduced collegiality* ($M=3.73$), and *growing sense of community* ($M=3.58$).

The item with the highest average score in *increased rule compliance* was “creating an atmosphere that emphasizes compliance” to the COVID-19 guidelines ($M=4.64$, $CV=0.11$), followed by “eating alone” ($M=4.52$, $CV=0.14$) and “inform/share the frequently changing guidelines and foster interest” ($M=4.33$, $CV=0.17$). To comply with the guidelines, nurses ate alone on their days off (not eating with their families) and during the hospital’s working hours. In addition, they refrained from talking but were encouraged to inform/share any changes in guidelines with colleagues.

Increased conflicts occurred due to differences in opinions between the department, infection control office, and other departments when transporting confirmed patients ($M=4.42$, $CV=0.14$) and experienced “communication breakdown with other employees” due to work overload ($M=4.27$, $CV=0.17$). The next highest scores were observed for *reduced collegiality*, mostly due to the “increase in alternating nursing assignments for the isolation ward to increase manpower” ($M=3.91$, $CV=0.32$), “decreased

personal friendships between employees due to reduced socialization such as ward dinners” ($M=3.76$, $CV=0.26$), and “increased individualism” ($M=3.52$, $CV=0.34$). Some responded that their “sense of community” increased as they came together to overcome the chaotic situations, although the average score was the lowest for this item ($M=3.58$, $CV=0.32$).

3.4.2. Communication and Conflict Resolution Measures. During the COVID-19 pandemic, “non-face-to-face communication through SNS, bulletin boards, videos, and phones” increased ($M=4.12$, $CV=0.19$), while “vertical communication through unit managers” increased ($M=3.70$, $CV=0.25$) and most of the education in hospitals showed “transition to cyber-education, non-face-to-face education, reduced verbal communication” ($M=3.55$, $CV=0.35$).

Regarding conflict resolution measures, the score was highest for: “the attitude of a senior or chief nurse to take the initiative” ($M=3.70$, $CV=0.31$) and “efforts to resolve conflicts between employees through communication” ($M=3.70$, $CV=0.24$). Other conflict resolution measures included: “efforts to understand/sympathize with each other and trust department members” ($M=3.67$, $CV=0.22$), “resolving conflicts through conversations between department heads” ($M=3.45$, $CV=0.28$), “engage in more conversations to find a solution” ($M=3.27$, $CV=0.33$), and “meet with the chief nurse to provide an opportunity to talk about grievances” ($M=3.21$, $CV=0.35$). The lowest score was observed for the item, “avoiding conflict and just moving on” ($M=2.76$, $CV=0.44$).

3.4.3. Health Problems Faced by Nurses during the COVID-19 Pandemic. The most frequently reported health problems faced by nurses during the COVID-19 pandemic were physical health problems ($M=4.55$), followed by mental health ($M=4.33$) and social health ($M=4.19$) problems, with an overall average of 4.35 (Table 4).

The highest physical health score was for “increased fatigue due to frequent shiftwork to cover for infected colleagues” ($M=4.82$, $CV=0.08$). If a previously scheduled nurse was unexpectedly confirmed to be positive for COVID-19, other nurses had to step in to complete the work. The scores for “increased fatigue from increased workload” due to strict quarantine guidelines such as multistep infection prevention measures and wearing protective gear ($M=4.76$, $CV=0.09$) and “feeling sick due to COVID-19 infection” ($M=4.70$, $CV=0.11$) also were high. In addition, even though the self-quarantine period was seven days according to the quarantine guidelines with confirmed COVID-19 infections, “infected nurses could only take five days off and were physically exhausted” ($M=4.48$, $CV=0.19$). The scores for “worsened back pain due to frequent patient turning/position change and increased incontinence care” were also high ($M=4.36$, $CV=0.20$).

The highest mental health score was “increased emotional labor in dealing with guardians and other caregivers” ($M=4.76$, $CV=0.09$), followed by “increased stress due to heavy workloads” ($M=4.64$, $CV=0.14$), “increased anxiety

TABLE 3: Changes in nursing organizational culture during the coronavirus disease 2019 (COVID-19) pandemic.

Categories	Mean \pm SD	Items	Mean	CV
Changes in the atmosphere	4.25 \pm 0.44	(1) Creating an atmosphere that emphasizes compliance	4.64	0.11
		(2) Eating alone (while working and at home)	4.52	0.14
		(3) Inform/share the guidelines and foster interest	4.33	0.17
		(4) Only work-related conversations allowed during work	3.52	0.30
Increased conflict	4.15 \pm 0.22	(1) Increased conflicts between the main department, infection control room, and other departments when transporting confirmed patients	4.42	0.14
		(2) Overwork leads to communication breakdown with other employees	4.27	0.17
		(3) Increased sensitivity/reactivity to each other	4.06	0.19
		(4) Work style conflicts as multiple department personnel are mixed	3.85	0.28
Decreased collegiality	3.73 \pm 0.16	(1) Increase in alternating nursing assignments for the isolation ward to increase manpower	3.91	0.32
		(2) Decreased personal friendships between employees due to reduced socialization, such as ward dinners	3.76	0.26
		(3) Increased individualism	3.52	0.34
Growing sense of community	3.58 \pm 0.00	(1) Increasing sense of community to overcome the crisis together	3.58	0.32
		(1) Non-face-to-face communication through SNS, bulletin boards, videos, phone calls, etc.	4.12	0.19
		(2) Vertical communication through the unit manager	3.70	0.25
Communication and conflict resolution measures	3.64 \pm 0.34	(3) Transition to cyber-education, non-face-to-face education, reduced verbal communication	3.55	0.35
		(4) Communication with caregivers and guardians by broadcast	3.18	0.39
		(1) The attitude of a senior or chief nurse to take the initiative	3.70	0.31
		(2) Efforts to resolve conflicts between employees through communication	3.70	0.24
Conflict resolution measures	3.39 \pm 0.32	(3) Efforts to understand/empathize with each other and trust department members	3.67	0.22
		(4) Resolving conflicts through conversations between department heads	3.45	0.28
		(5) Engage in more conversations to find a solution	3.27	0.33
		(6) Meet with the chief nurse to provide an opportunity to talk about grievances	3.21	0.35
		(7) Avoiding conflict and just moving on	2.76	0.44

due to the risk of transmission to own families" ($M = 4.58$, $CV = 0.12$), and "increased stress due to conflicts with guardians and difficulty communicating with patients" ($M = 4.52$, $CV = 0.14$).

For social health, the item with highest score was "improved societal awareness about nurses during the COVID-19 pandemic" ($M = 4.48$, $CV = 0.17$). Many participants also reported "decreased usual leisure activities due to increased fatigue" ($M = 4.45$, $CV = 0.14$) and that "frequent absenteeism due to fellow nurses' infections/illnesses and extended working hours disrupted family life" ($M = 4.36$, $CV = 0.17$). Many participants also said that they felt "disconnected from social relationships due to social distancing and compliance with quarantine measures" ($M = 4.18$, $CV = 0.22$) and that they were "socially isolated when they were confirmed to have COVID-19" ($M = 4.09$, $CV = 0.24$). Additionally, many responded that it was "painful to prioritize and focus only on hospital work" (i.e., forsaking their normal daily lives/routines during the pandemic) ($M = 3.94$, $CV = 0.28$).

4. Discussion

This study was conducted to determine the changes in work roles and complaints of nurses providing direct patient care for inpatients in South Korean tertiary hospitals during the COVID-19 pandemic and to explore nurses' perceptions of organizational culture and nurses' health problem during the crisis. The study showed that Korean nurses experienced increased work intensity, performed multiple tasks without additional staff, and demonstrated various physical, psychological, and social symptoms while coping with the COVID-19 situation.

Korea's COVID-19 pandemic management utilized a risk-control strategy to manage the possibility of risk at an acceptable level using effective containment measures [10]. Accordingly, all people in contact with confirmed patients were tracked, classified as close contacts, and required to follow the quarantine guidelines. Therefore, whenever patients with confirmed COVID-19 or close contact were unexpectedly identified in multibed inpatient rooms, all required multistep nursing activities had to be carried out according to the quarantine guidelines, which were burdensome and complicated tasks.

Direct nursing tasks that required donning protective gear repeatedly and continued compliance with the strict quarantine guidelines increased physical fatigue and burden, while the number and frequency of indirect nursing tasks such as patient transport management and environmental management (i.e., cleaning/sterilizing room and bed) also increased rapidly [11, 26]. The emotional labor of nurses intensified as they addressed perpetual flurry of complaints from both patients and guardians [26].

Due to the insufficient staffing of nurses, most patients in South Korean medical institutions, except those in few hospitals with special (integrated nursing care service) wards, voluntarily have resident guardians who provide care (usually family members or hired help). These guardians perform some of the nonskilled nursing work, such as

providing incontinence care and washing/dressing the patients [27]. However, during the pandemic, the number of caregivers on duty was limited due to quarantine requirements. Therefore, nurses had to perform more frequent ward rounds to monitor patient conditions, procure supplies for patients and caregivers, and manage the ward.

Tasks such as changing diapers and assisting with meals (which were typically performed by guardians) became additional tasks for nurses, as the allowed number of guardians was limited due to the COVID-19 guidelines. Other added-on indirect nursing work such as purchasing and delivering of goods (water, snacks, etc.) for quarantined patients also increased. Nurses also had added-on work of other personnel, such as phlebotomist, dietary, and janitorial staff [28]. As most hospitals restricted access to other nonnursing personnel to prevent the spread of infection, nurses had to perform nonnursing work, such as collecting blood and other laboratory specimens, delivering/serving meals, and disinfecting/sterilizing supplies.

In addition, when moving patients with COVID-19, the movement of others in hallways, elevators, and other areas had to be controlled. Therefore, they had to follow strict quarantine procedures, including notifying other patients and caregivers, and contacting facility management. Nurses were also required to provide numerous explanations and make announcements. These include explaining the policies, such as having only one resident guardian per patient; checking and explaining the COVID-19 guidelines when going out/leaving the hospital or visiting; monitoring the proper application of guardians' masks and hospital room curtains, management of guardians' outings, and separation from visitors as needed; and knowing/enforcing infection control guidelines and hospital regulations.

This study illustrates the reality of Korean hospitals, where nurses are expected to perform a myriad of patient-related tasks, including the role of doctors, phlebotomist, nursing assistants, and clinical pathologists, as well as the role of room management, transport, and cleaning services, without any specific job role limitations. Nurses in South Korean hospitals have expressed distress regarding the inability to eat, use the bathroom, and engage in whatever task they have to perform [15]. Distress among nurses gained attention during the COVID-19 pandemic.

This is also a problem with the current legal system, where the role of nurses is not clearly defined in the law but only mentioned in a single line in the Medical Service Act revised in 1973, "nursing or medical attendance of the sick or pregnant women" [29]. Although in Korea, the role of nurses over the past 5 years has become more sophisticated and broader in scope with the rapid development of medical technology, the law has not been updated, creating a myriad of problems [30]. The definition of the role of nursing is unclear; therefore, the advanced tasks performed by nurses cannot be verified whether they are legal, but all the tasks in hospitals can easily be transferred to nurses.

In addition, the ratio of patients to nurses in Korean hospitals is high by default. A study reported that the patient per nurse ratio (16.3 patients per nurse) was very high and was 2-3 times higher than that of either the United States or

TABLE 4: Health problems faced by nurses during the coronavirus disease 2019 (COVID-19) pandemic.

Categories	Mean \pm SD	Items	Mean	CV
Physical	4.55 \pm 0.21	(1) Increased fatigue due to frequent shiftwork to cover for infected colleagues	4.82	0.08
		(2) Increased fatigue from increased workload due to strict quarantine guidelines (multistep protective measures, wearing protective gear, etc.)	4.76	0.09
		(3) Feeling sick due to COVID-19 infection	4.70	0.11
		(4) When infected, nurses could only take five days off and were physically exhausted	4.48	0.19
		(5) Increased musculoskeletal and other physical symptoms due to increased intensity of work and frequently wearing uncomfortable protective gear	4.42	0.16
		(6) Worsened back pain due to frequent patient turning/position change and increased incontinence care	4.36	0.20
		(7) Muscle weakness and decreased physical strength	4.27	0.21
Psychological	4.33 \pm 0.39	(1) Increased emotional labor in dealing with guardians and other caregivers	4.76	0.09
		(2) Increased stress due to heavy workloads	4.64	0.14
		(3) Increased anxiety due to the risk of transmission to own families	4.58	0.12
		(4) Increased stress due to conflicts with guardians and difficulty communicating with patients	4.52	0.14
		(5) Difficulty in coping with stress	4.39	0.16
		(6) Increased stress due to insufficient care time per patient due to heavy workloads	4.18	0.20
		(7) Increased loneliness and depression	3.97	0.20
		(8) Low self-esteem ("I studied for 4 years and got a diaper license.")	3.61	0.30
Social	4.19 \pm 0.27	(1) Improved societal awareness about nurses during the COVID-19 pandemic	4.48	0.17
		(2) Decreased usual leisure activities due to increased fatigue	4.45	0.14
		(3) Frequent absenteeism and extended working hours interfered with family life	4.36	0.17
		(4) Disconnected from social relationships to keep social distance and to comply with quarantine measures	4.18	0.22
		(5) Socially isolated when they were confirmed to have COVID-19	4.09	0.24
		(6) Painful to prioritize and focus only on hospital work	3.94	0.28
		(7) Nurses caring for COVID-19 patients were avoided by others	3.79	0.26

the United Kingdom [31]. Even before COVID-19, it was reported that 63.2% of nurses in South Korean hospitals skipped meals more than once a week due to workload, 48.2% did not have annual leave/vacation, and 81.0% were at high risk for accidental injuries due to insufficient staffing [32]. The COVID-19 pandemic has exacerbated the poor working conditions of these nurses.

Another challenge for nurses was the inability to take time off for holidays or weekends due to the frequent shift changes. For example, it was common for an off-duty nurse to cover for a colleague who could not report to work due to an unexpected COVID-19 case. Despite the quarantine guidelines of self-quarantining for 7 days in the event of COVID-19, nurses often had only five days off before returning to work. The reason was that the hospital was not staffing enough nurses and was running shifts with fewer staff, so no nurses were available to cover the vacant duties. Nurses became exhausted and often experienced symptoms, such as physical pain, fatigue, depression, anxiety, and posttraumatic stress disorder because of long hours of high-intensity labor, lack of rest, and limited manpower [33–35]. If no nurses were available to replace them, the workload increased due to overwork. If a nurse suddenly resigned midshift, the remaining nurses suffered with a heavier workload [11, 17].

These poor working conditions during the pandemic contributed to nurses' health problems, which were not only physical and psychological symptoms due to the stress and

strain at work, but also social, such as limited contact with family and friends to protect patients. With less time and opportunities for stress relief and self-care, prolonged negative emotional and psychological states can affect nurses' mental health and quality of nursing [36]. Therefore, systematic coping support for nurses to meet their physical and mental needs is important [37], as well as providing reasonable job accommodations (i.e., flexible shiftwork schedules, appropriate time-off for proper rest and self-care) [7, 38]. However, such support systems are rare in Korea.

As a result of this poor working environment, the resignation rate of Korean nurses is increasing yearly. In 2018, 42.7% of new nurses working in tertiary or general hospitals resigned within a year of hire; this number surged to 52.8% in 2021 (during the COVID-19 outbreak) [39]. Currently, the average year worked for hospital nurses in South Korea is only seven years and eight months, with 52.1% having less than five years of experience [40]. A sufficient number of well-skilled and experienced nurses are important to provide high-quality nursing, especially in the case of future disasters. However, during the COVID-19 response, a major issue in South Korea's disaster response system was identified as the availability of human resources [41].

To address the shortage of nurses, the Korean government has promoted a policy of continuously increasing the number of admissions to nursing schools. Therefore, the number of nursing admissions in Korea has increased to the highest among Organization for Economic Cooperation and

Development (OECD) countries, although the number of nurses actually working in clinical practice is lower than the OECD average [42, 43]. In other words, most graduate nurses cannot bear the poor reality with the nature of the work and eventually leave the field. To ameliorate this problem, the Nursing Workforce Human Rights Act, which stipulates the number of patients per nurse, was proposed by civil society organizations [44], and the Nursing Act, which stipulates the role and scope of nurses, passed the National Assembly with difficulty, but was not funded and abandoned due to the medical associations, various interest groups, and political reasons [45]. The COVID-19 pandemic has shown that policy and institutional changes to maintain a stable workforce of qualified nurses are very urgent and can no longer be postponed.

Meanwhile, the biggest change in the organizational culture of nurses was “compliance with COVID-19 guidelines,” which has emerged as top priority. Such strict compliance was an effort by nurses to control dangerous situations as much as possible. Previous studies showed that nurses implemented infection control measures more strictly than others to prevent the spread of infection and to limit contact not only between medical personnel in hospitals but also with own family members [11].

In addition, conflicts between employees and departments increased amid confusion, with a breakdown in communication. Face-to-face meetings disappeared and collegiality between employees decreased as they mainly communicated non-face-to-face. However, the leadership of nurses in charge or the unit managers was mentioned as the driving force in resolving conflicts, and difficult situations were overcome through dialogue and trust between departments [11, 17].

Studies demonstrate that effective nursing leadership is critical for disaster response. In a study of nursing leadership in South Korea during the COVID-19 pandemic, Oh et al. found that nursing leaders played an important role in providing clear communication, facilitating team collaboration, and allowing nurses to access appropriate protective gear and resources [46]. The authors argued that nursing leaders should possess the skills necessary to effectively manage and support clinical teams.

In summary, hospital nurses in South Korea experienced physical, psychological, and social health problems during the pandemic as they endured increased work intensity, insufficient leave, inadequate support and resources, and a lack of legislation on their role. However, through their dedication, leadership, and commitment to following guidelines, nurses have overcome the challenges.

The unprecedented COVID-19 pandemic was very challenging and difficult for medical personnel worldwide. During the pandemic, nurses worldwide faced numerous challenges, such as fear of contagion, burnout from excessive work, physical fatigue, moral pain, and high level of stress [7, 47–49]. However, in past disasters, altruistic nurses overcame crises with a sense of vocation [50, 51]. Nurses strengthened their sense of solidarity and formed cooperative relationships in dealing with the COVID-19 [8, 9, 40]. The positive organizational culture and

atmosphere played a pivotal role in overcoming adversities or difficult challenging situations by enhancing individual nurses’ responsibilities for human-centered care [11, 13, 52].

Based on the study findings, we suggest the following.

First, healthcare laws and regulations should be revised and overhauled by effectively reducing patient-nurse ratios and legally clarifying nurses’ professional roles to reduce excessive workloads and burdens on nurses.

Second, approaches should be explored to improve the organizational culture of nursing and the leadership of nurse managers.

Third, a national support system for nurses’ mental and physical health is needed.

4.1. Strengths and Limitations. This study collected data from 36 nursing experts from six tertiary hospitals nationwide in South Korea. Owing to the limitations in sampling, these results cannot be generalized. Another limitation is that the data were derived from the perspective of nurses and do not reflect the views of the whole hospital, including other professions. Nevertheless, using the Delphi technique, we obtained a consensus from the recruited experts regarding the changes in work, organizational culture, and health problems faced by nurses working in top tertiary hospitals during the pandemic. It is also meaningful in that it provides a picture of the realities faced by nurses based on their first-hand account of the work crisis.

4.2. Implications for Nursing Management. This study has shown that, despite the many challenges Korean nurses faced, their sacrifices were vital to the nation’s efforts to overcome the pandemic. It has also highlighted the problems caused by the lack of adequate staffing and a clear legislation on the role of nurses. In conclusion, this study suggests that policies to address the legal and institutional deficiencies related to the nursing workforce are urgently needed to prepare for future disasters and protect public health and lives.

In the future, nursing educators and clinical professionals should actively discuss and conduct research on the appropriate deployment of nursing staff, defining the scope of nurses’ roles and duties and improving the working environment for nurses. Concurrently, they should continue to demand legal and institutional improvements from hospital administrators and the state. Research should also focus continually on developing nurses’ leadership skills.

5. Conclusions

The results of this study showed that the workload and work intensity of South Korean hospital nurses increased significantly, and their physical, mental, and social health deteriorated during the COVID-19 pandemic. The reason for this was the unprecedented crises and related confusion caused by the pandemic itself, as well as the characteristics of South Korean medical institutions. Due to the high patient to nurse ratio, the intensity of nurses’ work is too high. This is further compounded by the fact that role of nurses is not

legally defined, which placed nurses in disadvantaged position and became worse during the pandemic. However, to overcome the crises, the nursing organizational culture had a strongly supportive atmosphere of the guideline compliance with an increased sense of community. Even though conflicts between employees and departments grew as the pandemic persisted, these were resolved based on trust and communication between departments, with effective nursing leadership playing an important role.

The relationship between a mother and her newborn can be determined through two concepts: “bond” and “attachment.” Currently, there are no instruments that assess these phenomena jointly. *Objective.* This study aims to develop a valid and reliable instrument to determine the quality of the postnatal bond and attachment in the mother-child relationship. *Methods.* In Spain, a multidisciplinary panel of experts was involved in creating the “Maternal-Child Bond and Attachment (VAMF, for its initials in Spanish)” tool. The tool was piloted on a group of women and applied to the target population of women with children aged between 6 weeks and 18 months to determine the psychometric characteristics: internal consistency Cronbach’s α was used. An exploratory factor analysis was conducted, a study of convergent validity with the scale and predictive validity with the Maternal Postnatal Attachment Scale (MPAS) using Pearson’s correlation coefficient, and a study of reliability was carried out using the intraclass correlation coefficient. *Results.* 1155 women participated, with a mean age of 34.5 years. The VAMF showed good internal consistency for the scale with 29 items ($\alpha = 0.836$). In the exploratory factor analysis (EFA), an explained variance of 49.71% was observed with 6 components. Convergent validity showed an adequate correlation, with a Pearson correlation coefficient with the MPAS scale of 0.679. The VAMF questionnaire presented an excellent predictive capacity in the bond subscale, with an area under the ROC curve of 0.90 (95% CI: 0.87–0.93), and a poor predictive capacity in the attachment subscale, with an area under the ROC curve of 0.69 (95% CI: 0.63–0.76) to predict MPAS scale scores. In the test-retest, the VAMF presented a very good adequate degree of absolute agreement (ICC: 0.86; 95% CI: 0.72–0.93). *Conclusions.* The VAMF is a new valid and reliable instrument for determining the quality of the mother-child bond and attachment.

1. Introduction

The development of the mother-newborn relationship is crucial, as the way in which this relationship is established will determine its future evolution, and creates the precedent on which the rest of the newborn relationships will be established throughout life [1, 2].

Different factors influence the formation of a mother-child relationship and can affect bonding and attachment, key aspects within this relationship, and can cause issues in both the mother and the newborn. Maternal mental health influences the formation of the maternal-child bond, and the presence of depressive symptoms, anxiety, or posttraumatic stress symptoms are related to difficulties in establishing this

bond and adapting to the maternal role, difficulties in the response of the mother toward the needs of the newborn, and issues in the level and quality of subsequent attachment [3–8]. Likewise, the health status of the newborn, prematurity, and the presence of comorbidities are factors that affect the bonding process and the establishment of attachment [8]. High levels of stress hinder the development of a bond, change the quality of the interaction between the mother and child, and affect the mother's behavior, which may, in turn, affect the child's behavior and executive function, which is responsible for monitoring and regulating cognitive processes during the performance of complex cognitive tasks [8–10]. Adequate quality in mother-child interaction facilitates the child's socioemotional, behavioral, and cognitive development and could even be related to the child's physical health [11]. Alhusen et al. [12] highlighted the importance of the mother-child bond as a health concept, considering it a predictor of neonatal health and well-being.

Most women establish an adequate relationship with their children, although a significant number of mothers present difficulties in establishing this relationship [1]. In the United States, it is estimated that approximately 65–70% of children have a secure attachment style, while the remaining 30% have an insecure attachment style [13].

Two fundamental concepts are related to the relationship between mother and child: "bond" and "attachment." These two concepts are closely related and are even used as synonyms to refer to the mother-child relationship, but both cover different aspects and moments of the said relationship [14–17].

The term "attachment" is a broad and complex concept within the mother-child relationship. Attachment can be considered as the affective bond that an individual, the newborn, establishes with a specific figure, in this case, the mother, and is a discriminatory, specific, and lasting behavior [18]. Attachment refers to reciprocity and interaction between the mother and child [15]. It can be understood as an affective bond of social origin, not innate, based on cognitive, emotional, and behavioral components and remains relatively stable throughout life. It manifests itself in the form of efforts by the newborn to seek and maintain proximity to the mother, behaviors encompassed within the "attachment behavior" [19, 20]. Hence, establishing attachment relationships with others is fundamental for human survival [21].

Three types of attachments have been established. Children with a secure attachment style use their mothers as a secure base for exploration, intensifying attachment behavior in episodes of separation. When reuniting with the mother, the child seeks contact and proximity. Children with an insecure-avoidant attachment style are quite independent and engage in exploratory behavior regardless of the mother's presence. When they are separated from their mother, they barely cry; when reunited, they mix proximity-seeking and avoidance behaviors. Finally, children with an insecure-ambivalent attachment style show signs of anxiety and distress during separation. When the mother returns, they seek close contact mixed with anger and resistance [13, 21–23].

A bond is understood as the emotional connection or union that a mother experiences toward her child [15, 16, 24]. It could be defined as a maternal affective state, with the mother's feelings and emotions toward her child as indicators of the bond established between the two [24]. This bond begins to form during pregnancy, and even before it, and continues to develop after birth [17, 25].

The bond is unidirectional, from the mother to the fetus, referring to the mother's emotional response to her child. In contrast, attachment is bidirectional, between the mother and the newborn, specifically referring to the reaction of the newborn, in the form of organized and stable behavior directed toward the main caregiver, the mother, in order to ensure the protection and safety of the newborn [15–17, 26–28]. The bond develops in the early phase of the maternity process and is related to the care provided by the mother to the newborn; while attachment is a later process, which generally occurs after childbirth, and is focused on the search for care by the newborn [14, 16, 26, 27].

The use of both concepts to refer to the mother-child relationship is complex, which is why some authors choose to use the term "mother-child relationship," which combines both "bond" and "attachment" [15, 16, 29].

There are instruments designed to measure bond and instruments that measure attachment, with the following standing out: Maternal-Fetal Attachment Scale (MFAS) [15, 30], Prenatal Attachment Inventory (PAI) [15, 31], Maternal Antenatal Attachment Scale (MAAS) [15, 32], Pre- and Postnatal Bonding Scale (PPBS) [15, 33], Maternal Postnatal Attachment Scale (MPAS) [15, 34], Postpartum Bonding Questionnaire (PBQ) [15, 35–37], and y Maternal-to-Infant Bonding Scale (MIBS) [15, 38].

In addition, there are other measurement instruments focused on mother-child interaction in specific situations, particularly evaluating the child's reaction through a series of objective parameters, in order to determine the type of attachment. Among these instruments are the aforementioned "stranger situation" and the Massie-Campbell scale [39].

Different measurement instruments assess the quality of the bond, pre- and/or postnatal, and the attachment between mothers and children. These instruments focus on determining either the bond or attachment, closely related phenomena that are the cornerstone of the mother-child relationship. However, no single instrument has been identified that allows the assessment of both parameters, either to assess the joint impact of both parameters or independently, depending on the interest at each moment with the advantages that this entails. There is a need for an instrument that can determine the quality of bonding and attachment using a single questionnaire, in order to early detect suboptimal bonding and/or attachment in newborns aged between 6 weeks and 18 months. This instrument could be used in a quick, easy, and practical way in clinical-care settings to intervene and prevent early dysfunctions that may have negative consequences for the mother-child dyad.

Therefore, we aimed to develop a valid and reliable instrument to determine the quality of the postnatal bond and attachment in the mother-child relationship.

2. Methods

2.1. Phase 1: Design and Questionnaire Development. A bibliographic search was carried out in the main health sciences databases (Scopus, Web of Science (WoS), ProQuest, CINAHL, and PubMed) from November 2021 to February 2022.

After reviewing in detail 40 existing instruments for measuring the bond, attachment, and different aspects of the mother-child relationship, and after consulting with professionals in pediatrics, neonatology, midwifery, nursing, psychology, psychiatry, and anthropology, a questionnaire was developed comprising of 31 items divided into two subscales: a bond subscale made up of 18 items and an attachment subscale made up of 13 items. This led to version 0 of the questionnaire “Mother-Child Bond and Attachment” (VAMF, for its initials in Spanish).

2.2. Phase 2: Expert Panel. After obtaining version 0 of the VAMF questionnaire, it was evaluated by a multidisciplinary panel of experts. Twelve experts from different disciplines were contacted: nursing, pediatrics, midwifery, pediatric nursing, psychiatry, neonatology, psychology, and anthropology, for its evaluation. It was also taken into account that the experts came from different regions of Spain to consider the cultural and linguistic variety that could exist when interpreting the questions and answers of the questionnaire. They were contacted via e-mail, inviting them to participate in this research as experts in mother-child relationships by evaluating the questionnaire prepared. Once they agreed to participate, they were sent the original questionnaire, and they were asked to evaluate it, assigning a score of 1 (best score) to 5 (worst score) to each of the items that make up the questionnaire based on four parameters: writing, understanding, relevance and general assessment. Likewise, a section was included for them to provide any observations they considered appropriate on each item. Regarding the evaluation of the questionnaire in general, an observation section was set up for its evaluation in general terms and for them to make the contributions/suggestions they considered appropriate.

Once the 12 evaluations were received, the feedback was collated, and the appropriate corrections were made based on the experts’ opinions, obtaining version 1 of the questionnaire. The modified questionnaire was sent back to the panel of experts for a second evaluation, after which their approval was received.

2.3. Phase 3: Pilot of Questionnaire. Women with children between the ages of 6 weeks and 18 months were actively recruited in the Nursing (through the Healthy Child Program and the Vaccination Program), Midwife, and Pediatrics offices of the Dr. Ricardo Fernández Valadés Health Center (Jódar, Jaén) between the months of May and August 2022. A sample of 15 mothers was obtained who were given appointments to come in and complete the VAMF questionnaire together with the MPAS questionnaire. Once the questionnaire was completed, an interview was conducted

with each mother so that they could evaluate the VAMF and make the contributions they considered appropriate: they assessed whether the statement of each item was correct, understandable, and had an adequate length; the adequacy of the items; the categorization of the answers; the general opinion of the mother about the items; length; and format of the questionnaire and if they found any difficulty when completing it. In addition, they were asked to evaluate the questionnaire in general and to make any contributions or suggestions they considered appropriate.

After this pilot, one of the items was modified, obtaining version 2 of the questionnaire.

2.4. Phase 4: Application of the Instrument to the Target Population to Determine Its Psychometric Properties

2.4.1. Design and Subject Selection. For this part, a cross-sectional validation study was carried out with women who had a child in Spain. This phase of the study was carried out from September 2022 to March 2023 in Spain. The inclusion criteria were women aged between 18 and 45 years, with a biological child whose age is between 6 weeks and 18 months, who have previously signed the informed consent for participation in the study. The exclusion criteria were mothers of multiple births (two or more newborns) and those who do not speak or do not know the Spanish language (language barrier).

To recruit women for our study sample, different associations that were related to pregnancy, childbirth, and postpartum and support groups for breastfeeding and parenting throughout the Spanish territory were contacted. Following the application of inclusion and exclusion criteria, participants were informed about the objective and mode of participation in the study. Once they consented to participate, they were provided with the questionnaire online.

The sample size was estimated according to the criteria for carrying out a factorial analysis. These criteria consider 10 subjects for each item [40]. Therefore, we needed a sample of at least 310 participants.

2.4.2. Information Sources. To collect the necessary information for validation, a questionnaire was developed consisting of sociodemographic and clinical variables of both the mother and the newborn, which included the validated tool “MPAS” [34, 41], and the new tool to be validated, “VAMF” version 2. For its distribution, contact was made with different associations related to pregnancy, childbirth, and the postpartum period, and with support groups for breastfeeding and parenting throughout the Spanish territory. After applying the inclusion and exclusion criteria, the participating women were informed and accepted the informed consent for participation in the research, and the questionnaire was administered to them.

2.4.3. Measuring Instruments. The postnatal attachment was evaluated using the “Maternal Postnatal Attachment Scale” (MPAS) questionnaire. This questionnaire was developed by

Condon and Corkindale in 1998 and assesses the mother's emotional response to her newborn. It is made up of 19 items that describe the mother's feelings toward her baby/child. Each item is scored using a Likert-type scale ranging from 1 (worst score) to 5 (highest score), except for items with inverse scores. The lower the score, the less the bond between the mother and the child. The MPAS presents good psychometric capabilities, with adequate internal consistency ($\alpha = 0.78$) [34, 38, 41].

2.5. Statistical Analysis. For sociodemographic and clinical data, absolute and relative frequencies were used to describe the qualitative variables, and the mean and standard deviation (SD) were used to describe the quantitative variables.

First, the reliability analysis was performed using Cronbach's α to assess internal consistency (IC). The IC tells us to what extent the items in question are correlated with each other and how they fit together and measure the same concept. Cronbach's α is one of the most widely used measures to assess the reliability of a scale. Its values range from 0 to 1. One of the most accepted rules is to consider $\alpha > 0.9$ as excellent, $\alpha > 0.8$ as good, $\alpha > 0.7$ as acceptable, $\alpha > 0.6$ as questionable, $\alpha > 0.5$ as poor, and $\alpha < 0.5$ as unacceptable [42].

To determine the scale's validity, we analyzed three of the most common types: construct validity, convergent validity, and criterion validity.

Regarding construct validity, we carried out an exploratory factor analysis (EFA) to determine the underlying factors through the principal component analysis (PCA). Before performing the EFA, we analyzed the Kaiser–Meyer–Olkin (KMO) tests and Bartlett's tests of sphericity, which indicate whether this analysis was appropriate to apply. For this to be the case, the KMO must be above 0.6 and as close as possible to 1, and the Bartlett sphericity, which consists of the statistical hypothesis test, must be less than 0.05 to reject the null hypothesis of sphericity and ensure that the factorial model is adequate to explain the data. In the EFA, we use varimax rotation to help clarify the allocation of items to different factors. To determine the number of factors to maintain, we used the Kaiser criterion, which is one of the most widely used criteria; factors with eigenvalues greater than unit value are retained [43].

Next, the convergent validity was studied. For this, we studied the relationship between the VAMF and the MPAS using the Pearson correlation coefficient, as well as the predictive capacity of the VAMF scale and its two attachment and bond subscales with the MPAS scale. In addition, the predictive capacity of the VAMF scale over the MPAS scale was estimated. To do so, the MPAS variable was dichotomized for a score below the 10th percentile (low bond). The area under the ROC curve (AUC) was estimated with their respective 95% confidence intervals, as well as the Youden index to determine the best cut-off point.

The next step was to determine the criterion validity. In this analysis, the scores obtained in the test were compared with some factors that could be an obstacle to the establishment of the bond and secure attachment, such as the type of birth, admission of the newborn, type of breastfeeding,

hospital stay, and skin-to-skin contact. Thus, a bivariate analysis was carried out using the Pearson or Student–Fisher chi-square tests, depending on the qualitative or quantitative nature of the variables. The results were considered statistically significant when $p \leq 0.05$.

Lastly, intraobserver reliability was evaluated using a test-retest test in a sample of 30 women who took the questionnaire again 24 hours after completing the first one, using the intraclass correlation coefficient in this case.

Version 24.0 of the statistical package SPSS was used.

2.6. Ethical Considerations. The Research Ethics Committee of the Province of Jaen approved this study (DCVA-21/2012-N-21). First, mothers had to read the information sheet about the study and its objectives and then they accepted the informed consent for participation in the study. Once the informed consent was accepted, they completed the questionnaire.

All methods were carried out in accordance with relevant guidelines and regulations. Informed consent was obtained from all participants.

3. Results

3.1. Participant Characteristics. 1155 women participated (66 declined to participate) with a mean age of 34.5 years (SD = 3.90), and 58.4% (675) were married. 88% (1016) did not have any disease. For 56.5% (653) of the women, this was their first pregnancy. 41.9% (484) reported having had health problems related to pregnancy. 58.6% (667) of the women had a normal vaginal birth, and 80% (924) used analgesia during it. 78.4% (905) started breastfeeding early after birth, and 83.7% (967) had skin-to-skin contact after birth. Regarding the babies, the mean age was 8.6 (SD = 5.56) months, 4.6% (53) were premature, and 83.5% (965) were still breastfeeding. The data can be consulted in Table 1.

3.2. Psychometric Properties

3.2.1. Internal Consistency. To assess the internal consistency, Cronbach's α was used for the entire questionnaire. During the first evaluation of all the items, it was observed that removing items 5 and 6 improved the scale's total score. Thus, for the scale without these two items, the α was 0.836. With this modification, all alpha values scored above 0.823 when removing an item. The α values for each factor are shown in Table 2. After removing these items, we proceeded with a new enumeration of the questions, modifying the scale to 29 items (version 3 of the questionnaire). All corrected item-total correlations were above 0.

3.2.2. Intraobserver Reliability (Intraobserver Stability). Finally, the test-retest test was carried out by administering the VAMF questionnaire to a group of 30 mothers who completed it twice, separated by a period of 24 hours. The analysis showed excellent agreement, with an intraclass correlation coefficient of absolute agreement of 0.86 (95% CI: 0.72–0.93) and a consistency intraclass correlation coefficient of 0.85 (95% CI: 0.71–0.93).

TABLE 2: Internal consistency VAMF (version 3) after eliminating 2 items.

Variable	Corrected item-total correlation	Cronbach's α
Total		0.836
<i>On removing items</i>		
(1) I feel happy when I am with my baby	0.461	0.827
(2) I feel overwhelmed when I am with my baby	0.262	0.833
(3) I like rocking or hugging my baby	0.293	0.833
(4) I feel proud when my baby does new things	0.157	0.836
(5) I like the time I spend with my baby	0.487	0.827
(6) I like to play with my baby	0.370	0.830
(7) I feel calm when I am with my baby	0.490	0.826
(8) Seeing my baby smile makes me happy	0.163	0.836
(9) My baby's cry irritates or annoys me or makes me feel helpless	0.274	0.835
(10) I find it difficult to separate from my baby	0.251	0.837
(11) I feel capable of identifying my baby's needs	0.258	0.835
(12) I like to talk to my baby	0.350	0.832
(13) Being with my baby makes me anxious and/or stressed	0.340	0.831
(14) I feel like I love my baby a lot	0.392	0.832
(15) Looking after my baby gives me satisfaction	0.474	0.827
(16) I don't feel caring with my baby	0.330	0.831
(17) My baby is calm when with me	0.526	0.825
(18) My baby smiles spontaneously	0.520	0.825
(19) My baby laughs when I play with them	0.528	0.825
(20) My baby maintains their gaze at me	0.477	0.827
(21) My baby is irritable or restless when not with me	0.110	0.840
(22) My baby perceives my feelings via my gestures and tone of voice	0.396	0.829
(23) My baby cries when I am no longer present	0.163	0.838
(24) My baby shows signs of happiness when seeing me again after a period of separation	0.503	0.824
(25) My baby calms when hearing my voice	0.543	0.823
(26) When I smile at my baby, my baby smiles back	0.502	0.825
(27) My baby tries to get my attention frequently	0.287	0.834
(28) My baby prefers to be in the crib or pram instead of my arms	0.104	0.837
(29) My baby expresses happiness at my displays of affection (hugs, kisses, etc.)	0.530	0.824

3.2.3. *Exploratory Factor Analysis.* The KMO test gave a value of 0.901, and the Bartlett test of sphericity was <0.001. Therefore, the EFA was carried out. Six components explained 49.71% of the variance. The first component consisted of items 18, 19, 20, 22, 24, 25, 26, 27, and 29 and represented 21.14% of the variance. The second component, made up of items 3, 5, 6, 12, 14, 15, and 16, explained 11.04% of the total variance. The third factor, made up of items 1, 2, 7, 9, 13, and 17, explained 6.09% of the variance. The fourth factor, made up of items 10, 21, and 23, represented 4.31% of the variance. The fifth factor, which includes items 8 and 28, explained 3.62% of the variance. The sixth factor, which includes items 4 and 11, explained 3.52% of the variance. In addition, all anti-image diagonal correlations showed figures greater than 0.750, except for items 23 and 25 with values of 0.659 and 0.660, respectively. Table 3 presents the items of the scale along with their respective factorial weights.

3.2.4. *Convergent Validity.* Next, convergent validity was studied with the MPAS scale, observing a statistically significant association ($p < 0.001$) with a Pearson correlation coefficient with a total scale of 0.679. This correlation was also studied when separating the items related to the bond and to the attachment, observing for the case of the bond,

a higher correlation coefficient of 0.766 and a lower attachment of 0.370.

3.2.5. *Predictive Validity.* In the case of predictive validity, it was decided to use the MPAS variable and use scores below the 10th percentile of the scale as the cut-off point, standing at 75 points. In this way, we determined the predictive capacity of the VAMF scale and the two attachment and bond subscales on the probability of having low scores on the MPAS. Observing that the VAMF scale, in the bond subscale, has an excellent predictive capacity for the MPAS scale with an area under the ROC curve of 0.90 (95% CI: 0.87–0.93), for the global VAMF scale, the predictive capacity was good with AUC of ROC of 0.85 (95% CI: 0.81–0.90), while the predictive capacity was poor if we used the attachment subscale with an AUC of ROC of 0.69 (95% CI: 0.63–0.76) (Figure 1). The Youden index was 98.5 points for the VAMF scale, 54.5 points for the VAMF-attachment subscale, and 40.5 points for its VAMF-attachment subscale.

3.2.6. *Criterion Validity.* For this analysis, we studied the relationship between various variables that could affect the condition of the mother and the newborn and their

TABLE 3: Rotated component matrix.

Item	Components					
	1	2	3	4	5	6

The bold values indicate the highest correlation between the variable and the component, and shows in which component the item is located.

FIGURE 1: Predictive capacity of the VAMF questionnaire and the attachment and bond subscales for the MPAS scale for a percentile score of <10 (75 points).

relationship with the scores of the VAMF scale and the two attachment and bond subscales. As can be seen in Table 4, among the variables that could affect the maternal condition, we found a statistically significant association ($p < 0.05$) between the VAMF scale and the type of birth; postpartum complications; hospital admission days; health status in the 6 weeks postpartum; mental health problems; depression during pregnancy; tiredness or fatigue during pregnancy, childbirth, or postpartum; and anxiety during pregnancy, childbirth, or postpartum. Regarding the bond subscale, a statistically significant association ($p < 0.05$) was found with the variables type of birth; postpartum complications; days of hospital admission; ICU admission; state of health in the 6 weeks postpartum; mental health problems; depression during pregnancy; tiredness or fatigue during pregnancy, birth, and the postpartum period; and anxiety during pregnancy, birth, and the postpartum period. For its part, the score on the attachment subscale had a statistically significant association ($p < 0.05$) with the type of birth variable. In Table 5, the variables related to the newborn that have a statistically significant association ($p < 0.05$) with the total score of the VAMF scale were gestational age at the time of birth, hospital admission at birth, early initiation of breastfeeding, excessive crying, and colic of the infant. The bond subscale presented a statistically significant association ($p < 0.05$) with the variables hospital admission at birth, health problems, excessive crying, and infant colic. In contrast, the score on the attachment subscale showed a statistically significant association with the early onset of breastfeeding and colic of the infant. The skin-to-skin contact variable did not present a statistically significant association with the VAMF scale ($p = 0.233$) nor with the bond ($p = 0.114$) and attachment ($p = 0.722$) subscales.

4. Discussion

The VAMF questionnaire showed good internal consistency for the scale with 29 items. The EFA indicated that 49.71% of the variance of the VAMF was explained by dividing the items into 6 components. Convergent validity was studied with the MPAS scale [41], showing adequate correlation. Regarding predictive validity, the VAMF scale presented an excellent predictive capacity in the bond subscale and a poor predictive capacity in the attachment subscale. In the test-retest test, the VAMF showed good intraclass correlation.

The VAMF comprises two subscales, one for assessing the bond and the other for assessing the attachment. The total internal consistency of the VAMF was good ($\alpha = 0.836$), higher than that identified in the original version of the MPAS questionnaire [34], which measures bonds after birth, and showed an acceptable internal consistency with a Cronbach's α of 0.78. Also, the Spanish version of the MPAS adapted in 2016 by Riera-Martín et al. [41] presented an acceptable internal consistency, with a Cronbach's α of 0.75, lower than that found in our results. The PBQ [35], used to measure the postpartum bond, presented good internal consistency, with Cronbach's α ranging from 0.76 to 0.87 on the global scale, and the scores are in line with those identified in the VAMF. However, the Spanish version of the

PBQ, adapted and validated by García-Esteve et al. [44], obtained excellent internal consistency, with a Cronbach's α of 0.90 for the scale's total score, which is somewhat higher than that of the VAMF. In the convergent validity, compared to the MPAS scale, the VAMF presented a Pearson correlation coefficient of 0.679 for the total scale, showing a higher correlation in the bond subscale ($r = 0.766$) and lower for the attachment ($r = 0.370$). This correlation is in line with what each subscale measures, as the MPAS scale measures postnatal bonding, presenting a high correlation with the bonding subscale of the VAMF. In contrast, the attachment subscale measures a different phenomenon, with a poor correlation with the MPAS.

The analysis of the predictive validity showed an excellent predictive capacity in the bond subscale, while in the attachment subscale, it showed a poor predictive capacity, and these findings are in line with what was previously indicated. When using the MPAS scale for the analysis, as an instrument for measuring the postnatal bond with good psychometric capacities, it is seen that the predictive capacity of the questionnaire in the bond subscale is high, while the attachment subscale, which measures a reality closely related but different to the bond, shows a poor predictive ability. The predictive power of the global questionnaire is good. The PBQ questionnaire shows a positive predictive capacity of 0.79, varying with the presence and type of disorder in the relationship between mother and child, decreasing with the presence of rejection toward the child or maternal anger [35], and being poorer than that of the global VAMF questionnaire and much lower than that of the attachment subscale.

Regarding the maternal factors that are related to the scores of the VAMF questionnaire and its subscales, postpartum complications; hospital admission days; health status during the 6 weeks postpartum; mental health problems; depression during pregnancy; tiredness or fatigue during pregnancy, childbirth, and postpartum; and anxiety during pregnancy, childbirth, and postpartum had a statistically significant association with the VAMF global score. The bond subscale is related to the type of birth; postpartum complications; length of hospital admission; ICU admission; state of health in the 6 weeks postpartum; mental health problems; depression during pregnancy; tiredness or fatigue during pregnancy, birth, and postpartum period; and anxiety during pregnancy, birth, and postpartum. In the adaptation and validation of the Spanish version of the PBQ, a positive correlation was found between the presence of depressive symptoms and changes in the bond [44]. Likewise, Taylor et al. [38] found a relationship between depressive symptoms and mother-child bonding using the MIBS scales and the EDPS questionnaire, along with two other scales, showing that the presence of depression is related to worse bonding, which is in line with what was identified in our results. Likewise, the type of birth showed a correlation with the attachment subscale, which could be related to the increase in maternal oxytocin levels during childbirth, which could be a facilitator of mother-child attachment, related to the appearance of behaviors that favor bonding and maternal-filial attachment after childbirth, as

well as with the increase in cortisol levels [45]. In the newborn, there is a release of norepinephrine, cortisol, and vasopressin during the passage through the birth canal, where the increase in the concentration of adrenaline would be related to the formation of attachment, since these levels are related to olfactory learning after the birth [45]. Likewise, maternal feelings before childbirth and the possible consequences for the newborn play a fundamental role in establishing attachment [8]. On the other hand, newborn factors such as the gestational age at the time of birth, hospital admission at birth, early initiation of breastfeeding, excessive crying, and infant colic showed an association with the overall VAMF score. Focusing on both subscales, the bond subscale is associated with hospital admission at birth, newborn health problems, excessive crying, and infant colic, while the attachment subscale is associated with early onset of breastfeeding and infant colic. Skin-to-skin contact did not correlate with the VAMF scale or with any of its two subscales. After conducting a review of the literature, Olza-Fernández et al. [45] showed the benefits of skin-to-skin contact, being an essential part in the development of the mother-child relationship, since it helps the newborn in conserving energy, adjusting the acid-base balance, regulates respiration, and has a calming effect, as well as increases maternal attention to the newborn and reduces maternal cortisol levels. During skin-to-skin contact, an oxytocin discharge is produced, which is related to the increased

response of mothers to the signals emitted by the newborn and could play an important role in the initiation of breastfeeding [45]. Klaus and Kennell [46] in their “bonding theory,” affirmed that skin-to-skin contact was the determining factor for the development of the bond between the mother and the child. However, as has also been identified in our results, other authors, such as Myers [47], indicated that, while the premise that skin-to-skin contact is a determining factor is true, it is not the only one related to bond development.

4.1. Strengths and Limitations. The number of participants in this study was high, much greater than the minimum sample size calculated. The sample includes women from different regions of Spain, which is why possible linguistic, social, or cultural differences that may exist between these areas may be reflected. As it is a questionnaire, a possible selection bias associated with nonresponse must not be ruled out because the number of women who did not respond was very low. Although, there are no indications or reasons to suggest that the women who did not participate would have responded differently from those who did. The group of experts was made up of the different professional profiles that are involved in the attachment, bonding, and parenting process. These experts have extensive experience in teaching, clinical care, and research on the parenting, attachment, and bonding process. The

authors have already validated and designed instruments that are applied in the perinatal stage [48].

5. Conclusions

In conclusion, the VAMF is a new tool that presents good psychometric properties for measuring the mother-child bond and attachment in mothers and children aged between 6 weeks and 18 months and can be applied easily by professionals in the clinical-care setting. Due to its good psychometric capabilities, this tool could be systematically integrated into clinical practice in pediatric or pediatric nursing consultations. It could be employed as a routine component of the health assessment for a child, aimed at identifying any disruptions in the mother-child relationship between 6 weeks and 18 months of age. This approach would function as a screening mechanism, assisting healthcare professionals in early detection and enabling targeted interventions to strengthen the bond and attachment.

5.1. Relevance for Clinical Practice. The creation of the VAMF questionnaire will allow us to detect bond and attachment alterations in an easy and quick way by nurses and doctors in contact with mothers and children in the clinical practice. Early detection of suboptimal forms of bond and/or attachment will help medical staff to prevent negative consequences on mother-child dyads, such as mental health problems on mothers or difficulties in establishing new relationships in the future by the child. A future line of continuity with the topic is proposed in which the questionnaire is applied and the consequences and factors that are associated with the quality of the maternal-child bond and attachment are known.

Data Availability

The data that support the findings of this study are available on request from the corresponding author. The data are not publicly available due to privacy or ethical restrictions.

Ethical Approval

The Research Ethics Committee of the Province of Jaen approved this study at their meeting on November 25th, 2021 (DCVA-21/2012-N-21). All methods were carried out in accordance with relevant guidelines and regulations.

Consent

Informed consent was obtained from all participants.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

Maria Antonia Diaz-Ogallar conceptualised and visualised the study, developed the methodology, performed the formal analysis, investigated the study, curated the data, wrote the original draft, and wrote, reviewed, and edited the study.

Antonio Hernandez-Martinez conceptualised the study, developed the methodology, performed the formal analysis, investigated the study, curated the data, wrote the original draft, and reviewed and edited the study. Manuel Linares-Abad conceptualised the study, developed the methodology, investigated the study, and reviewed and edited the study. Juan Miguel Martinez-Galiano conceptualised the study, developed the methodology, investigated the study, curated the data, supervised the study, administered the project, wrote the original draft, and reviewed and edited the study.

Background. Nurse emigration, often termed “brain drain,” poses significant challenges to Ghana’s healthcare sector. **Aim.** This study explores nurse managers’ perspectives on determinants and strategies for mitigating nurse emigration in Northern Ghana. **Methods.** Sixteen nurse managers were interviewed using semistructured interviews between October and December 2023. Purposive sampling was used to select the participants. QDA Miner Lite version 6 was used for systematic coding and thematic data analysis, following the conventional content analysis approach. **Results.** Following data encoding and classification, the study identified three primary categories: determinants of brain drain, impact of brain drain on the healthcare system, and mitigating factors of brain drain. **Conclusion.** The study reveals that various factors, including inadequate pay, limited opportunities for career growth, and lack of access to technology, drive the brain drain among Ghanaian nurses. These lead to negative impacts on the healthcare system, such as increased workload, reduced patient satisfaction, and a shortage of skilled nurses. To tackle this issue, solutions including offering career advancement opportunities and improving salaries and working conditions among others have been highlighted to mitigate the brain drain among Ghanaian nurses.

1. Introduction

The migration of nurses, particularly from low- and middle-income countries to those with higher incomes, is a major global issue that has gained worldwide attention. Unfortunately, the recruitment tactics used by many of these low- and middle-income countries, especially in Africa, have made the situation worse as they face difficulties retaining

their nursing graduates who their educational institutions have trained [1].

This outflow of skilled professionals from developing countries to developed countries is commonly referred to as the “brain drain” [2]. The term was first used by the British Royal Society in the 1960s to describe the large departure of professional scientists, physicians, and university lecturers from developing countries. It has since become a major

concern globally [3, 4]. According to a 2015 report by the World Health Organization, developed countries are experiencing a severe shortage of healthcare workforce, despite dealing with an aging population and an increased prevalence of chronic illnesses. This shortage of highly skilled nurses is not only due to needs-based factors but also because of the high demand for nurses, which is expected to increase in the coming years. Consequently, it is highly likely that this high demand will severely deplete the pool of skilled nurses in developing countries [5].

Nurse migration has been observed across most Organization for Economic Co-operation and Development (OECD) countries, with a significant increase in the number of nurses migrating to these countries since the early 2000s. In fact, the numbers have more than doubled between 2000 and 2016. Additionally, between 2011 and 2018, the figures increased by about 20%, constituting over 7% of the nursing workforce in the OECD region. In 2021 alone, OECD countries employed an overwhelming 550,000 nurses [6, 7], indicating the need for constructive measures to manage this phenomenon effectively.

Ghana's history of migration is characterized by dynamic and multifaceted factors, deeply rooted in historical events and a tradition of population mobility. Urban migration, in particular, has played a pivotal role in livelihood strategies within the country. In the context of professional movement, nurses often transition across various levels of healthcare facilities, from rural to urban settings, and from clinical and research roles to administrative positions [8, 9].

Recent policy shifts in Ghanaian healthcare, such as initiatives aimed at improving salaries, enhancing working conditions, and providing career advancement opportunities, have attempted to mitigate nurse emigration [10, 11]. However, the effectiveness of these policies in addressing the root causes of nurse migration remains a critical concern [3, 12].

Despite significant advancements in the Ghanaian healthcare system over the past three decades [13], the country grapples with a substantial loss of healthcare professionals to foreign countries, presenting a critical challenge [14].

A considerable number of Ghanaian nurses choose to migrate to developed countries such as the United Kingdom, the United States, Australia, Canada, and more recently, Barbados and the United Arab Emirates, in pursuit of better job opportunities [15]. According to the Ghana Registered Nurses' and Midwives' Association, over 6,000 Ghanaian nurses have relocated to foreign countries within a two-year period, with an additional 14,000 nurses seeking financial clearance for the same purpose [16]. This trend is further underscored by data from the United Kingdom's National Health Service (NHS), which recorded a notable increase in the number of healthcare workers, including nurses, with Ghanaian heritage [10]. According to Iddrisu [17], about 60% of Ghanaian nurses harbor intentions to leave the country and seek employment opportunities elsewhere.

The decision of nurses to migrate is influenced by a complex interplay of push and pull factors. Pull factors pertain to attractive conditions present in the health systems

of destination countries, while push factors refer to undesirable features of the healthcare systems in origin countries [18]. In Ghana, a range of push factors, including low salaries, limited access to modern technology, restricted educational opportunities, low job satisfaction, and political instability, contribute to nurses' motivation to seek opportunities abroad [3, 18, 19]. Failure to address this trend could lead to increased clinical workloads, decreased quality of care, and heightened mortality and morbidity rates due to reduced access to essential healthcare services [5, 20]. Given the urgency of this issue, this qualitative study was conducted to explore the perspectives of nurse managers regarding the determinants and mitigating factors of nurse migration, specifically focusing on Northern Ghana.

2. Methods

This qualitative study used a conventional content analysis approach to delve into the contributing and mitigating factors of nurse migration in Ghana. Content analysis was deemed appropriate as it is suited for describing phenomena with limited understanding or fragmented knowledge about them [21, 22]. Given the ambiguous nature of the phenomenon of nurse brain drain in Northern Ghana, content analysis was chosen to bring clarity and insight into this complex issue.

Participating nurse managers were purposefully selected from three hospitals in Tamale (Tamale Teaching Hospital, Seventh Day Adventist, and Tamale West Hospital), the capital city of the Northern Region. Participants were purposefully selected from different departments within each hospital. The study included 16 participants, 9 females and 7 males, all with a minimum of 5 years of managerial experience. The sample size of sixteen was determined based on the principle of data saturation, where we observed that no new insights were emerging from additional interviews, ensuring that the sample size was sufficient to capture the breadth and depth of perspectives on the topic. The criteria for selecting participants included factors such as years of managerial experience (minimum 5 years), current active service in clinical or managerial roles, and willingness or consent to participate. The study relied on nurse managers for their frontline leadership roles and extensive workforce experience, aiming to comprehensively understand and address the issue of nurse attrition in the region.

Data were collected through in-depth face-to-face interviews that lasted 45 to 60 minutes. The interviews were conducted in quiet settings in participants' offices, as they mostly preferred.

The interview process commenced with questions aligned with the study's objectives, followed by probing inquiries to delve deeper into specific aspects. Each interview began with an open-ended question, such as, "As a nurse manager, could you share your insights on the issue of brain drain among nurses?" This approach fostered comprehensive discussions and elicited rich qualitative data. Depending on the responses, further probing questions were asked. The data collection continued until data saturation was reached, ensuring comprehensive coverage of relevant insights.

The data analysis employed a conventional approach without predetermined categorization structures. This method unfolded over three phases: preparation, organization, and report writing. Initially, in the preparation phase, each interview served as a unit of analysis. Transcripts were meticulously transcribed verbatim and iteratively reviewed to grasp overarching categories.

All audio recordings were transcribed verbatim by two independent transcribers to ensure accuracy. The transcripts were then imported into a qualitative data analysis software, QDA Miner Lite version 6, for systematic coding and thematic analysis. To begin the analysis, the researchers engaged in open coding, wherein initial concepts and patterns were identified. Axial coding was employed to categorize and relate codes to each other, allowing for the emergence of preliminary themes.

During the organization phase, units of meaning within each interview were identified, condensed, and openly coded. Similar codes were then grouped into subcategories and overarching main categories. Finally, in the reporting phase, the latent meaning of the data was presented as the study's results [23].

Efforts were made to ensure the reliability and confirmability of the findings. The credibility of the findings was further bolstered by meticulous attention to the content analysis process, including selecting meaningful units, categorizing data, and recognizing similarities and differences among categories. To this end, ample time was dedicated to data collection and analysis. A member check was also conducted (Graneheim & Lundman, 2004), and two other authors independently reviewed the data for peer validation.

The team obtained ethical clearance from the Tamale Teaching Hospital ethical unit with reference number TTH/R&D/SR/267. Before the interviews, participants received detailed information about the study, including its objectives, potential risks, and benefits. Each participant provided informed consent, ensuring their voluntary and confidential participation in the study.

3. Results

In this study, a diverse group of participants contributed valuable insights, enabling the authors to draw meaningful conclusions regarding the brain drain phenomenon in Ghana. Table 1 presents the demographic data of the participants. The analysis of the findings highlighted three major categories along with 12 subcategories, as seen in Figure 1.

3.1. Determinants of the Brain Drain. The determinants of brain drain have emerged as one of the main categories, highlighting the factors that drive the phenomenon of brain drain. Understanding these determinants is crucial for policymakers and researchers aiming to address and mitigate the consequences of brain drain. It explores the complex interactions between factors influencing the brain drain issue in Ghana, focusing on four subcategories: Financial

Challenges and Incentives, Professional Environment and Support, Healthcare System and Dynamics, and Technology and Innovation.

3.1.1. Financial Challenges and Incentives. All the participants in this study revealed that one of the main reasons for nurses leaving the country is the financial challenges and incentives. Nurses' earnings are inadequate for significant expenses such as buying a car or a house. To achieve such goals, nurses often have to take high-interest loans, which causes financial strain. As a result, in retirement, nurses often face difficult living conditions. On the other hand, it was noted that nurses who have migrated to foreign countries have better economic prospects and can often achieve their goals. They can enjoy a better quality of life and often return to their home country to contribute significantly. Also, some participants mentioned delayed promotions, the search for a better life for themselves and family, and the absence of health insurance coverage as the reasons why nurses travel out of the country.

"I think our salary is just from hand to mouth. Before you can do any big project, you have to go for a loan. Before you get a house or car, you have to go for a loan and if you look at those nurses who have retired, their living conditions are not that appreciable. I have seen a colleague who has gone outside for less than two years and things have changed. He is able to get a house and he has his own car. 'Why won't you also want to go and get those things?'" (Participant 5).

"They will send the money home so that they will take good care of the family they have left" (Participant 3).

"There is no proper health insurance for workers who work in hospitals. When you are sick, you still have to take care of yourself and pay out of pocket" (Participant 14).

3.1.2. Professional Environment and Support. Our findings showed that nurses are undervalued and disrespected in the healthcare sector, a significant factor driving their emigration. The difference in status between medical doctors and nurses is one reason for this, as several participants pointed out. They emphasised that even when a nurse has advanced degrees and extensive experience exceeding that of a newly qualified medical doctor, healthcare facilities often fail to acknowledge their expertise, and the nurse is unable to attain a position of authority or denied a promotion to merit their experience. This is in contrast to doctors who are frequently promoted to higher ranks. It is high time that healthcare organizations recognize the qualifications and expertise of nurses and treat them with the respect they deserve. During the interviews, several participants expressed that the government policy mandates that a nurse who serves for a certain number of years should be given a study leave to pursue further programs if they wish to. Participants noted that workplace bullying and discrimination against nurses were prevalent in most health facilities, contributing to an unpleasant work environment.

TABLE 1: The sociodemographic profile of the participants in this study.

Participant	Age in years	Gender	Work experience	Qualification	Considering or intending to work abroad
Participant 1	58	Female	24	Bachelors	No
Participant 2	48	Female	25	Bachelors	No
Participant 3	56	Female	31	Bachelors	No
Participant 4	40	Female	16	Masters	Yes
Participant 5	35	Male	10	Bachelors	Yes
Participant 6	33	Male	6	Masters	Yes
Participant 7	41	Male	14	Bachelors	Yes
Participant 8	38	Male	13	Bachelors	Yes
Participant 9	36	Male	14	Masters	Yes
Participant 10	42	Female	13	Masters	Yes
Participant 11	36	Female	13	Masters	Yes
Participant 12	39	Female	14	Masters	Yes
Participant 13	39	Female	18	Masters	Yes
Participant 14	39	Male	14	PhD	Yes
Participant 15	40	Male	17	Bachelors	No
Participant 16	37	Female	10	Masters	Yes
Mean \pm SD or total (%)	41.0 \pm 7.1	Female: 9 (56.2%) Male: 7 (43.8%)	16.0 \pm 6.3	Bachelors: 7 (43.8%) Masters: 8 (50.0%) PhD: 1 (6.2%)	Yes: 12 (75.0%) No: 4 (25.0%)

Source: field data (2023).

“When a nurse goes to school to acquire higher degrees and comes back, the highest rank they can attain is a chief nursing officer in the institution. They cannot go any higher” (Participant 3).

“You go to a district hospital where there is a medical superintendent. The medical superintendent has completed medical school, done his housemanship for just two years and comes out as a medical doctor. Whereas there is a nurse, who has been working there for more than 20 years and has experience sometimes to the extent that some have higher degrees than the medical doctor. They still become subservient. The only way the government can stop nurses from going outside the country is when they start to see nurses as important and pivotal in the health delivery” (Participant 9).

“Then also, there are a lot of bureaucratic systems in place in our society. So, the government says that when you work a certain number of years, you should be allowed to go and get upgraded. You should go to school [...] People have worked ten years, and they are still chasing study leave” (Participant 6).

...“So, for me, the main factor is bullying in the system and among us as nurses. It might come out subtly as if it is not there, but it’s a big issue” (Participant 11). “[...] I see nurses discriminated against, and so they leave the shores of the country. For now, I don’t see any good policy for nurses, which explains why people are leaving” (Participant 15).

3.1.3. Healthcare System Policies and Dynamics. Participants voiced concerns about the inadequate availability of essential logistics required for life-saving procedures. Furthermore, despite acquiring additional training in specialised skills, some nurses continue to face obstacles in accessing the necessary equipment. These collective challenges demotivate them, fueling a growing inclination to explore practice opportunities in other countries. The participants also cited their organization’s lack of interaction with employees to address issues, the government’s recent policy to export nurses, and the delay in recruitment of graduate nurses as significant factors propelling nurses to leave the country. Participants emphasised the importance of feeling respected and recognized in their professional endeavours, which does seem to exist.

“You need consumables (such as gloves, cannulas, and syringes), but they are not there. When the patient comes in an emergency state, you have to write for a relative to go and buy it before you can attend to the person. You look at the patient as helpless but can’t do anything. Common oxygen flow meters, you won’t get them. You go, and then they ask you questions such as, “What are you using it for?” It’s frustrating” (Participant 12).

“Even the government encourages the exodus of nurses; they started thinking they had enough and have been exporting to Barbados. So now, people have gone to Barbados, and they have realised that it is better there, so they are unwilling to return” (Participant 9).

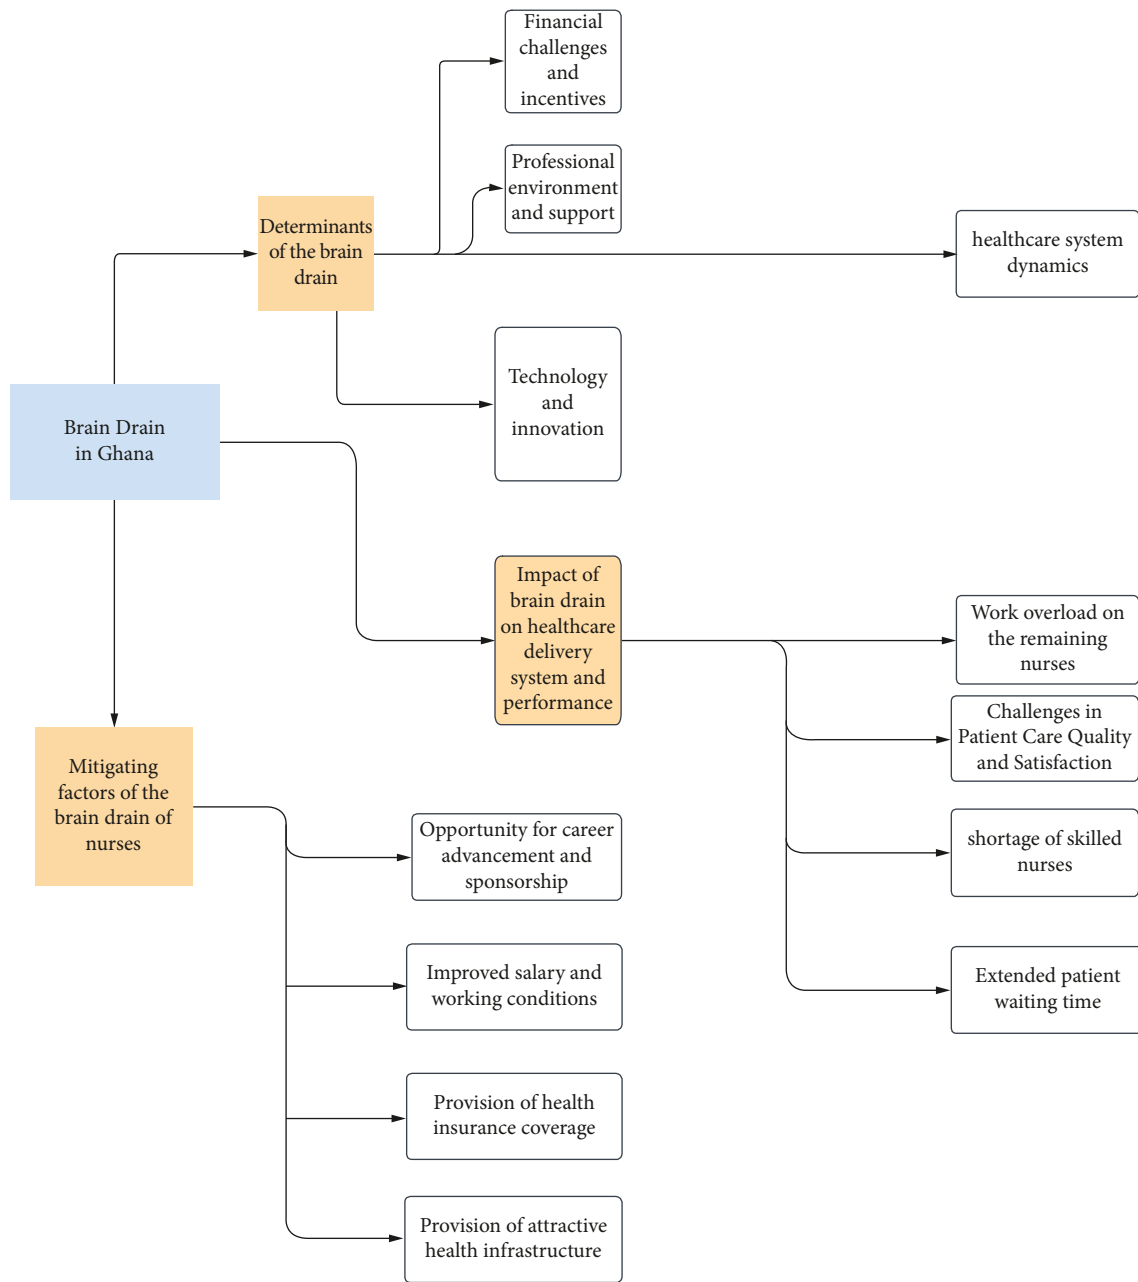

FIGURE 1: Categories and subcategories that emerged from the interview data.

3.1.4. *Technology and Innovation.* According to our findings, one of the main reasons why nurses are leaving their home countries is their curiosity about modern technology. Many nurses are highly motivated to practice in other countries after seeing the technological advancements on television and social media.

Although they may rely on manual methods in their home countries, they aspire to experience the technologically advanced lifestyle available in foreign countries. This curiosity becomes a compelling driving force for them.

“We see it on TV and on social media that this time, this is the current trend that is going on, and we are still doing the old-fashioned things. Sometimes, out of curiosity, you will want to go and taste life on the other side of the island” (Participant 2).

3.2. *Impact of Brain Drain on Healthcare Delivery System and Performance.* One of the major categories was the impact of brain drain on the healthcare delivery system and performance. The findings unveil the multifaceted repercussions of

brain drain on healthcare provision, shedding light on healthcare systems' complexities. The subcategories included the Shortage of Skilled Nurses, Challenges of Patient Care Quality and Satisfaction, Work Overload on Remaining Nurses, and Extended Patient Waiting Time.

3.2.1. Shortage of Skilled Nurses. Our findings indicate that nurses with significant expertise and experience are predominantly those leaving the country. Participants underscored the substantial loss incurred by the departure of these experienced nurses, emphasising the critical benefits of retaining them, mainly as patient care demands have heightened in recent years. Furthermore, they highlighted the potential risks to the country's ability to meet its targets for the Sustainable Development Goals (SDGs) if the shortage of skilled nurses within the healthcare system persists. The ongoing exodus of proficient nurses could severely undermine the healthcare system's capacity to deliver quality care, impeding progress towards achieving the SDGs. This scenario necessitates urgent attention and strategic interventions from policymakers to mitigate the adverse impacts and ensure a stable and competent nursing workforce.

"...It is affecting the nursing profession in Ghana; those who have the experience and knowledge in nursing are rather leaving. Meanwhile, they have been trained by the Government of Ghana" (Participant 8).

"Of course, we have international standards to follow like the SDGs and we need skilled nurses to help us achieve such goals. So, if all the skilled nurses are leaving the country, leaving the less. It will affect our achievement of the SDGs" (Participant 5).

3.2.2. Challenges in Patient Care Quality and Satisfaction. The reduced compensation and increased workload could lead to the remaining nurses inadvertently expressing frustration towards patients, resulting in dissatisfaction with the care provided. Furthermore, there is concern about the potential decline in patient care standards due to the insufficient training of other cadres of nurses who may likely remain after most registered nurses have migrated. These staff may face challenges in implementing proper care plans, ultimately affecting patient care quality.

"If there is more work and less pay, you will become frustrated. Some of us cannot hide our frustrations. We will also extend it to our clients. So, the clients will come and they are not satisfied with whatever activities or care that we have rendered to them rendering the whole health system useless because our optimum goal is to make our clients satisfied" (Participant 2).

"Nursing care plan has been one of the things that we want to implement but we are not able to do it because of the cadre of staff. The few diploma nurses with the volume of certificate nurses who they have, they don't learn it [...] and for you to implement the nursing care plan, it needs

much attention [...] So, there is no way that they will be able to master it to be able to provide proper care, so low standard of care. That is what we are all wailing at, the low standard of care" (Participant 4).

3.2.3. Work Overload on the Remaining Nurses. Many participants emphasised that a significant consequence of nurses migrating abroad is the increased workload placed on the remaining nursing staff, adversely affecting their well-being. This augmented strain frequently impedes these nurses from dedicating adequate time to deliver the level of care that patients require. The overburdened staff face heightened stress levels, which can lead to burnout, decreased job satisfaction, and, ultimately, a further reduction in the quality of patient care. Additionally, the diminished workforce may struggle to maintain standard care protocols, potentially resulting in higher rates of medical errors and compromised patient outcomes. This scenario underscores the urgent need for strategies to support the remaining nursing staff, such as improving working conditions, ensuring adequate staffing levels, and providing mental health resources to sustain both nurse and patient well-being.

"It is affecting us because the number of nurses is reducing and that is putting a strain on the remaining staff, eventually affecting the care we give to our patients" (Participant 1).

Additionally, nurses' workload will include mentoring newly recruited nurses, as they represent the remaining pool of experienced nursing staff.

"The burden on them would be like mentorship because that means that we have employed more like recruited new nurses, and they the few ones left have to begin to mentor them" (Participant 16).

3.2.4. Extended Patient Waiting Time. The participants observed that insufficient nursing staff attending to patients would result in longer wait times. This issue arises because the limited nursing workforce is required to complete ward rounds and other activities before they can address the needs of patients in critical areas, such as the Outpatient Departments (OPDs). Consequently, the time-sensitive demands of patients requiring immediate attention may not be met promptly, exacerbating patient dissatisfaction and potentially compromising patient outcomes. The cascading effects of these delays can strain the entire healthcare system, highlighting the critical need for adequate staffing to ensure efficient and effective patient care. Ensuring sufficient nursing personnel is essential for maintaining the flow of care delivery and upholding the standards of healthcare services.

"[...] If we are many, at least some will be at the ward to carry out the rounds, and some will be at the OPD to take care of the patients. But if the numbers reduce, it will be like some few or one person. The person has to go forward

rounds, finish, and then come to the OPD and attend to those waiting. So, the waiting time will increase automatically” (Participant 12).

3.3. Mitigating Factors of the Brain Drain of Nurses. The third and final main category identified in this study was the mitigating factors of nurse brain drain, encompassing four subcategories: Opportunities for Career Advancement and Sponsorship, Improved Salary and Working Conditions, Provision of Attractive Health Infrastructure and Policies, and Provision of Health Insurance Coverage. Mitigating factors are crucial in addressing the brain drain of nurses. Critical insights into practical strategies for retention and recruitment within the nursing profession were uncovered through this research.

By analyzing these factors, this study illuminates actionable pathways for mitigating the adverse effects of nurse brain drain, ultimately contributing to enhancing healthcare delivery systems in Ghana. Implementing these strategies can foster a more stable and satisfied nursing workforce, which is essential for achieving sustainable improvements in healthcare quality and accessibility.

3.3.1. Opportunity for Career Advancement and Sponsorships. Numerous participants emphasised the importance of providing career advancement opportunities for deserving nursing staff as a strategic measure to minimise nurse migration. They suggested that these opportunities should include full or partial sponsorship for the desired programs, thereby enhancing nursing personnel’s professional development and retention. By investing in the career growth of nurses, healthcare institutions can foster a more committed and skilled workforce, reducing the propensity for migration and ensuring better continuity of care within the healthcare system.

“If opportunities are given to deserving staff to pursue their career, they may stay” (Participant 5).

“Career development and advancement could help if only it will come with good incentives. As I stated, for instance, If I am going to develop myself [...] and then all my fees are gone by 50% [...] Why would I go? I would stay” (Participant 9).

3.3.2. Improved Salary and Working Conditions. Consistently, all participants proposed that a key strategy for addressing nursing migration is for the government to enhance nurses’ salaries and working conditions. Improved compensation and working environments would strongly incentivise nurses to remain in the country. To mitigate the impact of the brain drain phenomenon, participants suggested that healthcare facilities should offer on-site accommodation to nurses. Additionally, participants recommended that the government introduce policies to standardise wages, ensuring fair and competitive compensation across the healthcare sector. These measures would

improve nurse retention and promote a more stable and effective healthcare system.

“The solutions are to improve nurses’ salary and working conditions. If nurses’ working conditions are improved, many people will not go away. When you are in your town or city, life will be better than going outside” (Participant 8).

The participants also emphasised the importance of incentivising nurses working in remote areas. This is particularly significant due to the numerous challenges faced by these nurses, including inadequate access to basic necessities such as clean drinking water and electricity and poor road infrastructure. Providing additional incentives for nurses in these regions would acknowledge their unique hardships, encourage retention, and improve the quality of healthcare services in underserved areas.

“Trained nurses don’t want to go to some places to work mainly because the roads are terrible. If you have your family living in the city then you have to always travel all the way down” (Participant 11).

3.3.3. Provision of Attractive Health Infrastructure and Policies. Several participants suggested the government renovate aging hospital buildings to enhance their appeal. They also emphasised the importance of constructing new hospitals and facilities to ensure efficient patient management. It is crucial to ensure that basic items required for patient care are readily available in healthcare facilities. Furthermore, three of the sixteen participants proposed reinstating a commitment or bonding mechanism for nurses after completing their training. This measure could reduce the number of nurses who migrate abroad, helping retain skilled healthcare professionals within the country.

“Government should make our hospitals attractive. The hospitals are old and there are no new buildings. At times it is the beauty of the hospital that attracts somebody to go and work there” (Participant 3).

“There should be policies in place that when you finish nursing school, you should serve the country for this number of years. After that, if you choose to leave, that’s okay. But then it should be such that by the time those people decide to leave, you have people that have been trained also like mentorships. Then any point they exit, they have another set that can take care of the system” (Participant 11).

3.3.4. Provision of Health Insurance Coverage. Participants suggested that the government’s implementation of a comprehensive health insurance policy for healthcare workers could significantly enhance nurse retention.

By providing robust health insurance coverage, the government would address a critical aspect of job

satisfaction and security, thereby reducing the incentive for nurses to seek employment opportunities abroad. Comprehensive health insurance would improve the overall well-being of healthcare workers and demonstrate a tangible commitment to their welfare, which is essential for fostering a loyal and dedicated workforce. This policy could be a pivotal component in a broader strategy aimed at mitigating the adverse effects of brain drain within the nursing profession.

“Another expectation is that if the government comes up with a policy that helps workers maybe health insurance policy [...] that can also help them to stay [...]” (Participant 10).

4. Discussion

This study explored nurse managers' perspectives on the factors influencing and potential solutions for the brain drain of nurses in Northern Ghana. The multifaceted nature of this phenomenon indicates that migration is not driven by a single factor alone. Financial challenges, opportunities for professional growth, social considerations, workplace conditions, and political factors all play significant roles in nurses' decisions to migrate. The findings highlight the issue's complexity, underscoring the need for comprehensive and multifactorial strategies to effectively address the brain drain in the nursing sector [24].

Our research found that economic factors, such as low salaries and the desire to provide a better life for their families, are significant contributors to the nursing brain drain. These findings align with previous studies, which have similarly identified meagre salaries [3, 11, 25–27] and the desire to secure a better life for family [10, 28] as primary reasons for nurses leaving their home countries. Similarly, Lanati and Thiele [29] revealed nurses' migration is largely due to push factors such as economic challenges (low average salary) and pull factors including higher wages, improved quality of life, growing economy, and prestigious educational opportunities.

Moreover, this research underscores the critical role of working conditions in exacerbating nurse emigration, contributing significantly to brain drain. Previous studies consistently underscore the pivotal role of the work environment on nurses' decisions to seek opportunities abroad. For example, recent research elucidated how the scarcity of essential consumables and equipment is a compelling factor driving nurses to relocate to other nations—a finding congruent with existing literature [30, 31].

Improving workplace conditions and introducing effective financial incentives are crucial to minimising nurse migration issues due to economic factors and challenging work environments. This dual approach addresses nurses' financial needs and job satisfaction, fostering retention and strengthening healthcare systems.

Furthermore, the absence of opportunities for skill enhancement and career advancement, coupled with delays in promotions, has been identified as a key driver of nurse migrations. This finding reinforces the conclusions from

comparable studies on the subject [10, 11, 32]. The government and the Ministry of Health should consider addressing this issue to tackle the challenges posed by brain drain in the country.

In our recent study, political factors, such as delays in recruiting graduate nurses and the recent policy of exporting nurses, emerged as significant determinants of nurse brain drain. This finding resonates with the research conducted by Poku et al. [10] which highlighted how political decisions impact nurse migration. Specifically, nursing graduates often face prolonged periods of unemployment, waiting over two years before securing a job due to bureaucratic delays. The recent practice of nurse exportation by the government makes nurses perceive an oversupply of trained professionals, further encouraging migration. To address this issue, policymakers should consider implementing reforms to streamline the recruitment process for nursing graduates, reduce waiting times for employment, and enhance transparency in government policies regarding nurse exports. Providing clear information on the rationale behind such decisions can help alleviate concerns and discourage unnecessary migration, ultimately mitigating nurse brain drain.

Our findings highlight that brain drain exacerbates work overload among remaining nurses, diminishing patient satisfaction. As nurses pursue better opportunities abroad, the patient-to-nurse ratio increases, necessitating the remaining staff to shoulder the workload. This finding resonates with similar studies by Yuksekdog [33]; Poku et al. [10]; Kadel and Bhandari [34]; and Rolle et al. [35], which have all documented the added burden on nursing personnel during periods of brain drain. Increased nurse workload is linked to reduced patient satisfaction and poorer outcomes [36, 37]. This correlation underscores the importance of advocating for humanistic care in nursing practice.

By fostering a culture of empathy and patient-centred care, we can strengthen the nurse-patient relationship, elevate the quality of nursing services, enhance patient satisfaction, and bolster professional recognition for nurses [38].

The present study revealed that the brain drain among nurses leads to newly trained nurses being introduced into the healthcare system with fewer experienced mentors available. Experienced nurses who leave take with them valuable knowledge and skills acquired over years of practice, leaving newly recruited nurses without the necessary expertise and guidance. Evidence indicates that patients' perceptions of hospital care are strongly associated with missed nursing care, directly related to inadequate professional nurse staffing [39–41]. For example, the study conducted by Karaca and Durna [42] revealed that patients were more satisfied with the care provided by experienced nurses, as the nursing care they received during hospitalisation was excellent. Therefore, the government could set up mentorship programs, supportive work environments, and opportunities for continuous training and skill development so that the remaining nurses can advance their knowledge and skills to provide quality care to patients.

Our research underscores that the continual migration of nurses poses a significant obstacle to attaining the Sustainable Development Goals (SDGs). This challenge is closely tied to the International Council of Nurses [43] assertion that nurses play a pivotal role in achieving the SDGs and that without adequate investment in the nursing profession, success in these global objectives is unattainable. The SDGs, established in September 2015 with the initiative of the World Health Organization (WHO), aim to foster measurable progress across social, economic, and environmental dimensions by 2030. Nurses are vital to this endeavour, serving as primary healthcare providers in all communities and settings. Their crucial role is highlighted by the fact that they outnumber doctors by nearly three to one [44]. However, an uneven distribution of nursing personnel weakens health systems, as Peters et al. [37] noted, ultimately hindering SDG targets' achievement. Addressing the challenges of nurse migration is crucial for the sustainability of healthcare systems and for realising the broader goals of global development outlined in the SDGs.

This study found that ongoing nurse brain drain increases patient waiting time. This may be explained by the reduced number of nurses in the healthcare system and hospitals when they migrate to foreign countries, especially in the absence of active recruitment efforts to replace those who have left. Waiting time indicates the quality of healthcare services [45, 46]. Prolonged waiting times significantly contribute to patient dissatisfaction [47, 48] and can have negative impacts on patient adherence to medication treatment regimens, clinical outcomes, the likelihood of patients returning to see their care providers, and the probability of patients recommending their care providers to others [49].

The current study underscores the pivotal role of government initiatives in creating an empowering work environment conducive to nurse retention. A predominant theme among participants was the desire for support in continuing their education through training and avenues for career advancement. They believed such support would enhance their personal development and professional standing and enable them to serve their communities better. This sentiment aligns with findings from research by Iwu [50] and Lartey et al. [51] which highlighted the effectiveness of providing opportunities for continuing education, career progression, and fostering a supportive workplace culture in stemming the nursing exodus. Furthermore, insights from Poudel et al.'s [52] study on nurses in preregistration programs in Nepal shed light on the motivations behind migration aspirations. The majority desired to migrate, with many citing access to educational opportunities abroad as a primary driver. However, they agreed they would stay in their home country if similar educational prospects were available locally. This underscores the importance of not only providing educational opportunities but also ensuring their accessibility to nurses, thereby fostering retention and mitigating the urge to migrate.

A significant finding of this study is that providing accommodation for nurses could be an effective strategy to mitigate brain drain. When implemented by healthcare

organizations, this practical solution alleviates the financial burden of renting from external landlords and allows nurses to concentrate more fully on their professional responsibilities. These findings, in line with the research conducted by Adzei and Atinga [53], underscore the importance of housing as a crucial incentive for retaining healthcare personnel within a nation, providing healthcare administrators, policymakers, and researchers with actionable insights [54].

5. Conclusion

The study underscores numerous factors contributing to the emigration of Ghanaian nurses, which consequently leads to significant adverse effects on the healthcare system. These include heightened workload among remaining nurses [55], diminished patient satisfaction, lowered standards of care, a shortage of skilled professionals, impeded progress towards Sustainable Development Goals (SDGs), and prolonged patient waiting times. Effectively addressing this challenge necessitates a comprehensive approach. This involves implementing various potential solutions, such as offering career advancement pathways, enhancing salary and working conditions, bolstering health infrastructure, ensuring equitable pay, providing health insurance coverage, maintaining adequate supplies of consumables and equipment, offering accommodation support, and implementing bonding arrangements. It is crucial to address these multifaceted issues comprehensively to mitigate nurse brain drain and strengthen the resilience of Ghana's healthcare system.

5.1. Limitations of the Study. While this study shed light on the determinants and mitigating factors of the brain drain among Ghanaian nurses, it focused only on nurse managers in Northern Ghana, restricting the generalizability of the findings to a broader population of Ghanaian nurses. Also, there might be bias in selecting participants, especially if nurse managers who agreed to participate have distinct views or experiences compared to those who declined.

Existing studies have identified specific factors influencing some dimensions of evidence-based practice (EBP) competence and use. However, the way these factors interact still needs to be clarified. The purpose of the study was to test a model based on the Determinant Frameworks that explain the relationships and the direct pathways between the characteristics of the nurses, the context, and the implementation strategies and the dimensions of EBP competence, attitude, knowledge, skills, and use of EBP. A cross-sectional study was carried out in Spain during January and February 2020, involving 2,370 nurses employed in public health centers across all autonomous communities within the National Health System. An online survey was administered to gather data, addressing various topics related to the nurses' characteristics, the context in which they worked, the implementation strategy, and their competence in evidence-based practice (EBP). As depicted in the conceptual framework, a structural equation model was constructed to test the hypothesized relationships among key study variables. The model obtained showed a good fit ($\chi^2/df = 3.20$, $p < 0.001$; RMSEA = 0.030 [90% CI 0.025, 0.036]; CFI = 0.989; GFI = 0.990; TLI = 0.983). The context, more specifically, the dimensions of nurse participation in the center's affairs, nursing foundations for quality of care, nurse manager ability leadership and support of nurses, and implementation strategy have a direct and positive effect on EBP use. Training in EBP, reading scientific articles, and having a doctorate are associated with higher competence and knowledge in EBP. The final fit shows the #Evidencer model for the use of EBP (#EvidencerMUSEBP) with two main components: the contextual and strategic factors that influence the implementation of EBP and the characteristics of the professionals, such as their training and reading of articles, which have an impact on EBP competence. This model could guide healthcare organizations in proposing comprehensive interventions to improve EBP use and the competency of nurses.

1. Introduction

The competency of health professionals in evidence-based practice (EBP) plays a fundamental role in adopting and implementing EBP in clinical settings [1]. Recent research has shown, in general terms, a lack of EBP competency in nurses in many countries and practice settings [2–4]. EBP competency comprises four dimensions: attitudes, knowledge, skills, and use of EBP, which can reach different levels of progress in professionals [5]. The literature on the subject

shows that health professionals, including nurses, have positive attitudes and beliefs about the importance and value of EBP for improving the care of patients and moderate levels of their EBP knowledge and skills. However, an adequate level in these dimensions does not necessarily result in changes in behavior, as the use of EBP in daily practice is generally low in all disciplines [6].

Nurses' EBP competency is intricately linked to individual characteristics, the work environment, and implementation strategies. Examining this relationship provides

a more comprehensive understanding of how various factors influence the adoption and application of EBP.

First, professional characteristics, such as age and educational level, are positively associated with EBP competence. Research suggests that younger nurses and those with higher education levels exhibit stronger competence in EBP [3, 7]. More specifically, a Master's degree is associated with enhanced EBP knowledge and use [8]. In addition, specific EBP training has been associated with positive beliefs about EBP [8], and having experience in research has been associated with EBP knowledge and skills [9]. The clinical competency and professional values of nurses, as well as their role as mentors for nursing students, are key drivers of competence in this area [10, 11].

Second, the work context plays a crucial role. Organizational factors, such as the availability of resources and institutional support, have been shown to influence EBP competence [9]. Specifically, active participation in the center's affairs and leadership roles has significantly influenced EBP competence [12]. Furthermore, access to resources such as the Internet [13] and bibliographical databases [8] contributes to competence in this area. There are factors such as working in a magnet hospital that show contrary results depending on the country. A study conducted in Saudi Arabia led to an association with attitude towards EBP [14]. In contrast, a study conducted in the USA showed a lack of differences in the competencies of nurses, regardless of whether they worked in a magnet hospital or not [3].

Third, implementation strategies play a crucial role in EBP competence. Specific EBP training and the presence of specialized mentors have been associated with positive beliefs and increased knowledge of EBP [8]. Moreover, research has demonstrated that mentorship and an organizational culture supportive of EBP positively impact professionals' competence in EBP [10, 11].

As highlighted, research should test models to determine which variables have the most influence on EBP [3]. Existing studies have identified specific factors that could influence some of the dimensions of EBP competence. However, the underlying mechanisms of these relationships and how these factors interact between them still need to be clarified. Up to the present, two studies have been conducted with nursing professionals who tried to develop an explanatory model about the factors associated with competence and implementation of EBP. The first of these was conducted in the USA and was based on the ARCC© Model. The results showed that EBP culture and mentorships were key variables that directly affected the knowledge, beliefs, competence, implementation, work satisfaction, and retention of nurses [15]. On the other hand, the second study, conducted in Saudi Arabia, used a conceptual framework developed from published background works [16]. The skills and beliefs about EBP were the main factors related to their use and were also mediated by factors such as the EBP training of the nurses. The facilitators and barriers also had a significant impact on the application of the EBP [16]. However, these results have a limited generalization to other cultural settings. Cultural factors influence EBP adoption in healthcare

professionals by shaping attitudes toward authority, communication styles, beliefs about health, and the emphasis on collectivism or individualism. Addressing cultural nuances is crucial for tailoring effective implementation strategies. Besides, there are variables that were not found in either model that could be interesting to consider.

Among the theories and conceptual frameworks developed to explain factors that influence the implementation of EBP, the Determinant Frameworks [17] present elements that are adequate for the establishment of an initial conceptual framework that allows testing the influence of certain factors on the competency and use of EBP by nurses. In general terms, these frameworks include five types of determinants: implementation object, characteristics of the professionals, end users, context, and strategy for facilitating the implementation and recognize, based on a systemic approach, the existence of relationships within and between the different levels, although the relationships between these determinants still need to be clarified [18].

In 2020, we conducted a national study in Spain with nurses, in which many variables that monitored three of the determinants mentioned in that model were measured. Specifically, these were the characteristics of the professionals, the context, and the strategy for facilitating the implementation [4]. Beginning with the initial conceptual framework proposed [17], the starting hypothesis to be tested was the existence of a positive relationship between the characteristics of the professionals, the context, and the strategy for facilitating the implementation with EBP competence and, at the same time, with the dimensions that shape it (Figure 1). The great heterogeneity between the studies investigating the factors and determinants of the competence and use of EBP does not allow us to be more specific a priori. Therefore, the purpose of the present study was to develop and test a model supported by the Determinant Frameworks that could explain the relationships and the direct pathways between the nurses' characteristics, the context, and the strategies of implementation, with the dimensions of the EBP competence, attitude, knowledge, skills, and use of EBP.

2. Materials and Methods

2.1. Design. The EBP competence of nurses was evaluated with the data from an observational, cross-sectional, and national study conducted in Spain between January and February 2020 [4]. This timeframe offers a unique insight into the EBP competence of nurses in a pre-pandemic context. At the same time, this study design allows for the simultaneous collection of data at a single point in time, offering a snapshot of the relationships and variables of interest in a same country.

2.2. Participants and Setting. The study included nurses who worked at public health centers from the National Health System in all the autonomous communities in Spain. The following were the selection criteria: nurses currently employed at public health centers affiliated with the NHS,

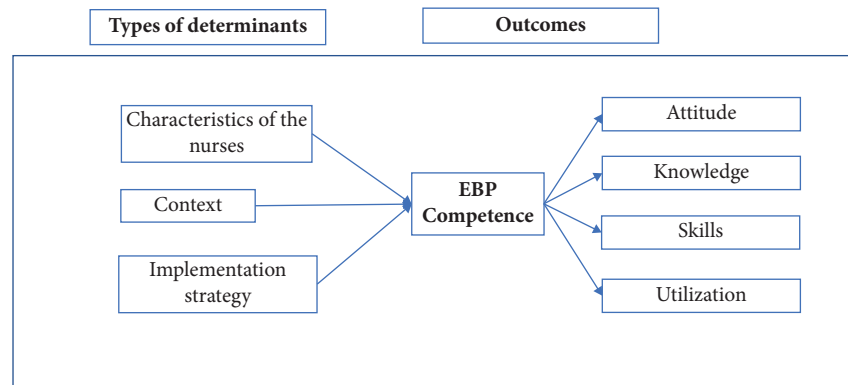

FIGURE 1: Conceptual model. The relationship between types of determinants and EBP competence.

with at least one year of work experience, and working either at a hospital or primary care center with any type of contract.

Data were collected through an online survey using a collaborative national campaign named #Evidencer. The sampling was nonprobabilistic, with voluntary participation among professionals who chose to engage after receiving the invitation. The campaign extended invitations to nurses nationwide via social media, professional associations, trade unions, and scientific organizations to enhance representation.

2.3. Variables and Instruments. The online survey included questions about the characteristics of the nurses, context, strategy for facilitating the implementation, and EBP competence.

2.4. Characteristics of the Nurses. The sociodemographic and professional variables of the nurses included were age, sex, time since completing the Nursing degree, professional experience, level of education that includes bachelor, specialist nurse (refers to formal and officially recognized training that equips professionals with specific clinical competencies in various areas such as obstetrics, community health, and pediatrics), master's degree, and doctorate degree, training on EBP, number of articles read in the last month, nursing students' mentor, and use of the Internet and other digital tools to access scientific information.

2.5. Context. To analyze the organizational context of clinical practice, the Spain-validated version of the questionnaire Practice Environment Scale of the Nursing Work Index (PES-NWI) was utilized to measure the context of nursing practice in health organizations. This instrument has been validated in Spanish in the hospital and primary care contexts [19, 20]. Both versions are similar with the same number of items and the original five-factor model. The Spanish versions of the questionnaire demonstrate robust psychometric properties, including validity and reliability. As outlined in these articles, the validation process underscores the instrument's capacity to effectively measure the nursing work environment in the Spanish context of community and hospital. In order to ensure accuracy, we

used a neutral version of the items or employed two terms where necessary, to accommodate nurses from both contexts. The questionnaire contained 31 items organized into five factors: factor 1 includes nurse participation in the center's affairs (9 items); factor 2 includes nursing foundations of quality of care (10 items); factor 3 includes nurse manager ability, leadership, and support (5 items); factor 4 includes staffing and resource adequacy (4 items); and factor 5 includes nurse-physician relations (3 items). The items were scored with a Likert scale with four response options (from "strongly disagree" to "strongly agree").

In addition to the PES-NWI, we looked at other factors related to the work environment, such as employment status, type of contract, work location, context of care (hospital or primary care), and access to the Internet while at work.

2.6. Strategy for Facilitating the Implementation. This determinant was evaluated by asking the nurses if they worked at a center that was part of the "Best Practice Spotlight Organization (BPSO®) implementation program." These are healthcare centers that participate in the international Registered Nurse' Association of Ontario (RNAO) program for the implementation of Clinical Practice Guidelines (CPGs). This program has been implemented in Spain since 2012, and centers are selected through a competitive process; the centers present the proposals for implementing and evaluating the RNAO CPG in 3 years. The implementation methodology followed in all centers is an adaptation of the knowledge to action model, which includes the following phases: (a) identify the problem and select the available knowledge; in this case, those provided by the CPG; (b) adapt the recommendations to the local setting; (c) assess the obstacles and the facilitators of the use of knowledge; (d) plan and execute the application; (e) supervise the use of knowledge; (f) evaluate the results to determine the success of the application; and (g) develop sustainability strategies [21].

2.7. EBP Competence. To assess the EBP competence, the "Evidence-Based Practice Competency Questionnaire, Professional version (EBP-COQ-Prof®)" was utilized. This tool was validated in Spanish, with adequate validity and

reliability. It allows measuring the self-perceived EBP competence of nurses [5]. Cronbach's α for each scale dimension was 0.888, indicating good internal consistency. A final model was tested with four oblique factors and 35 items. The model fit indices were $\chi^2 = 1,935.92$ ($df = 554$; $p < 0.001$), $\chi^2/df = 3.49$, CFI = 0.932, TLI = 0.927, and RMSEA = 0.093 (90% CI = 0.097–0.108). Factors I is attitude (8 items, range 8–40); factor II is knowledge (11 items, range 11–55); factor III is skills (6 items, range 6–30); and factor IV is utilization (10 items, range 10–50). The items are scored using a Likert scale from 1 to 5 (from “strongly disagree” to “strongly agree”). The overall score for evidence-based practice (EBP) competence ranges from 35 to 175 points, with a higher score indicating greater competence.

2.8. Analysis of Data. Data analysis was performed using the SPSS statistical package version 22.0 and AMOS version 20 (IBM Inc., 2013, NYC). Descriptive statistics were calculated to describe the participants' background characteristics (e.g., basic demographic variables and work-related variables) and key study variables (i.e., EBP competence, context, and strategies for facilitating the implementation of PBE programs). We further examined if any background characteristics were associated with key study variables using one-way ANOVA (for the EBP competence). Pearson's correlation coefficients were also calculated to examine the associations between key study variables.

A structural equation model (SEM) was constructed to test the hypothesized relationships among key study variables as depicted in the conceptual framework (Figure 1). The variables showed adequate normality for the maximum likelihood estimation (MLE) method, i.e., skewness $>2-3$ and kurtosis $>7-10$ [22]. The significance of the regression coefficients was evaluated after estimating the parameters. The effects with $p \leq 0.05$ were considered significant. The fit of the model was evaluated using $\chi^2/df < 5$, the root mean square error of approximation (RMSEA) values ≤ 0.08 , and the comparative fit (CFI), goodness of fit (GFI), and Tucker-Lewis index (TLI) values ≥ 0.90 indicate a good fit [23].

2.9. Ethical Considerations. The study was approved by the Ethics Committee of the University of Murcia (ID: 2540/2019). The nurses were invited to participate voluntarily through an online survey. They were informed about the study's objectives, making it clear that their participation was completely anonymous and that they provided their consent to participate by sending it.

3. Results

The nurses who completed the survey ($n = 2370$) had a mean age of 41.3 (SD = 9.8), a high percentage were women (79.80%), slightly more than half had a Master's degree (55.6%), and about 30% worked in an organization that was implementing the BPSO® program. The remaining socio-demographic variables are shown in Table 1.

questionnaire with level of education, EBP training, reading scientific articles, and being a nursing student mentor. Also, sex, use of social networks, having internet access at work, and working in a BPSO® center were associated with the utilization dimension and total competency.

Significant correlations were also observed between the quantitative sociodemographic variables, the dimensions from the PES-NWI, and the dimensions from the EBP-COQ Prof© questionnaire (Table 3). Age, the time since completing the nursing degree, and work experience showed significant and inverse bivariate correlations with attitude, knowledge, total EBP competence, and the dimension from the PES-NWI collegial nurse/physician relation, while positive correlations were obtained with nurse participation in the center's affairs and nursing foundations for quality of care. The dimensions from the PES-NWI showed correlations with the dimensions from the EBP-COQ that oscillated between 0.020 and 0.094 with attitude, between 0.055 and 0.151 with knowledge, and between 0.134 and 0.217 with skills. The dimension use of EBP showed the strongest correlations, with all the dimensions from the PES-NWI obtaining values between 0.306 and 0.535.

3.1. Structural Equation Modeling

3.1.1. Testing the Initial Hypothesized Model. The preliminarily hypothesized model (Figure 2) showed a poor fit ($\chi^2/df = 16.62$, $p < 0.001$; RMSEA = 0.081 (IC del 90% 0.077, 0.085); CFI = 0.885; GFI = 0.938; TLI = 0.837). After evaluating modification indices and parameter estimates, numerous paths were nonsignificant; subsequently, they were removed to make the measurement model more theoretically parsimonious.

3.1.2. Testing the Modified Model. The influencing factors on EBP competence were specified (Figure 3 and Table 4). The modified model showed a good fit ($\chi^2/df = 3.20$, $p < 0.001$; RMSEA = 0.030 (90% CI 0.025, 0.036); CFI = 0.989; GFI = 0.990; TLI = 0.983). Explicitly, EBP competence was significantly influenced by work context ($\beta = 0.26$, $p < 0.001$), level of education (Doctorate) ($\beta = 0.07$, $p < 0.001$), EBP training >150 hours ($\beta = 0.23$, $p < 0.001$), and read >3 articles ($\beta = 0.26$, $p < 0.001$). The study findings show that work in a BPSO® center had an indirect effect on EBP competence. In total, the factors explained 25% of the variance on EBP competence.

The knowledge dimension of EBP competence was significantly influenced by level of education (Doctorate) ($\beta = 0.13$, $p < 0.001$), EBP training >150 hours ($\beta = 0.11$, $p < 0.001$), and read >3 articles ($\beta = 0.11$, $p < 0.001$). In addition, the abovementioned variables, work in a BPSO® center and the work context, had an indirect effect on the knowledge dimension of EBP competence. In total, the factors explained 61% of the variance on knowledge dimension.

Finally, the utilization dimension of EBP competence was significantly influenced by Nurse Participation in the center's affairs ($\beta = 0.10$, $p < 0.001$), Nursing Foundations for

Quality of Care ($\beta = 0.26$, $p < 0.001$), Nurse Manager Ability Leadership and Support of Nurses ($\beta = 0.10$, $p < 0.001$), and work in a BPSO® Center ($\beta = 0.10$, $p < 0.001$). Furthermore, work in a BPSO® center, work context, level of education (Doctorate), EBP training >150 hours, and reading > 3 articles had an indirect effect on the utilization dimension of EBP competence. The factors explained 59% of the variance in the knowledge dimension (Table 4).

4. Discussion

Following the Determinant Framework [17], our study presents the first empirical model that tested the relationship of certain variables associated with the characteristics of the professionals, the context, and the implementation strategies with EBP competence and utilization of a national sample of nurses in Spain whose sociodemographic and professional characteristics aligned with those of Spanish nurses employed in public health centers [24]. The final fit shows a model mainly linked to the utilization of EBP by clinical nurses. This model will be referred to as the #Evidencer model for the use of EBP (#EvidencerMUSEBP).

The #EvidencerMUSEBP model consists of two main components. The first component is related to the utilization of evidence-based practice (EBP), which includes determinants associated with the context and implementation strategy. The second component is related to the characteristics of professionals, such as their training and reading of articles. This component is directly linked to EBP competence, knowledge, and skills. The #EvidencerMUSEBP model suggests that although professionals may possess sufficient knowledge and skills in EBP, it may translate into something other than an equivalent use of EBP. This is consistent with findings from many studies [6]. It can also explain why interventions that solely focus on training professionals only improve their knowledge and skills without significantly impacting the use of EBP [25, 26]. Without a doubt, the model is complex and requires a systematic strategy that can synchronously and cohesively influence different factors to improve the use of EBP. This conclusion aligns with the findings of a recent review on the implementation of change in nursing practice [27].

In our study, we found that the determinants "context" and "implementation strategy" accounted for 59% of the variation in the utilization of evidence-based practice (EBP). This indicates a considerable effect size. We use the Practice Environment Scale of the Nursing Work Index (PES-NWI) to evaluate the clinical environment, a reliable tool widely used to assess nursing practice environments across multiple countries [28]. Also, this instrument includes the most common dimensions of the context described in the determinant frameworks widely used in evidence science; the majority of the frameworks outlined contextual determinants that could be ascribed to organizational support, financial resources, and social relations and support, as well as leadership, organizational culture, and climate [29]. Our findings showed that the overall score in the practice environment was directly related to EBP competence, which aligns with previous studies [12]. In addition, we discovered

TABLE 3: Relationships among sociodemographic variables, PES-NWI dimensions, and EBP-COQ Prof © dimensions.

institutions having a nursing philosophy directly influence the use of EBP in clinical practice. Our findings are consistent with other recent studies [30–33].

Regarding the dimensions evaluated in the context, it is surprising that the dimension of staffing and resource adequacy, commonly viewed as a barrier against the use of research in clinical practice [34, 35], did not influence the use of EBP. This finding is consistent with previous studies [36]. Experts have pointed out that resource and personnel availability may be favorable for applying EBP, but they must be accompanied by leadership, promotion opportunities, and participation in the institution for EBP use to be effective [29]. This idea emphasizes the fact that we are dealing with a complex model, and a systemic strategy that can influence the different factors in a synchronous and coordinated manner is needed to address it.

Concerning the determinant of “strategy for facilitating implementation,” which is defined as the methods or techniques utilized to improve the adoption, application, and sustainability of a program or clinical practice [37], it has been assessed through the implementation program of clinical practice guidelines named BPSO® of the RNAO. The model showed a positive and direct relation between participation in this program and the use of EBP. This strategy involves the institution in both the implementation and development of Clinical Practice Guidelines (CPGs). It requires the support of executive directors and nurse managers at healthcare centers, promoting teamwork and a culture of change. These aspects are deemed fundamental for successfully implementing evidence-based practices [38]. In line with our results, applying the BPSO® program has shown favorable results in using EBP in clinical practice in health centers in Spain [39, 40] and other countries [41, 42]. These findings, consistent with previous studies, provide new empirical evidence supporting the link between organizational support for innovation and the adoption of innovative practices [43].

The #EvidencerMUSEBP model also suggests that the implementation strategy indirectly affects EBP competence and knowledge, mediated by the practice environment, suggesting that the strategy to facilitate the implementation of evidence also positively influences these two aspects at a secondary level. Empirical evidence has demonstrated that training professionals on aspects related to the culture of change and EBP knowledge included in the BPSO® program leads to improvements in EBP competence and knowledge [44]. These results confirm that the successful application of the EBP strategy tends to require a process of active change directed towards the use of the intervention by individuals and the organization [45] to achieve a change in the practice environment that, at the same time, influences the competence of professionals.

Concerning the determinant characteristics of the nursing professionals related to the training and direct contact with scientific updating and the overall score of the PES-NWI (context), the determinants showed a direct relationship with EBP competence, explaining 25% of the variance. In addition, the variables related to the characteristics of the professional (having a doctorate, having more

than 150 hours of EBP training, and reading more than three articles per month), together with the overall score of the PES-NWI mediated by its effect on the general EBP competence, explained 61% of the variance, while having a doctorate also influenced EBP skills, although the relationship was weak. These findings are significant, as negative feelings or a lack of interest in research by nursing professionals have been described [46], so activities that promote the association between research and nursing practice should be promoted starting at the initial levels of nurse training. Also, the final model did not retain variables associated with the sociodemographic characteristics of the professionals, such as gender, age, or years of work experience, which are significant in previous studies [47]. This omission suggests that in the fitting of the final model, these variables did not play a determinant role. Scientifically, these variables may exert limited influence on evidence-based practice (EBP) competence and utilization compared to factors more directly linked to the profession, environment, and implementation strategies. Moreover, their exclusion may contribute to a more parsimonious and specific model, mitigating issues related to multicollinearity and emphasizing determinants more pertinent to the effective adoption of EBP in clinical settings.

The results contribute towards prioritizing the determinants on which health organizations should propose interventions to improve EBP use and competence. The #EvidencerMUSEBP and the associations established between the determinants studied show that it is vital to consider the characteristics of the professionals, the context, and the implementation strategies in a manner that is integrated and nonfragmented, as the successful application of EBP depends on the combinations of different determinants. Adopting an excessively reductionist approach, in which an intervention is conducted in a single variable, will not have the ability to influence the improvement of the use of EBP. Two or more determinants can be combined to create efficient effects and with an amplified effect that acts on nurses' use, knowledge, skills, and EBP competence.

The study's findings have notable implications for nurse managers, emphasizing the need for leadership development to promote evidence-based practices. Nurse managers can play a pivotal role in shaping organizational culture, fostering participation, and strategically engaging in programs like BPSO® for successful EBP implementation. Customized implementation strategies, continuous professional development, and a focus on creating supportive environments are key considerations for nurse managers aiming to enhance EBP competence among their teams.

5. Limitations

It is important to acknowledge certain study limitations that can affect the interpretation of its results. First, the selection of participants relied solely on nurses' willingness, and data collection was done through online surveys. These two factors may have introduced bias in the selection process as the characteristics of the nurses who participated may differ from those who chose not to participate or those who do not

have access to the internet. We could not identify whether the nurses' master's degree was professionalizing or research based. This difference could affect the number of research hours and, consequently, influence the results. Second, conducting a more detailed examination of the potential limitations associated with the positive correlation between participation in the BPSO® program and the use of Evidence-Based Practice (EBP) would be helpful. Future research should focus on exploring contextual factors that may influence the effectiveness of the program, such as differences in organizational structure, nursing contexts like hospital and primary care, varying levels of engagement among participants, or potential challenges in implementing the program. This deeper analysis will provide a more balanced perspective and facilitate a better understanding of the program's real-world applicability and potential areas for improvement.

Furthermore, while the study evaluated multiple variables related to the organizational context, it is essential to note that these variables were based on the perceptions of the participants as proposed by the questionnaire utilized, and this may not have comprehensively captured all the relevant aspects of the work environment that could have influenced EBP competence. For future research, it is recommended to test the #EvidencerMUSEBP separately in hospital and primary care contexts and compare results across different regions. In addition, including additional determinants of the model that were not analyzed in this study, such as the type of evidence and the end users, and to evaluate the impact of these factors in the #EvidencerMUSEBP would provide further insights.

6. Conclusions

The #EvidencerMUSEBP model incorporates characteristics of professionals, context, and implementation strategies, demonstrating a solid fit. This model provides empirical evidence that directly associates the characteristics of the nursing professionals, such as a high level of education, reading articles, and EBP training, with EBP knowledge and skills, thereby indirectly impacting the use of evidence.

On the other hand, the context conceived as the practice environment, which includes a nursing perspective, and is backed by institutional leaders and organizations that promote the feeling of belonging of the professionals, together with strategies such as the implementation of the CPG BPSO® program, exerts a direct influence on EBP adoption. These factors, at the same time, exert an indirect effect on EBP competence and knowledge.

The study emphasizes the vital role of leadership for nurse managers in promoting evidence-based practices, highlighting the need for customized strategies and continuous professional development to enhance competence within healthcare teams. A key aspect is that healthcare services managers and providers must internalize the need to jointly address these elements, recognizing that improvement in EBP requires comprehensive, synchronous, and coordinated actions on all fronts.

Data Availability

The data used to support the study are available from the corresponding author upon request.

Conflicts of Interest

The author declares that there are no conflicts of interest regarding the publication of this paper.

Acknowledgments

We want to thank all the nurses who uninterestingly participated in this research study and the institutions that have shared this research study among its members. This study was supported by a grant from the Spanish Ministry of Science and Innovation (Grant PID2019-106545GA-I00 funded by MCIN/AEI/10.13039/501100011033).

Aims: The main goal of this research is to identify, through expert consensus, the key factors that determine the span of control (SOC) of first-line nurse managers (FLNMs) in the Spanish healthcare system.

Background: The SOC is a management concept which has usually been defined as the number of subordinates reporting to a superior. In nursing, however, it is much more complex. This complexity is shaped by various factors related to patients, healthcare professionals and organisational structures. Nursing leaders must thoroughly consider these factors and their determinants, which necessitate a comprehensive assessment. Given the significant impact an inadequate SOC can have on patients, professionals and the organisation, it would be beneficial to address this issue. In nursing, studies on this subject are practically nonexistent and focus solely on the number of subordinates, highlighting the need for research in this area.

Methods: Between September and December 2022, a Delphi study was conducted. Forty-five experts were invited to participate. The study involved nurse administrators, FLNMs, university professors, renowned researchers and other non-health professionals related to health management. The participants completed an online survey over three phases. Factor analysis was performed on the items for which consensus was reached. The jamovi software version 2.3.15 was used for data analysis.

Results: A total of 35 experts participated in at least one of the three phases of the Delphi study. Following a comprehensive analysis of the identified factors, a consensus was reached on 31 of them. These were subsequently grouped into four categories: unit category (16 items, including complexity, resource management, conflicts and protocolisation and monitoring of activities), professional category (five items: number of staff, staffing stability and skill level and diversity of staff), FLNM category (four items: autonomy, experience and education and leadership style) and organisation category (six items: digitisation and information systems, education, research and implementation evidence-based practice and performing guards).

Conclusions: Our research shows a high degree of consensus amongst participants in identifying the determinants and degree of relevance of SOC-related aspects. Although SOC is not currently assessed, all stakeholders agree that there are a large number of variables that should be considered when appointing a FLNM.

Implications for Nurse Managers: Nursing managers can better assess the health of the organisation and improve performance by understanding the factors that influence the SOC of FLNMs. Due to the lack of previous studies, understanding these factors will allow the development of methods and tools tailored to the characteristics of different health systems.

Keywords: Delphi method; first-line nurse manager; hospital; management; nursing; span of control

1. Background

Nurse managers play an important role in achieving the goals of healthcare organisations within their respective nursing units and departments [1, 2], especially in aspects relating to leading and coordinating quality improvement work [3]. The nurse manager collective includes first-line nurse managers (FLNMs). This position is defined as individuals who have direct responsibility for patient/resident care units, with nurses and other care providers reporting to them. They are responsible for recruitment and performance management. There is no level of management below them, and they may be responsible for managing more than one unit [4].

One key aspect of the role of FLNMs is human resource management. This is where the concept of span of control (SOC) comes in. SOC originated as a business concept in the 1930s to describe the number of subordinates reporting to a superior [5]. However, the evolution of the term has been nuanced as knowledge of the subject has increased, from the number of full-time equivalent employees [6] to the number of people reporting to a manager [7].

An updated literature review suggests that SOC is a multidimensional phenomenon influenced by a variety of different factors related to the workplace, the unit workers, the FLNM and the organisation [6, 8–12]. Healthcare is becoming complex due to factors such as the need for efficient care, advancements in technology and research, longer life expectancy and the increasing complexity of patient care. In addition, challenges in recruiting and retaining healthcare professionals are contributing to the need for professional practice redesign [13].

SOC theory [14] proposes that there is a size of SOC at which maximum effectiveness is achieved. However, the literature does not offer a specific number or formula for determining the ideal number of direct reports in an optimal SOC [14].

Following this argumentation line, the 2002 Final Report of the Canadian Nursing Advisory Committee encouraged employers to explore and evaluate the characteristics of an appropriate, manageable SOC for clinical managers that allows them to perform assigned functions and be available to meet the needs of nurses and patients [15].

A handful of healthcare-specific studies have examined the impact of SOC on various outcomes: patients (e.g., patient safety and satisfaction) [4, 16, 17], employees (e.g., employee satisfaction, behaviour, turnover and safety) [18–21], FLNM (e.g., influence on leadership, job demands, role, behaviour and skills) [22–24] and organisation (e.g., loss of talent, reputation and organisational outcome) [6, 12, 25].

Only in few health systems, such as the one of Canada [13], a tool has been developed and implemented to determine the SOC of a FLNM. A questionnaire was designed to support objective decision-making on SOC, with a total of eight indicators grouped into three dimensions: staffing, programme and unit characteristics. These dimensions include unit complexity, management of material resources and general services, assigned staff, skills/autonomy (junior

professionals), stability (turnover and absenteeism), staff diversity, programme diversity and managed budget.

It should be borne in mind that the health systems of each country are different and condition the functioning of health organisations, so the particular characteristics of each country should be studied in order to propose the most appropriate tool.

Under this background, the perspective of nurses should be considered to identify the main determinants of the SOC of a FLNM in the Spanish health system. To do this, it is necessary to have the vision and experience of experts at the national level.

Amongst the qualitative research techniques, one of the most appropriate for this purpose is the Delphi method. This is a consensus technique developed by the Research and Development Corporation (RAND Corporation) in the 1950s to obtain expert agreement on various phenomena [26]. The Delphi method is now used on the Internet in a form commonly referred to as e-Delphi, where researchers conduct the Delphi in an online survey platform to collect data and facilitate communication between the researcher and experts [27].

The aim of this study is to identify the main factors determining the SOC of FLNMs in hospitals within the Spanish health system, using the Delphi technique and with the participation of a panel of experts on the subject at the national level.

2. Methods

2.1. Study Design. A three-round Delphi survey (Phases 0, 1 and 2) was implemented, including expert panellists, iterative rounds, statistical analysis and consensus building. The Delphi method was selected to generate ideas from the expert panellists' own knowledge and experience in their different fields of action.

The Delphi method is a technique used to achieve consensus amongst experts from various disciplines on a specific topic [28–31]. Its main strength lies in allowing anonymous interaction amongst experts, who can access the responses of others without knowing their identities or authority on the subject. This enables participants to modify their responses in successive rounds, controlled by a coordinating group, until the responses represent the majority opinion. This study facilitated an anonymous exchange of opinions and expertise, allowing experts to assess and modify their views in line with group consensus, thus promoting a collaborative and informed decision-making process.

The coordinating group consisted of the principal investigator (a nurse with over 24 years of experience in the Spanish public health system, including the last 10 years in diverse management positions) and three experts in management (two specialising in healthcare management and one with a background in business).

The survey was conducted three times via online questionnaires between September and December 2022. LimeSurvey was used as an anonymous online survey tool to send the questionnaires and receive the responses.

2.2. Participants. In order to obtain a model valid for the entire Spanish territory and to avoid possible biases due to the characteristics of the regional health services, it was decided to form a panel of expert's representative of the whole country.

The method proposed by Okoli and Pawloski [28] was used to select the panel of experts: (a) nursing administrators, (b) FLNM and (c) other health professionals, e.g., university professors, renowned researchers or other non-health professionals related to health management. A group of 45 national experts was selected and invited to participate through an e-mail describing the objectives and procedures.

2.3. Data Collection

2.3.1. Generate an Item Pool. In order not to condition the participants' opinions, they were asked to list aspects related to SOC in Phase 0 of the study. Therefore, this step was explored by asking the expert panellists an open-ended question: 'List as many key factors as possible to consider in determining the SOC of a FLNM.' There were 30 separate sections within the questionnaire for this purpose, as well as a final section for any additional comments.

2.3.2. Questionnaire Design. Prior to the consultation, a review of the existing literature on the SOC in nursing was undertaken to gain a better understanding of the topic and to identify possible aspects that had not been mentioned by the expert panel.

We implemented a search strategy to identify the existing work related to nurse manager SOC. We searched Medline, Web of Science and Embase for the literature using the following search terms: nurse administrator, nurse manager, FLNM, nursing supervisor, head nurse, nurse management, charge nurse, SOC, span of management, work group size and nursing.

The recommendations of Dillman et al. were followed for the development of the questionnaire and the periodicity of sending reminders for the online questionnaire [29].

The initial questionnaire produced unstructured, qualitative data which were transcribed verbatim into Word documents. A thematic analysis was carried out to identify recurring themes [30, 31]. The documents were systematically examined to identify related or similar themes as well as dissimilar themes. This stage of the analysis was carried out independently by the researcher and the Delphi study coordination group.

Comparative notes were used to validate the emerging concepts. The themes identified were then used to formulate items for the subsequent second and third rounds of questionnaires. These themes formed a first questionnaire, grouped into different dimensions, to be evaluated by the panel of experts. For this purpose, a five-point Likert scale was used to answer the questions, without distinguishing between positive and negative SOC impacts. The questions related to two dimensions: (a) the degree of relevance of the item to the FLNM management SOC (1 = *not relevant*,

2 = *less relevant*, 3 = *relevant*, 4 = *very relevant* and 5 = *extremely relevant*) and (b) whether such an item should be included in a final SOC assessment tool for an FLNM (yes/no). In addition, a space for comments or questions to the coordination group was included.

In the second and third surveys, the response data were tabulated and presented by the researcher, showing the percentage of choices and the distribution of responses for each item. The panellists' comments were used to reformulate or clarify the wording of the various items.

After each phase, the results and relevant comments were anonymised and provided to the participants in a detailed report sent by e-mail.

2.4. Extraction of Items: Statistical Analysis. In any Delphi-based study, the definition of consensus must be a priority. Therefore, for this research, consensus was defined using two criteria: (i) more than 80% of the participants in the round should indicate 'YES' to the need for the item to be part of a tool to determine the SOC of a FLNM, and furthermore, (ii) the item should be rated with an average of three or more on the five-point scale.

jamovi software Version 2.3.15 was used for data analysis. Mode, median, mean, standard deviation, interquartile range and percentages are presented.

2.5. Ethical Consideration. Questionnaires were distributed to participants via e-mail accompanied by a link to an anonymous online survey tool (LimeSurvey). Individual names of respondents were anonymised.

The purpose and methods of the study were explained to participants at the beginning of the first questionnaire, and they were informed that their cooperation was voluntary and that there would be no disadvantage for nonparticipation.

Participants' rights to autonomy were respected, and informed consent was obtained through written explanations of the benefits, rights and risks associated with the research study. Consent to participate was implied by the return of the questionnaire, which included an explicit checkbox to accept the conditions of the study. Confidentiality was strictly maintained throughout the data collection phase of the study.

The questionnaires were accessible only to the researcher, which ensured the highest level of confidentiality. Participants shared their opinions anonymously; the data collected were collated to represent group perspectives while maintaining individual anonymity. The results were presented in an aggregate form, representing the collective opinion of the members of the expert panel. This study was approved by the Comité de Ética de la Investigación de la Comunidad Autónoma de Aragón: CEICA (C.P.-C.I. PI22/351).

3. Results

The Delphi study was conducted to determine the content/face validity of items that would later be used in the development of a validated assessment instrument.

3.1. Experts. Of the 45 experts invited, 43 accepted the invitation: seven did not participate and one participant decided to leave the study after it had started. The number of participants per phase was 29 in Phase 0, 31 in Phase 1 and 29 in Phase 2. Three phases were completed by 22 participants. Figure 1 shows the date of completion and details of participation in each phase of the Delphi study. All participants' contributions were taken into account, regardless of whether they participated in one, two or all three phases.

3.1.1. Results of Phase 0 of the Study. A total of 29 experts participated in this first phase of the study by answering the following question: 'List the most important factors to consider when determining the SOC of a nurse manager.' The number of responses ranged from a maximum of 29 from one participant to a minimum of five, with a mode = 12 and a median = 11 responses.

The answers ranged from very general to very specific, for example, one of the managers gave the following answer 'The number of professionals who depend on the FLNM', while a FLNM stated the following: 'The large number of professionals in charge (about 45 amongst the four shifts) of the FLNM, including the time dedicated to calculate personal schedules and adequate coverage of the unit.' The total number of items generated in this phase was 29.

3.1.2. Results of Phases 1 and 2 of the Study. The questionnaire for Phase 1 contained 31 items (29 items from panellists and two items from the literature review) and an open-ended question after each section to collect panellists' questions and comments. The questionnaires for Phase 2 consisted of 34 items, including three items created on the basis of comments from the second survey. A descriptive analysis of the results obtained in Phases 1 and 2 is shown in Table 1.

The table illustrates the evolution in the acceptance of the items by the expert panel, expressed as the mean of the degree of relevance of the item to the FLNM management SOC (1 = not relevant and 5 = extremely relevant). The items related to the unit identified by the expert panel and those added by the coordinating group after consultation of the available literature are shown in Table 2. A total of 15 items were identified in Phase 0 of the Delphi study to be evaluated in Phase 1. In the Phase 1 observations, the expert panel included three new items, which were added to be evaluated in Phase 2. Upon review of the expert panel's comments, it became evident that modifications to the wording or the addition of explanatory texts were necessary to facilitate the comprehension of four items (U04, U05, U11 and U12). Finally, a total of 16 items were agreed in the 'unit' category, which were grouped into four indicators: complexity (U02, U03, U05, U07, U09, U12, U13 and U15), resource management (U06, U10 and U16), conflicts (U04 and U11) and protocolisation and monitoring of activities (U01, U08 and U14). The Items U17, 'Interdisciplinary communication and maintenance of care processes and circuits', and U18, 'The presence of a clinical nurse specialist in the unit to support the management and monitoring of processes and projects', were not accepted.

A total of six items related to professionals were identified in Phase 0 of the Delphi study and were evaluated in Phases 1 and 2 (Table 3). Following the completion of Phase 1, it became necessary to elucidate the meaning of Items P01 and P03. In the case of P01, the following text was added: 'It will be necessary to assess the need for job-oriented training of the professional (staff of the unit or service, but also "pool" staff).' The only item that was not retained was Item P06, which pertained to the average age of professionals in the unit. Finally, five items were agreed upon in the 'professionals' category which were grouped into three indicators: the number of staff (P02), staffing stability (P01, P04 and P05) and skill level and diversity of staff (P03).

A total of four items related to FLNMs were identified in Phase 0 of the Delphi study, all of which were evaluated and accepted by the expert panel (Table 4). The category 'FLNM' was grouped into three indicators: autonomy (F02), experience and education (F03 and F04) and leadership style (F01). Prior to commencing Phase 2, it was observed that Item F03 pertained to a range of training modalities, including those pertaining to master's degrees, soft skills, information technology (IT) and other disciplines.

A total of six items related to organisational characteristics were identified in Phase 0 of the Delphi study, all of which were evaluated and accepted by the expert panel (Table 5). It was necessary to modify the wording of Item O02 and add the following explanatory text: This can be related to new professionals but also to new procedures, techniques or new working dynamics. This process involves the planning, implementation and evaluation of improvement actions. It should be noted that this does not necessarily imply that the entire process must be carried out by the FLNM. The 'organisation' category was composed of three indicators: digitisation and information systems (O01), education, research and implementation of evidence-based practice (O02, O03, O04 and O05) and performing guards (O06).

4. Discussion

To the best of our knowledge, this is the first study carried out on this subject in Spain and in Europe, which could provide the basis for the development of a tool for the objective assessment of the SOC for this geographical context. In Canada, however, there is a study that presents a tool for assessing the SOC, called The Ottawa Hospital Clinical Management SOC (TOH-SOC) decision-making indicator tool [13]. This tool has been used in various hospitals in the United States and Canada, demonstrating the need to assess the SOC and to do so on a regular basis [4, 16, 24, 32, 33].

Comparing the SOC determinants identified by our Delphi study with those used in the TOH-SOC, most of them were identified by our expert panel, and some new ones are included. For instance, the professional's category exhibits a high degree of alignment with the Canadian model, with all items reflected coinciding with those of Canada. Other categories, such as the management of material resources, have been subdivided into a dimension

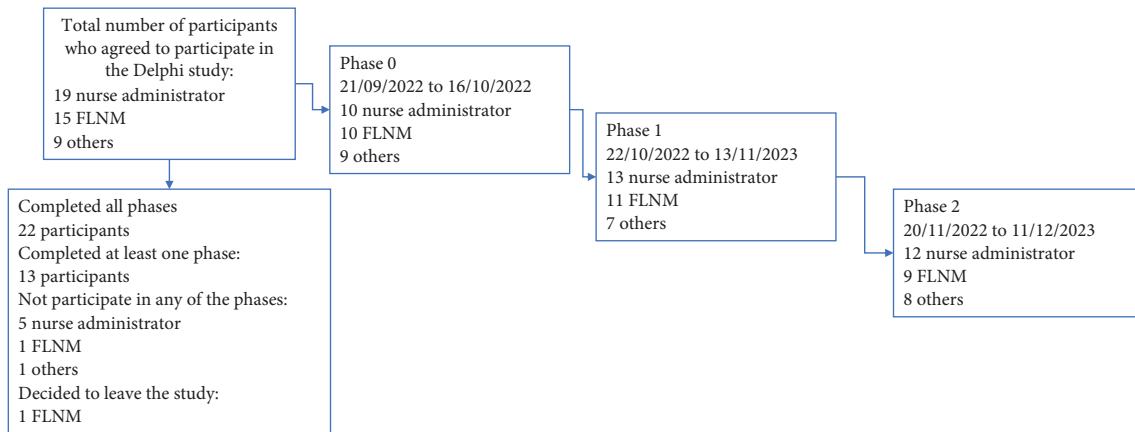

FIGURE 1: Flowchart of Delphi study phases.

TABLE 1: Description of items by phases and categories: unit, professionals, FLNM and organisation.

ID	Statement	Phase	Mean \pm SD (1-5)	IQR
U.01	Commitment to risk management and patient safety	1	4.23 \pm 0.805	1.0
		2	4.21 \pm 0.774	1.0
U.02	Variability/complexity of patient care	1	4.29 \pm 0.902	1.0
		2	4.17 \pm 0.848	1.0
U.03	Unit operating hours	1	3.26 \pm 1.316	1.5
		2	3.41 \pm 0.907	1.0
U.04	Unit working climate	1	3.84 \pm 1.157	2.0
		2	4.14 \pm 1.125	1.0
U.05	Number of different units under the permanent care of the FLNM	1	3.71 \pm 0.824	1.0
		2	3.93 \pm 1.033	2.0
U.06	Management of a large amount of equipment	1	3.68 \pm 1.107	1.0
		2	3.38 \pm 1.015	1.0
U.07	Number of patients treated in the unit	1	3.19 \pm 1.138	1.5
		2	3.31 \pm 1.072	1.0
U.08	Unit monitoring of activities, achievement or service objectives	1	3.90 \pm 0.944	2.0
		2	4.07 \pm 1.193	2.0
U.09	Interdisciplinary communication and maintenance of care processes and circuits	1	3.45 \pm 1.121	1.0
		2	3.59 \pm 1.150	1.0
U.10	Management of material resources (not included in automated replenishment systems such as Kanban)	1	3.23 \pm 1.023	1.0
		2	3.52 \pm 1.184	1.0
U.11	Communication with patients, relatives and/or carers accompanying persons	1	3.10 \pm 1.165	2.0
		2	3.62 \pm 1.147	2.0
U.12	Patient turnover rate in the inpatient units managed by the FLNM	1	2.48 \pm 1.151	1.5
		2	3.21 \pm 1.082	1.0
U.13	Frequency with which the capacity of the unit or service is exceeded	1	3.32 \pm 1.107	1.0

P.05	Turnover rate	1	3.58 \pm 1.057	1.0
		2	3.93 \pm 0.923	0.0
P.06	Average age of professionals in the unit	1	1.71 \pm 0.973	1.0
		2	2.41 \pm 0.867	1.0
F.01	Leadership style	1	3.65 \pm 1.305	2.0
		2	4.14 \pm 0.953	1.0
F.02	Decision-making autonomy	1	4.00 \pm 1.065	1.5
		2	4.10 \pm 1.081	1.0
F.03	Education of the FLNM	1	3.48 \pm 1.313	2.0
		2	3.90 \pm 0.939	2.0
F.04	Years of experience in management	1	2.23 \pm 0.990	2.0
		2	3.10 \pm 1.235	1.0
O.01	Digitalisation and technological support: HR management, management of material resources and general services and information systems	1	4.10 \pm 1.076	1.0
		2	4.04 \pm 0.778	1.0
O.02	Competence assessment and identification of training needs of the unit's professionals	1	3.65 \pm 1.199	2.0
		2	4.04 \pm 0.906	1.0
O.03	Participation in research projects, EBP, R&D&I and dissemination of results	1	3.00 \pm 1.155	2.0
		2	3.82 \pm 0.902	1.0
O.04	Presence of students in the unit	1	2.61 \pm 0.989	1.0
		2	3.36 \pm 0.942	1.0
O.05	Existence of transversal support units to support the FLNM	1	2.74 \pm 1.125	1.5
		2	3.32 \pm 1.143	2.0
O.06	Carrying out guards as FLNM	1	2.19 \pm 1.167	2.0
		2	3.14 \pm 1.302	2.0

Note: Items not available in Phase 1. The IC of the mean assumes that the sample means follow a *t*-distribution with N-1 degrees of freedom.

Abbreviations: EBP, evidence-based practice; FLNM, first-line nurse manager; IQR, interquartile range; Na, not available; O, organisation; P, professional; R&D&I, research, development and innovation; U, unit.

comprising items, thereby differentiating the management of materials, equipment and pharmacy. Amongst those items that do not appear in our research are the following: 'actual litigation', 'number of directors' and 'budget', all of which are more related to the characteristics of the health systems from which the assessment tool originates.

Most studies on the SOC are based on the number of people reporting to a superior and the consequences on the different parties involved. These consequences may include, for example, increased medication errors and nosocomial infections [16], affecting the satisfaction of the FLNM [4] or the organisational behaviours of nurses [23]. Attempting to solve the problem by focussing on the consequences without first identifying the source of the problem may result in inappropriate measures being taken. Consequently, it is imperative to ascertain the factors that influence the SOC of FLNMs in order to implement targeted interventions at the source of the problem.

In general, organisations do not take the SOC into account when designing their staffing structure [34] and, in the case of nursing, it is common to overlap medical units with

nursing units, without considering that the role of a FLNM goes far beyond the management of human and materials [19, 32, 35, 36]. It is important to consider the desired outcomes for these units and the organisation, such as improving quality of care, increasing professional satisfaction or reducing costs associated with middle management positions. As resources are limited, managers and organisations need to work together to fine-tune the SOC to achieve the greatest number of objectives [37].

It is at this point that the SOC needs to be measured to assess its adequacy and to provide the necessary support to FLNMs. Understanding the key aspects that determine the SOC can lead to an improved working environment for nurses, the delivery of high quality patient care and a reduction in costs for organisations [38]. In fact, to support FLNMs sometimes is only needed administrative assistance [33] or a comanager [39, 40]. This support can lead to increased job satisfaction and a lower risk of burnout syndrome, which in turn reduces the likelihood of employees leaving their jobs [25, 41]. In addition, it can result in improved performance for the units and teams that they lead.

TABLE 2: Rating of items on unit characteristics by phase, expert group and overall agreement percentage.

ID	Unit characteristics Statement	Delphi Phase 1			Delphi Phase 2			Was the item accepted?
		Group	Mean	Item acceptance	Group	Mean	Item acceptance

The results of our study show that 31 items should be considered to determine the SOC of a FLNM. The inclusion of a panel of experts with a variety of perspectives is necessary to get a complete picture of the determinants of the SOC of FLNMs. This study included the views not only of FLNMs, but also of nurse administrators, university nursing professors and health management economists, both active and retired, from different regions of Spain. Although this approach may have reduced consensus on certain points, it enabled us to achieve the proposed objective of this research.

One of the most crucial aspects of implementing any change within an organisational setting is to ensure the involvement of all relevant parties at each stage of the

process [42–46]. Only through this approach can critical points that might otherwise go unnoticed be identified. Furthermore, when decisions are made through a shared and consensual process, the implementation and acceptance by employees is more straightforward. This need for diverse perspectives has motivated the inclusion of professionals from different fields in our study. A critical aspect that was taken into account was the positions held by the panellists, who were national nurse leaders. It was recognised that power differentials amongst participants could have a significant impact on the quality of the data if an alternative method, such as focus group interviews, had been used to collect the data.

TABLE 5: Rating of the items on the organisation characteristics, by phases, expert group and item acceptance.

ID	Characteristics of organisations Statement	Delphi Phase 1			Delphi Phase 2			Was the item accepted?
		Group	Mean	Item acceptance	Group	Mean	Item acceptance	
O.01	Digitalisation and technological support: HR management, management of material resources and general services and information systems	NA	4.23	96.77%	NA	3.91	100%	Yes

		FLNM	2.18		FLNM	3.22		
		Others	2.43		Others	2.50		

Note: Items accepted: More than 80% of participants agreed with the item, with an average score of three or more on the five-point scale.
Abbreviations: EBP, evidence-based practice; FLNM, first-line nurse manager; NA, nurse administrator; R&D&I: research, development and innovation.

It is important to note that a large number of the determinants identified relate to the characteristics of the unit or units responsible for the FLNM. These determinants include the 'unit working environment', which to a large extent influences the interaction between professionals and the degree of support and cooperation [47–51]. If the working environment is positive, it will make it easier to achieve the unit's goals and will allow users to perceive that the staff are working as a team, thereby improving the patient experience. It is noticeable that FLNMs are the ones who rate this item the lowest, especially when they are in direct contact with staff. This may be due to their experience in their own units, with fewer conflicts and a favourable working environment.

In the case of the nurse administrators, they gave greater importance to aspects such as the achievement of objectives and risk management [52, 53], the working climate of the unit [54, 55] and the management style of the FLNM [56, 57]. These results are to be expected, given that their functions and experience give them an overall view of the organisation, a global vision and distance from the aspects that characterise the day-to-day running of the nursing units and services.

On the contrary, the contributions of the FLNMs had their highest scores in aspects related to human resource management, such as staff turnover, number of new professionals and staff absenteeism in their units. These results are not surprising, given that managing staff to keep units running can take up 20%–40% of the FLNM's working time [58]. This can be seen as the visible part of the iceberg of managing a nursing unit.

One aspect that should be highlighted for its novelty, and which is not included in the TOH-SOC tool, is that the panel of experts has added a number of determinants related to the FLNM, such as the management style exercised, the autonomy granted to them in decision-making, training (both before and after access to the management position) and years of experience in management functions. Particularly noteworthy in this study is the training of FLNMs and the low importance they themselves attach to it. In our view, this is one of the fundamental pillars that will characterise their performance as nurse managers. Specific training at the time of taking up the position should not be a prerequisite, but it would be highly recommended that FLNMs receive structured training at the time of taking up the position. Training should be at masters level in management, on the basis that clinical expertise does not prepare the new nurse manager for the wide range of competencies required for success [21, 59]. This will allow them to gain a broader range of knowledge and tools, as well as an overview of the organisation as a whole.

The leadership style employed by FLNMs when directing work teams is of particular relevance. The FLNM is responsible for the leadership of their nursing units, thus becoming a management element with the potential to positively impact the quality of care in their unit. In order for FLNMs to be able to exercise leadership, they must have the necessary conditions in their workplace, including an ideal SOC. In Doran's words, 'no leadership style can overcome

the effects of a wide SOC' [7] in order to achieve these objectives. This training should also be complemented by leadership training, which is essential to strengthen their management skills, promote a positive working environment, improve the quality of care and ensure better coordination and communication within the care team [33, 60]. Of the different types of leadership, FLNMs should be trained in relational leadership [61] and, above all, transformational leadership [22, 62, 63], as it is an effective model for improving healthcare quality and outcomes, professional commitment and patient satisfaction, all through empowering and motivating professionals.

It is interesting to note the assessment of autonomy in decision-making, which was one of the highest rated items overall by the expert panel. As described in previous research, autonomy is associated with higher levels of empowerment and job satisfaction, leading to improved organisational commitment, reduced job stress and higher employee retention [54, 64]. We should not forget that FLNMs, as middle managers in a strategic position between central management and professionals, can provide an operational and efficient response in a variety of situations, thus reducing bureaucracy within organisations. The establishment of this trust in the FLNM's ability to perform its duties effectively represents a model of positive leadership from the nurse administrators towards their subordinates. Furthermore, it demonstrates a commitment to the decentralisation of work and decision-making.

5. Limitations

This study has several limitations. Firstly, it was carried out in only one country, Spain. Therefore, the findings are only applicable to the country in which the study was conducted, although they could be relevant to other similar health systems. Furthermore, the outcomes could serve as a foundation for researchers in other contexts or health systems, enabling them to tailor them to their specific circumstances.

Contact with potential members of the expert panel was made through the Asociación Nacional de Enfermeras Gestoras (ANDE), contacts of the coordinating group and the use of social media profiles of other professionals with recognised nursing expertise. This may have resulted in some relevant nurse leaders and their expertise being excluded. In addition, not all experts participated in all phases of the study, so results may have varied depending on their responses.

A disadvantage of the Delphi approach identified in the literature relates to the clear definition of consensus. The literature suggests that 51%–70% agreement represents consensus. In our study, to overcome this limitation and as a strength of the study, consensus was set at over 80%.

6. Conclusions

Our research shows a high degree of consensus amongst participants on the determinants and degree of relevance of SOC-related issues. This makes it clear that, although SOC assessment is not currently taken into account, all

stakeholders strongly identify the variables that should be taken into account when appointing a FLNM.

The participation of a panel of experts at the national level has allowed the identification of a total of 31 items, grouped into 4 dimensions (unit, professionals, FLNM, and organisation) that should be considered to assess the SOC of FLNMs in Spanish public hospitals.

7. Implications for Nursing Management

By understanding the determinants of the SOC of the FLNM, nurse administrators could better understand and assess the status of the organisation and facilitate the FLNM's capacity to adopt an effective leadership style, thereby preventing them from departing from their position. Leadership exerts a considerable influence on the quality of care delivered in their unit and on employee engagement and conduct.

As the results of the present study are refined, it will be possible to develop a tool for weighing the factors influencing SOC, thus facilitating the creation of a common framework for discussion. This tool will enable hospital managements to develop a unified standard for the assessment of the demands of FLNMs, which together with other aspects such as competency development will lead to interventions to improve the working conditions of nurse managers. Creating a robust, grounded tool that objectively assesses SOC will be an important support instrument in assessing the expanding roles of the FLNM. A correct determination of the SOC, carried out periodically, together with the appropriate support measures, can influence an improvement of the results observed in patients, professionals and the organisation.

Background. Considering the importance of psychological first aid, which is the first priority when a disaster occurs, developing a web-based simulation training program for nurses and confirming its effectiveness is necessary. **Aim.** This study aimed to develop an interactive simulated education program as a psychological first aid program for nurses and verify its effectiveness. **Participants.** Nurses working in hospitals and the community who had not participated in psychological first aid training in the last year were recruited. **Methods.** A web-based interactive simulated educational program for psychological first aid was developed. To verify its effectiveness, a randomized controlled trial design was used. The experimental group participated in a web-based educational program, while the control group was provided self-learning data in the form of e-books. The program's effects on disaster response core competencies, problem-solving abilities, and self-leadership capacity were measured. We used descriptive statistics to analyze the general characteristics, and independent *t*-tests were used to analyze the differences before and after the intervention. **Results.** The core competencies for disaster response ($t = -2.239$, $p < 0.05$, Cohen's $d = 0.59$), problem-solving abilities ($t = -2.753$, $p < 0.01$, Cohen's $d = 0.72$), and self-leadership capacity ($t = -2.073$, $p < 0.05$, Cohen's $d = 0.54$) showed a statistically significant difference between groups. **Conclusions.** The web-based simulation education program for psychological first aid training developed in this study effectively enhanced nurses' ability to respond to disasters and improved their problem-solving abilities and self-leadership capacity. Thus, nurses can use the educational program as a tool to learn psychological first aid. This trial is registered with KCT0008965.

1. Introduction

Earthquakes are natural disasters with an immense capacity for destruction that cause large-scale casualties and enormous economic losses over a short period of time. In addition to social and economic damage, they can cause psychological problems among victims [1]; residents of earthquake-damaged areas experience long-term anxiety, depression, post-traumatic stress, and suicidal thoughts [2]. They may find it difficult to return to daily life and experience post-traumatic stress disorder if such psychological problems are overlooked [3].

To overcome this challenge, psychological first aid (PFA) is provided to victims at a disaster site. This refers to the

activities conducted immediately after a disaster to help victims with their practical needs and reduce their psychological problems [3, 4]. As an essential activity, PFA is prioritized at disaster sites to meet the psychological needs of disaster victims and prevent post-traumatic stress disorder [5]. To effectively perform PFA, one must be familiar with the characteristics of disasters and psychological problems of victims, in addition to having disaster response capabilities to cope with such situations [6]. However, practitioners deployed at disaster sites experience empathy fatigue, secondary trauma, and exhaustion while performing PFA. Therefore, increasing their ability to care for and manage their needs is crucial [7]. For example, when self-leadership

is high, work performance [8] and problem-solving improve [9].

Disasters have characteristics that are difficult to fully reproduce through traditional methods such as role-play or simulation education [10]. However, with varying degrees of realism and fidelity, it is possible to effectively simulate disaster scenarios. As such, providing learners with a sense of realism through web-based simulation education is important [11, 12]. Learning through experience is an important element of simulations; accordingly, Kolb [13] emphasized the importance of experience in learning, explaining that learning is a continuous process that combines experience, cognition, perception, and action.

Online education has seen a significant rise in popularity in recent times, with gradual use of web-based simulation education [14]. Web-based simulations have the advantage of transcending spatial and temporal limitations [15] and allowing for repeated learning and immediate feedback [16].

Web-based virtual practice uses standardized patients rather than graphics to ensure learners experience a higher sense of realism [17]. Considering the importance of PFA, developing a web-based PFA simulation training program can be an effective educational strategy for expanding learners' capabilities. Therefore, this study aimed to develop a web-based interactive PFA simulation training program and verify its effects on the disaster response core competencies, problem-solving, and self-leadership of nurses involved in earthquake relief.

2. Methods

2.1. Study Design

2.1.1. Development of the Web-Based PFA Simulated Education Program. The program was developed following the five stages of the ADDIE model (Analysis, Design, Development, Implementation, and Evaluation).

In the analysis stage, major educational topics and content were developed based on both domestic and international education materials and practical guidelines on PFA. To identify education needs, interviews were conducted with eight community nurses who had completed PFA training. These interviews revealed the necessity for realistic and highly immersive education, the opportunity for repeated participation, and an online format for the training.

In the design stage, educational objectives and content were structured for each phase, including pre-learning, pre-briefing, simulation, and debriefing.

The process in the development stage comprised three phases. The first phase involved developing the simulation scenarios and quizzes. The researcher created the content through a literature review, preliminary needs assessment, and consultations with one disaster mental health expert, two case managers, and nine earthquake disaster victims in South Korea. The second phase involved producing the simulation videos, wherein standardized patients and nurses acted according to the scenarios. The third phase involved

creating multimedia content following a storyboard that was developed using Articulate Storyline 3.

In the implementation stage, the developed content was tested and evaluated. Six experts in system development conducted a heuristic evaluation to identify issues with the system interface [18]. The evaluation scores averaged 4.26 ± 0.22 out of 5 points, and the converted score out of 100 was 85.15 ± 4.47 . Additionally, to verify the usability and educational effectiveness of the online program from the user's perspective, user evaluations were conducted with 10 nurses holding at least a master's degree. The educational content was evaluated using a 5-point Likert scale. The usability and usefulness of the content were assessed using a tool for evaluating virtual gaming simulation [19].

The evaluation, usability, and usefulness of the content averaged 4.46 ± 0.46 , 4.41 ± 0.43 , and 4.45 ± 0.44 out of 5 points, respectively. The converted scores, respectively, were 89.17 ± 9.14 , 88.20 ± 8.56 , and 89.00 ± 8.76 out of 100 points. Additional feedback included issues such as video playback stopping intermittently, requests to change the position of the navigation buttons, providing information on the sequence of the quiz questions, and reducing the display time of the quiz pop-ups. The results and feedback from experts and user evaluations were incorporated into the revisions, and the final version of the content was based on these inputs.

Lastly, the evaluation stage aimed to confirm the effectiveness of the developed web-based program.

2.1.2. Evaluation of the Web-Based PFA Simulated Education Program.

This study was designed as a single-blind randomized controlled trial to evaluate the effectiveness of the program. The effects of the program were evaluated by a single researcher. The principal researcher generated the random allocation sequence, enrolled participants, and assigned participants to interventions. The guidelines outlined in the CONSORT statement for reporting randomized controlled trials were adhered to. Participants were randomly assigned to either the experimental group, which received the web-based PFA interactive simulated education, or the control group, which received self-learning materials in the form of e-books. To maintain a single-blind design, the group assignments were known only to the researchers to properly administer the interventions, and not to the participants (Figure 1).

2.2. Participants. The inclusion criteria for participation included being nurses working in hospitals and the community who had not participated in PFA training in the last year as well as having access to a personal computer and being able to use it without difficulty. The exclusion criteria included nurses who were undergoing treatment for any illnesses or who had difficulty operating the online program. The sample size was calculated using G*power 3.1.9.2. Based on a comparison of two groups (*t*-test) in simulation-based intervention studies [20], the required sample size was determined with a significance level (α) of 0.05, power ($1-\beta$)

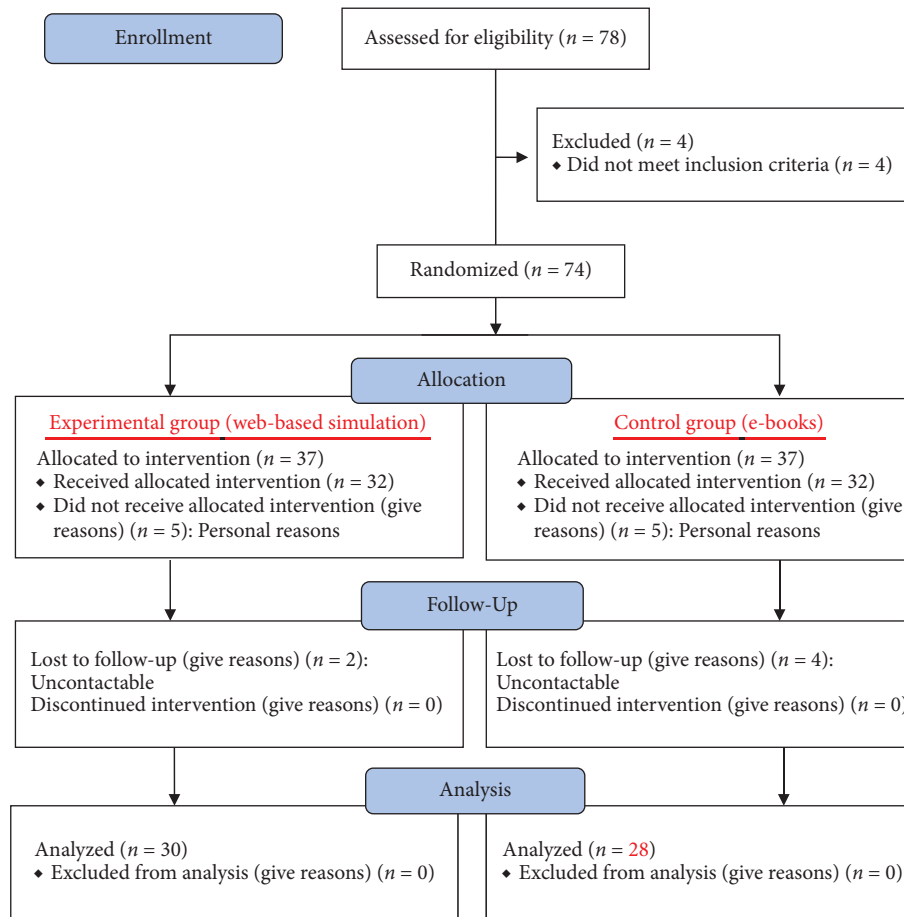

FIGURE 1: CONSORT diagram.

of 0.80, and effect size (d) of 0.8. The results indicated that 52 participants were needed. Considering the potential dropout rate, the sample size was increased to 60, with 30 participants in the experimental group and 30 in the control group. The researcher posted recruitment notices on social network communities of hospitals and organizations in five South Korean cities and explained the purpose and methods of the study to the potential participants. Written consent was obtained from the nurses who agreed to participate in the study.

Initially, 74 participants agreed to participate and completed the pre-survey questionnaire. Serial numbers were assigned in the order of registration to the study participants and the SPSS randomization function was used to determine the experimental and control groups. The participants were not informed to which group they belonged. After completing the pre-survey questionnaire and prior to the intervention, two participants from the experimental group of 37 could not be contacted, and five could not participate owing to personal reasons. In the control group of 37, four participants could not be contacted and five could not participate owing to personal reasons. The final number of participants was 30 in the experimental group and 28 in the control group.

2.3. Measurements. To evaluate the effectiveness of the program, we administered the Perceived Competence Scale for Disaster Mental Health Workforce (PCS-DMHW) to the participants and assessed their problem-solving ability and self-leadership capacity both before and after the intervention. The pre-assessment also included one additional section on participants' sociodemographic characteristics, including sex, age, religion, years of work experience, field of work, and history of PFA training.

2.3.1. Disaster Response Core Competencies. To measure disaster response core competencies, the PCS-DMHW, developed by Yoon and Choi [21], was used. This tool measures the competencies required for mental health personnel to effectively respond to disasters. It includes 24 questions: six on knowledge (disaster understanding and customized support), nine on attitude (vocation, ethics, and qualifications), and nine on skills (problem-solving, communication, and information delivery). The answers are scored on a 5-point Likert scale ranging from 0 (not at all true) to 4 (strongly true). Total scores range from 0 to 96, with a higher score indicating a higher perception of competence in the relevant area [21]. Cronbach's α was 0.95 for Yoon and Choi [21] and 0.91 in this study.

2.3.2. Problem-Solving Ability. Problem-solving ability was measured using the process behaviors of problem-solving developed by Lee et al. [22] and revised by Park and Woo [23]. This tool comprises 25 questions on problem discovery, problem definition, devising a solution to the problem, implementing the solution, and reviewing the solution. The answers are rated on a 5-point Likert scale ranging from 1 (not very) to 5 (almost always), with total scores ranging from 25 to 125. Higher scores indicate a better problem-solving process. Cronbach's α was 0.90 for Park and Woo [23] and 0.95 in this study.

2.3.3. Self-Leadership Capacity. Kim [24] translated a self-leadership questionnaire developed by Manz [25] to measure self-leadership capacity. It comprises 15 questions across six subscales (self-expectation, rehearsal, goal-setting, self-reward, self-criticism, and constructive thinking). The answers are rated on a 5-point Likert scale ranging from 1 (not at all) to 5 (very much), with total scores ranging from 15 to 75. Cronbach's α was 0.90 for Kim [24] and 0.90 in this study.

2.4. Procedure. The researchers created a storyboard of the pre-learning, pre-briefing, simulation, and debriefing screens. Details such as sound effects, blinking, and characters were selected for each scene, and the narration was created as an MP3 file using an artificial intelligence voice actor. The content was produced by a content development expert using Articulate Storyline 3 (Figure 2). The content was then reviewed and revised more than five times by the researcher.

A uniform resource locator (URL) allowing access to the program was sent to the experimental and control groups. By clicking on the URL, a screen opened in a new browser window, and the learner could participate in the training. The intervention was conducted between November 1 and November 7, 2020. The web-based PFA simulation applied to the experimental group was an educational program comprising four learning areas: pre-learning, pre-briefing, simulation, and debriefing (Table 1). The time required for learning ranged from 50 minutes to 1 hour. The control group was provided psychological support material in an e-book format. The e-book included only text and comprised 44 pages. After reading one page, participants had to click an arrow to move to the next page. The self-study content covered psychological support systems in the aftermath of earthquakes, characteristics of earthquakes, PFA, stabilization therapy, and frequently asked questions by earthquake victims.

2.5. Data Collection. Data were collected using an online questionnaire created by the researcher using Google Forms. Informed consent was obtained from all participants prior to data collection. Participants agreed to participate by checking a consent box on the first page of the Google Forms survey. The survey included items from the PCS-DMHW as well as items on problem-solving

ability, critical thinking, and sociodemographic characteristics. When the researcher sent a link to the pre-questionnaire on a participant's social networking service, the participant clicked on the link and completed the questionnaire. The time required to complete the preliminary questionnaire was 15–20 minutes. Participants were required to provide their names to match the pre- and post-survey responses. The survey clearly stated that participants' names would be replaced with unique identification numbers after the completion of the post-survey. After all surveys were completed, the researcher replaced the participants' names with identification numbers. The data are stored on a password-protected computer accessible only to the researcher.

2.6. Data Analysis. The collected data were analyzed using SPSS/Mac SPSS 26.0. Participants' general characteristics, disaster response core competencies, problem-solving processes, and levels of self-leadership were analyzed using frequency, percentage, average, and standard deviation.

To assess pre-intervention homogeneity between the experimental and control groups, chi-square tests, Fisher's exact tests, and independent samples *t*-tests were used. Additionally, the homogeneity of the dependent variables between the experimental and control groups was assessed using independent samples *t*-tests. The normality of the distributions in both groups was tested using the Shapiro–Wilk test. Finally, to evaluate the effectiveness of the simulation education program, changes in the research variables before and after the intervention were analyzed using independent samples *t*-tests. Cohen's *d* was used to calculate effect sizes using means and standard deviations from pre- to post-test. According to Cohen [26], effect sizes of 0.20, 0.50, and 0.80 represent small, moderate, and large effects, respectively.

2.7. Ethical Considerations. This study was approved by the Chung-Ang University Institutional Review Board. Participants who voluntarily agreed to participate signed a written consent form. They were informed that they could stop or withdraw from the study at any time. Their personal information was anonymized for confidentiality. After the study, the data will be stored for three years and then disposed of in a manner that makes restoration impossible.

3. Results

3.1. Demographic and Clinical Characteristics. Table 2 presents the demographic and clinical characteristics of the participants. The mean age of the experimental group was 38.47 ± 9.37 years and that of the control group was 37.86 ± 6.85 years. The experimental and control groups had 12.83 ± 7.84 years and 12.93 ± 6.39 years of work experience, respectively. A total of 21 (70.0%) nurses in the experimental group and 23 (82.1%) in the control group had not participated in PFA training in the past; there was

Note: ① introducing the context of the simulation, ② providing general information of the client, ③ the first scene of the simulation, ④ interactive simulations from the learner’s perspective, ⑤ taking quiz games during the simulation, and ⑥ providing real-time quiz commentaries.

TABLE 1: Content of the web-based simulation program for psychological first aid training.

Main menu	Middle menu	Submenu
Pre-learning	Earthquake	(i) Earthquake video (ii) Characteristics of earthquakes
	Disaster mental health	(i) Definition of disaster (ii) Characteristics of disaster victims
	Psychological first aid	(i) Definition of PFA (ii) Steps, preparations, attitude (iii) Basic goals (iv) Caution (v) Core activities of PFA (vi) Self-care
	Organizational structure	(vii) Role of organizations
Pre-briefing	Introduction	Introducing the simulation scenario (informing users that they must visit a disaster site and perform PFA), explaining that a quiz is presented
	How to participate	Instructions on how to participate in the quiz
	Client information	Providing general information of the client
	Client situation	Description of the subject’s situation when an earthquake occurs
	Learning objectives	Present five learning goals
Simulation		12 video clips and 11 quiz games
Debriefing		Self-debriefing—click the menu to go to the debriefing screen and write

no statistically significant difference between both groups according to PFA training experience ($\chi^2 = 1.17, p = 0.363$). Furthermore, there were no statistically significant differences between both groups in terms of all general characteristics; therefore, the experimental and control groups were homogeneous.

3.2. *Effects of the Program.* Table 3 presents the effects of the program. The experimental group’s disaster response core competencies score increased from 51.20 ± 10.46 to 73.93 ± 12.28 after the program, while the control group’s score increased from 54.68 ± 12.11 to 69.57 ± 9.44 , indicating a statistically significant difference between the two groups

TABLE 2: General characteristics and homogeneity of participants ($N=58$).

TABLE 3: Effects of the program ($N=58$).

Variables	Groups	Pre-test	Post-test Mean \pm SD	Difference	ES (d)	t	p
Core competencies	EG ($n=30$)	51.20 \pm 10.46	73.93 \pm 12.28	22.73 \pm 13.25	0.59	-2.239	0.029*
	CG ($n=28$)	54.68 \pm 12.11	69.57 \pm 9.44	14.89 \pm 13.41			
Problem-solving	EG ($n=30$)	75.90 \pm 15.82	90.57 \pm 16.56	14.67 \pm 10.53	0.72	-2.753	0.008**
	CG ($n=28$)	76.75 \pm 16.80	82.64 \pm 17.91	5.89 \pm 13.64			
Self-leadership	EG ($n=30$)	56.87 \pm 9.01	62.07 \pm 8.59	5.20 \pm 6.09	0.54	-2.073	0.043*
	CG ($n=28$)	57.14 \pm 7.72	59.00 \pm 6.81	1.86 \pm 6.18			

Note. CG = control group; d = Cohen's d ; EG = experimental group; ES = effect size; SD = standard deviation; * $p < 0.05$; ** $p < 0.01$.

($t = -2.239$, $p = 0.029$). This result demonstrated a medium effect size (Cohen's $d = 0.59$).

The experimental group's problem-solving process score changed from 75.90 \pm 15.82 to 90.57 \pm 16.56 after the program, while that of the control group increased from 76.75 \pm 16.80 to 82.64 \pm 17.91, indicating a statistically significant difference between the two groups ($t = -2.753$, $p = 0.008$). This improvement demonstrated a medium effect size (Cohen's $d = 0.72$).

The experimental group's self-leadership score increased from 56.87 \pm 9.01 to 62.07 \pm 8.59 after the program, while that of the control group changed from 57.14 \pm 7.72 to 59.00 \pm 6.81, indicating a statistically significant difference between the two groups ($t = -2.073$, $p = 0.043$). This difference demonstrated a medium effect size (Cohen's $d = 0.54$).

Figure 3 comprises three separate figures that illustrate the mean differences in the study variables between the experimental and control groups. From the left, the first, second, and third figures indicate disaster response core competencies, problem-solving ability, and self-leadership capacity, respectively. They highlight the changes from pre- to post-intervention for both groups.

4. Discussion

This study aimed to develop a web-based PFA simulation training program for nurses and verify its effectiveness. First, the results showed that the disaster response core competencies of the experimental group were significantly different

from those of the control group. This result is similar to that of a study that confirmed the effectiveness of a PFA curriculum comprising three hours of theory and three hours of practice for participants, including psychiatric and non-psychiatric experts; the participants' disaster mental health competency scores increased significantly [27]. When a large-scale disaster occurs, nurses rush to the site without being fully prepared to provide psychological support [28]. However, if nurses do not have the capacity for PFA, their confidence may decrease; they may become exhausted [27, 29] and experience secondary trauma [30]. For nurses to maintain their expertise and competency, a web-based education program that allows repetitive education and has relatively fewer time and space constraints can be helpful.

Second, the problem-solving processes of the experimental group showed a significant difference compared with that of the control group. This is consistent with a study that showed that problem-solving skills can be improved through critical thinking during PFA training [31]. Disaster situations require various problem-solving processes, but workers deployed to disaster sites lack the required critical thinking, organizational skills, and problem-solving skills and are insufficiently prepared [32]. Previous studies have shown that high-fidelity simulation education is more effective than web-based education for problem-solving processes [33]. However, the activities performed by learners who participate in web-based simulations to solve problems have a practical effect in improving problem-solving skills [34] and are recommended for education in fields where face-to-face education is difficult or dangerous.

FIGURE 3: Mean differences in the study variables.

Hence, web-based training programs are needed and must be encouraged.

Third, the study results confirmed that the experimental group exhibited improved self-leadership. This finding is similar to previous studies that have reported that simulation education improves learners' self-leadership [35, 36]. Self-leadership is important for nurses at disaster sites to manage crises and work with team members and organizations [37]. A study analyzing the effects of PFA training on teamwork found that self-leadership influences safe behavior in disaster situations and helps both oneself and the organization by performing self-directed activities [38]. Although there are limited studies confirming improvement in self-leadership through web-based simulation education, which restricts direct comparisons, previous research provides some supportive evidence. For instance, a study on high-fidelity simulation education for high-risk maternity care reported improvements in students' self-leadership [35]. Another study comparing high-fidelity simulation education with video-based education found that the simulation education group demonstrated enhanced critical thinking and self-directed learning [36]. This is because simulation-based education, which includes an active problem exploration process, is more effective in improving self-leadership compared with passive education [36].

The results of this study confirmed that nurses' core disaster response competencies, problem-solving processes, and self-leadership improved after web-based PFA simulation training. They also confirm that the web-based PFA training program developed in this study can be used as educational material for nurses to provide effective PFA. Additionally, this educational program is expected to increase nurses' core disaster response capabilities in disaster situations, help them engage in effective problem-solving processes, and achieve results through a self-directed attitude.

5. Limitations

This study had some limitations. First, as validity was verified through convenience sampling when recruiting research participants, caution is needed when generalizing the research results. Second, the participants in this study included nurses with experience in PFA; therefore, the possibility that the effect of previous training may have influenced the results of this study cannot be ruled out. Third, a single researcher applied and evaluated the intervention, which may have introduced

potential biases. Finally, the study's findings may not be widely applicable to all nurses or other healthcare professionals, as the sample was limited to a specific group. Future research should include a more diverse sample to improve the generalizability of the results.

6. Conclusions

This study developed a PFA training program in the form of web-based simulations. The training program reflects the work characteristics of nurses, thereby allowing learners to participate regardless of time and place and enabling repetitive education. The program provides educational opportunities for nurses to become more confident when providing psychological support to disaster-affected individuals. Nurses are expected to ultimately be trained as key practitioners who not only provide disaster psychological support but also contribute to improving the capacity for it.

7. Implication for Nurses' Management

The educational program developed in this study has the advantage of enabling repeated education for nurses regardless of time and place. Compared with existing PFA training, theory and practical training may be possible in a relatively shorter period of time, thus motivating learning and meeting the training needs of nurses. This increase in educational opportunities can increase nurses' confidence in providing psychological support to disaster victims. Thus, nurses are expected to ultimately be trained as key practitioners in and contribute to improving the capacity for disaster psychological support.

Background. Emergency nurses may experience various fatiguing duties and suffer more pressure, so it is necessary to promote their professional or work-related quality of life, especially during tough periods. **Aim.** To describe the development of the multidimensional narrative support system and explore its effectiveness and feasibility among emergency nurses. **Design.** An action research was conducted in Shanghai, China, from 2022 to 2023. **Methods.** Two cycles of action research were adopted in the emergency departments of two tertiary general hospitals in Shanghai, China. A total of 20 and 13 emergency nurses from different posts participated in each cycle. Multiple methods and tools, such as validated instruments, self-designed questionnaires, and individual and focus group interviews, were used to collect short- and long-term data. The EQUATOR guidelines on reporting action research were used as the guideline for this study. **Results.** The multidimensional narrative support system was gradually modified to promote its feasibility. Involved emergency nurses actively participated in different activities and proposed relatively positive and satisfying remarks. Quantitative data showed the significantly instant or long-lasting improvements in emergency nurses' professional and work-related quality of life, as well as their self-compassion, and perceived social support. Various categories were summarized about the participants' experiences, perceived long-term effects, and suggestions on the multidimensional narrative support system. **Conclusion.** The multidimensional narrative support system integrates narrative methods and psychological activities and provides multidimensional support for emergency nurses. In spite of various challenges, the system shows good feasibility and significant influences on emergency nurses' well-being and quality of life. **Implications for Nursing Management.** The multidimensional narrative support system may action as a novel intervention for the overall improvements of clinical emergency nurses, which can be recommended to other populations with targeted modifications and training, so as to achieve good generalization in different departments.

1. Introduction

The emergency department is a stressful working environment where nurses may experience physically and psychologically fatiguing duties and suffer more time pressure [1]. Even well clinically trained, emergency nurses also admitted difficulties in interpersonal relationships, high level of responsibility, and absence of feedback for work [2]. In recent years of COVID-19, emergency nurses were directly involved in the pandemic, which made them susceptible to infection and higher levels of stress [3]. Therefore,

emergency nurses may be at risk of negative experiences and emotions and report low levels of professional or work-related quality of life [3, 4].

Professional quality of life is a general construct and involves positive and negative aspects of work life, including compassion satisfaction, compassion fatigue, and burnout [5]. Professional quality of life may not only influence nurses' job performance but also affect their physical and mental health [6, 7]. Work-related quality of life refers to the quality of experience and condition of life as people interact in the employee-employer relationship [8], which was

revealed to correlate with individual's physical and emotional wellbeing, the quality of services, and outcomes related to patients [9]. Consequently, it is necessary for nursing researchers and managers to promote emergency nurses' professional or work-related quality of life, especially in the context of tough periods.

In recent years, various interventions and programs have been developed for nurses to achieve their overall well-being. The Compassion Fatigue Resiliency Program is a structured, comprehensive training program to prevent compassion fatigue and improve resilience, which has been implemented among different populations [10, 11]. Pehlivan and Güner [10] designed a randomized controlled trial with a large sample of oncology-haematology nurses and found that compassion satisfaction scores of nurses participating in this program were significantly higher than those who did not. The mindfulness-based stress reduction (MBSR) incorporates meditation, body and breath awareness, and mind-body practices, and various studies revealed that MBSR was effective to manage stress, enhance resilience and compassion satisfaction, and reduce burnout [12, 13]. Considering the time commitment of traditional MBSR, a 3-minute mindfulness intervention was explored with 3 times of breathing exercise per day over 4 weeks, demonstrating significant reductions in compassion fatigue [14], which proved the efficacy of small MBSR on reducing the physiological stress of nurses [12]. Inspired by the above-mentioned activities, Fu et al. [15] developed an educational program integrating compassion fatigue resiliency, mindfulness respiration, and relatives and friends' support, which had short- and medium-term positive effects on nurses' professional quality of life, as well as physical and mental health. Considering the significance of compassion in nursing profession, McVicar et al. [16] developed a compassionate mind model-based curriculum and found that the 12-month course for health visiting students might reduce their fears of compassion, as well as compassion fatigue.

In addition to the psychological interventions, some physical relaxations and herb therapies were also used for promoting nurses' professional quality of life. The progressive muscle relaxation exercises were intervened for nurse managers, and these exercises over 8 weeks were revealed to significantly decrease their levels of compassion fatigue and burnout [17]. Considering the effects of patchouli oil inhalation on reducing healthy adults' stress and sympathetic nerve activity, Shin et al. [18] designed a randomized controlled trial to investigate the effects of patchouli inhalation, which reported reduced levels of stress and increased compassion satisfaction among emergency nurses.

During the COVID-19 pandemic, a randomized controlled experimental study was carried out to investigate the effects of motivational messages sent to emergency nurses for 21 days, and higher job satisfaction and communication skills and lower compassion fatigue were reported [19]. A 12-week intervention of structured debriefing sessions was explored among trauma health care professionals experiencing patient death, and three questions were asked at every

debriefing around the relationship-based care model [20]. Besides using storytelling or narrative alone to address psychosocial stress in health care professionals, expressive arts interventions are gaining their popularity and were found to have more favorable outcomes [21]. Phillips et al. [22] combined storytelling, reflective writing, music, and psychoeducation to aid oncology nurses on awareness and expression of work-related emotions and indicated that the storytelling through music was feasible and acceptable to address work-related emotions and psychosocial stress.

This study focused on those individual, work-related, and perceived supportive factors of emergency nurses' professional quality of life, which were reported in the hierarchical multiple regression and path analysis models [7, 23] and took advantage of narrative or storytelling to develop the multidimensional narrative support system (MNSS) from the perspectives of individual, expert, and colleague, aiming to improve emergency nurses' professional and work-related wellbeing. To make the MNSS theoretically solid, several relevant models or theories were referenced as the theoretical bases of this study.

Reflective writing is a process of personal and creative writing for reflection on patient care and socialization into medicine [24]. Shapiro et al. [24] put forward its conceptual model, in which the first phase is individual and solitary writing, requiring writers' personal voice, imagination, creativity and reflection, as well as the loss of certainty and authority. During the writing, writers should also recognize and respond to those emotions triggered in patient care [24]. The second phase in the model is small-group reading and discussion, which could lead to the acknowledgement of vulnerability and risk-taking for the writers, and the exercise in witness and mindfulness for the listeners [24]. The two processes may contribute to practitioners' professional development and well-being, together with improved patient care [24]. In view of above-mentioned applicable elements and goals, the reflective writing model was selected to design the primary steps of the MNSS.

Expressive writing is an individual-focused intervention, which aims to promote emotional expression during adaptation to stressful situations, and consequently improves overall health from the emotional, social, biological, and cognitive levels [25]. In the standard protocol of expressive writing, participants can focus on their deepest thoughts and feelings about a negative life experience that they choose and write for 15 to 20 min for several sessions over a few days [26]. Although the writings were usually brief exercises over a limited period, the process definitely invited people to think about their emotions and lives in general. Relatively loose and vague requirements on expressive writing times and intervals present good suitability to guide the writing phase of the MNSS. These features may provide emergency nurses with relaxing atmosphere to express their emotions freely and help to heal their ailments [25, 26].

This study aimed to adopt the action research design to develop and refine the MNSS and further explore its effectiveness and feasibility. Research questions of this study were as follows: how was the process of MNSS developed and refined by two cycles of action research? What effects

did the MNSS have on emergency nurses? What were the experiences of emergency nurses who participated in the MNSS?

2. Materials and Methods

2.1. Design. The mixed-method action research was used to develop and implement the MNSS, as well as explore its effects among emergency nurses. Action research can be used to describe and explain social situations while implementing a change intervention aimed at improvement [27, 28]. Cyclical activities including planning, acting, observing, and reflecting were conducted for two rounds exactly from July, 2022, to February, 2023, in this study. The observation and reflection phases helped to develop new initiatives and address the knowledge-action gap [29]. Enhancing the QUALity and Transparency Of health Research (EQUATOR) guidelines on best practice in reporting action research was used as the guideline for this study [30]. Ethical approval was obtained from the institutional review board of the university.

2.2. Settings and Participants. This study was performed in the emergency departments of two tertiary general hospitals in Shanghai City, China. The emergency departments consist of multiple sections and provide comprehensive emergency patient care. Nurses in the emergency departments undertake the posts in the resuscitation room, infusion room, intensive care unit, observation room, and precheck and triage table, etc. Two sampling strategies of purposive and convenient sampling were used for each research cycle. The eligible criterion was the nurses working in the emergency departments for at least one year. After the lecture on “*Emotion Management and Narrative Writing*” and the introduction of MNSS for nurses in the emergency department, eligible nurses were invited by nursing managers for participation. In the first cycle, the recommendations of nurse managers were referenced to select participants and then the participants completed the pre-intervention survey. In the second cycle, the sequence of recruitment and preintervention survey was changed, and those nurses reporting the score of compassion fatigue ≥ 2.5 in the survey were invited by the nursing manager as potential participants.

2.3. Research Team. The research team consisted of nursing researchers and assistants, nurse managers, and psychologists. The researchers and assistants were responsible for the whole process of developing and applying the MNSS, as well as assigning the tasks to other team members. Nurse managers mainly assisted the recruitment of participants and the time schedule of activities. The psychologists participated in and organized the group training.

2.4. Development and Application of MNSS

2.4.1. Planning and Development. Considering the relevant factors of professional quality of life among emergency

nurses, such as those negative individual experiences, the levels of working stress, self-compassion, and perceived social support [7, 23], the above-mentioned conceptual model of reflective writing and the method of expressive writing were utilized to develop the MNSS. Consequently, the draft of MNSS was developed with the aims to develop emergency nurses’ self-compassion, improve their professional and work-related quality of life, and gain organizational support. The multidimensional activities in the draft included five procedures over a period of 4 weeks, which were lecture, narrative writing (individual dimension), group discussion (colleague dimension), interview analysis (expert dimension), and group training. An expert meeting was organized to revise the draft, and 8 nursing experts with the background of nursing humanities, nursing management, and emergency and critical care nursing were invited to discuss the rationality and feasibility of the draft. The 90-minute recording of the expert meeting was transcribed literally and then summarized into the following suggestions on multidimensional activities:

- (1) The lecture should face all emergency nurses and serve as an opportunity for professional learning.
- (2) The topic of writing should be identified, while the time of writing should not be required.
- (3) The literary level of writing is not of high significance, while the key elements of narration should be involved.
- (4) Interviews should be combined with writing, and the research team should have the ability to reconstruct and reply to the writing from a third perspective.
- (5) The period of 4 weeks may be too tight, and the period should be extended.

The above suggestions were fully considered to revise the draft MNSS. The modified activities in the first-cycle action research contained five steps, which were narrative training for nursing managers, lecture for emergency nurses (expert dimension), narrative writings and interviews (individual and expert dimensions), story rewriting and sharing (individual, colleague and expert dimensions), and group training and discussion (individual, colleague, and expert dimensions).

2.4.2. Application and Improvements. The first-cycle application of the MNSS started in the first season of 2022. The narrative training and the first two lectures for emergency nurses were held in February, 2022. Owing to the outbreak of COVID-19 in Shanghai, the first cycle was postponed to July, 2022. Considering the COVID-19 prevention and control policies, the left lectures and all individual interviews were adjusted to online forms. Moreover, due to high working intensity and difficult shift scheduling in the clinical practice, participants were not forced to take part in the activities of story sharing and group training. The details of the MNSS application in the first cycle are demonstrated in the Table 1. Based on the reflection of the first cycle, several

TABLE 1: Details of the activities in the two cycles of MNSS.

Step	First cycle		Second cycle	
	Activity	Details	Activity	Details

TABLE 1: Continued.

Step	Activity	First cycle Details	Others	Activity	Second cycle Details	Others
Fourth step	Story rewriting	Participants: researchers Activity: to analyze the writings and interviews and rewrite the event from the researchers' perspective; 20 stories were rewritten	Date: 2022.08-09	Reflective writing	Participants: 10 participants completed the writing Topic of writing: reflection on the event and your experiences of compassion fatigue based on previous interviews, rewrote stories, and sharing experiences	Date: 2023.01-02
		Participants: 11 participants, nursing researchers, assistant, managers Contents: (i) Five participants voluntarily shared their own rewritten stories (ii) Other participants communicated their feelings and relevant experiences (iii) All participants completed a survey on previous activities	Date: 2022.09 Duration: about 100 min Form: offline activity			
Fifth step	Group training and discussion	Participants: 9 participants, nursing researchers and assistant, and psychologists Topic: team building activity/group discussion and summary Objectives: (i) To relieve work stress and negative emotions (ii) To activate the enthusiasm of teamwork (iii) To master effective communication skills (iv) To obtain support from the group and peers (v) To enhance the ability of self-regulation (vi) To discuss the experiences of and suggestions on the MNSS	Date: 2022.10 Duration: about 75 min Offline activity: floor curling	Group training and discussion	Participants: 7 participants, nursing researchers and assistant, and psychologists Topic: team building activity/group discussion and summary Objectives: (i) To relieve work stress and negative emotions (ii) To obtain support from the group and peers (iii) To discuss the experiences of and suggestions on the MNSS	Date: 2023.02 Duration: about 90 min Offline activity: "talking about yourself"
		Participants: 11 participants, nursing researchers, assistant, managers Contents: (i) Five participants voluntarily shared their own rewritten stories (ii) Other participants communicated their feelings and relevant experiences (iii) All participants completed a survey on previous activities	Date: 2022.09 Duration: about 100 min Form: offline activity			

improvements on the MNSS were summarized and implemented in the second cycle.

- (1) Considering the difficulty in training nursing managers to analyze and rewrite stories in a professional narrative way, their narrative training can be canceled.
- (2) The preintervention survey should be conducted before the recruitment, and those nurses with a higher level of compassion fatigue should be enrolled.
- (3) Writing topics should be covered in one time, so as to make the writing coherent and compress the research time. One individual writing and one interview can be considered.
- (4) The topic of writing should be more focused, and a second writing with the topic of reflection can be added after story sharing.

The revised second-cycle MNSS consisted of five steps (lecture for emergency nurses, narrative writing and interview, story rewriting and sharing, reflective writing, and group training and discussion), and the details are also reported in the Table 1. Because of the different organizational structure in the second emergency department, the introduction lecture was held only once. The frequency of narrative writing and interview was reduced to improve the integrity and efficiency. Rewriting of the participants' stories required researchers' deep analysis of those writings and interviews, which were directed by narrative competence, defined as the skills required to recognize, absorb, interpret, and be moved by the stories one hears or reads [31]. When rewriting stories, the researchers combined textual, creative, and affective skills, following the procedures of identifying the original story's structure, adopting multiple perspectives, imagining interpretations and multiple endings, and entering the story's mood [31]. The process of story sharing could arouse mutual understanding between the individuals and colleagues and might function as a kind of peer support. The reflective writing provided participants an opportunity for reflection and summary. Different activities of group training organized by psychologists were attempted in two cycles to explore probably different effects.

2.5. Data Collection. A mixed-method data collection was performed in this study, and various data were collected prior, during, and after the MNSS using quantitative measures and qualitative methods, to facilitate the observation and reflection phases of the action research. The surveys on the effects of MNSS were conducted before (T1) and immediately after (T2) the application of MNSS with 3 instruments in the first cycle and 4 instruments in the second cycle. For better understanding of the long-term effects of the MNSS, the surveys were also implemented about 1 to 1.5 years after the MNSS (T3) concurrently among those participants in both cycles. To understand participants' evaluations on the MNSS and their perceived self-improvements, self-designed questionnaires were

administered in both cycles. Meanwhile, qualitative data on participants' perceived benefits and difficulties, as well as suggestions on the MNSS, were collected through overphone interviews, group discussions, and open-ended survey questions from the participants.

The mixed-method design adopted a concurrent data analysis process, in which both quantitative and qualitative data were integrated during the analytic stage to provide a comprehensive explanation on a specific phenomenon, that was the effectiveness and feasibility of the MNSS [32]. The logical relations between the qualitative and quantitative methods in this study assumed to be complementary, where two parts of the results supplemented each other. It was supposed that those qualitative results might support and complement the quantitative findings of the MNSS's effectiveness, as well as provide sufficient feedback on the MNSS required by the action research. Consequently, the triangulation process in this study might promote complementary results from qualitative and quantitative data [32], so as to enhance the overall validity of the findings.

2.6. Measurements

2.6.1. Professional Quality of Life. The Professional Quality of Life Scale was developed by Stamm [5]. Shen et al. [33] developed and validated the Chinese version of the scale, including a total of 25 items for three independent dimensions of compassion satisfaction, compassion fatigue, and burnout. Items were rated on a 5-point Likert response set, with two items reversely scored. A higher score indicated a higher level of the dimension. Cronbach's α coefficients of the dimensions ranged from 0.758 to 0.821.

2.6.2. Work-Related Quality of Life. Van Laar et al. [34] developed the Work-Related Quality of Life Scale, and the 2nd edition of the scale was translated into Chinese and modified by Shao et al. [35]. The Chinese version scale consists of 7 subscales and 33 items rated on a 5-point Likert response set. The items of the Stress at Work subscale need reverse scoring to calculate the total score. A higher score indicates higher work-related quality of life. Cronbach's α coefficient of the Chinese scale was 0.939.

2.6.3. Self-Compassion. The self-compassion scale was developed by Neff [36], and the Chinese version was validated by Chen et al. [37]. This scale consists of 26 items, contributing to six subscales. Three subscales represent positive aspects of self-compassion, while the other three assess opposite states. Items are rated on a 5-point Likert response set. The opposite items need reverse scoring to calculate the total score, and a higher score indicates higher self-compassion. Cronbach's α coefficient of the Chinese scale was 0.84.

2.6.4. Social Support. The multidimensional scale of perceived social support was developed by Zimet et al. [38]. The Chinese version scale was translated and validated by Huang

et al. [39], measuring subjectively perceived support from family, friends, and significant others (e.g., leaders and colleagues). Items are rated on a 7-point Likert response set. A higher score indicates higher perceived social support.

2.6.5. Evaluations and Perceived Benefits of MNSS. The self-designed questionnaires were used to understand participants' evaluations on the MNSS and their perceived self-improvements. The number of evaluation items on the whole MNSS and rewrote stories was 12 and 6; the numbers of self-improvement items on the whole MNSS and activities of writing, story sharing, and group training were 9, 8, 12, and 7, respectively.

2.6.6. Semistructured Interviews and Open-Ended Questions. Semistructured interviews were conducted with the participants, and the interview outline was designed to guide them to reflect on their experiences in the MNSS and to provide improvement suggestions. All interviews were conducted and recorded with the participants' consent by the researchers. Moreover, open-ended questions were used in the T3 survey to explore participants' perceived long-term effects, targeting on associated changes in nursing work and personal life in the past year.

2.7. Data Analysis. IBM SPSS 22.0 was used for statistical analysis of the collected data. Descriptive statistics were calculated to examine continuous variables ($\bar{X} \pm S$) and categorical factors [n (%)]. Repeated-measure ANOVA was used to compare the scores of involved variables across timepoints (T1, T2, and T3), so as to examine the effectiveness of the MNSS. Assumption of sphericity was tested using Mauchly's test. For those data violated sphericity, the Greenhouse–Geisser correction was adopted. Pairwise comparisons used Bonferroni corrections. The Wilcoxon signed-rank test was used to analyze the differences between the short- and long-term perceived improvements among the participants in each cycle. Statistical significance was revealed when p values were less than 0.05. Those data collected in the interviews and open-ended questions were analyzed using the Colaizzi seven-step content analysis, including the steps of familiarization, identification of meaningful statements, construction of meanings, clustering of themes, detailed description, development of basic structure, and verification of basic structure [40].

3. Results

3.1. Sample Characteristics. In both cycles, emergency nurses with different working posts and years were purposively selected to maximize the diversity and comprehensiveness of the results. In the first cycle, a total of 20 nurses agreed to participate in the MNSS. Over half (12, 60.0%) of them had the professional title of nurse, and 8 (40.0%) were senior nurses. Seven participants (35.0%) had working experiences of 1 to 3 years, seven (35.0%) with 4 to

6 years, and six (30.0%) with over 7 years. Their working posts included precheck and triage (2, 10.0%), resuscitation (2, 10.0%), infusion (9, 45.0%), intensive care (3, 15.0%), observation (3, 15.0%), and injection (1, 5.0%). Owing to the dimission of one participant, only 19 participants of the first cycle completed the long-term T3 survey. In the second cycle, 14 nurses with the score of compassion fatigue ≥ 2.5 agreed to participate, while one nurse dropped out owing to turnover. A total of 13 nurses participated in the MNSS and completed the surveys across three timepoints. Seven (53.8%) participants were nurses, 5 (38.5%) were senior nurses, and 1 (7.7%) was a supervisor nurse. Seven participants (53.8%) had working experiences of 1 to 3 years, four (30.8%) with 4 to 6 years, and two (15.4%) with over 7 years. Their working posts included precheck and triage (1, 7.7%), resuscitation (8, 61.5%), infusion (2, 15.4%), intensive care (1, 7.7%), and observation (1, 7.7%).

3.2. Descriptions of Writings and Interviews. In the first cycle, 19 participants completed two writings, with the average word counts to be (677.68 ± 308.16) and (391.95 ± 203.74) . All 20 participants underwent two interviews, and the average interview time was (24.95 ± 5.09) min and (24.60 ± 7.45) min. Researchers rewrote one story for each of the 20 participants, with the average word count of (2045.65 ± 499.46) . In the second cycle, 13 participants completed the writing, with the average word count of (660.77 ± 282.11) , and participated in the interview, with the average interview time of (25.00 ± 5.80) min. Researchers also rewrote one story for each participant, with the average word count of (1686.46 ± 453.94) . Ten participants completed the reflective writing, and the average word counts were (336.20 ± 129.89) .

3.3. Comparison of Measurement Variables. As reported in Table 2, the scores of self-compassion among the participants increased significantly across the three timepoints in both cycles, and the T3 scores were significantly higher than those T1 scores ($P = 0.024, 0.001$). In the second cycle, the scores of burnout among the participants decreased significantly across the three timepoints, while the T3 scores of burnout and compassion fatigue were both significantly lower than their T1 scores ($P = 0.008, 0.014$); the scores of work-related quality of life and perceived social support among the participants changed significantly across the three timepoints, and the T1 score of work-related quality of life was significantly lower than those T2 and T3 scores ($P = 0.027, 0.008$); besides, the T1 score of perceived social support was significantly lower than those T2 and T3 scores ($P < 0.001, P = 0.002$), and the T2 score was significantly higher than the T3 score ($P = 0.038$).

3.4. Evaluations and Perceived Benefits. Participants reported their evaluations on the MNSS (Table 3), as well as their perceived self-improvements (Table 4). The numbers of participants choosing specific item levels were reported. The long-term perceived improvements among the participants

TABLE 2: Results of repeated measures analysis in the two cycles ($\bar{X} \pm S$).

Cycle	Time points	Compassion satisfaction	Burnout	Compassion fatigue	Self-compassion	Work-related quality of life	Perceived social support
First cycle ($n_1 = 19$)	T1: pre-MNSS	3.43 ± 0.735	2.49 ± 0.584	2.44 ± 0.478	3.28 ± 0.382	3.42 ± 0.628	—

TABLE 5: Qualitative data on the experiences of participants.

Activity	Category	Quotations
Relaxing opportunity to talk and express emotions	Beginning to focus and reflect on own emotions	<p>“The interviews were relaxing and good. I could relieve my feelings in this process” - participant 1</p> <p>“In the past, I would not pay attention to my emotions. When I wrote my story, I needed to notice the change of my emotions... These could help to clarify my emotions at work and in life” - participant 4</p>
	<p>Helping to relieve stress at work</p> <p>Feeling being healed and valued</p>	<p>“The interviews could effectively relieve the pressure at work” - participant 22</p> <p>“When I shared my story, I could feel that I was understood, so I would like to continue and express my emotions... I could get good feedback, and the process was really healing.” - participant 5</p>
Finding methods to improve future work	High-quality and enlightening rewrote stories	<p>“I could sort things out step by step. This method of writing can be used in my future work to help me identify and solve problems” - participant 7</p>
Rewrote stories and sharing	Gaining more perspectives on events	<p>“The rewrote stories are good and can touch on the key points... The stories can give me a sense of enlightenment” - participant 23</p>
	Helping to guide future work	<p>“After sharing those negative emotions at work, I started to relax myself. I tried to understand others and avoid direct conflicts” - participant 7</p> <p>“I could learn from other colleagues, like how to deal with interpersonal relationships, how to behave well in my work... It was a process of reflection” - participant 9</p>
Group training	Interesting activity to relieve work stress	<p>“The activity was very interesting, and could help me relieve the stress” - participant 11</p>
	Familiar with colleagues and promote team building	<p>“We were not familiar with each other at the beginning. But we cooperated and adjusted ourselves... We behaved like a team and made efforts to achieve the same goal... We had to organize the team quickly and effectively” - participant 10</p>
Whole process	Satisfied with good researchers and colleagues	<p>“The teachers were very responsible and the colleagues were very helpful” - participant 22</p> <p>“I was very satisfied with the system” - participant 25</p>
	<p>Promoting oneself comprehensively</p> <p>Reflection on previous experiences</p>	<p>“The process could promote our expression ability and improve ourselves... Therefore, we can treat the patients better and regulate our emotions” - participant 12</p> <p>“It was opportunity for reflection... If we communicate together, we can find problems that we cannot see, and then we will gather together to discuss” - participant 27</p>

TABLE 6: Qualitative data on perceived long-term effects of participants.

Category	Quotations
Change of mentality and emotions	<i>"I am more optimistic. When I encounter an emergency, I can keep calm"</i> -participant 23
	<i>"Now I feel happier than when I was during the epidemic, and the atmosphere is no longer depressing"</i> -participant 33
Understanding of and passion for nursing work	<i>"I do what I can to complete my own work and help those patients. I believe "don't try to be perfect, but try your best"</i> -participant 30
	<i>"When things happen to me, I become less stubborn. I also gain new motivations for nursing work"</i> -participant 6
"Standing in patients' shoes"	<i>"When the communication with patients is not fluent, I can remind myself to stand in their shoes and be more empathetic"</i> -participant 19
	<i>"The level of my empathy, together with the interpersonal communication ability have been improved"</i> -participant 2
Better coping with personal emotions	<i>"When communicating with patients and families, I pay more attention to my tone and attitude. I can adjust negative emotions quickly, and do not bring bad emotions to other patients"</i> -participant 18
	<i>"Now I can relieve my negative emotions well and don't let those emotions influence me for too long"</i> -participant 23
Cultivation of thinking habits and interests	<i>"I will review my work and life periodically, and develop a clearer plan for my future career and life"</i> -participant 3
	<i>"I can better balance my work and life, and cultivate some interests of my own"</i> -participant 12

of the two cycles were significantly lower than their short-term perceived improvements, respectively ($Z = -2.142$, -2.499 , $p = 0.032$, 0.012).

3.5. Qualitative Data. Those data on the experiences of participants in the MNSS, as well as their perceived long-term effects of the MNSS, were reported in Tables 5 and 6. Table 7 showed the data on suggestions that participants proposed on the MNSS.

4. Discussion

This study adopted the action research process and evaluated the short- and long-term effectiveness of the multidimensional narrative support system (MNSS) on emergency nurses during and after the period of COVID-19. Among those interventions targeting on the nurses' compassion satisfaction, compassion fatigue, and burnout, different outcomes were reported. A 3-minute mindfulness intervention, the 3Rs educational program and those progressive muscle relaxation exercises showed their effects on decreased compassion fatigue and burnout [14, 15, 17]. Short-term inhalation of patchouli oil might reduce emergency nurses' compassion fatigue and increase their compassion satisfaction [18]. Unlike the significant promotion on professional quality of life achieved by the compassionate mind model-based curriculum [16], a 12-week pilot of structured debriefing sessions revealed no significant differences in all three aspects before and after the interventions [20]. The different results in the two cycles of this study might be explained by the characteristics of nursing work in two units, the disparities and diversities of those shared stories, and the psychological activities of group training. Besides, during the second cycle of this action research,

China optimized the COVID-19 control policies in a 10-point notice released on December, 2022. With the adjustment of policies, the rapidly increasing number of infected patients imposed additional working challenges on emergency nurses. Future research can also explore the specific effects of different activities on the participants.

Self-compassion can be regarded as "the support toward oneself when experiencing suffering or pain caused by personal mistakes and inadequacies or external life challenges" [41]. Perceived social support in this study involved those participants' subjectively assessed support from family, friends, as well as leaders and colleagues. Quantitative results proved the short- and long-term effectiveness of MNSS on its promotion of participants' self-support and perceived social support, indicating that those activities in MNSS, such as writing and interviewing, might help emergency nurses take a kinder and less judgmental approach to their sufferings [41], and story sharing and group training could provide them some extent of peer and organizational support. Results of repeated measures showed that work-related quality of life was significantly improved after the MNSS in the second cycle, indicating that the MNSS might function as an effective administrative system for the participants to achieve career growth and contribute to a favorable job environment for emergency nurses [8]. The efficiency of MNSS in the second cycle might be first attributed to the medium level of work-related quality of life before the MNSS and also confirmed its necessity when emergency nurses were exposed to unpredictable changes and stressful situations during the COVID-19 pandemic [4].

Results provided evidence that the novel support system was a scientific and logical approach refined by two cycles of action research. Besides, the MNSS was proved to be feasible and acceptable for emergency nurses, as the high portion of positive evaluations revealed that the participants showed

TABLE 7: Qualitative data of suggestions on the MNSS.

Activity	Category	Quotations
Writing and interviewing	Focusing on a recent event	<p>“If something unhappy happened recently, I could use the methods of writing and interviewing. I need to find a way to express my emotions”-participant 8</p> <p>“The topics of writing should be various and rich”-participant 13</p>
	Providing one or different topics for writing	<p>“We could use a case as the target to trigger the writers’ memory.” Then you may find different reactions during the writing”-participant 10</p>
Listening and sharing	Shortening intervals and times	<p>“The duration for writing and interviewing was a bit long... They should be connected more closely to help me maintain a clear mind”-participant 11</p>
	Adding methods to relieve emotions	<p>“I think the two writings can be combined as one, that is, we can write a coherent writing at one time”-participant 15</p> <p>“When talking about something, I may still have the emotions of anger and excitement. At this time, some methods of relief and regulation should be used”-participant 4</p>
Group training	Providing offline activities to promote passion	<p>“Online and offline activities could be combined. For example, stories can be shared online, which makes it easier for sharing. We can discuss offline to exchange feelings more directly”-participant 28</p>
	Sharing stories with different themes	<p>“Most of the shared stories had the same topic. It might be more meaningful to choose some stories with conflicting views, which could promote exploration”-participant 22</p>
Whole process	Going outside for group activities	<p>“Many types of group activities can be carried out in the park... We can also try those outside activities”-participant 16</p>
	Providing various forms of activities	<p>“The activities could be more various, providing different forms of activities for the participants”-participant 27</p>
Providing chances to achieve immediate communication	Necessary to promote participants’ understanding	<p>“It’s necessary to think how to help the participants have a more open mind to participate in this activity at the beginning, and how to help them have a full understanding”-participant 16</p>
	Better to invite those nurses who are emotional	<p>“Young nurses might have more psychological changes”-participant 12</p> <p>“For those people who cannot relieve themselves, they can write more about these things and analyze the reasons”-participant 16</p>
Providing chances to achieve immediate communication		<p>“If I am angry today, I can write down what happened... People who see it can respond to my writing in a timely manner”-participant 25</p>

strongly agreement on the MNSS. The outbreak of COVID-19 in Shanghai during 2022 imposed profound impact on the whole research. Consequently, the form of interviews, lectures, and sharing were adjusted to online and the time for each activity was relatively flexible considering the working schedules of most participants [22]. This strategy provided a relaxing atmosphere for participants and might not add much stress on them, which appeared to be a critical feature of the MNSS.

Participants' perceived self-improvements and qualitative data also confirmed the short- and long-term effects of MNSS. Their improved communication, reflection, and collaboration skills might facilitate their daily work in emergency departments and function as effective strategies to increase operational efficiency, improve job satisfaction and patient care, and promote comprehensive personality growth [42, 43]. The MNSS also provided a chance for participants to relieve negative emotions at work during the COVID-19 pandemic, which could reduce patient safety risks and improve health care provider well-being [44]. Comparison between participants' perceived short- and long-term self-improvements indicated that the effects of MNSS might fade over time, especially the level of social support revealed in the repeated measurement. Although long-term effects were well documented in this study, involved activities should be carried out regularly with appropriate frequency to better consolidate the effectiveness of MNSS.

After participants finished their writing and interviews, they were surprised by the experiences of healing and changing, which was consistent with the study on the storytelling through music intervention [22]. Participants proposed constructive suggestions on writing, indicating their interest in writing after the intervention. Most participants were satisfied with their rewrote stories and agreed that the rewrote story was a significant gain for them. Rewrote stories played several roles in the MNSS, including appealing for participation, summary of participants' experience, and response and support to participants. The process of organizing, exploring, and making meaning from multiple perspectives might value the context of an individual's experiences, allowing for a deeper exploration of their stories [45]. Some participants stated that they were enlightened by the rewrote stories and thought that the reorganized stories were better than their original ones.

To explore the feasibility and effects of different activities, floor curling and group talking were adopted in group training of each cycle. According to the qualitative results, the game of floor curling showed remarkable effects. Some participants believed it was a new and interesting activity for them and also an opportunity to improve the ability of teamwork. Curling is a kind of team sport that can reveal the importance of effective communication, as athletes must exactly perceive what their teammates say in the game [46]. To achieve better performance, athletes in curling should make correct and fast decisions, support each other, and cope with stress [46], which were similar with the working conditions of emergency nurses. Future MNSS should provide more various and outdoor activities for the participants.

The MNSS also features its comprehensiveness, as various activities were selected and designed from dimensions of individual, colleague, and expert. The writing process is considered as a solitary act, in which each individual must retreat into oneself, contemplate events, and imagine various meanings [24]. Based on each participant's writing, experts in humanistic sciences organized individualized interviews and reconstructed their stories, providing support for participants. During story sharing and group training, participants might feel the support from their colleagues. The peer support is a key element of the MNSS, similar with the peer-support program in which colleagues may understand present stressors more easily and have a great deal of compassion for their peers [47]. Some participants believed that peers' sharing helped them gain more perspectives and understandings and suggested sharing stories with different themes in the future.

4.1. Limitations and Recommendations. Several limitations should be considered in this study. As conducted during the period of COVID-19, some activities of MNSS were restricted to online forms, which might reduce the effects. Future research should explore the feasibility and effectiveness of MNSS featuring multiple face-to-face activities. This study was conducted in two tertiary general hospitals in Shanghai City, which limited its generalizability to other populations of emergency nurses. The MNSS should be promoted to other hospitals of different levels in different cities to test its applicability comprehensively. Modifications are welcomed to develop unique MNSS for different emergency departments and even other populations of clinical nurses. Moreover, competent nursing managers with narrative abilities should be cultivated.

5. Conclusion

This research described the development and implementation of a novel professional support system, the multidimensional narrative support system, for emergency nurses during the period of COVID-19. The five-step system integrated the narrative methods of reflective and expressive writing, as well as diverse psychological activities, and provided multiple support systems from the dimensions of colleagues and experts. The action research design was adopted in this study to modify the MNSS fully considering the participants' experiences and suggestions, which empowered the emergency nurses to refine such a support system for their own overall improvements. Despite the challenges from COVID-19, the MNSS was proved to have good feasibility, providing information about the applicability of this support system for nurses working in emergency departments. The MNSS reported a significant influence on improving emergency nurses' well-being and quality of life, and it could be recommended in more hospitals to benefit more emergency nurses.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The authors declare that there are no conflicts of interest regarding the publication of this paper.

Authors' Contributions

Yue Deng is the co-first author of this article.

Acknowledgments

We gratefully acknowledge those emergency nurses who were involved in the research for their efforts in sharing and participation. We also thank those nursing managers, psychologists, and statisticians for facilitating and guiding the MNSS. We appreciate the financial support from the Youth Programme of the National Natural Science Foundation of China (71904199).

Introduction. This study introduces the Portuguese Transcultural Nursing Leadership Questionnaire (QLTE-PT), a pioneering instrument designed to assess leadership behaviours in multicultural nursing work environments, addressing gaps in current leadership assessment tools. **Aim.** This study aimed to develop and validate the Portuguese Transcultural Nursing Leadership Questionnaire (QLTE-PT). **Methods.** It was conducted as a sequential exploratory mixed-method study, integrating DeVellis's steps for instrument development. Items were formulated based on a literature review and a focus group study, and the content validity was evaluated by a panel of experts. A methodological approach involving nurses registered in the Portuguese Order of Nurses with leadership experience in multicultural nursing work environments was employed to further conduct an exploratory and a confirmatory factor analysis to assess the instrument's structure and psychometric properties. **Results.** One hundred forty-five items were initially generated, of which 39 were included in the QLTE-PT following content validity assessment by a panel of experts. EFA revealed a factor structure of 25 items loading on six factors, explaining 64% of the total variance. The overall Cronbach's α coefficient of the questionnaire was 0.90. This six-factor structure was tested by CFA, revealing a final model of 23 items and six factors, with a good quality of adjustment (CFI = 0.980, TLI = 0.976, SRMR = 0.078, and RMSEA = 0.070). Both convergent and discriminant validity were confirmed. **Conclusions.** The QLTE-PT demonstrates good psychometric properties and is suitable for assessing transcultural leadership behaviours of nurse managers and leaders in multicultural nursing work environments. **Implications for Nursing Management.** The QLTE-PT can assist nurse managers to improve their leadership behaviours, promote supportive working environments for their multicultural nursing staff, and improve the quality of care provided to patients from different cultural backgrounds.

1. Introduction

The interconnectedness and interdependence between nations, along with the exchange of people, goods, services, and information, have contributed to cultural diversity in workplaces, communities, and globally. This requires leaders who can guide multinational projects and lead people or groups from different cultural backgrounds in organizations, producing appropriate responses to their customers' needs with different cultures and expectations [1, 2]. Against this backdrop, the concept of transcultural leadership has gained prominence, advocating for the development of people and organizations equipped to address the challenges that arise from globalization, increased competition, and power asymmetries [3].

Defined as the process of articulating, implementing, and nurturing a global cultural vision and creating multicultural synergy [4], transcultural leadership is pivotal in various sectors, including healthcare. Within the nursing discipline, transcultural nursing leadership focuses on the culturally sensitive transformation journey. This involves tailoring behaviours, processes, and products to meet the cultural needs of both nurses and patients, challenging traditional paradigms, and guiding the delivery of culturally congruent care [5]. Such leadership is essential not only for delivering culturally congruent care to patients and achieving optimal health outcomes for all populations [6, 7] but also for effectively managing the challenges of culturally diverse nursing teams [5].

Cultural diversity among patients and healthcare professionals is a current scenario in Portuguese healthcare organizations [8]. Portugal hosts more than half a million of immigrants [9], who face several difficulties when accessing health services, such as discrimination, lack of information and knowledge on how the Portuguese healthcare system works, administrative barriers, and cultural and linguistic barriers that hinder communication with the employees and healthcare professionals of the National Health Service [10]. According to a study developed by Dias et al. [11], a majority of immigrants consider that having been in Portugal for a short time (85.1%), lacking knowledge about legal rights to health access (78.9%), being alone in Portugal (76.9%), having insufficient financial resources (75.6%), existence of complex bureaucratic procedures for health services access (75.2%), language differences (59.8%), absence of interpreters (49.5%), challenges in expressing symptoms and recognizing illness (46.9%), distrust towards health professionals (45.7%), and beliefs, religious, and cultural traditions (27.7%) are factors that condition their access and utilization of health services in Portugal.

In addition, recent data from the Portuguese Order of Nurses *Ordem dos Enfermeiros* [12] reveal that 1348 nurses registered in 2022 were from foreign countries. According to Silva and Fernandes [13], despite the reports of a good welcome, immigrant nurses report challenges and difficulties during their integration in Portugal. These difficulties and challenges are related to the recognition of academic degrees and the differences in roles, skills, autonomy, and hierarchy in professional relationships, working conditions/resources, and language, particularly differences in technical nursing terms between Portugal and their home countries. Foreign nurses in Portugal also identify experiences of discrimination from patients and colleagues and unequal treatment by their managers, such as discrediting their knowledge, exclusion from training, unbalanced work distribution, abuse of power, and no opportunities for professional development, specifically being a team leader or mentoring nursing students [13]. According to Primeau et al. [14], it is important that organizations ensure healthy work environments free of discrimination and with opportunities for this particular group of nurses to achieve their career goals.

The diversity and related challenges in Portuguese healthcare settings highlight the need for a nuanced understanding and effective management of cross-cultural dynamics, accentuating the importance of transcultural nursing leadership. Nurse managers are pivotal in this context, as they are responsible for promoting culturally congruent care to patients from different cultural backgrounds and developing favorable work environments for multicultural nursing teams [15]. The challenges they face in providing better support to their teams and developing effective leadership styles [16], especially when managing nurses from different cultures, are significant. This complexity is a growing concern in Portugal [17–21] and the complexity that cultural diversity adds to these environments must be recognized.

There are no studies or instruments to assess transcultural nursing leadership. The most commonly used tools to assess nursing leadership competencies are the Ambulance Nurse Competence scale, Leadership Practices Inventory, Clinical Leadership Needs Analysis Instrument, Cotter Preceptor Selection Instrument, Performance Evaluation Tool, Leadership and Management Inventory, Advanced Practice Nursing Competency Assessment Instrument, and Kuopio University Hospital Transformational Leadership Scale [22]. Given the absence of instruments assessing transcultural nursing leadership in multicultural settings, i.e., in healthcare settings where nurses from different cultural backgrounds work and where care is provided to culturally and linguistically diverse patients, this study aimed to do the following:

- (1) Develop the Portuguese Transcultural Nursing Leadership Questionnaire (QLTE-PT) specifically tailored to assess nurse leaders and managers' leadership behaviours in multicultural nursing environments in Portugal
- (2) Validate the QLTE-PT by assessing its internal consistency, confirming its construct validity through exploratory and confirmatory factor analyses, and establishing both its convergent and discriminant validity

2. Materials and Methods

A sequential exploratory mixed-method study was conducted in two stages [23]. The first stage aimed to develop the questionnaire. The second stage followed a quantitative study to analyze its psychometric properties.

The questionnaire development and validation process were based on DeVellis's [24] steps for instrument development which are as follows: (a) determine what is intended to be measured; (b) generate a set of items; (c) determine the measurement format of the instrument; (d) review the set of items formulated from a panel of experts; (e) consider the inclusion of validation items; (f) apply the items to a sample; (g) evaluate the items; and (h) optimize the dimensionality of the instrument.

2.1. Generate a Set of Items. Items were generated based on a scoping review and a focus group, which are both strategies to generate a pool of items for new instruments [25, 26].

2.1.1. Scoping Review. The scoping review was conducted in accordance with JBI guidelines [27], aiming to map the personality traits, competencies, behaviours, and leadership styles of nurse leaders and managers impacting the outcomes of multicultural nursing teams. Papers published in English, Portuguese, and Spanish languages were searched through electronic databases, such as CINAHL, MEDLINE, Nursing & Allied Health Collection, MedicLatina, Psychology and Behavioural Sciences Collection, Wiley Online Library, and Scopus. We did not restrict the publication dates in our scoping review due to the lack of previous literature reviews on this topic. This approach enabled us to

comprehensively access the best available evidence without temporal constraints. The search strategy comprised the following keywords: nursing leadership, leadership traits, competencies, behaviours, skills, and styles; multicultural nursing teams, and nurses' outcomes.

2.1.2. Focus Group. A qualitative, exploratory focus group study was conducted to explore the strategies used by nurse managers in creating favorable work environments for multicultural teams and delivering culturally congruent care to diverse patients [28]. A convenience sample of five Portuguese nurses with experience leading multicultural nursing teams was recruited to participate in the study. A semistructured interview was performed with questions aimed at eliciting participants' insights on transcultural nursing leadership, effective management interventions for multicultural nursing teams, and strategies to improve culturally congruent care. Qualitative data were recorded and transcribed for content analysis.

Based on the results of both studies, a list of the most relevant nurse leaders and managers' behaviours in multicultural nursing work environments was produced. The items were revised to ensure appropriate wording and to remove duplicates. A first draft of the questionnaire was prepared.

2.2. Determine the Measurement Format of the Instrument. All items of the questionnaire were scored based on a 5-point Likert scale ((1) "never," (2) "rarely," (3) "sometimes," (4) "frequently," and (5) "always"), representing a continuum of the frequency of nurse leaders or managers' behaviours in multicultural nursing work environments. This choice is based on Boateng et al.'s [25] guidelines, which advocate that response scales with five to seven points have higher reliability than Likert-type response scales with less than five points.

2.3. Reviewing the Set of Items Formulated from a Panel of Experts. Once the items had been formulated, an assessment of the questionnaire's psychometric properties was conducted to analyze whether it was adequate and accurate in assessing transcultural nursing leadership, as well as to evaluate its validity and reliability [29]. This stage comprised two phases: content validity and construct validity.

Content validity is invaluable for the quality of a newly developed instrument [29]. Since there is no specific statistical test for this purpose, it is common to use a panel of experts to assess the set of items formulated and validate whether they accurately represent the construct measured by the new instrument [30].

The experts were recruited by convenience in a Portuguese association of nurse managers and leadership. Following the recommendations of Polit and Beck [26], it was defined that at least two rounds would be performed to determine the content validity of the items and the questionnaire as a whole. In the first round, each item was assessed regarding its degree of relevance, clarity, simplicity

and ambiguity, on a scale of 1 (not relevant) to 4 (very relevant), according to the criteria described by Yaghmale [31]. Once assessed in each criterion, the content validity index of each item (I-CVI) was calculated based on the ratings assigned by the experts regarding its degree of relevance [26, 29].

Following the authors' recommendations, it was determined that items with a I-CVI of <0.78 would be excluded from the questionnaire [26, 29]. The items with a I-CVI of ≥ 0.78 but with values of <1 in the criteria of clarity, simplicity, and ambiguity, estimated according to the previous formula were reformulated. After this process of item deletion and reformulation, a second round of relevance assessment of the remaining and reformulated items was carried out. The I-CVI of each item was calculated and the overall content validity index of the questionnaire (Ave-CVI) was estimated from the average of the I-CVIs [29]. It was considered that a I-CVI ≥ 0.78 on each item and an Ave-CVI of ≥ 0.90 would be indicative of an excellent content validity [26]. The estimated value of Ave-CVI in the second round would determine the need for questionnaire reformulation and additional rounds.

2.4. Consider the Inclusion of Validation Items. Although it is possible to include additional scales that may provide information about the validity of the final questionnaire [24], it is recommended that researchers limit these efforts at this stage of developing a new instrument. According to Worthington and Whittaker [32], it is advisable to keep the overall length of the questionnaire as short as possible and directly related to the central aim of the study. Worthington and Whittaker [32] also argue that there is a potential risk that items from other scales may interact with the items designed for the new instrument, interfering with its development process. Therefore, it is important to avoid influencing the items' responses during the initial phase of instrument development, thus limiting the use of additional measures [32]. Understanding the risks highlighted by Worthington and Whittaker [32], it was decided to not include validation items as recommended by DeVellis [24].

2.5. Evaluating and Refining the Instrument. Following the establishment of content validity, a quantitative and cross-sectional study was conducted to identify the core dimensions of transcultural nursing leadership and to confirm the reliability of the instrument. For this purpose, an exploratory factor analysis (EFA) was performed followed by a confirmatory factor analysis (CFA).

Nurses registered in the Portuguese Order of Nurses in the categories of nurse manager, nurse specialist, or nurse, with current or past leadership experience in multicultural nursing work environments were invited to participate in this study. Nurses without leadership experience in multicultural nursing work environments were excluded. The sample size was based on guidelines recommending five to ten participants for each questionnaire item to ensure a robust analysis in EFA and CFA [33].

During EFA, the correlations between items were assessed using the Kaiser–Meyer–Olkin (KMO) measure to ensure that they were suitable for factor analysis. The analysis was then performed using an appropriate estimator for ordinal data (WLSMV), robust to deviations from normal distribution [34]. For the extraction of factors in our EFA, we employed the principal component as the method to identify the initial structure of latent factors, followed by an oblique rotation to explore the relationships between these factors. The number of latent factors identified considered both the eigenvalues greater than 1 and the scree plot. We then retained factors explaining a significant portion of the total variance and removed individual items with factor loadings below 0.50.

The instrument was refined by repeating EFA, ensuring that each factor was reliable and represented by at least two items. The quality of the factor structure was assessed using the root mean square residual (RMSR) index.

Confirmatory factor analysis was performed to assess the validity of the factor structure identified in EFA. It analyzed the existence of outliers by analyzing the square distance of Mahalanobis (D^2). The normality of the variables was assessed by the uni- and multivariate asymmetry ($|Sk| < 3$) and kurtosis ($|Ku| < 10$) coefficients [35]. The quality of the model was assessed through the indices proposed by Brown [36] and Marôco [35]: CFI (< 0.8 : bad fit), TLI ($(0.9; 0.95)$: good fit), SRMR (≤ 0.08 : good fit), and RMSEA (> 0.08 – 0.10 : unacceptable; $(0.05; 0.08)$: acceptable; and ≤ 0.05 : very good). Necessary adjustments were made based on modification indices greater than 11 and theoretical justification, as recommended by Marôco [35].

Finally, item reliability was assessed based on the proportion of variance accounted for by the latent factor, with a target value of 0.25 or higher [35]. The overall instrument's reliability, as well as that of individual factors, was determined using Cronbach's alpha, setting a minimum acceptable level of 0.70 [37]. Construct validity was established through analyses of convergent and discriminant validity [30, 35]. Missing values were handled with the pairwise method in both EFA and CFA.

All statistical analyses were conducted in RStudio (© 2009–2022 RStudio, PBC) using packages “polycor,” “psych,” “lavaan,” and “lavaanPlot.”

2.6. Ethical Considerations. This study was first approved by the Ethics Committee of the Nursing School of Lisbon (approval no. 216/2022/CE), as part of the doctoral research project. Authorization and support were requested from a Portuguese association of nurse managers and leadership to recruit nurses to integrate the panel of experts to perform the content validity of the questionnaire. Once the content validity phase was completed, authorization and support were also requested from the Portuguese Order of Nurses to disseminate the study to its members and invite those with the experience of leadership in multicultural nursing work environments to complete the questionnaire online. All participants approved their participation through an electronic consent form, without which they could not proceed

to data collection. All participants were informed that they could withdraw from the study at any moment. Anonymity and data confidentiality were guaranteed.

3. Results

3.1. Generation of Items. A total of 115 and 63 items were formulated from the scoping review and the focus group study, respectively. After removing duplicates and similar items, 145 items composed the initial version of the QLTE-PT.

3.2. Content Validity. A total of six members of the Portuguese association of nurse leaders and managers participated in the panel of experts, meeting the minimum number of experts recommended to assess the content validity of an instrument [29]. Half of the participants were female, with a mean age of 53.8 years ($SD = 7.7$) and 31.7 years of professional experience ($SD = 7.4$). More than 50% held a master's degree or PhD degree, 16.7% were nurse specialists, and 16.7% had a bachelor's degree. About 67% were nurse managers. All experts of the panel stated that they worked or had worked with professionals from different cultural backgrounds, but none of them were or had been emigrants. None of the participants had education in multiculturalism.

Of the 145 items rated by the experts regarding their degree of relevance, 98.6% ($n = 143$) had a I-CVI ≥ 0.78 . Two items were excluded from the questionnaire due to I-CVI = 0.67. Only two participants wrote comments/suggestions for improvement, which were “simplify some items.” In some cases, it may even be necessary to “split one item into two” and “some questions were too long, which makes it difficult to answer them.” However, these two participants did not specify items for these actions. Due to the lack of specific guidance on which items to modify, a conservative approach proceeded in the revision process. The original structure of the items was maintained, focusing instead on improving items' clarity, simplicity, and reducing ambiguity. Fifty-one items, which had clarity, simplicity, or ambiguity indices below 1, were rephrased. These revised items, along with the others, constituted a set of 143 items that underwent a second round of evaluation. Five of the six experts from the previous round participated in the second round. Of the 143 items, 94.4% ($n = 135$) obtained a I-CVI of ≥ 0.78 and eight were eliminated due to a I-CVI of < 0.78 . No comments or suggestions for improvement were made in the second round. The questionnaire showed an Ave-CVI of 0.96. As a strategy to obtain a more parsimonious set of items, it was decided to consider the items' Content Validity Ratios (CVRs).

Twenty-nine items were identified as essential/very relevant with CVR = 1. It was decided to retain 10 additional items, despite having a CVR of < 1 , given their relevance highlighted in the literature. For instance, item “I adapt my leadership style according to the expectations, values, habits, beliefs, and cultures of the members of the nursing team member” was aligned with established theoretical

frameworks [3, 38] and empirical studies [5, 28] within the field that underscore their significance in assessing transcultural leadership. These decisions resulted in a total of 39 items included in the QLTE-PT, categorized into seven hypothetical dimensions: impartiality and nurse manager's ability to adapt, understand, accept, and respond to cultural differences; professional and sociocultural integration of immigrant nurses; standardization of nursing practice; supporting professional development; managing problems in multicultural teams; intercultural communication; and culturally congruent services and care. Figure 1 summarizes the process of item generation, inclusion, and exclusion from the QLTE-PT.

3.3. Reliability of QLTE-PT

3.3.1. Sample Characteristics. Four hundred and sixty-three nurses answered the questionnaire between November 2022 and March 2023, among whom 79.3% were female and 21.7% were male. The average age of the participants was 41.3 years ($SD = 10.6$), and the mean length of professional nursing experience was 18.2 years ($SD = 10.6$). More than 20% reported working or having worked abroad, namely, in Belgium, Brazil, Cape Verde, France, Germany, Guinea-Bissau, Indonesia, Oman, São Tomé and Príncipe, Saudi Arabia, Switzerland, Timor-Leste, and the United Kingdom. Data about education level, professional category, work unit, exposure to other cultures and in which context, training in multiculturalism, and international professional experience are comprehensively presented in Table 1.

3.3.2. Exploratory Factor Analysis. EFA was performed to identify the relational structure among the 39 items of the QLTE-PT. The findings of the preliminary factor analysis showed a KMO value of 0.85, which indicates the adequacy of the instrument's items for factor analysis. The factorability was confirmed for the 39 items by Bartlett's test of sphericity ($X^2 = 1370.5$; $p < 0.001$).

According to the criterion of eigenvalue greater than 1 and in line with the scree plot, the relational structure of the QLTE-PT would be explained by the nine latent factors explaining 73.2% of the variance. This initial factor structure of the questionnaire resulted in a problematic factor with only one item (item A32). Subsequent attempts to refine the structure by extracting eight factors still yielded another one-item factor (item A17). Even when reducing the factors to seven, the internal consistency of the two factors fell below the recommended threshold of 0.70 ($\alpha = 0.62$ and $\alpha = 0.66$). To improve the questionnaire's psychometric properties, we conducted further analyses, ultimately settling on a factor structure with six factors, which provided a more coherent and interpretable model. The factor structure comprising six factors was successfully derived, explaining a total variance of 64%. Fourteen items were removed due to factor loadings below 0.50. The six retained factors were found to aptly describe the correlational structure between the items, and the factor structure exhibited a good quality of adjustment

(RMSR = 0.059). The overall internal consistency of the questionnaire was demonstrated to be robust ($\alpha = 0.90$). In addition, each of the six factors retained in the factor analysis also showed a good internal consistency ($\alpha \geq 0.69$). These results affirm the reliability of the instrument both as a whole and in its individual factors. Table 2 provides a comprehensive summary of the factor loadings, communalities, percentage of explained variance, overall internal consistency, and individual factors' internal consistency.

3.3.3. Confirmatory Factor Analysis. The first CFA revealed an initial poor quality of adjustment (CFI = 0.961, TLI = 0.955, SRMR = 0.089, and RMSEA = 0.091). To enhance the model, outlier observations were removed. Items A24 and A25, which exhibited modification indices suggesting saturation in at least two other factors, were also removed from the model. Furthermore, we correlated the measurement errors of items with higher modification indices (A34-A35, A3-A4, A35-A6, A5-A6, A35-A31, and A15-A8) to improve the model quality. Following these refinements, the model demonstrated good fit indices (CFI = 0.980, TLI = 0.976, SRMR = 0.078, and RMSEA = 0.070) and good internal consistency, providing robust support for the factor validity of the QLTE-PT.

All items had standardized factor loadings greater than 0.50 and individual reliability ($\lambda_{ij} \geq 0.25$). It was observed that the average variance extracted (AVE) supported all factors' convergent validity. The discriminant validity of the factors was evaluated by comparing the AVE with the squared correlations between the factors (Table 3). It was found that each of the factors had an AVE greater than the square of its correlation with the other factors, which supported that all factors had a discriminant validity.

The first factor was designated as "supporting culturally congruent care" (CCC), the second as "managing intercultural issues" (MII), the third as "inclusive and unbiased management" (IUM), the fourth as "cultural sensitivity and adaptation" (CSA), the fifth factor as "integration in the nursing work environment" (INWE), and the last factor was designated as "adjusting care to cultural expectations" (ACCE). Figure 2 provides a visual representation of the final six-factor model of QLTE-PT.

4. Discussion

The development and validation of the Portuguese Transcultural Nursing Leadership Questionnaire (QLTE-PT) fills the gap in assessment tools for transcultural nursing leadership. It revealed a six-factor structure and 23 items that robustly encapsulate essential aspects of transcultural nursing leadership. These factors include supporting culturally congruent care, managing intercultural issues, inclusive and unbiased management, cultural sensitivity and adaptation, integration in the nursing work environment, and adjusting care to cultural expectations. The instrument demonstrates strong internal consistency, with an overall Cronbach's alpha value of 0.90, which is higher than the expected α and equal or higher than 0.70 for new instruments [37]. It explains a total

excellent content validity were assured, the high dimensionality of the questionnaire in its initial development phase raised concerns. In the early stages of questionnaire design, it should not be so long that it reduces the likelihood of potential participants answering or completing all the items, nor too short that it fails to cover all aspects of the construct it is intended to measure [32]. Such imbalances pose risks to the internal consistency of the construct and can affect the relationships and correlations among items within specific factors or domains [29]. As a strategy to obtain a more parsimonious set of items, it was decided to consider also the items' CVR as proposed by Lawshe, cited

by Almasreh et al. [29], which reduced the number of items from 135 to 29.

The inclusion of 10 additional items with a CVR of <1 proved to be a significant step in the development of the QLTE-PT. Only two of these items were dropped during the EFA due to factor loadings below 0.50, which underscores the importance and relevance of the remaining eight items, as they contribute meaningful dimensions to the overall construct despite their initial lower CVR scores.

The first factor, "supporting culturally congruent care," showed good internal consistency, as evidenced by a high Cronbach's alpha value ($\alpha=0.81$). This indicates that the

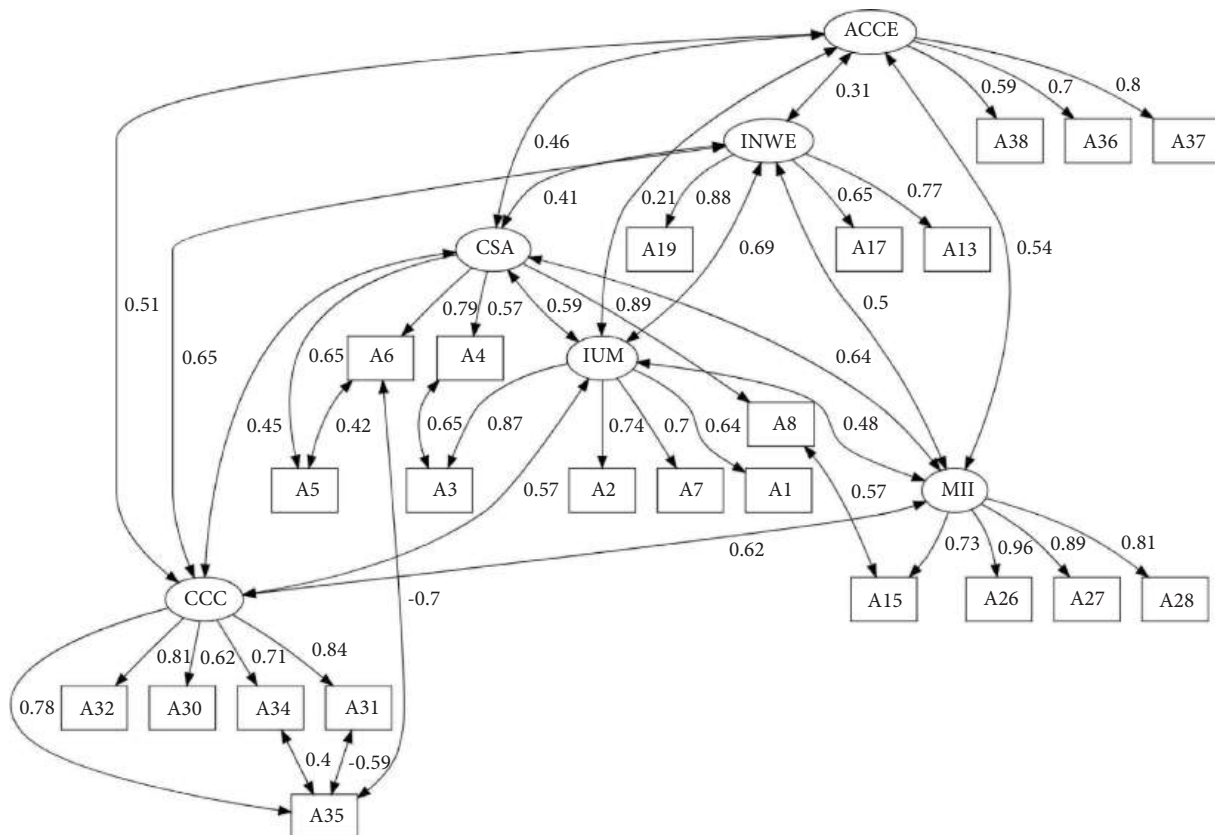

FIGURE 2: Six-factor model of QLTE-PT (CFI = 0.980, TLI = 0.976, SRMR = 0.078, and RMSEA = 0.070). Standardized loads and covariances.

items within this factor reliably measure the intended construct. The factor accounted for a significant portion of the total variance (13.9%), demonstrating its substantial contribution to the overall model. This factor comprises five items that encapsulate the actions taken by nurse leaders and managers to assist nurses in enhancing the quality of care they provide to patients from different cultural backgrounds. Examples of such actions include “I encourage immigrant nurses to take a course on the local language and facilitate their schedules to be able to attend it,” “I conduct trainings that enable nurses to provide culturally congruent nursing care,” and “I provide nurses with pamphlets and handbooks related to the delivery of culturally congruent nursing care.” These items align closely with the established strategies to improve culturally congruent care in nursing literature, which supports the convergent validity of this factor. According to Russell [7], a transcultural nurse leader engages nurses, nursing students, and other healthcare professionals in a learning process of what it means to deliver culturally congruent care to culturally diverse populations. Providing written documentation on culturally congruent care [39], introducing transcultural education in services [40] and encouraging nurses to attend culture-related training sessions and activities, and ensuring their coverage during their absence from the shift [41] are a few examples of how this learning process may be conducted that support this factor. This factor includes also an item related to the nurse leader or manager’s improvement to

communicate effectively with nurses of different nationalities and cultures, which is supported by the literature about the importance of engaging in ongoing training that enhances the skills related to culture and diversity in the workplace [41]. The discriminant validity of this factor is supported by its distinctiveness from other factors in the model. The relatively low correlations with other factors indicate that it measures a unique aspect of transcultural nursing leadership, separate from other leadership dimensions captured in the QLTE-PT.

The second factor “managing intercultural issues” contains four items, for instance, “I investigate events related to verbal or physical abuse, discriminatory behaviour, and harassment, and implement measures that reduce the risk of occurrence.” It comprises nurse leaders and managers’ attitudes and actions to prevent, resolve, and mitigate problems arising from cultural differences between nurses. This factor demonstrated a good internal consistency ($\alpha = 0.79$), reflecting the coherence of its four items in assessing leadership approaches to intercultural challenges. The factor’s significant contribution to the total variance (13.6%) underscores its importance in the overall construct of transcultural nursing leadership. Convergent validity for this factor is supported by literature emphasizing the critical role of nurse leaders in addressing and resolving cultural conflicts and fostering a harmonious work environment. For instance, Munkejord [42] argues that healthcare managers can contribute to challenging the ethnic pyramid often

identified in culturally diverse institutions by implementing diversity-sensitive measures. Encouraging and arranging dialogue and collaboration among staff are one of those measures that lead to better relationships and reduce ethically based discrimination [42]. Nurses from ethnic minorities need to feel supported in the nonthreatening work environment. They also need to know that corrective actions will be implemented if the behaviour of an employee or group of employees is considered harmful [43]. The distinctiveness of this factor from others in the questionnaire, as shown by its discriminant validity, highlights its unique role in transcultural nursing leadership.

Factor 3 was labelled as “inclusive and unbiased management” as it concerns the degree to which the decision-making process of the nurse leader or manager deviates from favoring some nurses. It demonstrated a significant internal consistency ($\alpha = 0.76$), which suggests that the item effectively captures the essence of unbiased and inclusive decision-making in transcultural nursing leadership. Factor 3 is composed of four items, including “I have a transparent policy in the unit regarding the method of organizing nursing care, schedules, holidays, annual appraisal, and promotions.” Convergent validity for this factor is evident in its alignment with existing literature on the importance of equity and impartiality in leadership, particularly within culturally diverse healthcare settings. Studies have highlighted that nurse managers who show favoritism, plan schedules, and vacations unequally among nurses of different cultural backgrounds, and promote nurses based on cultural criteria over merit, impact negatively on migrant nurses’ job satisfaction, retention, and professional development [44, 45]. Discriminant validity is also well-established, with this factor distinctly measuring characteristics of leadership that are separate from others, as suggested by its low correlations with other factors in the QLTE-PT. This uniqueness is crucial in a transcultural context where unbiased and inclusive management is key to harmonizing a diverse workforce.

The fourth factor “cultural sensitivity and adaptation” is composed of four items aiming to describe nurse leaders and managers’ sensitivity to cultural differences and how this sensitivity is reflected in their attitudes and behaviours towards nurses. The internal consistency of this factor ($\alpha = 0.76$) confirms the reliability of the items in measuring cultural sensitivity and adaptation in nursing leadership. This factor’s convergent validity is supported by the existing research, such as studies by Sharifi et al. [46], which emphasizes cultural sensitivity as an attribute of cultural competence in nursing, translating into valuing, respecting, and admiring cultural diversity and helping nurses to understand how people’s attitudes and views affect their behaviours and care-seeking patterns. Examples of such nurse manager’s sensitivity and adaptation included in the QLTE-PT are “I am open to realities that are different from mine” and “I adapt my leadership style according to the expectations, values, habits, beliefs, and cultures of the nursing team members.” The distinctiveness of this factor from other factors in the QLTE-PT is evident in its unique focus on leaders’ ability to respect, understand, and adapt to

cultural differences, as outlined by Matveev [47]. Transcultural leaders must demonstrate the ability to adapt to the distinct expectations of their organization, community, competitors, and clients [3]. This supports the factor’s discriminant validity, as it captures unique aspects of transcultural leadership not covered by other factors.

Factor 5 “integration in the nursing work environment” comprises three items which highlight interventions targeted at the professional integration of immigrant nurses into the specificities of the nursing practice in the host unit, for example, “I implement a clinical orientation program specific to my unit to develop competencies of immigrant nurses with different levels of knowledge and professional experience” and “I recourse to international protocols to guide and standardise nursing practice in the team.” This factor demonstrated a good internal consistency ($\alpha = 0.76$), indicating that the items are cohesively capturing the essence of immigrant nurses’ integration in the work environment. Convergent validity is reinforced through literature emphasizing the need for supportive nursing work environments for diverse nursing staff. Integration in multicultural nursing work environments is a bidirectional process that involves efforts not only by the immigrant nurses but also by the host organization [48]. Rovito et al. [49] warn that sometimes nurses need to “unlearn” practices of nursing care that were common in their home country, since they are not a part of the nursing practice in the culture of the host country. According to Safari et al. [50], several strategies are needed to guide immigrant healthcare professionals in the culture of the host country before starting their clinical practice. A clinical orientation program is an example of a strategy that minimizes the impact of the challenges and difficulties migrant nurses experience, improves their well-being, the quality of care, and mitigates the risks to patient safety [51]. It is the nurse manager’s responsibility to provide guidance, invest in multicultural education and mentoring for these nurses, guide their practice to provide safe and culturally congruent care, and ensure competence development and efficient use of their expertise [52]. Discriminant validity is evident, as this factor uniquely addresses the integration of immigrant nurses in the work environment, distinct from other transcultural nursing leadership characteristics evidenced in the other factors.

The last factor was labelled as “adjusting care to cultural expectations.” It demonstrated an acceptable internal consistency ($\alpha = 0.69$), indicating that the items are able to capture nurse managers and leaders’ interventions to meet patients’ cultural expectations regarding nursing care. This factor is composed of three items such as “I request religious support congruent with patients’ beliefs (e.g., Chaplain, Imam, Brahmin, Lama, and other spiritual leaders).” According to Leininger and McFarland [38], if patients receive nursing care that is not compatible and respectful with patients’ ways of life, beliefs, and values, they will demonstrate signs of stress, nonadherence, cultural conflict, and ethical or moral concerns. This factor is in line with the guidelines for the implementation of culturally congruent nursing care in organizations, namely, the provision of structures and resources needed to meet patients’ cultural

needs [53]. It is also supported by existing literature on the responsibility of nurse managers to provide culturally and linguistically appropriate services to diverse populations [28, 54]. This literature supports the convergent validity of this factor. Furthermore, the distinctiveness of the factor, evident through discriminant validity, confirms its unique role in the QLTE-PT, differentiating it from other factors.

Although there is an overall agreement about the scenario of cultural diversity among patients and healthcare workers in Portugal, no studies have attempted to describe the leadership behaviours of nurse leaders and managers in multicultural nursing work environments in this country. Therefore, this paper is innovative and grants a questionnaire that addresses nurse leaders and managers' leadership behaviours in multicultural nursing work environments with applicability in Portugal.

4.1. Study Limitations. The findings of this study contribute to the field by providing a reliable and valid instrument for assessing transcultural nursing leadership. However, it is important to consider the limitations of this study and the implications they have for the generalizability and interpretation of the results.

First, self-report measures were utilized in this study, which are subject to potential biases. Participants may have provided socially desirable responses regarding their leadership behaviours in multicultural nursing work environments, leading to response bias. Efforts were made to minimize these biases through clear instructions to participants and ensuring data anonymity. However, it is important to acknowledge this limitation probability.

In addition, despite QLTE-PT having good internal consistency and construct validity, further validation in different cultural contexts is necessary. The current study focused on nurses registered with the Portuguese Order of Nurses and with experience of leadership in multicultural nursing work environments. Future research should aim to conduct cross-cultural validation to ensure the questionnaire's robustness across diverse cultural contexts. Future research should also include a criterion measure to provide a more comprehensive assessment of the questionnaire's validity.

5. Conclusions

This study successfully developed and validated the Portuguese Transcultural Nursing Leadership Questionnaire (QLTE-PT). The final instrument, comprising 23 items across six factors, demonstrates robust psychometric properties, including good internal consistency and construct validity. The QLTE-PT captures essential aspects of transcultural nursing leadership, making it a valuable tool for evaluating nurse managers and leaders' behaviours in multicultural nursing work environments. While acknowledging the study's limitations, the QLTE-PT represents a significant contribution to nursing management, offering insights into leadership behaviours in diverse healthcare settings. Due to its potential interest of use in other countries with multicultural healthcare settings, we recommend the

development of guidelines with comprehensive information about different methodological approaches to support the decision-making and the quality of the cross-cultural adaptation process [55].

6. Implications for Nursing Management

The development and validation of the QLTE-PT hold important implications for nursing management and leadership. By providing a reliable and valid instrument to assess transcultural nursing leadership, the QLTE-PT offers nurse managers a valuable tool to gain insights into their own leadership behaviours in their multicultural units or organizations and acknowledges the needs of their nursing staff and patients from different cultural backgrounds. The questionnaire can assist nurse managers in identifying areas for improvement in their leadership and promotes a supportive work environment for their multicultural nursing staff, conducive to the well-being and engagement of nurses. It can also contribute to improving the quality of care provided to patients from different cultural backgrounds, ensuring patients' safety, satisfaction with nursing care, and higher levels of adherence to treatments.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

The first author has an individual doctoral scholarship supported by national funds through FCT - Fundação para a Ciência e a Tecnologia (2023.00958.BD). Background. New evidence on the digital competencies of healthcare leaders can provide essential knowledge for building training for the leaders to ensure high-quality patient care. **Objective.** The aim of this mixed-methods systematic review was to identify the current best evidence from qualitative, quantitative, and mixed-methods studies on healthcare leaders' digital competence experiences and perceptions and factors associated with it. **Methods.** A mixed-methods systematic review was conducted following the Joanna Briggs Institute guidelines for mixed-methods systematic reviews by including original qualitative and quantitative observational studies and mixed-methods studies published in English or Finnish between January 2012 and January 2024. The studies were retrieved from four databases (CINAHL, PubMed, Scopus, and Medici). In total, 4470 articles were screened, 122 were eligible for full-text screening, and 19 articles were included in the review according to the established inclusion and exclusion criteria. **Data Extraction and Synthesis.** Data tabulation and narrative synthesis for quantitative studies and content analysis for qualitative studies. **Results.** The synthesis of qualitative data identified five main categories that describe healthcare leaders' experiences with digital competencies: (1) the need for developing leader's own, professionals', and patients' competence in the digitalisation of healthcare, (2) the need for expertise in the health IT implementation process, (3) positive perceptions towards technology, (4) negative perceptions towards technology, and (5) ability to act as an advocate to implement technology into practice. Data from the selected quantitative studies presents that factors associated with the digital competence of healthcare leaders include individual characteristics, career characteristics, training, and other factors. **Conclusion.** This review suggests that developing and supporting healthcare leaders' digital competencies should be considered in healthcare organizations, research, and education to make their digital competencies meet the demands of increasingly digitalising healthcare development work.

1. Introduction

Digitalising services and their integration into patient care challenge the competence needed in social and healthcare [1]. The lack of education and training of healthcare leaders may explain the low success rate of implementing digital solutions in healthcare. Previous research has found that managers are often self-taught in the use of digital health services [2], and a knowledge gap has been recognised in the healthcare leaders' digital competencies in the rapidly

evolving and digitalising healthcare environments [3]. The digital working culture of healthcare has changed rapidly due to the coronavirus pandemic, for example, in digital work interaction. Primary healthcare leaders predict that digitalisation in healthcare will develop further [4]. Digitalising healthcare requires adaptation to the requirements and needs of the changing working life, both from employees and leaders [5], and to fully participate in healthcare management in an era of rapidly evolving health information technologies, nursing leaders need to acquire

health information technology skills related to their clinical leadership roles and responsibilities [3, 6]. The European Commission [7] defines digital competence as “the confident and critical use of Information Society Technology (IST) for work, leisure and communication. . . underpinned by basic skills in information technology to retrieve, assess, store, produce, present and exchange information, to communicate and participate in collaborative networks via the Internet.” Mainz et al. [8] reported in their review that digital competence in healthcare can be divided into technical, methodological, personal, and social skills. The technical competencies identified encompass proficiency in basic computer use and wireless devices, applied skills in digital health, anticipation of advanced digital capabilities, technology administration, ethical considerations, and legal aspects of digitalisation. Methodological competencies include proficiency in data and information processing, problem-solving abilities, continuous learning, project management, and research skills. Self-reflection, critical thinking, professionalism, creativity, and innovative behaviour are considered to be personal competencies; and focus on patients, working in teams, communication competence, teaching, and networking skills are categorised as social competencies in digital competence in healthcare.

Health information technologies have good potential to improve the quality, safety, patient-centeredness, and cost-effectiveness of treatment [9]. In the increasingly digitalising healthcare environments, the need for competence management of nursing leaders has been emphasised as healthcare organizations acquire and implement different technologies and health information systems to support nursing work. Nursing leaders need to participate in decision-making in the selection, planning, deployment, and evaluation of these technological procurements (Reference [10]). Due to the rapid integration of digital health technologies, healthcare leaders must have the expertise and confidence to implement and incorporate these technologies into healthcare [11] to support healthcare professionals’ digital competence and thus contribute to ensuring quality patient care [12]. According to Carson et al. [13], nursing leadership is crucial in enhancing electronic health record (EHR) satisfaction and usability by fostering a positive culture of staff engagement and promoting EHR adoption. Proficiency in EHRs is essential for nursing leaders to serve as role models for staff, enabling effective communication and support for evolving functionalities that enhance patient care workflows [13]. Due to some nurses’ insufficient digital competence, hospital management and nurse leadership need to recognise the critical role of aligning technology with tasks and individuals to ensure the successful adoption of health information technology [14]. Healthcare leaders and professionals have highlighted the importance of leaders’ role and digital competence in enhancing and disseminating digital skills; leaders need to grasp the principles and functionalities of digital tools and devices and understand their potential benefits for professionals and patients [15, 16].

Previous research has shown that healthcare leaders need help and training in using and introducing technology in their work community [2, 17, 18]. It has been found that healthcare leaders have not always received training in

information technology, or training has been insufficient [6, 19], for example, in the use of ICT and digital healthcare applications and programs [2]. According to Ravelin et al. [4], attention must be paid to the digital competencies of healthcare leaders because, according to their experience, leaders must first have capability in the use of information technology so that they can guide employees in the use of information technology. Healthcare leaders need capabilities and contextual competencies to effectively utilise complex digital tools in a changing environment, alongside improving digital health literacy, to inform strategic and operational decisions [20]. However, healthcare leaders continue encountering various barriers, such as infrastructure, technical, training, legal, ethical, time, and workload issues, when using digital health technologies, irrespective of care level or specific technology [21].

There is widespread optimism regarding artificial intelligence’s (AI) potential to enhance healthcare across diagnostics and treatment [22, 23]. When applied to nursing practice, AI can be a practical resource for leaders yielding positive outcomes in patient care and safety [24]. Also, Laukka et al. [25] suggest that AI can induce benefits on various areas of health care, including the work of nursing leaders. AI is ready to support healthcare workers across administrative tasks, clinical documentation, patient outreach, and specialised areas like image analysis and medical device automation [22]. AI systems offer notable potential in supporting comprehensive health services management and can aid doctors, nurses, and leaders in their roles [26]. For example, the integration of AI-driven triage systems can optimise operations in primary care and thus induce more proactive and tailored approach to healthcare delivery [23]. According to Neher et al. [27], healthcare leaders gearing up for AI implementation recognised its potential to improve healthcare, holding high expectations for its relative advantage; however, they were less certain about its evidence base, particularly regarding safety and effectiveness. Additionally, leaders were cautious about factors like trialability, adaptability, design, and costs [27]. Moreover, leaders have been reported to be concerned with the organization’s internal capacity for strategic change management and the possibilities to amplify competence and expertise in the use of AI systems [23]. Successful AI implementation and integration require a team with diverse expertise on AI, collaboration within and beyond the healthcare realm, and the development of an organisation-wide AI innovation culture where healthcare leaders play a significant role [23, 28].

In recent years, there has been more focus put on the digital competence of healthcare professionals at large [8, 12, 29–33], but in most cases, healthcare leaders have not been the main subject of the study, or their results have not been separated from other healthcare professionals’ results which makes it difficult to interpret specifically leaders’ digital competence areas or needs. Certain studies and reviews [3, 6, 34] have specifically looked at the digital competence of healthcare leaders, focusing on knowledge and skills, dismissing other aspects related to digital competence, such as personal and social skills. Examining these different aspects of healthcare leaders’ digital competence is

essential as it influences employees' acceptance and usage of technology [35, 36], which has positive outcomes on patient treatment and processes [31]. To enable innovative service provision in digital healthcare, there is a need to enhance the digital competence and understanding of digital transformation among current and future healthcare leaders [11]. Synthesis of the evidence on the digital competence of healthcare leaders can provide essential knowledge for building further training for the leaders and their employees to ensure high-quality patient care in digitalised healthcare environments. For this reason, this mixed-method systematic review aimed to gather the most recent evidence on healthcare leaders' digital competence perceptions and associated factors.

2. Materials and Methods

2.1. Study Design. The Joanna Briggs Institute guidelines for mixed-methods systematic reviews [37] were followed in the implementation of this review. This mixed-methods systematic review protocol is registered with the Center for Open Science incorporation OSF (Open Science Framework) registries [38]. In this study, healthcare leaders refer to all persons positioned as managers or leaders in social and healthcare contexts, such as nurse leaders, nurse managers, and chief nursing officers. A mixed-method review was conducted to explore qualitative evidence on healthcare leaders' experiences relating to digital competence and synthesise quantitative findings from previous research concerning digital competence areas and factors associated with leaders' digital competence.

The research questions were

- (1) What kind of experiences do healthcare leaders have with digital competence?
- (2) What kind of digital competencies have been described for healthcare leaders?
- (3) What kind of factors are associated with the digital competencies of healthcare leaders?

2.2. Search Strategy. Original qualitative and quantitative observational studies and mixed studies, including both methodologies published in English or Finnish between 2012 and 2022, were included in this review. The year limitation was set because of rapid digitalisation development in healthcare since the last decade [39]. Yet, a stricter timeframe was neglected as the phenomenon of knowledge, skills, and attitudes related to the use of IST has a significant history. The studies were initially retrieved from four databases (CINAHL, PubMed, Scopus, and Medic) in October 2022. An additional search was conducted at the beginning of January 2024 to include the most recently published publications. Data search strategies, including used keywords and complete search phrases for used databases, are presented in supplementary file 1. Inclusion and exclusion criteria were defined before performing a database search according to PICo [37] and PEO [40] criteria. An information specialist was also

utilised during this stage of the research. Inclusion criteria were (P) participants in different roles of healthcare leaders and managers at all levels of the organization; (I) & (O) the phenomenon of interest included digital competence (knowledge, skills, and attitudes related to the use of IST); and (Co) the context of healthcare organizations. For quantitative studies, (E) exposure of interest included factors related to the digital competence of healthcare leaders at all levels of the organization. Exclusion criteria included participants other than leaders or managers, e.g., social and healthcare professionals, for phenomena of interest or outcomes other than digital competence, and for contexts other than healthcare organizations. Study protocols, reviews, conference papers, books, and non-scientific research articles and texts published before 2012 in languages other than English or Finnish were also excluded.

2.3. Search Outcomes. The database search resulted in 6294 studies. Among these studies, 1824 duplicates were found and removed. In total, 4470 studies were screened by title and abstract, and 122 were eligible for full-text screening. In addition, the references of chosen studies selected for the review were checked against the inclusion and exclusion criteria, but this did not add any more studies to this review. Each researcher conducted the screening process independently, and conflicts were solved via discussion or by a third party until agreement was reached. A total of 19 studies were agreed to be included in the mixed-methods systematic review, including seven cross-sectional, ten qualitative, and two mixed-methods studies (Figure 1) against the inclusion criteria [41].

2.4. Quality Appraisal. The methodological quality of the selected 19 studies relevant to the inclusion criteria was assessed using The Joanna Briggs Institute (JBI) Critical Appraisal tools; a checklist for analytical cross-sectional studies [40] including eight assessment criteria was used for quantitative studies ($n=7$), and a checklist for qualitative research [42] including ten assessment criteria was used for qualitative studies ($n=10$). Mixed-methods studies ($n=2$) were assessed using both of these checklists. Four researchers (blinded for review) assessed the methodological quality of the studies separately and discussed possible disagreements in assessments until an agreement was reached. Quality assessment (maximum points 100%) for quantitative studies resulted in a score of 75% in four studies [43–46], 62.5% in one study [47], and 50% in two studies [48, 49]. For qualitative studies, a score of 100% was attained by one study [50], seven studies attained 80% [2, 51–56], and 70% by two studies [57]; Simpson., 2013. The mixed-methods studies by Kujala et al. [58] scored 75% for the cross-sectional and 60% for the qualitative approach, and Mottelson et al. [59] scored 37.5% for the cross-sectional and 80% for the qualitative approach. The detailed results from the methodological quality appraisal are presented in supplementary file 2.

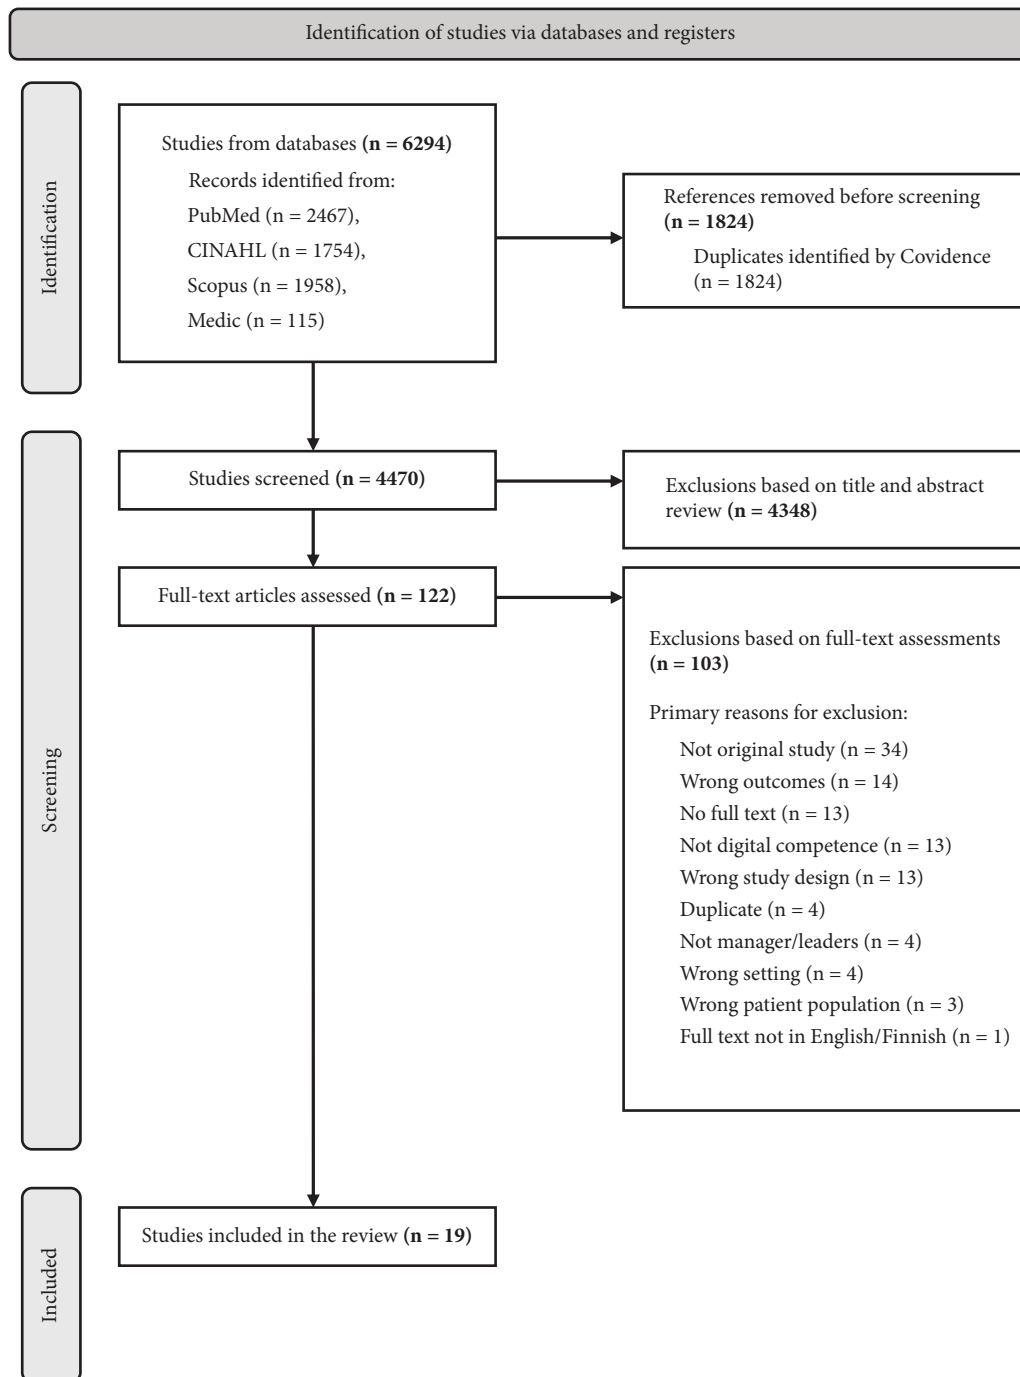

FIGURE 1: PRISMA flow diagram (Center for Reviews and Dissemination (CRD), 2009).

2.5. Data Extraction and Synthesis. Data extraction, including authors, the year of publication, the country of origin, purpose, participants, methodology, phenomena of interest or exposure of interest, outcomes, and the key findings, was assessed from all the articles included in the review (Table 1). The selected quantitative studies were synthesised using data tabulation and narrative synthesis. Qualitative studies were analyzed with content analysis to synthesise the results from healthcare leaders' digital competence experiences and descriptions [61].

3. Results

3.1. Characteristics of the Studies. The original studies were conducted in the USA ($n=5$), Finland ($n=3$), Portugal ($n=2$), Norway and Finland ($n=1$), Indonesia ($n=1$), Portugal and Brazil ($n=1$), Ghana ($n=1$), Qatar ($n=1$), Turkey ($n=1$), Japan ($n=1$), China ($n=1$), Denmark ($n=1$), and Australia ($n=1$). The study settings included specialised or university affiliated hospitals ($n=6$), public or general hospitals and healthcare organizations ($n=5$), a mixture of

TABLE 1: Extraction data.

Author(s), year, and country	Purpose	Participants	Methodology (design, data collection, data analysis)	Exposure of interest and outcome (PEO)	Key findings
Reference [47], China	To examine current informatics competency levels of nurse managers and to identify the variables that influence these competencies	Nurse managers in a general hospital affiliated with Harbin Medical University (<i>n</i> = 68)	A cross-sectional study A questionnaire. (First part queries about the general characteristics of the respondents, second part investigates nurse managers' informatics competencies using 49 informatics competency items identified by Hart in three categories: computer skills (25 items), informatics knowledge (20 items), and informatics skills (4 items)) Statistical analysis	Levels and variables Informatics competence	The study presents that nurse managers' informatics competency is at a medium level, and the level of their informatics knowledge was significantly higher than their informatics and computer skills. The variability in informatics competencies was determined at 71.2% with information education/training, nursing administration experience, and the level of education, and these were significant factors in affecting nurse managers' informatics competency levels. Higher education and informatics education/training were positively affecting factors, and longer nursing administration experience was shown to negatively affect informatics competency levels

Author(s), year, and country	Purpose	Participants	Methodology (design, data collection, data analysis)	Exposure of interest and outcome (PEO)	Key findings
Reference [59], Denmark	To investigate the attitudes to and experiences with video interpretation among charge nurses in a Danish University Hospital	Charge nurses (Position as managers closely involved in determining nursing practice.) (n = 99)	Mixed methods An electronic questionnaire (pretested, developed for the study) A descriptive statistics and thematic text condensation	Attitudes and experiences Video interpretation	Most charge nurses using video interpretation expressed satisfaction with the technology and ease of use, and frequent users were more satisfied with video interpretation than rare users. Charge nurses in outpatient clinics were more frequent users compared to the inpatient departments and acute areas. Video interpretation was seen as a tool helping increase the quality of care and communication when there are language barriers, and dialogue and the relationship between the nurses and the patients seemed to be improved by the technology. Some of the charge nurses mentioned that video interpretation helped save time in consultations, but some found the technology complicated to use. Four different themes occurred when asked reasons not to use video interpretation: professional concern, administrative barriers, patient's state of health, and using alternative approaches. Challenges in using video interpretation were mostly related to practical issues: poor Internet connection, technical problems, and lack of equipment

TABLE 1: Continued.

Author(s), year, and country	Purpose	Participants	Methodology (design, data collection, data analysis)	Exposure of interest and outcome (PEO)	Key findings
Reference [43], Ghana	To examine the factors that influence the use of information and communication technology among nurse managers	Nursing unit managers ($n = 108$) of the selected health facilities in the Volta region of Ghana who were performing the role of frontline managers	A cross-sectional study design A self-administered questionnaire (developed for the study) Statistical analysis	Factors influencing information and communication technology knowledge and use (sex, age group, years of experience, the rank of the respondents, computer training, computer ownership, and the use of computers before the current position) The use of information and communication technology	Younger nurse managers were significantly more able to use ICT in nursing care than their older counterparts. Bachelor's or higher degree showed increased use of ICT in nursing care. Higher work experience years had a decreased effect on the nurse managers' use of ICT, compared with those with fewer years of work experience. Lower work experience in years showed increased likelihood to use ICT in the workplace, than more work experience in years. Higher knowledge of ICT use was shown to be associated with computer training before the current position

TABLE 1: Continued.

Author(s), year, and country	Purpose	Participants	Methodology (design, data collection, data analysis)	Exposure of interest and outcome (PEO)	Key findings
Reference [17], Finland	To examine the current state of eHealth competencies of clinical leaders in two public healthcare organizations in Finland	Clinical leaders (nurse leaders 32%, social worker leaders 25%, physician and dentist leaders 11%, other leaders 13%, and managers 19% ($n = 98$))	<p>Mixed methods</p> <p>An online questionnaire developed for the study with multiple-choice and open-ended questions and a 5-point Likert scale</p> <p>Descriptive statistics for quantitative data, content analysis for responses to the open questions</p>	State eHealth competencies	<p>Leaders need to organize workflows, support healthcare professionals in the change, and make sure that eHealth service quality is good enough and that patients are informed and guided. Leaders' self-perceived eHealth competencies were the strongest regarding security and privacy protection, on which they had recently had training. Most leaders were confident in using eHealth applications and services and leading change and supporting their subordinates' competence. Leaders felt the least confident in communicating about the new eHealth services to patients, customer-centered service development, and planning new eHealth services implementation. Many leaders did not feel confident in their tasks, which indicates the need for training and support; leaders called for more information about eHealth services and their benefits and possibilities. The study indicates the need for training in managing change and planning the implementation of new eHealth services. Leaders have a critical role in ensuring the successful adoption of new eHealth services and supporting healthcare professionals in order to avoid resistance to change</p>

TABLE 1: Continued.

Author(s), year, and country	Purpose	Participants	Methodology (design, data collection, data analysis)	Exposure of interest and outcome (PEO)	Key findings
Reference [48], Portugal	To analyze the association between the characteristics of nurse managers and the use of information technologies in Portuguese hospitals	Nurse managers ($n = 138$)	A cross-sectional study Questionnaire Likert scale (developed for the study) Statistical analysis	Associations Use of information technologies	The study presents it is evidence that the perception of ease of use and utility of the nurse managers towards IT is influenced by the scenario in which they work and their socio-occupational characteristics, especially gender, complementary training, and time of experience in services and management. It was also presented that this perception is unique to each IT
Reference [45], Japan	To determine managers' and staff nurses' perceptions regarding the technological competency as caring in nursing (TCCN) theory in general hospitals in Japan	Nurse managers ($n = 96$) and staff nurses ($n = 325$)	A cross-sectional study design A web-based questionnaire using the TCCNI-R, a 5-point Likert scale Statistical analysis	Perceptions Technological competency	The study presents that the nurse managers were more aware of TCCN than the registered nurses. In the factor "technology and caring," the study presents that nurse managers were more aware of providing care using technology and also about technological competency as an expression of caring in nursing than registered nurses. In the factor of "technological knowing," nurse managers recognised more fully the need-to-know patient needs through technology than registered nurses

TABLE 1: Continued.

Author(s), year, and country	Purpose	Participants	Methodology (design, data collection, data analysis)	Exposure of interest and outcome (PEO)	Key findings
Reference [44], Turkey	To identify nurse managers' opinions on artificial intelligence (AI) and robot nurses	Nurse managers ($n = 326$)	A cross-sectional descriptive study 21-Item online questionnaire form (developed for the study) Statistical analysis	Opinions Artificial intelligence and robot nurses	Most of the nurse managers were aware of the concept of AI and robot nurses and saw that AI would be beneficial for nurses and would reduce nurses' workload, and more than half stated that basic education on AI and robot nurses should be included in university programmes. Half of the nurse managers brought out that robot nurses should only fulfil nurses' orders, and not to be used in providing patient care independently. In case, problems arise in the patient care provided by the robots, the majority of participants stated that engineers, hospitals, and lastly the nurses should take responsibility for the actions of robot nurses; to engineers, the responsibility and safety, and to nurses the ethical responsibility for patient safety and nursing care regarding to robots
Reference [46], Finland	To determine nurse managers' opinions of information system support for performance management	Nurse managers ($n = 419$)	A cross-sectional study design Electronic questionnaire, a 5-point Likert scale Statistical analysis	Knowledge and opinions Information system support for performance management	Good computer literacy and working in social care were positively associated with the features or performance management information systems (assessing nursing performance and clinical procedure, managing resources, and providing timely evaluation and reporting). The use of the systems to facilitate follow-up was strongly associated with assessing nursing performance and managing resources Available in-service training was found to have a positive impact on the leaders' use of the information system

TABLE 1: Continued.

Author(s), year, and country	Purpose	Participants	Methodology (design, data collection, data analysis)	Exposure of interest and outcome (PEO)	Key findings
Reference [49], Portugal	To identify the technological profile of nurse managers	Nurse managers ($n = 74$) from two settings: hospital center in the Portuguese north region ($n = 30$) and members of the Portuguese association of nurse managers and leadership ($n = 44$)	An exploratory, descriptive, quantitative study A self-administered questionnaire Statistical analysis	ICT use The management process	Statistically significant differences were found between the groups in the use of web technologies, chat, e-mail, and videoconferencing. Nurse managers from the hospital center had more experience in ICT use, either in general or as part of the management process (e-mail and videoconferencing)
Author(s), year and country	Purpose	Participants	Methodology (design, data collection, and data analysis)	Phenomenon of interest (PiCO)	Key findings

TABLE 1: Continued.

Author(s), year, and country	Purpose	Participants	Methodology (design, data collection, data analysis)	Exposure of interest and outcome (PEO)	Key findings
Reference [60], United States	To identify and validate the gaps existing between selected chief nurse executives (CNEs) self-ascribed lived experience information technology competencies and those laid out by the American Organization of Nurse Executives (AONE)	CNE members of the Health Management Academy (HMA) ($n=7$)	A qualitative study design Ethnographic interviews Thematic content analysis	Gaps Information technology competencies	In the study, five dominant and often interwoven themes emerged: technology knowledge, collaboration, health information technology (HIT) selection, executive leadership, and standardization. CNEs have chosen to bypass, amassing deep technology knowledge, and to look for nurse informaticians and clinical nurse specialists to provide the deep technology knowledge they do not possess. Limited technology knowledge leaves CNEs unable to champion the collection, analysis, and trending of nursing data in a chief medical officer-dominated HIT discussion. CNEs saw that their lack of deep technological knowledge often hindered effective cooperation across cross-departmental and cross-operational lines. CNEs did not see HIT as a strategic decision support tool for their own use but as a tool for nurses in their daily work and as a dashboard for management. CNEs demonstrated competency in the HIT decision-making process related to the evaluation, selection, deployment, and utilization, but the majority of the CNEs did not demonstrate competency to demonstrate an awareness of societal and technological trends, issues, and new developments as they relate to nursing

TABLE 1: Continued.

Author(s), year, and country	Purpose	Participants	Methodology (design, data collection, data analysis)	Exposure of interest and outcome (PEO)	Key findings
Reference [57], United States	To explore the attitudes of nursing home administrators and key managerial staff towards health information technology on the process of health IT adoption	Nursing home directors of nursing, case managers, nursing staff, kitchen staff, and administrative interns ($n = 42$) Primary sources of qualitative data are the administrators of the nursing homes	A qualitative case-study methodology Semistructured interviews based on the literature on health IT implementation in health care facilities and observer notes Inductive thematic analysis by integrating TAM and UTAUT model	Attitudes of nursing home administrators towards health information technology	The actions of the other nursing homes were seen as highly influencing social factors in managerial decision-making in implementing health IT. The administrator's conception of the potential benefits and usefulness of health IT was shown to support the procurement of technology adoption. Some nurse managers reported that without mandates from governments to adopt health IT, they have no intentions of health IT adoption and will have no systematic exploration of health IT implementations' positive effects on the quality of care and efficiency. Administrators' health IT implementation attitudes were affected by the price of the health IT system and the following upgrades on the computers and the staff training costs, the perception of staff's resistance to change, lack of strategic planning, evaluation, and cost-benefit analysis, the absence of regulatory pressures and satisfaction with current processes before the health IT. Administrators in nursing homes without health IT adoption had apathetic attitudes towards the change and innovation

TABLE 1: Continued.

Author(s), year, and country	Purpose	Participants	Methodology (design, data collection, data analysis)	Exposure of interest and outcome (PEO)	Key findings
Reference [2], United States	To explore how nurse managers use ICT to lead and communicate virtually in U.S. healthcare systems	Nurse managers of nursing service surgery line departments within a large, national healthcare system ($n = 16$)	A descriptive, exploratory qualitative design In-person, face-to-face interviews, a focus group, and survey questions on background information Statistical and inductive thematic descriptive analysis	Nurse managers' use of ICT in virtual leading and communication	Nurse managers are dependent on technology to complete all aspects of their tasks and communicate and organize. Nurse managers were often overwhelmed by the amount of emails, messages, software applications, websites, mechanisms, and devices needed to complete their tasks. Nurse managers called for personal mentorship and practical education on how to master technology use in their work effectively; they need to understand how to use the technology and the data it provides and to know how to apply the data for meaningful difference in organization and to impact patient care

TABLE 1: Continued.

Author(s), year, and country	Purpose	Participants	Methodology (design, data collection, data analysis)	Exposure of interest and outcome (PEO)	Key findings
Reference [51], Australia	To explore the perspectives of clinicians and service managers working in private mental healthcare regarding virtual reality (VR) use, including potential implementation barriers and facilitators	Clinicians ($n = 14$) and service managers ($n = 5$), aged 28–70 years working in a major private mental health hospital in Victoria, Australia	A qualitative study design Semistructured qualitative interviews Inductive thematic content analysis	The perspectives of staff in the use of therapeutic VR	To feel confident implementing VR technology, clinicians and managers identified knowledge and skills gaps; clinicians needed training in technical VR skills, assessing patient suitability, and managing ethical and safety risks, and managers needed “expert advice” to be informed about the evidence base, available hardware and software, training resources, and implementation strategies. Generally, clinicians and managers showed positive attitudes towards embracing new technologies. Staff perceived VR to be a relatively simple technology that clinicians and patients could easily learn to use, and some felt it makes clinical work easier. A service culture that values patient-centered care and innovation positively affected the staff’s overall positive attitudes to therapeutic VR. Perceived usability issues of VR systems were seen as barriers to their implementation

TABLE 1: Continued.

Author(s), year, and country	Purpose	Participants	Methodology (design, data collection, data analysis)	Exposure of interest and outcome (PEO)	Key findings
Reference [52], United States	To better understand direct care nurses and nurse leaders' perceptions of the barriers and facilitators that influence nurses' acceptance and use of remote visual monitoring (RVM) technology	Nurse leaders ($n = 6$) and direct care nurses ($n = 7$)	A qualitative descriptive study design Four semistructured focus group interviews (two nurse leader groups and two direct care nurse groups) Conventional content analysis	Perceptions of the factors related to nurses' acceptance and use of RVM technology	The content analysis resulted in five themes that addressed the barriers and facilitators to nurses' acceptance and use of RVM technology: (1) contextual human factors that impact nurse acceptance; (2) facilitators and barriers related to RVM's functionality; (3) nurse leaders' role in maintaining device availability and efficient use; (4) nurse leaders' role in promoting adoption of the technology; and (5) nurse leaders' role in valuing nursing professional judgement. Many leaders described advocating for RVM and providing education about the RVM protocol and its functions as ways to enhance its acceptance among nurses

TABLE 1: Continued.

Author(s), year, and country	Purpose	Participants	Methodology (design, data collection, data analysis)	Exposure of interest and outcome (PEO)	Key findings
Reference [53], Finland	To describe competence management in telemedicine from the perspective of health and social care frontline leaders	Frontline leaders from primary health care, specialised medical care, and social care (n = 10)	A qualitative study design Thematic interviews Inductive content analysis	Competence management in telemedicine	The interest and support of senior management were seen as important in telemedicine, and the role of frontline leaders is to support, encourage, and be positive and an example for the staff providing telemedicine. Leaders' positive attitude regarding technology and telemedicine was evident to be generally important, and leaders often run dedicated technology and telemedicine to give an example to professionals. When supporting the telemedicine provided by the professionals, leaders' characteristics such as credibility and easy accessibility were seen as important. Leaders perceived assessing professionals' competence in telemedicine to be challenging, but they recognised the different skills required for professionals in telemedicine. Good interaction between the leader and the professionals was seen as a key to successful telemedicine and competence management

TABLE 1: Continued.

Author(s), year, and country	Purpose	Participants	Methodology (design, data collection, data analysis)	Exposure of interest and outcome (PEO)	Key findings
Reference [55], Brazil and Portugal	To describe the potentialities and difficulties mentioned by nurse managers in the use of technologies in hospitals	Nurse managers (<i>n</i> = 71)	A descriptive-exploratory qualitative study design Semistructured interviews Thematic content analysis and work process theory	Potentialities and difficulties in the use of technologies	<p>The study pointed out that leaders need to be able to use different technologies simultaneously.</p> <p>Leaders pointed out that the use of technology is central to management planning and patient safety interventions and perceived that technology facilitates daily processes, communication, data collection, and the sharing of information and makes data more accessible. They highlighted the lack of training on technology and the challenges of time management in transforming data into information for decision-making.</p> <p>Leaders had time management challenges in the implementation of technology in nursing management work. They perceived that complete use of management technologies in hospitals is hindered by insufficient material resources and lack of functionality of technological instruments and saw a lack of interoperability between technological systems as a challenge. They also saw employees' lack of technology skills and knowledge as a challenge</p>

TABLE 1: Continued.

Author(s), year, and country	Purpose	Participants	Methodology (design, data collection, data analysis)	Exposure of interest and outcome (PEO)	Key findings
Reference [54], Norway and Finland	To map what experiences nurse leaders have encountered in connection with the change work that political decisions and reforms have created within the healthcare sector in the last 25 years	Nurse leaders ($n = 8$) from primary and specialist health services	A qualitative narrative study design Individual interviews with an open interview guide A four-step text condensation analysis	Experiences regarding the organizational changes	Leaders pointed out the lack of training in the introduction and use of equipment, as well as the need for training in the acquisition of computer systems and equipment. They perceived connecting and interacting on digital platforms as challenging. Leaders saw IT as a tool for acquiring new knowledge but reported having computer problems in everyday life
Reference [50], Indonesia	To explore the perceived core competencies of Indonesian first-line nurse managers within the context of the postpandemic era	Head nurses ($n = 7$) in a public hospital	A qualitative descriptive study design Face-to-face interviews Thematic analysis	Perceived core competencies	One of the four perceived core competencies was technological core competencies. Leaders perceived technological skills' improvement as a necessity and brought out the need to understand technology and how to use technological equipment, the knowledge how to use technological tools to support their work, and the need to understand online systems to be able to guide patients in their use. They also expressed the need to enable Internet access for nursing records and the ability to use information technology to find valid information. Leaders also brought out the need to participate in the creation and use of technology in management practices and pointed out that daily management relies on different technological tools and processes. Leaders reported having problems related to Internet access

TABLE 1: Continued.

Author(s), year, and country	Purpose	Participants	Methodology (design, data collection, data analysis)	Exposure of interest and outcome (PEO)	Key findings
Reference [56], United States	To investigate how nurse leaders experience using data to guide their inpatient staffing management decisions in the veterans' health administration	Veterans health administration nurse leaders ($n = 27$) across five management levels	A qualitative descriptive study design One-on-one, semistructured interviews Constant comparative method	Experiences in data usage for inpatient staffing management decisions	Leaders lacked the knowledge about data availability and perceived a lack of appropriate user education, guidance in the use of data, and support from their superiors. Leaders expressed that incomplete or inadequately aggregated data challenge the data usability and cause delays in data reporting. They also pointed out that data inaccessibility is a general challenge in the process. Poor system interoperability and data combination were reported as significant drawbacks

specialist, primary and private hospitals and health centers providing health and social care services ($n=4$), private hospitals ($n=2$), and a nursing home ($n=1$). Two studies [56, 60] included participants from national health management networks. The studies included a total of 1639 participants who were healthcare leaders in different positions and levels, such as nursing unit managers, executive directors, assistant executive directors, directors of nursing, head nurses, nurse managers, nurse leaders, charge nurses in managerial positions, service managers, frontline leaders, and chief nurse executives.

3.2. Healthcare Leaders' Experiences with Digital Competence Based on Qualitative Data Synthesis. The selected qualitative studies examined the following areas of digital competence: (1) the need for developing the leader's own, professionals' and patients' competence in the digitalisation of healthcare, (2) the leader's need for digital competence and expertise in the health IT implementation process, (3) positive perceptions towards technology, (4) negative perceptions towards technology, and (5) ability to act as an advocate to implement technology into practice (Table 2).

3.2.1. The Need for Developing Leader's Own, Professionals', and Patients' Competence in the Digitalisation of Healthcare. The first main category entailed the categories of knowledge and information needs in eHealth and health IT and the need for knowledge of the evidence base and regulatory expertise. In the study by Kujala et al. [58], leaders expressed that they cannot support their employees and patients without knowing about the new eHealth services. Leaders brought out their need to gain information and knowledge about eHealth services and their benefits and possibilities. Functionality, interoperability, usability of the eHealth services, and shortage of equipment and time resources generally in eHealth were considered challenging. According to Bezboruah et al. [57], leaders need to gain knowledge of health IT types and forms available, clinical and administrative health IT and their maintenance and potential exploitation in the facility, and health IT's challenges and benefits. They had concerns about customising the software functionality and choosing the right vendors for health IT. Moreover, leaders saw participating in technology development as one core competency area [50].

Leaders lacked knowledge about data availability and perceived there was a lack of appropriate user education and guidance in the use of data [56]. Leaders in the Bezboruah et al. [57] study lacked information regarding health IT software's usefulness, utility before, and ease of use after adoption. Insufficient information on health IT systems and their usage resulted in inadequate communication with the personnel and challenges in mutual understanding, which hindered health IT adoption. Gunawan et al. [50] report that leaders perceived technological skills' improvement as necessary. Leaders brought out the need to understand technology and how to use technological equipment, the knowledge of how to use technological tools to support their work, and the need to understand online systems to guide patients in their use. They also expressed the need to enable

Internet access for nursing records and the ability to use information technology to find valid information.

Leaders perceived that they must ensure the quality of new eHealth services [58]. In the Myllymäki et al. [53] study, telemedicine services were seen as the subject of continuous development from the leaders' perspective, so leaders evaluated telemedicine services regularly. Leaders also brought out the need to participate in creating and using technology in management practices [50]. They pointed out the lack of training in introducing and using equipment and the need for training in acquiring computer systems and equipment [54]. Leaders expressed the wish to learn new technical skills [58] and stressed the lack of skills as one reason for not using certain technologies [59]. Sharpp et al. [2] state that leaders felt that they were expected to be able to use new technologies without any introduction or training, and at the start of positioning as leaders, leaders were frustrated with learning and accessing technology. Leaders were generally confused with the number of mechanisms, websites, and software applications needed to complete their tasks. For example, to compile information related to patient safety, leaders need to access data from multiple technological sources. Additionally, Vandresen et al. [55] pointed out the leaders' ability to use different technologies simultaneously. In their study, leaders also highlighted the lack of training in technology and time management challenges in transforming data into information for decision-making. According to Simpson [60], most leaders cannot advocate for the nursing technology needs in the technology assessment process. Leaders saw that regular sharing of information digitally and in person and handling remote appointments are the primary methods they use in managing telemedicine-related knowledge [53].

Leaders stated that establishing and maintaining relationships was challenging when communicating virtually [2], as is to connect and interact on digital platforms [54], and they need to share information via WhatsApp and communicate in Zoom meetings [50]. Handling a significant amount of emails takes many leaders' time, which has been experienced as a hindrance to effective leadership. Multi-tasking was essential to keep on top of all the emails and text messages [2]. Leaders pointed out the need for expert advice about the evidence base, available hardware and software, training resources, and implementation strategies of virtual reality [51]. Leaders also stated that mentorship could ease their orientation with new technology [2], and they expressed the need to reach contact and responsible persons [58]. In using data, leaders expressed a lack of support from their superiors [56]. Lack of access to a helpdesk was seen as hindering video interpretation usage [59]. Organisations' strategic guidelines for telemedicine were perceived as a foundation supporting leaders' work [53]. Leaders were poorly informed about legal and ethical issues related to client data, information, and confidentiality [60]. According to Chung et al. [51], leaders perceived the need to develop specific strategies for promoting ethical and safe use of virtual reality. Leaders were unaware of the current evidence base regarding virtual reality [51] and lacked awareness of societal and technological trends, issues, and new developments related to nursing [60].

TABLE 2: Results of the content analysis of healthcare leaders' experiences with digital competence.

Sub-categories (<i>n</i> = 26)	Categories (<i>n</i> = 10)	Main categories (<i>n</i> = 5)
Need for information and knowledge about eHealth services		
Need for knowledge in health IT	Knowledge and information-related needs in eHealth and health IT	The need for developing leader's own, professionals' and patients' competence in the digitalisation of healthcare
Need to be able to evaluate digital service activities		
Need for training in technology	The need for knowledge of the evidence base and regulatory expertise	
Need to know how to communicate through technology		
Need for mentoring/expert advice with technology		
Need for legal and ethical competence		
Lack of knowledge on an evidence base		
Lack of implementation skills		
Lack of implementation knowledge	Lack of expertise in implementation	The leaders need digital competence and expertise in the health IT implementation process
Lack of motivation to implement health IT	Motivation and background in implementation	
Need to know how to plan and renew eHealth services		
Technologies are easy to use		
Technology is a valuable and practical tool	Positive usability experience	Positive perceptions towards technology
Openness towards technology	Positive impact of technology on activities	
Technology is necessary		
Technology improves operations		
Lack in IT functionality and material resources	Negative usability and accessibility experiences	Negative perceptions towards technology
Data availability problems	Encountering problems related to technological systems	
Poor interoperability of systems		
Challenges in data combining		
Need to have the ability to educate professionals about technology		
Need for guidance skills in eHealth	Training and guidance skills	Ability to act as an advocate to implement technology into practice
Need to take account of negative attitudes of professionals during implementation	Showing support and example	
Need to advocate for technology to professionals		
Need to support professionals with technologies		

3.2.2. The Leaders' Need for Digital Competence and Expertise in the Health IT Implementation Process. The second main category consisted of the categories needing more expertise in implementation, motivation, and background in implementation. Leaders stated the need to learn implementation and customer-centered development work and perceived themselves as needing help to plan the implementation of eHealth services [58]. To feel confident implementing virtual reality technology into the nursing practice, leaders recognise gaps in their skills and knowledge to be addressed [51]. According to Bezboruah et al. [57], some leaders implemented health IT in their institution without systematic planning before the implementation process, and in Kujala et al.'s [58] study, leaders perceived that eHealth service implementations were not monitored using measures. Leaders saw that they needed to participate in and support data integration [50] but had time management challenges in implementing technology in nursing management work [55]. Reluctance to change or limited information was the factor referred to when leaders did not implement health IT [57]. Leaders stated that institutional pressures influence health IT adoption, and some leaders said they would only implement additional health IT systems with mandates from the government [57]. Additionally, the process of implementing health IT tended to be imitated by successful counterparts. According to Simpson [60], leaders are knowledgeable in implementing information systems in the nursing practice environment. Still, in the study by Kujala et al. [58], leaders revealed their uncertainty in planning and renewing the eHealth services and operations.

3.2.3. Positive Perceptions towards Technology. The third main category consisted of categories' positive usability experience and positive impact of technology on activities. Leaders pointed out that technology is central to management planning and patient safety interventions [55] and saw IT as a tool for acquiring new knowledge [54]. Leaders reported using data for benchmarking, planning, and decision-making [56]. In the Mottelson et al. [59] study, leaders were generally satisfied with video interpretation and perceived that the technology was easy to use. According to Chung et al. [51], leaders stated that virtual reality technology is comparatively easy to master and perceived as simple. Leaders identified the potential of remote virtual monitoring to be a useful tool [52]. Also, in the Chung et al. [51] study, leaders saw virtual reality as a practical tool and positively accepted new technologies. Myllymäki et al. [53] reported that it is generally essential that leaders possess a positive attitude towards technology and telemedicine and that leaders' willingness to develop and reform telemedicine operations and their sincere interest in their employees promotes the development of telemedicine activities. Sharpp et al. [2] stated that leaders see technology as necessary for leading and cannot perform their tasks without technology. Leaders also pointed out that daily management relies on different technological tools and processes [50] and perceived that utilization and generation of data are necessary for adopting evidence-based practices [56]. Leaders saw that well-organised technology improves patient safety

outcomes, saves time and effort, and can help standardise competencies, introduce things, and improve communication [2]. In Vandresen et al. [55] study, leaders perceived that technology facilitates daily processes, communication, data collection, and information sharing, making data more accessible.

3.2.4. Negative Perceptions towards Technology. The fourth main category consisted of categories of negative usability and accessibility experiences and encountering problems related to technological systems. Leaders reported having computer problems in everyday life [54] and having problems related to Internet access [50]. Furthermore, they perceived that the complete use of management technologies in hospitals is hindered by insufficient material resources and a lack of functionality of technological instruments [55]. In the Wong et al. [56] study, leaders expressed that incomplete or inadequately aggregated data challenge the data usability and cause delays in data reporting. They also pointed out that data inaccessibility is a general challenge. Also, in the Vandresen et al. [55] study, leaders saw a lack of interoperability between technological systems as a challenge with using management technologies in hospital settings. Poor system interoperability and data combination were reported as significant drawbacks, according to Wong et al. [56]. In their study, leaders perceived the lack of intraorganizational harmonisation in software usage as a challenge in using data to guide inpatient staffing management decisions. They also saw that data system configurations challenged the timely addressing of events. Inconsistencies in data collection and reporting across different data tools were perceived to hamper effective decision-making in staffing management, as was data fragmentation. In addition, accumulating and compounding data from different data tools were experienced as time-consuming and challenging.

3.2.5. Ability to Act as an Advocate to Implement Technology into Practice. The fifth and final main category consisted of categories training and guidance skills and showing support and example. In Vandresen et al.'s [55] study, leaders saw employees' lack of technology skills and knowledge as a challenge. Kujala et al. [58] study revealed that leaders are concerned about training, engaging, and committing employees to new eHealth services. In the Hawksworth et al. [52] study, leaders saw providing education and advocating remote visual monitoring as a way to enhance its acceptance among professionals, and providing education about remote visual monitoring and advocating it to the professionals were also seen as patient safety strategies. Leaders brought out the need to guide professionals and patients in eHealth and felt that guiding different patient groups in eHealth is challenging [58]. Leaders also expressed fear of employees' resistance to change and negative attitudes regarding eHealth [58]. They felt they needed to consider employees' negative attitudes in the implementation process [51]. The leader's role includes explaining technology's effects on employees' workflow [52], and leaders often use technology

to act as an example for employees [53]. Advocating health IT systems' effective applications and functionalities to employees was hindered by the leader's lack of complete information on health IT systems [57]. Leaders' characteristics were seen as important in supporting employees in telemedicine, and good communication between leaders and employees was a key position in successful telemedicine actions [53]. Leaders' support and interest in telemedicine were seen as important for practice, and leaders' roles in telemedicine included supporting and encouraging employees, being positive, and acting as an example [53].

3.3. Healthcare Leaders' Digital Competence and Factors Associated with It Based on the Quantitative Data Synthesis. The selected quantitative studies examined the following areas of digital competence: "Use of information communication technology and computer skills [43]," "Knowledge of artificial intelligence and robot nurses [44]," "Attitudes about technology use [48]," "Informatics competencies [47]," "Technological competency as caring in nursing [45]," "Information system support for performance management [46]," and "ICT use [49]."

Data from the selected quantitative studies present that factors associated with the digital competencies of healthcare leaders include individual characteristics entailing the gender and age group, career characteristics entailing the education level, years of experience, employment position, experience in nursing administration, years of management and years of service and training entailing computer training before current status, information education/training, the experience of receiving education on caring in nursing, artificial intelligence and robot nurse courses, the experience that in-service training is constantly available, and the experience of having adequate in-service training to use information systems. Other factors associated with the digital competencies of healthcare leaders included, for example, technological knowledge, computer and software use and ownership, type of institution and speciality, user experience, and computer literacy (Table 3 and Figure 2).

From individual characteristics, gender and age are associated with the use of information communication technology and computer skills [43], knowledge of artificial intelligence and robot nursing [44], and attitudes about technology use [48]. It was evident that females' computer knowledge was lower than that of males, and the proportion of females not knowing how to use computerised patient monitoring systems was higher than that of males. Therefore, males' ICT ability was higher than females [43]. It is also evident that nurse leaders' age is significantly associated with the use of ICT; nurse leaders aged between 29 and 39 years were able to use ICT in nursing, while nurse leaders aged 50 years or older abilities were found lower, younger nurse leaders were more able to type using keyboards, use software applications for planning and making decisions, compose and send emails, use the Internet to locate and download items, and conduct other computer tasks compared to their older counterparts [43]. Ergin et al. [44] study presented a significant association between participants' gender and the belief that AI and robot nurses would be beneficial for

nursing, and it was evident that females believed that AI and robot nurses would be helpful for nursing. The study also found that older nurse leaders (aged 31–40) reported statistically significantly having heard more of the concepts of AI and robot nurses than younger nurse leaders [44]. Also, Martins et al. [48] reported that gender is significantly associated with the perception of utility and ease of use of different ICTs.

From career characteristics, education level is associated significantly with the use of information communication technology and computer skills [43], with informatics competencies [47], and with knowledge of artificial intelligence and robot nurses [44]. In the Adatara et al. [43] study, there was a significant association between nurse leaders' educational level and ICT use, and it was evident that nurse leaders with a bachelor's degree or higher education were using ICT in nursing care more than nurse leaders with lower education. In the Yang et al. [47] study, nurse leaders' education level significantly impacted their informatics competencies, which implies that a higher education level increases nurse leaders' informatics competency. Ergin et al. [44] found a statistically significant difference between the thought that AI and robot nurses would benefit the nursing profession and their educational level, presenting that nurse leaders with undergraduate degrees believed that AI and robot nurses would benefit nursing.

Experience (years/length) and the employment position were significantly associated with the use of information communication technology and computer skills [43], knowledge of artificial intelligence and robot nurses [44], and technological competency as caring in nursing [45]. Higher work experience in years was found to be a decreasing factor in ICT use among nurse leaders, and employment position has a significant association with leaders' computer knowledge, presenting that nurse leaders with higher positions have less computer knowledge compared to those with lower rank [43]. Ergin et al. [44] study presented a significant association between participants' seniority in the position and the employment position and the belief that AI and robot nurses would benefit nursing. It was evident that nurse leaders with 0–15 years of seniority in the position and position as ward supervisors believed that AI and robot nurses would benefit nursing. Additionally, the study presented a significant relationship between the idea that AI and robot nurses would replace nurses and nurse leaders' employment positions; ward supervisors did not think that robots would replace nurses [44]. Nakano et al. [45] reported a significant association between nurse leaders and nurses' technological competency in caring in nursing (TCCN). Their years of experience, presenting that a length of experience of five to less than ten years showed significantly lower TCCNI-R (Technological Competency as Caring in Nursing Instrument-Revised) scores than those with years of experience of 20 to less than 30 years.

Experience in nursing administration associated with informatics competencies [47]. This study showed that nursing administration experience negatively affects nurse leaders' informatics competencies, presenting that having more administrative experience is associated with lower

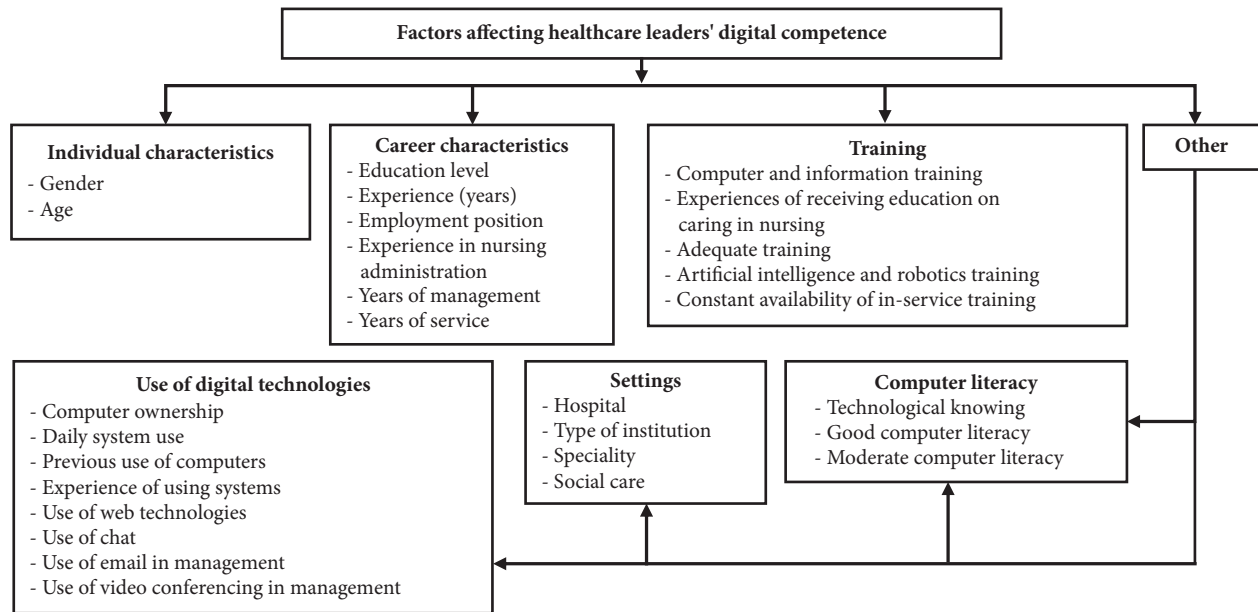

FIGURE 2: Factors affecting healthcare leaders' digital competence.

informatics competencies. Years of management and service are associated with attitudes about technology use [48]. Martins et al. [48] found significance in the perceived utility of the discussion groups, the time of experience in the services, and the usefulness of SINAI (a device to access information from other information devices) technology and time of experience in management. The results revealed that leaders with less time of service did not perceive the discussion groups as a useful tool, and this device was not considered useful among most leaders. Additionally, SINAI was also a technology not perceived as useful by leaders with less experience [48].

From training characteristics, computer training before the current position is associated with the use of information communication technology and computer skills [43], information education/training with informatics competencies [47], experiences of receiving education on caring in nursing with technological competency as caring in nursing [45], and taking courses about artificial intelligence and robot nurses with knowledge of artificial intelligence and robot nurses [44]. According to Adatara et al. [43], nurse leaders who had had computer training prior to positioning as a nurse leader possessed more knowledge of ICT use compared to nurse leaders who had not had computer training prior to the position and computer ownership and the use of computers before positioning as a nurse leader were factors influencing the nurse leaders usage of ICT. Yang et al. [47] study presented that nurse leaders' computer and informatics skills were lower than their informatics knowledge. In their study, it was evident that information education or training has a significant impact on nurse leaders' overall informatics competencies. In the experience of receiving education on caring in nursing, about half of the nurse leaders had partaken in an in-service educational activity on Technological Competency as Caring in Nursing (TCCN), and it was evident that nurse leaders were more

aware of the TCCN than the staff nurses [45]. In the Ergin et al. [44] study, there was statistical significance between the seniority and educational background and the status of taking courses related to AI and robot nurses, 0–15 years of seniority, and undergraduate degree. Saranto et al. [46] reported that the experience of receiving enough in-service training to use information systems was associated with assessing nursing performance and providing timely evaluation and reporting. Moreover, they reported that the experience of constant availability of in-service training is significantly associated with assessing nursing performance and managing resources.

From other factors associated with the digital competencies of healthcare leaders, hospital, type of institution, and speciality are related to attitudes about technology use [48], technological knowing associated with technological competency as caring in nursing [45], and computer ownership and previous use of computers before appointment as a unit leader associated with the use of information communication technology and computer skills [43]. In the perception of utilities and practicalities of different IT surveyed in the Martins et al. [48] study, the hospital type and setting were seen as significant factors, and it was evident that nurse leaders working in private hospitals perceived greater utility and ease of use of different ICTs, especially regarding e-mail, SINAI, and SISQUAL. For the perception of ease of use of e-mail, intranet, forum, Sape, Sonho, and Aida, and the perception of the utility of e-mail, discussion group, Sape, and Hepic having expertise was proven statistically important [48]. In the Nakano et al. [45] study, results from factor technological knowing showed that nurse leaders recognise the need-to-know patient needs through technology and provide care to the ever-changing patient condition more fully than the staff nurses. In the Adatara et al. [43] study, computer ownership and the use of computers before positioning as a nurse leader influenced

the nurse leaders' usage of information and communication technology.

In the Saranto et al. [46] study, good computer literacy and working in social care correlated positively with the three performance management information system features: assessing nursing performance and clinical procedures, managing resources, and providing timely evaluation and reporting. The statement "I use some systems facilitating follow-up of activity every day" is strongly associated with assessing nursing performance and managing resources, as 3 to 6 years of experience of using systems was negatively associated with managing resources. The study by Vaz and Landeiro [49] compared various technologies between the two groups of leaders from different settings (hospital center and nurse leader association). The use of web technologies, chat, e-mail, and video conferencing for any purpose, and management had statistical differences between the groups.

4. Discussion

This mixed-methods systematic review aimed to gather the most recent evidence on healthcare leaders' perceptions and experiences of digital competence and associated factors based on qualitative, quantitative, and mixed-methods studies. This review's results present that healthcare leaders' digital competence is a broad concept that includes and is associated by various factors. The original studies included in this review revealed that there is a clear need to develop healthcare knowledge and skills related to digitalisation, to improve their competence regarding digitalisation-related implementation competence, and to raise their level of education since it has been found to have an impact on their use of technology in healthcare settings.

According to the results of the qualitative analysis, there is a need to develop leader's own and others' competence in the digitalisation of healthcare since leaders expressed their knowledge and information-related needs in eHealth and health IT [2, 51–53, 57–60]. Leaders called for information about eHealth services [58], health IT [57], the ability to evaluate digital service activities [53, 58], the competence to communicate through technology [2, 53], and training about technology [2, 58–60]. Leaders also perceived that they need legal and ethical competence to acknowledge the regulatory issues in digitalisation [51, 60], and they brought out especially the lack of knowledge of the evidence base of the digital services and solutions [51, 57, 60]. Still, only a few studies included information about leaders' ethical competence in digitalisation, even though the knowledge of ethical concepts is a significant domain in digital competence [32]. Therefore, future research should aim to gain more information about leaders' ethical competence and legal aspects when utilising digital tools.

The results of this study support previous findings relating to leaders' need to receive continuous education. Training in digital health should emphasise competencies that are pertinent to specific groups of healthcare professionals, their roles, seniority levels, and work settings [32]. The enhancement of digital competence among healthcare

leaders necessitates collaborative efforts within government, educational institutes, professional organizations, and healthcare organizations. In order to produce a competent and relevant health management workforce, the current training and development directed for healthcare leaders at the organizational level and the review of higher degree teaching curricula to incorporate emerging digital competency requirements for healthcare leaders need to be changed. Reference [11].) Laukka et al. [18] conclude that leaders' education has not yet been modified to meet rapid changes in digitalisation. Therefore, leaders benefit from additional training or even participating actively in digital service development. Also, Laukka et al. [62] report that leaders may gain specific informatics skills and knowledge needed for decision-making regarding digital health services, for example, via education. In the study by Carson et al. [13], leaders' proficiency in using the EHR system was enhanced through training sessions. Strudwick et al. [10] present that healthcare organizations need to see leaders with specific informatics expertise as essential to effective health information technology decision-making, implementation, optimisation, and evaluation. Supporting leaders' digital competence development through continuous education accelerates advancement opportunities and assists in gaining an appropriate competence [5]. On this account, we recommend that the development of healthcare leaders' competence in technology use via various educational activities is necessary. Most importantly, we suggest that organizations should put effort on leaders' intellectual humility, curiosity, courage, and developmental maturity to enhance digital competence preceding concrete educational activities or training and to direct the necessary developmental activities to relevant leaders.

Our results implicate that healthcare organizations should put effort into implementing and utilising mentoring activities and expert advice [2, 51, 53, 58, 59]. The provision of mentoring and peer support also has the potential to enhance leaders' work well-being [63], yet further research on the suitable and effective mentoring methods and contents to improve healthcare leaders' digital competence is needed. Leaders' attendance in training or other methods of digital competence development is challenged by a lack of resources, such as time, expenses, or broader organizational support. Therefore, the organizations and work units should create more forceful structures and possibilities that enable the identification, evaluation, and development of leader's digital competence to encourage the use of digital technologies to their full extent and indicate a broader support system as the leaders themselves are mostly motivated towards the utilization of new technologies according to the results of our study. In a study by Kulju et al. [64], utilising a multimethod approach, supplementary materials, and opportunities for practicing new skills and exchanging experiences or inquiries seems to offer an effective strategy for delivering digital competence education to healthcare professionals. In light of our findings, we recommend that these factors could also be considered in training healthcare leaders to enhance their digital competence. Moreover, AI concepts should be woven into the curriculum of all

healthcare leaders' education programs to enhance the AI literacy and skills of leaders interacting with AI-based systems. This integration is crucial for organizations to enhance current working flow systems, navigate change, and effectively cultivate a culture that evolves with rapid technological advancements [24, 28, 65]. Yet, future research should focus on identifying the specific methods and their effectiveness on leaders' digital competence development, as there is a research gap in this area.

The analyzed qualitative research revealed that healthcare leaders need expertise in the implementation process regarding digitalisation in healthcare settings [51, 57, 58, 60] since leaders brought out the lack of implementation related skills [58], knowledge [51, 57, 58], and motivation [57] needed to implement the health IT into practice. The leaders' lack of motivation to increase the rate of use of health IT has also been recognised in other studies [66]. A review by Ingebrigtsen et al. [20] showed that leaders' IT knowledge positively affected information technology adoption. Their review presented that leaders possessing technical informatics skills and previous experience in IT project management are likely to develop a vision that creates long-standing engagement in the use of IT, are motivated in IT adoption, and are prepared for the adversities regarding implementation. Additionally, previous studies indicate that leaders' full engagement in digital health improves service implementation [62]. However, leaders need more support in role identification and do not understand the implementation procedure [67]. Senior leadership support is crucial for fostering a shared vision among various stakeholders and achieving the desired impact, for example, when implementing AI into healthcare [68]. As healthcare employees' technology acceptance, and thus indirectly their motivation to commit to the current work responsibilities, is reliant on the leader's digital competence [35], it is valuable to find relevant possibilities to improve healthcare leaders' skills, knowledge, and motivation when implementing digital health according to the findings of this review.

The qualitative synthesis revealed additionally that healthcare leaders need to be able to act as advocates to implement technology into practice [51–53, 57, 58]. According to the results, this calls for skills in training and guidance [51, 52, 58] and showing support and example to the employees by advocating for technology [52, 53, 57]. The importance of leaders' actions showing a good example to employees by using technologies in practice has also been evident in other studies [16, 18, 69] and sometimes providing training to the employees by acting as a teacher themselves [62]. Also, Kujala et al. [17] pointed out the frontline leaders' role in sharing the vision with the staff, involving them in the planning, and supporting their positive attitudes in eHealth services implementation. Our results also revealed the healthcare leaders' need to consider professionals' negative attitudes during implementation processes [51, 58], which is similar to the results by Laukka et al. [18]. As leaders' role in supporting digital technology implementation and employee's digital competence are inevitable, we suggest that leaders focus on supporting healthcare professionals through proactive mentoring to

ensure a digitally competence workforce and reinforce role clarity [70].

In our review's qualitative synthesis, leaders expressed mostly positive perceptions towards technology with experiencing positive usability of the technology [51–53, 59] and recognising its positive impact [2]. However, according to Sharpp et al. [2], leaders were often disconcerted by the variety of technologies to complete their tasks. They felt that they were expected to know how to use different technologies without introduction or training, which brought out feelings of frustration with accessing and learning technology, especially when starting in a leadership position. Laukka et al. [18] found similar results, that leaders sometimes feel digitalisation is stressful but also an easing element in their work. Moreover, in our study, leaders expressed negative perceptions concerning lack of IT capabilities and physical resources [50, 54, 55], data availability problems [56], poor interoperability of systems [55, 56], and challenges in data combining [56]. Issues with data interoperability and availability and lack of digital competence can induce several risks, such as endangering patient safety, delaying care processes, and challenging timely decision-making as part of managerial responsibilities. Therefore, we propose that leaders must be mindful of the various effects of digitalisation as part of their digital competence.

The analyzed quantitative data presented that leaders' age was significantly associated with their digital competence, implying that younger leaders could use ICT in nursing more than their older counterparts [43]. Moreover, leaders' educational level significantly impacted several researched digital competencies, implicating that higher education, more specifically, a master's degree, promotes leaders' informatics competencies [47]. Higher education positively impacts the use of information communication technology and computer skills [43], which supports our proposal for raising the healthcare leaders' educational level to increase their digital competence. Higher work experience in years was a decreasing factor in ICT use among nurse leaders [43]. More administrative experience was associated with a lower level of informatics competencies [47]. We suggest that there is a need to pay attention to developing the more experienced and older leaders' digital competence, for example, through reverse mentoring, since according to previous research, reverse mentoring is considered an effective approach in developing the senior employees' up-to-datedness with technology [71, 72]. This can potentially support the leaders' work well-being, satisfaction, and effective functioning in digitalising healthcare in their remaining years of practice yet factors such as authoritative leadership styles in different cultures may challenge the implementation of reverse-mentoring.

The quantitative data also revealed the impact of gender on the digital competence of healthcare leaders, as the results show that females' digital competencies, more specifically in computer and patient monitoring system knowledge, are generally lower than males' [43]. On the other hand, results from Ergin et al. [44] show that females are more optimistic than males about the impact of AI and robot nurses on nursing care. Moreover, one study concluded that female

leaders are more heavily influenced by the utility and ease of use of different ICTs [48]. In light of these findings, we recommend paying particular attention to developing female leaders' technological know-how yet means to change the attitude environment relating to the use of new digital solutions should be targeted more vigorously towards male leaders. Still, more research on the effect of the leader's gender on digital competence on a wider scale is needed.

5. Limitations and Strengths

Our review has some limitations. In our review, we found only one study referring to the digital competence of nurse managers in social care [46]. Therefore, our results refer only to the digital competencies of healthcare leaders. Some of the relevant studies regarding our inclusion criteria may have been left out of this review even with the systematic process to prevent publication risk and even though we searched four databases and checked the reference lists of the included studies since we left out the grey literature and limited the timeframe and language to English or Finnish. In this review, conducting a meta-analysis was impossible; however, tabulation and data synthesis supported the reliability of the presented data of the chosen studies. Each chosen study's quality assessment uses the JBI quality appraisal tool. One study [59] scored lower than 50% in quality assessment but was still included in the final data synthesis. The sensitivity analysis by excluding that one study was not possible according to the chosen data synthesis methodology. This review summarised the results of studies conducted in different countries. There may be differences in the digitalisation of social care and healthcare between these countries, which need to be recognised in results' generalizability. The PRISMA 2020 statement: a guideline for reporting systematic reviews was used to increase the transparency of this report [73].

6. Conclusions

The results of this review indicate that healthcare leaders must possess a wide range of digital competencies to work effectively in the constantly developing healthcare environments. Considering the geographical diversity of the articles incorporated in our review, we can infer that the digital competence of healthcare leaders holds worldwide significance in healthcare management. The research discussed in this review suggests that developing and supporting leaders' digital competencies should be considered in healthcare organizations, research, and education to meet the demands of increasingly digitalising healthcare development work. We see leaders' mainly positive attitudes towards digital competence as a favourable factor for their competence development. So, we are suggesting that leaders should embrace an active role and take responsibility in actively seeking opportunities where their digital competencies can be improved. Simultaneously, leaders should be mindful of the pitfalls of digitalisation's effects and challenges and reflect these aspects as part of their digital competence. We suggest that to increase healthcare leaders'

digital competence, healthcare organizations should prioritise the development of policies, structures, and processes to ensure effective design, planning, and implementation of innovative adoption while also dedicating financial resources to support management workforce development.

We also propose that healthcare organizations should develop different models and practices to reinforce and transfer leaders' digital competencies through various activities. In-house training should focus on the specific digital systems to be implemented in the organization before their roll-out, and continuously available user support should be provided. The training should aim to increase healthcare leaders' digital skills needed in their daily work and a comprehensive understanding of the benefits and disadvantages of digital tools in supporting patient-centered, effective, and evidence-based care in digitalised healthcare. Prior to education, leaders' developmental maturity should be investigated to avoid potential waste or inefficient use of resources. We propose that data interoperability and accessibility issues be identified and resolved at the organizational level to help healthcare leaders work in digital environments. As our results showed, leaders' education level significantly impacts their digital competencies, and digital competence should be considered in the curriculum of healthcare leaders. With the increasing use of AI in healthcare, we see that the AI perspective needs to be taken into account as part of healthcare leaders' digital competence, both at the educational and organizational level. In terms of further research, more information is needed on leaders' ethical and legal competencies as part of digital competence and the complexities of introducing AI-based systems to healthcare practice. We also recommend future research to investigate interventions that can support digital competence development of more mature leaders effectively and comprehensively since their digital competencies were found to be lower than those of their younger counterparts.

Nurse-led digital transformation promotes nurses' participation and leadership in digital health. It also aims to improve the quality of care and patient satisfaction. The objective is to describe the priorities of nursing managers in the field of digital health and their beliefs related to the digital transformation led by nurses. The methodology used is a qualitative-descriptive study. The data were collected by means of the implementation of playful-reflective workshops. Open and/or closed questions were used, to which participants responded using their mobile phones, by capturing QR codes. A group of 32 nursing managers from the Spanish private hospital sector were invited to participate by means of purposive sampling. Data were analysed using the Braun and Clarke thematic analysis performed by two researchers independently. Of the 32 participants, 25 were women. The average age was 38 years. The main utility of the use of technology in health environments that they noted was innovation, followed by communication. Another utility mentioned repeatedly was that of visibility, considering digital media as a way to show the population the role of a nurse. They also noted time savings and error reduction. Moreover, as barriers to the implementation of technology, participants pointed out the lack of skills or equipment, institutional support, and the care burden. This study shows that nursing managers are aware of the need and benefits that nurse-led digital transformation can bring about. These findings can pave the way for promoting a nurse-led digital leadership culture.

1. Introduction

Digital health or e-health is not only a trend or a fashion but also a necessity that healthcare professionals must incorporate into their daily practice to establish new channels of communication with the patient and society, as well as to maintain lifelong learning and build knowledge with other professionals and institutions globally [1, 2]. Digital health is defined by the WHO as the cost-effective and safe use of information and communication technologies in support of health and related areas, including clinical care services, health surveillance, health literature and health education, knowledge, and research [3]. In this regard, public and private organizations implement e-health systems in health centres and among health professionals as a way to reach the patient, save costs, streamline procedures, etc. [4–6]. The

benefits of digital health for patients have been promoted in numerous publications in recent years, either in the form of exchange communities [7–9] or at the individual user level [10–13]. Digital health literacy can be seen as a useful tool for health education, promoting healthy lifestyles, reducing complications, or monitoring patients with chronic diseases [14, 15]. This is especially relevant in times of uncertainty like what happened during the COVID-19 pandemic, where not only cost reduction or immediacy was crucial but also protecting patients by minimizing unnecessary visits to health centres was crucial [16, 17]. In this sense, authors such as Fronczek et al. consider that the arrival of the pandemic has nurtured nurses' use of the Internet and social networks as an amplifier of their voice, a way to reach communities easily and quickly, influence health policies, and exercise active leadership [18]. In fact, nurses are in a privileged place

in the health system because they are the most numerous professionals in all health systems worldwide and have an important role in patient education and follow-up. Nurses, through their work, contribute to improving patients' ability to understand and use health information for their own health [19]. However, while the use of digital media implies a proactive and positive attitude, it also requires training; few healthcare systems are committed to the lifelong training in digital skills [20] although successful implementation requires, especially, institutional support [21]. The incorporation of technology in patient care is the responsibility of the system as a whole and cannot depend only on the goodwill or interest of professionals, and it must be supported by institutions and collegiate organizations, as well as regulated by the state at a higher level and included in the national curriculum [21, 22]. We have rephrased the sentence "This is especially relevant . . . health centres was crucial" for clarity. Please confirm that this is your intended meaning.

Nurse-led digital transformation (NLDT) is an approach that focuses on the participation and proactive leadership of nurses in all facets of digital health [23]. This transformation is a journey of improvements and changes that focus on patients, practice, and education. NLDT incorporates digital tools to improve the quality, safety, and integrity of nursing care. This includes the use of innovative technologies such as robotics, telemonitoring, and the use of mobile applications or devices to improve the quality of nursing care [24]. Therefore, this digital transformation aims to improve the quality of care and it increases patients and nurses' satisfaction [25].

In Spain, it is known that the lack of institutional support is an important barrier when applying technology in nurse practice [20]. Internationally, several authors also point to healthcare organizations as responsible for facilitating resources and spaces for the use of technology, as well as providing healthcare professionals with the time and opportunities to learn how to use them [21]. This is especially relevant for nurses who have not received training in this area during their undergraduate studies [22]. As our previous studies were based on nurses without management positions, we consider in this case that the institutions are led and managed by managers, and therefore, it is interesting to know their vision on this issue. However, the beliefs of nurse managers regarding digital transformation and the professional use of such technology are not well known yet. Therefore, the objective of this study is to describe the phenomenon of digital transformation led by nurses from the perspective of nursing managers. A detailed understanding of this new area of nursing will identify barriers, limitations, facilitators, and possible applications, helping to offer possible solutions to integrate technology in the field of care. This study is a starting point when focusing on identifying the weaknesses and strengths of NLDT. Only by being aware of these limitations will nurses be able to advance in professional development, including care in the digital world as part of new skills [26].

2. Materials and Methods

2.1. Study Design. This study used a qualitative-descriptive design. This type of study provides a detailed description of the bias aspects of events or experiences from a subjective perspective [27]. In addition, a qualitative-descriptive design allows capturing the richness and complexity of the phenomenon under study [28] and provides a complete and detailed description of a phenomenon without extensive interpretation or theorization [29]. The research followed the Consolidated Criteria for Reporting Qualitative Research (COREQ) [30].

2.2. Participants and Instruments. The study involved nursing managers from private hospitals in Spain. Their participation formed an integral component of a voluntary training initiative offered by their respective institutions. The present study undertook a qualitative examination of the data collected, specifically pertaining to the digital transformation spearheaded by nurses. The data were collected through the facilitation of playful-reflective workshops. These workshops were designed as collaborative workspaces, engineered to foster collective engagement and reflective inquiry within work-play-reflection sessions. Such sessions are meticulously structured, incorporating a diverse array of participatory tools [31], with group dynamics and techniques meticulously tailored to align with a central theme and objective [32]. Both open-ended and closed-ended inquiries constituted the framework for data elicitation, with participants leveraging their mobile devices to respond via a QR code embedded within the presentation materials. Further elaboration on the utilized tools and their respective functionalities is detailed in Table 1.

Table 2 shows the questions asked, as well as the tool used, and a brief explanation of the mode of question or activity used. The questions included in this study are of our own elaboration, based on the results obtained in previous studies. For the questions about competencies, the authors have followed the digital competency framework established by the Spanish Ministry of Education [33].

This type of tool has already been used in previous studies in qualitative research contexts for the collection of opinions and generation of subsequent debate among professionals [34–36] and also with patients [37].

For ideas and the generation of group work, Miro is a useful option to foster collaboration among students, giving them a workspace to generate ideas freely and share resources [38]. In addition, Miro boards encouraged creativity and promoted a collaborative, meaningful learning experience [39]. Each response was coded by assigning a number to each participant to make it easier to work with the data.

2.3. Data Collection. The health system in Spain is a system in which public hospitals (financed 100% by the State) and private hospitals (financed by private capital) coexist and even collaborate. These private hospitals serve patients who

TABLE 1: Tools used and functionality.

Digital tool	Justification and usefulness
Slido https://www.slido.com/	This tool allows you to make questionnaires with different types of questions that can be answered interactively from a mobile phone. In this case, it was used to collect open answers. The answers are obtained anonymously and are displayed on the classroom screen, which allows interaction and discussion later during the session
Mentimeter https://www.mentimeter.com/	This tool also allows interactive questionnaires that attendees can answer from their phone. The questions used in this case were the word clouds (to start a topic or extract information about what most interests the group), test questions, and the visual scale (to perform group comparisons)
Miro https://miro.com/	This tool allows working in groups visually using brainstorming techniques, design thinking, canvas model, etc. In this case, brainstorming was used for collecting group ideas and later the bull eye diagram for prioritizing ideas

TABLE 2: Questions and modality used.

Question	Tool and type of question
<i>Applicability of technology in nursing</i>	
In short, what can technology be useful for?	Mentimeter Word cloud
What is nurse-led digital transformation for you?	Slido Free written reply
What possible uses could we give to technology in your hospital/service?	Miro Group brainstorming and brainwriting
Which of these ideas would you carry out first because you consider it a priority?	Miro Bull eye diagram for prioritizing ideas in a group
<i>Digital skills of nursing managers</i>	
I would say that I manage (on a scale of 5 points, being the worse mark—1 and the best mark—5) in:	
(i) Social networks	Mentimeter
(ii) Searching for quality information	Likert scale
(iii) In content creation: videos, blogs	
(iv) Safety issues in the network	
Which of the digital competences do you consider most useful for nurses' functions?	Mentimeter Sort through
<i>Constraints, barriers, and future expectations</i>	
If you could have super digital power, what would it be?	Mentimeter Short answer
Are nurses prepared to care in technology? (yes/no/I don't know)	Mentimeter Test type question
What barriers or limitations do we have to apply technology as a collective/individual level?	Mentimeter Short answer

pay to receive benefits and patients referred from the public system who do not pay to receive assistance, due to agreements with the State. Private hospitals in Spain represent 56% of all hospitals. The data collection phase was overseen by the principal researcher, a female PhD holder, who assumed the role of instructor during the face-to-face course conducted between November 2022 and January 2023. These instructional sessions were held within the academic confines of a university situated in Madrid. Engaging in this initiative were nursing managers actively partaking in a voluntary lifelong learning endeavor facilitated by their respective private hospitals spanning Spain. Noteworthy is the diverse spectrum of professional

experience exhibited by these nursing managers in their roles. The duration of the session extended to four hours of intensive face-to-face training. Participants were apprised at the outset of the training regarding the qualitative analysis awaiting their submitted exercises, integral to the current study. Full elucidation regarding the study's objectives and procedures was provided. Participants were accorded the autonomy to determine the inclusion of their exercises in the study, with no repercussions ensuing from their decision. It is worth noting that all participating nursing managers consented to and expressed satisfaction with the incorporation of their exercises as primary data for this qualitative inquiry.

Data collection ended once the data saturation was reached [40]. Data saturation in qualitative research refers to the point at which gathering additional data no longer yields new or insightful information or perspectives related to the research questions or objectives [41]. It signifies that the researcher has obtained a comprehensive understanding of the phenomenon under investigation, and further data collection would not contribute substantially to the richness or depth of the findings. In practical terms, reaching data saturation implies that recurring themes, patterns, or categories have emerged consistently across the collected data, and new data points are unlikely to introduce novel insights or perspectives [42]. In the context of this study, which involved the analysis of exercises created by participants in a leadership workshop designed for nursing managers, saturation manifested in a manner that differed from the conventional paradigm. Saturation was deemed to have been achieved when the exercises ceased to proffer novel insights, and the analytical process left no inquiry or reflection unaddressed.

Prior to the face-to-face sessions, detailed information on the study was provided to participants by e-mail. Those who agreed to participate received new written and oral information and were given a space to clear up any doubts before signing the informed consent. Participants did not receive financial compensation for their participation. No data were collected that could reveal the identity of the participants. The data were treated confidentially with access only to the investigation team. The study was conducted according to the ethical and legal rules of the Declaration of Helsinki and the Good Clinical Practice of the European Union. This project was approved by the Ethics Committee of the Catholic University of Valencia with the code UCV/2022-2023/001. None of the invited participants refused to participate or dropped out.

2.4. Data Analysis. The research team entered the data into a database for subsequent thematic analysis, following the method proposed by Braun and Clarke [43]. For a correct triangulation of the data, that is, to verify and compare the information obtained by collecting data in different methods and sections [44], the textual elements were reviewed, and their categorization was carried out, later, by a second researcher. In this way, data analysis expanded, deepened, and reduced the possibility of misunderstandings, thus clarifying the meaning and veracity of the information obtained in the testimonies. Finally, the resulting report was discussed with the research group and, through reflective thinking and critical reasoning, changes were made until a consensus was reached.

2.5. Rigour. To ensure the credibility, transferability, dependability, and confirmability of the study, Guba's criteria were meticulously applied throughout the research process. This involved a collaborative effort between two experts well-versed in e-health and qualitative methods. Each expert independently reviewed the assigned codes, themes, and interview quotations, with any discrepancies resolved

through discussion. Additionally, to mitigate the risk of misinterpretation, a native editor/translator conducted backtranslation. Continuous discussion and reflective thinking among all researchers at every stage of the study contributed to its rigour, credibility, and overall trustworthiness.

The methodological strategies employed in this study aligned with established practices for data trustworthiness, encompassing an audit trail, bracketing, coding checks, categorization, continuous feedback, ongoing data interaction, participant confirmation, peer debriefing, structural corroboration, and referential adequacy [45, 46]. The iterative process of data translation involved persistent discussions within the research team to safeguard data integrity [47]. Upholding the authenticity of meaning during dissemination [48] was ensured through the rigorous review of source and target language codes, categories, and exemplar quotes by three external bilingual experts. Additionally, the study's credibility and consistency were maintained by providing a detailed description of the data collection process and documenting results with quotations from the transcripts. Furthermore, findings underwent scrutiny and verification through consensus meetings involving the research team and two experts specializing in qualitative research and gender identity issues.

3. Results

Thirty-two nursing managers from private hospitals participated, of whom 25 were women. The average age of the participants was 38 years old. The centres in which they work are located in different geographical areas of Spain: Andalusia, Valencia, Catalonia, Madrid, Canary Islands, Basque Country, and Galicia. Thematic analysis of the data identified four themes:

- (a) Utility and concept of NLDT
- (b) Essential and advanced digital skills
- (c) Barriers to NLDT
- (d) Immediate applicability of the NLDT

This is a group of participants who identify themselves as users with moderate-advanced skills in the use of social networks and in the search for digital information, with moderate-competence in digital security issues, which are self-described as beginners in the field of digital content creation.

3.1. Utility and Concept of NLDT. From the speeches of the participants, the digital transformation led by nurses could be defined as the set of digital tools that allow nurses to facilitate their daily work, especially in the area of communication and improvement of clinical records, which is beneficial for both patients and professionals. The main utility attributed to the use of technology in healthcare environments is innovation, mainly associated with communication. The technological tools are described as elements that allow a rapid and agile dissemination of information, thanks to which it is possible to unify criteria

that allow the progress of the implementation of unified registries. In short, according to the participating nurse managers, the use of information technologies allows them to give visibility quickly and effectively to certain interventions that, indirectly, improve professional and patient safety and contribute to optimizing key resources such as time.

Figure 1 shows an example of a word cloud, in this case, related to the question of the usefulness of the technology.

“I believe [NLDT] is the development and application of digital media in the world of nursing. It is that the staff of the world of nursing can create, develop and give visibility to our collective and serve us as a working tool.” (Participant 3)

“[NLDT] is the application of new technologies integrated into nursing work as a vehicle for improvement and innovation. It consists of adding digital tools to our work to improve results and communication.” (Participant 11)

One of the benefits that also emerges recurrently in the responses of the participating nurses is the visibility of the profession, considering digital media as a way to show the population what the role of the nurse is and strengthen their professional identity.

“[NLDT] is giving more vision to the profession through digital media.” (Participant 7)

“[NLDT] is to bring the nursing world to users through the digital world, publicising the work of the nurse.” (Participant 8)

3.2. Essential and Advanced Digital Skills. In the workshops, participants were asked to agree on the essential digital competence for the professional performance of nurses. Communication is again identified as the first option, accompanied by collaborative actions. The group then decided that the next essential digital competence for nurses was information and digital literacy, and ultimately skills related to solving technological problems, Internet security, and digital content creation.

“[NLDT] is a change in management by means of digital platforms or applications to facilitate access to everything, being nurses who guide or define users’ needs.” (Participant 2)

“We need to have digital tools for the day to day of our profession and update the practice of nursing and new technologies.” (Participant 9)

These results make sense when the group is asked to discuss which area they would like to have advanced skills. In this case, it highlights the need to improve the use of computer programs, create apps, solve technical incidents, and know how to create digital content.

“[I would like] to have more knowledge in the field so that I can put it into practice and teach others.” (Participant 13)

“[I would like] to create apps that I can use in my daily practice of my profession.” (Participant 22)

3.3. Barriers to NLDT. The barriers identified by the group for the regular use of digital technology for nurses were mostly ignorance or lack of the necessary tools and skills. The participants point out that they do not have a favourable infrastructure, which also refers to institutional culture and the feeling of belonging to the institution. In this respect, they indicate that an adaptive process is necessary to allow the incorporation of these new competencies but that the current reality of the system and the age of many professionals do not ease such adaptation. Similarly, a considerable number of participants indicated that the current care burden is not compatible with the acquisition of new skills such as ICT.

“Having an idea, but not knowing how to develop it due to a lack of knowledge of technological management. In addition, there is a lack of computer devices in the workplace to enable their development.” (Participant 17)

3.4. Immediate Applicability of NLDT. As participants engaged in lively brainstorming sessions, the rich tapestry of ideas surrounding the integration of digital technology within hospital environments began to unfold. A plethora of insights, totalling over 150, emerged, encapsulating the collective wisdom and foresight of nursing managers. Amidst the flurry of ideas, several overarching subthemes emerged, shedding light on the multifaceted potential of digital innovation in healthcare settings. From the efficient management of personnel to the seamless integration of newcomers, participants envisioned a future where digital solutions would revolutionize the administrative landscape of hospitals. In the realm of patient care, the concept of geolocation and waiting time optimization emerged as a central theme. Participants passionately discussed the possibility of utilizing digital tools to enhance patient tracking and streamline waiting times, thereby ushering in a new era of efficiency and patient-centred care.

“I’ve been considering the advantages of a mobile app for tracking patients in the hospital. It could provide peace of mind to families by updating them on their loved one’s location, whether in the ER, getting X-rays, or in surgery, fostering a deeper sense of connection and support.” (Participant 15)

“I’ve been reflecting on ways to improve patient admissions at our center. Imagine the convenience of bypassing long queues with a robotic admission system or similar technology. It has the potential to transform the patient experience, minimizing wait times and streamlining admissions for a more efficient process.” (Participant 23)

implementation of technology. Along the same lines, there are authors who point to collaboration as a driving force behind the adoption of digital tools [49–54]. It is evident, therefore, that communication and digital collaboration are competencies considered fundamental for nurses nowadays since they can allow them to advance in their professional and personal development. This could be due to the infinite possibilities offered by social networks and digital tools in a globalized and connected world to contact other professionals and learn from these exchanges. However, it is important to bear in mind that a significant digital division remains and that there may be significant differences due to generational, cultural, or even resource availability issues.

In this study, we observed how participants consider the use of technology as a priority for monitoring and follow-up, improving management, process performance, quality, and safety. These benefits coincide with those already obtained in other studies on this subject [55] and with publications that indicate that nurses need these skills to provide safe care to patients [22, 56]. It is clear that these benefits and concerns regarding the quality and safety of patients are a common point among management nurses, regardless of the context in which they work.

As shown in this research, nursing managers highlight barriers to the use of new technologies such as a lack of skills, as well as the high care burden and lack of institutional support. These reasons have already been contrasted in another previous research carried out by the authors in similar contexts [57]. Some authors also mention possible causes such as professionals not integrating ICT in their practice, a lack of time [58] as well as a lack of digital skills and competencies [59, 60]. The lack of institutional support and the low level of training that professionals receive make the gap between the demand of the population and the supply by health workers even more complex [21]. In the specific case of Spanish nurses, the lack of time is a real problem as it is far below the ratio of other countries according to the WHO, the OECD, and the General Council of Nursing [61].

It is interesting to note that, in this study, nursing managers consider the use of digital tools to accompany and train new nurses entering hospitals very useful. According to Sharpp [62], these tools would be an engine to generate motivation and even boost new leaders: leaders who promote relevant changes, bearing in mind that true leadership is someone capable of creating healthy work contexts, promoting self-efficacy, and motivating nursing leadership [63]. However, the state of digitalization in health varies considerably between European countries [64]. In Spain, only 44% of studies in nursing include training in digital competence in their curricula [1]. In other countries, such as Finland, public guidelines have been implemented in this area since 2015, helping to improve the level of digital competence of nurses [56]. Therefore, it would be advisable to have educational policies that integrate this competence transversely and continuously in the training of future nurses.

This research shows that nurse managers do not usually create digital contents and that they do not have competence in this area although they would like to have them as they

consider them useful. Along the same lines, a quantitative report was published by the Signo Foundation in health managers in Spain [65]. This report also noted the participants' low content creation competence although in this case, only 12% were nursing managers. In this regard, Korte et al. also referred to the importance of nursing managers to generate engagement in the implementation of new technologies. In fact, this author points out that *Management actions can provide a structural framework and training so that nursing leaders can ensure their staff's engagement in using unknown devices, too* [53].

It is important to note that digital resources are powerful tools for the monitoring of people with chronic pathologies [66], and they can be used to understand the behaviour of patients in relation to health [67, 68] and be useful to educate the population and offer quality healthy advice [69]. Some authors, such as Rubel [70], insist on the need for professionals to lead the creation of quality content for patients, thus avoiding misinformation. However, the authors consider it essential that patients actively collaborate in this process of creating digital educational content, as other authors have [71].

This study presents a number of limitations that must be taken into account. The main limitation that can be cited in this study is the collection of data in groups. This data collection technique has advantages and disadvantages that should be assessed by the research team. In this case, we opted for group techniques given the active and creative dynamics of the activities, always looking for a summative discourse. With all participants holding similar positions, it was thought that there would be no hierarchical differences limiting speeches. The fact that all participants were managers in private institutions could also be indicated as a limitation. However, the fact of coming from different geographical locations within the country brings considerable richness to the data since the experiential discourse becomes summative given its heterogeneity. It is important to note that 78% of the participants in this study are women, which may not represent the reality of other institutions or geographical areas. According to WHO, only 25 per cent of senior positions in health organizations are held by women nurses [72].

5. Conclusions

This study shows how nursing managers value the NLDT positively. In fact, they consider digital tools to be useful for improving the safety and efficiency of nurses' work and, in addition, they underline their impact on improving the visibility and recognition of the profession at a social level. Along the same lines, managers consider that the most important competencies for the nursing profession are communication and collaboration. Despite the managers' identification of all these positive factors, they also mentioned factors that hinder digital leadership, such as the lack of digital competencies, the high burden of care, and the lack of institutional support. It is expected that the results obtained in this analysis will be useful to establish a basis for future studies, which could include mixed methodologies

with a multicentre approach to identify and understand the barriers and facilitators faced by nurse managers when implementing technology in clinical services. This could be the starting point for educational, institutional, and monitoring proposals for technology integration to promote digital transformation and nurse leadership in this area. The nursing manager must be sensitive to NLDT, focusing on care, also in the digital environment, on professional-patient collaboration, giving the latter a leading role. Therefore, we recommend the use of participatory action research and other participatory qualitative methods by managers and nurses when designing materials, resources, and campaigns in the digital and technological environment.

Background. Few studies have analyzed the negative outcomes of disruptive behaviors in the nurse-physician relationship in patient care and their impact on patient safety. These multicausal studies significantly relate to organizational, institutional, and professional attitudinal risk factors. **Aim.** Analyze healthcare professionals' perceptions of disruptive behavior and factors associated with patient safety climate in the nurse-physician relationship at the hospital level. **Methods.** A multicenter cross-sectional study was conducted with a sample of 370 nurses and physicians assigned to different public hospitals in the Murcia/Spain region, applying the adapted and validated Spanish version of the Nurse-Physician Relationship Scale: Impact of Disruptive Behavior on Patient Care. The analysis used proportions or means (standard deviation (SD)), univariate and multivariate linear regression models, and the chi-square test. **Results.** Disruptive behavior was more prevalent in the ICU (81.6%) and the emergency department (67.8%). Professionals indicate that fear of reprisals is the main barrier to the reporting system. Likewise, stress and frustration are more associated with disruptive behavior and influence the safety climate. **Conclusion.** Professionals indicate that disruptive behaviors can have a negative impact on clinical outcomes. Age and type of service were identified as the most relevant socio-occupational factors. Stress, frustration, and communication problems are the factors that most influence the safety climate.

1. Introduction

The healthcare industry is considered one of the most complex sectors in the world, alongside aviation and nuclear energy. Labor relations within healthcare systems are especially noteworthy, as they contribute to an environment that is more susceptible to risks and failures. Furthermore, the likelihood of failures increases with the complexity of a system [1]. Interprofessional relationships between healthcare professionals are crucial in developing strategies to reduce disruptive behaviors and improve patient safety. Before this investigation, we conducted a systematic review to identify disruptive behaviors in nurse-physician

relationships and their impact on patient care [2]. However, we found limited international studies and none conducted within Spain's healthcare domain. This indicates a significant gap in the literature on disruptive behaviors in nurse-physician dynamics. Therefore, further research is necessary to understand healthcare personnel's perceptions of the factors contributing to disruptive behavior and areas that require improvement to prevent such behavior.

There is no consensus on the definition of disruptive behavior and safety climate. Nevertheless, this study aims to contribute to resolving this issue or advancing current knowledge. Concerning disruptive behaviors, we define them as actions that impede interpersonal communication,

strain work relationships, and hinder the sharing of crucial information among professionals, thereby directly impacting the quality of the care process [3, 4]. According to the patient safety culture [5], disruptive behaviors can lead to errors in the care process. Our study defines safety climate as how organizational factors influence the safety culture perceived by professionals and institutions [6, 7]. Specifically, patient safety culture is a strategic focal point to encourage healthcare professionals to adopt attitudes and behaviors that encourage patient safety [8]. Moreover, it fosters a nonpunitive environment in which individuals at all levels of an institution or organization (including caregivers, managers, and administrators) pledge to improve patient safety by promoting error reporting as a source of learning rather than blame [9, 10]. Cooper et al. stress the significance of fostering an organizational culture that esteems professionals, caregivers, managers, and administrators who adeptly navigate ethical conflicts impacting the quality of the care process. This culture encompasses effective communication (encompassing behavior management, staff safety status, and attitudes) and procedures (encompassing participation in decision-making, adherence to protocols, and task allocation) [11]. The perception of an unfavorable environment can lead to behaviors associated with horizontal violence, which negatively impacts patient safety [5]. On the other hand, creating a safe environment that promotes an improved safety climate can positively influence professionals' perceptions of workplace safety, leading to more favorable attitudes and behaviors toward patient safety. Research indicates a notable reduction (76%) in adverse event rates associated with such improvements [9, 12].

Many factors that cause disruptive behaviors are closely related to patient safety culture, particularly communication and teamwork. These factors significantly influence compliance with safe work practices [13] and healthcare professionals' perception of a safe environment [14]. Disruptive behaviors may be linked to low job satisfaction due to poor work relationships and co-worker communication [15]. Organizational risk factors at work [16], which include various aspects such as strategies, behavior, and attitudes adopted by healthcare centers to improve the safety environment, can influence professionals' perceptions. The attitudes and approaches of institutional managers and professional burnout can significantly affect emergency nurses' satisfaction and quality of work life.

For a long time, healthcare professionals and institutions did not openly acknowledge disruptive behaviors or measure their impact. In 2001 and 2002, the American Association of Critical Care Nurses (AACN) recognized the need to address the working relationships between nurses and management physicians. They emphasized the importance of establishing a reporting system for disruptive behaviors in healthcare facilities. They stated that such behaviors could not be ignored because they disrupt the workplace and can lead to unpleasant incidents and possible workplace accidents [17, 18]. In 2005, disruptive behaviors were observed to affect patient care and attention [19, 20]. In 2004, the Institute for Safe Medication Practices highlighted potential

risks to patient safety due to the approach to medications. They stated that the disruptive behavior of some physicians inhibits nurses from asking questions or providing information about the use of drugs. This behavior is labeled "dangerous silence" and can be interpreted as abusive behavior by some physicians that prevents nurses from answering questions or seeking clarification [21]. In 2008, Rosenstein et al. [22] found that healthcare professionals identified disruptive behaviors as a cause of adverse events that disrupt the chain of patient safety. In 2012, the same author emphasized the connection between disruptive behavior and patient safety. The study revealed that nearly 33% of physicians and nurses believed that these behaviors could lead to adverse events, and, more alarmingly, 12.3% of them were associated with an increased risk of patient mortality [23].

Disruptive behaviors generate vertical workplace violence and are considered a public health problem with global repercussions, affecting the entire healthcare system in its multiple spheres and levels [24]. As part of its healthcare quality accreditation process for healthcare institutions, the Joint Commission has made it mandatory for institutions to implement policies that address disruptive behavior. These policies should be based on human capital prepared to handle the complexity of the healthcare environment. The aim is to prevent and control factors associated with disruptive behavior while ensuring patients' safety and protecting healthcare professionals' occupational health (physical, mental, and emotional) [25]. This study aims to analyze healthcare professionals' perceptions of disruptive behavior and factors associated with patient safety climate in the nurse-physician relationship at the hospital level.

2. Materials and Methods

2.1. Study Design. A multicenter cross-sectional study was conducted to assess the perceptions of healthcare professionals at the hospital level about disruptive behaviors and factors associated with the patient's safety environment. The research was conducted at the hospital level within the network of public hospitals in the Murcia region. This region encompasses nine referral hospitals, each corresponding to one of the nine Health Area Managements of the Murcian Health Service. Specifically, this study was conducted in five of the nine referral hospitals.

2.2. Participants. The sample consisted of nurses (direct care), administrative nurses (indirect care/management), physicians (direct care/management), and administrative physicians (indirect care/management) assigned to different clinical and surgical services.

The study included all physicians and nurses working in public hospitals in the Murcia region, Spain, who met the following criteria: (a) had a contractual relationship (permanent/interim) with any of the hospital services, (b) had worked for more than a year in the service/unit and job position, (c) were Spanish or naturalized citizens and belonged to different work shifts, and (d) agreed to

participate in the study. We excluded professionals with temporary contracts or on standby (holidays or temporary leave) because these contracts were subject to short periods in the same department/unit/plant and high staff turnover, which could bias the perception of the safety climate and work relationships.

The professionals were identified based on the hospital's human resources lists.

2.3. Procedure. During the study period, from January to July 20, 2022, a researcher was responsible for providing and collecting evaluation instruments. The researcher personally delivered each instrument to participants and explained the importance of their participation in the study. No personal data were included in the instrument to ensure anonymity and confidentiality. Participants were instructed to complete the scales and group them by units/services. The completed scales were collected and sealed in an envelope. In April 2022, a reminder intervention was conducted to increase the response rate.

2.4. Measurements. The instrument used was the Spanish version of the original "Survey on the nurse-physician relationship: The impact of disruptive behavior on patient care" [25]. This scale was cross-culturally adapted and validated for use at the hospital care level in Spain. [26]. In this study, the scale obtained a Relevance Index (RI) of 0.89 and a Pertinence Index (PI) of 0.94. The RI and PI values were both below 8, which was considered acceptable for each item and for the scale as a whole. Most of the items in the scale showed a moderate to almost perfect level of concordance between responses (16 items). The Intraclass Correlation Coefficient (ICC) values for these items were equal to or greater than 0.75, indicating excellent reproducibility. Additionally, all items in the scale showed a general agreement index of 100%. The scale is made up of 21 items. In the first part of the scale, the socio-occupational variables are presented: age, sex, service, and position (nurse and clinician or administrative physician). The latter was identified as nurse and clinician, which defines professionals who spend 50% or more of their working day in clinical tasks/direct patient care, and nurse and administrative/managerial physician, which represents professionals who spend 50% or more of their working day in administrative tasks/indirect management. Items 1 to 9 assess the perception of the environment, specifically the safety climate, in the relationship between nurses and physicians, addressing the presence and frequency of disruptive behaviors in different services and specialties. However, items 10 to 17 focuses on assessing the perception of the impact of disruptive behaviors on patient safety, considering various psychosocial aspects, adverse events, and dimensions such as communication and information. Items 18 to 21 focus on assessing the reporting system for disruptive behaviors and barriers that may hinder its effectiveness (Supplementary Table S1). This scale provides a comprehensive measure of the perception of disruptive behaviors in the relationship between physicians and nurses and their impact on patient care.

2.5. Data Analysis. Each item on the scale was used as a variable to assess healthcare professionals' experiences of disruptive behavior in the physician-nurse relationship and its impact on patient care. No missing data was present as we discarded incomplete questionnaires. This upheld data integrity for accurate analysis.

Proportions or means (standard deviation (SD)) were used to describe the participants' characteristics and the questionnaire's items. Univariate and multivariate linear regression models were used to analyze the perception of the environment of the physician-nurse relationship and the severity of problems caused by disruptive behavior. The chi-square test was used to compare the proportion of physicians and nurses who had witnessed disruptive behavior. We also used this test to examine the frequency with which physicians and nurses believe disruptive behavior negatively affects the team and patients. *P* values <0.05 were considered significant. All analyses were performed using SPSS software version 22.0 (IBM, Armonk, NY, USA).

2.6. Ethical Considerations. Approval was obtained from the Ethics Committee of the Catholic University of Murcia (Code No. CE041825) and from all participating hospitals to conduct the study. Furthermore, confidentiality and data protection are guaranteed by Organic Law 3/2018, of 5 December, on the Protection of Personal Data and the Guarantee of Digital Rights [27].

The Materials and Methods section should contain sufficient detail to repeat all procedures. It may be divided into headings if several methods are described.

3. Results

Of the 500 nursing and medical professionals from public hospitals in the Murcia region invited to participate in this study, 370 responded to the scale/instrument (74%). Most of the sample consisted of men (53%) between 20 and 29 years old (42.7%). 41.1% belonged to the emergency department. Regarding position/category, there were few differences in the frequency of participation, except for the low participation of administrative physicians (indirect assistance/management) (18.4%) in the other categories (Table 1).

The average perception of the nurse-physician relationship environment among the 370 participants was 8.05 (SD = 1.59).

Table 2 details the mean values for each variable studied and the results of the univariate and multivariate linear regression analyzes that identify the sociodemographic and occupational determinants of the environment of the nurse-physician relationship. The findings revealed a statistically significant association between the variable age range 30–49 years, both in the univariate (0.487, *p* < 0.05) and multivariate (0.566, *p* < 0.05) models, compared to the reference group (20–29 years). A significant association was also found with the administrative group (indirect care/management) of physicians in the univariate (0.975, *p* < 0.05) and multivariate (0.625, *p* < 0.05) models compared to physicians (direct care). The intensive care unit

TABLE 1: Characteristics of the participants.

Variables	<i>n</i> (%)
<i>Sex</i>	
Woman	174 (47.0)
Men	196 (53.0)
<i>Age</i>	
20–29 years	158 (42.7)
30–49 years	121 (32.7)
>50 years	91 (24.6)
<i>Job position</i>	
Physician (clinical)	97 (26.2)
Physician (administrative)	68 (18.4)
Nurse (clinical)	101 (27.3)
Nurse (administrative)	104 (28.1)
<i>Unit</i>	
Emergency department	152 (41.1)
Intensive care unit (ICU)	137 (37.0)
Surgery	81 (21.9)

(ICU) (univariate -0.453 , $p < 0.05$; multivariate -0.505 , $p < 0.05$) and surgery (univariate -1.090 , $p < 0.001$; multivariate -1.078 , $p < 0.001$) also showed significant associations compared to the emergency department. Nagelkerke's square R indicated that the independent variables used in the multivariate linear regression model explained 11.5% of the variance of the dependent variable.

According to the perception of nurses and physicians ($n = 370$), a higher prevalence of disruptive behaviors was observed in specific areas, the most affected being the intensive care unit (ICU) with 81.6% ($n = 302$), followed by the emergency department with 67.8% ($n = 251$) and general medicine with 58.6% ($n = 217$). Regarding the frequency of such behaviors according to specialty, respondents reported a higher incidence in general surgery with 83.0% ($n = 307$), followed by obstetric/gynecology with 45.9% ($n = 170$), and cardiology with 40.8% ($n = 151$). On the other hand, the specialty with the lowest frequency of disruptive behavior was anesthesia, with 13.2% ($n = 49$) of affirmative responses.

Table 3 shows that physicians (clinical) (87.6%) and administration/management nurses (81.2%) were the most frequent witnesses of disruptive behavior by a physician. When asked, have you ever witnessed disruptive behavior by a nurse at your hospital? A positive response from clinicians was observed (96.6%). Furthermore, compared to nurses, a significant difference was found and nurse clinicians (76.9%, $p < 0.001$) reporting more disruptive behavior from another nurse clinician.

In the multivariate model, the perception of the severity of disruptive behavior problems was primarily influenced by age and the care service. Table 4 shows that physicians and nurses in the age range between 30 and 49 years and those older than 50 years have a more marked perception compared to other age groups. Furthermore, the surgical service showed a significant influence on this perception in both professional categories, with coefficients of 0.911 ($p < 0.001$) for physicians and 0.674 ($p < 0.001$) for nurses.

When analyzing the impact of the results of disruptive behaviors in the nurse-physician relationship on the patient

safety climate, the following factors were identified: stress and frustration (219, 59.2%), loss of concentration (207, 55.9%), reduced teamwork (161, 43.5%), reduced information sharing (214, 57.8%), reduced communication (269, 80.0%), and problems in the nurse-physician relationship (256, 69.2%). When analyzing the differences between physicians and nurses in these factors, it was found that loss of concentration, reduction in transmitted information, and problems in the nurse-physician relationship have a significant implication ($p < 0.001$) on the patient's safety environment according to nurses compared to physicians (see Table 5).

When asked about the relationship of disruptive behavior with aspects or indicators related to patient safety, the following percentages were identified: adverse events (25.4%), patient safety errors (13.0%), quality of care (20.8%), patient mortality (14.9%), nurse satisfaction (33.2%), physician satisfaction (43.2%), and patient satisfaction (39.2%). When analyzing the differences between physicians and nurses, it was found that physicians have a significantly more negative perception of quality of care ($p < 0.001$) and patient mortality ($p < 0.001$) than nurses.

Most professionals, 83.8% ($n = 310$), indicated that they were aware of a possible adverse event that could have occurred as a result of disruptive behavior. Furthermore, 29.0% ($n = 90$) stated that such events could be severe. Some 47.3% ($n = 175$) indicated that they were aware of the following adverse events that had occurred as a result of disruptive behavior: lack of information (8.6%), delays in care (28.0%), misunderstandings between staff (26.9%), and misinformation provided to relatives (36.6%).

Four questions were asked about the system to prevent and report patient safety incidents. When asked whether incidents could have been prevented, 94.9% ($n = 166$) answered yes. Regarding the conduct procedure, 99.7% ($n = 369$) indicated that a code of conduct or protocol is in place to address disruptive behavior in their hospital. Of these, 27.8% ($n = 103$) stated that a protocol was followed, while 71.9% ($n = 266$) mentioned a code of conduct. Virtually all professionals (99.7%) stated that a nonpunitive recording system was in place for those who witnessed or experienced disruptive behavior. In terms of barriers or obstacles to reporting disruptive behavior, practitioners noted fear of reprisals (82.4%), lack of confidentiality (19.7%), feeling that nothing would change (31.6%), and no response or outcome (10.0%).

4. Discussion

Overall, professionals assessed the nurse-physician relationship environment positively, though disruptive behaviors were noted in clinical practice, potentially impacting safety climate and clinical outcomes. Age and service type emerged as key variables affecting perceptions of disruptive behavior impact. Stress, communication barriers, and nurse-physician relationship issues were linked to disruptive behavior. Nurses reported more negatively affected concentration and information transmission. Due to disruptive behavior, physicians perceived lower care quality, safety, and

TABLE 2: Univariate and multivariate analysis of the perception of the environment of the nurse-physician relationship.

higher mortality rates. Such behaviors also diminished satisfaction among patients, physicians, and nurses. Professionals recognized patient safety incidents associated with disruptive behaviors but did not understand safety incident taxonomy. A cultural perception hindered trust in reporting systems for learning and improvement, indicating a need for cultural change as a priority in improvement strategies.

Although disruptive behaviors are not uncommon [28, 29] and should be of concern for healthcare institutions to improve patient safety and foster a working environment conducive to positive outcomes [7, 30], few studies have been published on this problem in the healthcare setting. This is the first study in Spain, to our knowledge, that explicitly addresses disruptive behaviors in the healthcare setting. The first published studies correspond to Rosenstein

et al., the authors of the instrument used in our research. In 2002, they analyzed 1,200 questionnaires on the United States West Coast [25]; in 2005, there were 244 participants [31].

In recent years, studies like ours have obtained a lower response rate than ours (74%). For example, a study in Singapore had a response rate of almost 40% (39.9%), and most of the respondents were physicians (64.2%) [32]. This contrasts with our results. In the context of Iranian healthcare care, we found two relevant studies. One of them, carried out in health centers affiliated with the University of Isfahan, involved 248 professionals, most of them nurses [33]. The other study was carried out in four emergency departments, with 45 physicians and 110 nurses responding [34]. Considering cultural and social differences, the professionals participating in our study may have a greater postpandemic awareness, leading them to participate in studies to improve the psychosocial aspects associated with the care process.

According to our 10-point maximum rating scale, our professionals reveal a moderate-high degree (with an average of 8.05 points). Being between 30 and 49 years old and working in the surgery and ICU departments are the sociodemographic and occupational factors most influencing this perception. Regarding age, these results were expected, as it is likely that, with increasing age, professionals acquire more experience and a more critical view of their working environment, identifying aspects that may go unnoticed by their younger colleagues.

Regarding the type of service, several studies have found that emergency and operating room areas are the most significant in the manifestation of disruptive behavior [22, 23, 25, 33, 35]. These two environments are high-stress environments characterized by high communication flow and remarkable concentration. Surprisingly, our findings, in agreement with those of Rosenstein and O'Daniel [35], indicate that the emergency department is not significant in

overall perception; on the contrary, the intensive care unit (ICU) and the operating theatre are. The Nagelkerke *R* square coefficient of determination value of 11.5% highlights the importance of interpreting this result with caution and assessing the linear relationship with other socio-occupational variables in future research.

In terms of the type of department and specialty, there are different perceptions. When asked about the prevalence of disruptive behaviors by department type, the emergency department and the ICU are the most relevant in our study. However, in terms of specialty, they are more frequent in general surgery, which coincides with the study by Saghaei et al. [33]. This reflects that these services have a context characterized by high demand and a high level of technology

where life and death are separated by an instant or an error in care. It is understood that these characteristics can contribute to the perception of disruptive behaviors in these environments.

Our results reveal a significant discrepancy with the existing literature on the observation of disruptive behaviors. Previous research has indicated that clinicians and nurse clinicians frequently witness such behaviors in their work environments, primarily by clinicians. However, in our study, clinicians reported seeing disruptive behavior from other physicians and nurses with greater frequency than that reported by nurses, in line with the results of Lim et al. This finding is remarkable and contradicts the prevailing conception, suggesting that direct care nurses, who work in

contexts characterized by hierarchies, manifestations of authority, and negotiation of responsibilities, especially in emergency and operating rooms, are more susceptible to abusive behaviors from physicians.

Both older physicians and nurses show a higher perception of the severity associated with disruptive behaviors, with significant negative implications in the context of the surgical service. This phenomenon suggests that these factors are relevant in the professional assessment of the seriousness of disruptive behaviors. This finding indicates that more experienced practitioners may be more willing to express their views on disruptive behaviors' possible complications and effects.

According to the perspective of professionals and according to the existing literature, the main factors linked to disruptive behaviors that impact the safety climate include stress and frustration [32–39], poor communication [32], and problems in the nurse-physician relationship [33]. However, nurses report a more negative perception of lost concentration and reduced information transmission than their medical colleagues. This insight underscores the importance of communication and information for safer care [40, 41]. Professionals recognize the relevance of all aspects of communication for continuity of care and to promote a positive working relationship between nurses and physicians [42]. Both healthcare bodies and international organizations recognize that deficiencies in patient information transmission can cause substantial safety problems [42, 43]. Effective communication is a global goal to improve patient safety [44], as reflected in Strategic Objective 6: Information, research, and risk management of the World Patient Safety Action Plan 2021–2030 [45]. According to Astier-Peña et al. [46], this goal aims to ensure a better flow of information and knowledge to promote risk management and ensure more respectful care at all levels of care.

Regarding the undesirable clinical outcomes associated with disruptive behaviors, professionals point out that these directly impact the satisfaction levels of patients and professionals themselves, according to previous research [32–34, 47]. There is also evidence of their relationship with adverse events in clinical practice. Given the consequences and impact of disruptive behaviors, these results were predictable. The degree of satisfaction is not always determined solely by the structure or level of knowledge; it can be related to a culture of attitudes and behaviors that have a negative impact on working relationships [48, 49], compromising the safety climate, weakening teamwork, and affecting job satisfaction. Furthermore, our findings highlight that physicians are the ones who most strongly perceive the relationship between disruptive behaviors and poor quality of care and patient mortality, in agreement with another research [32, 34]. However, these cause-effect results must be assessed with caution, as other factors that have not been studied or may be intrinsically or hidden in negative behaviors and attitudes can be involved, which can be detrimental to the care process.

Although unwanted events due to disruptive behavior were not unexpected, as identified in other studies [20, 22, 25, 32, 34, 41, 45], we were surprised by the high

percentage observed in the investigated context. Professionals reported adverse events such as “misinformation to relatives,” “delay in care,” and “misunderstandings between staff.” We recognize that disruptive behaviors affect the safety climate and can have severe consequences on the job, compromising the nurse-physician relationship and creating obstacles to improving the quality of care. However, when examined from the perspective of the taxonomy of safety incidents proposed by the Heinrich Pyramid, we observe that, rather than events, they constitute patient safety incidents with the potential to cause patient harm [50]. These incidents are classified as near misses, indicating the possibility of having caused harm to the patient [50], and physicians indicated that these risk circumstances for patient safety could have been avoided. Furthermore, they noted clear guidelines in their centers on addressing disruptive behaviors, through protocols or codes of conduct. We believe that this aspect is relevant and should be integrated into the healthcare management strategies of each center and institution.

In examining the question related to the reporting system for disruptive behaviors witnessed or experienced, almost all practitioners indicated that it was a nonpunitive system. However, a significant proportion of them expressed that fear of reprisals was a major concern, acting as a substantial barrier to reporting such behavior. Furthermore, they reported a perceived lack of feedback or positive response as a consequence of the report. They noted that there was no change in practice, findings that are consistent with previous research [31, 33, 34, 47]. Against this backdrop, several questions arise. Is there truly a nonpunitive system, or does fear persist among professionals to speak openly and honestly about the reporting system? Do professionals understand the inherent meaning and function of a reporting system? Have health institutions succeeded in effectively implementing a reporting system? These questions raise fundamental questions about the culture of patient safety. Despite more than two decades since the publication of the report *To Err Is Human* [51], it remains imperative to address these issues to drive continuous improvement in quality and safety in healthcare. The foundation of all healthcare systems is an awakening towards improving patient safety, evidenced by joint efforts and focused attention on this crucial aspect. Despite two decades since the National Quality Forum's recommendation to implement safety culture as the first of its “30 safe practices,” there is still a way to go towards fully realizing this goal [52]. From our perspective, the “tip of the iceberg” represents only a visible fraction of a broader set of factors influencing or determining safe practice. We recognize that visible and invisible aspects intrinsically relate to patient safety culture. This culture, characterized by its nonpunitive nature and its focus on learning from mistakes, is a fundamental element in promoting safety and improving the quality of care [8].

This study is not without limitations. First, the sample used. Our study focused on five hospitals of the 9 Health Departments of Murcia Healthcare, Spain. This selection can restrict the interpretation of the results, as it is described as a global perception of professionals only in hospitals in

a specific region of Spain. Although it was not our main objective, it is important to note that including other professional categories could enrich the understanding of the general importance of disruptive behaviors. This aspect should be addressed in future studies. It is essential to remember that the subjects in our study represent only a sample of the total population, which also implies certain limitations regarding the generalizability of the findings.

The second aspect refers to the “Nurse Physician Relationship Survey: Impact of Disruptive Behavior on Patient Care.” Although the results of the previous study of adaptation and validation [24] in Spanish were satisfactory, certain important aspects must be considered. Not many questionnaires or scales have been found that specifically address disruptive behavior in the hospital setting. Although this scale covers all the issues relevant to our research objectives, few studies are available to compare the results obtained. In the Spanish context, none have been identified to date. More research is needed to assess the perception of disruptive behaviors in the hospital setting and their impact on patient safety using this national and international instrument to establish meaningful comparisons between different countries.

Finally, another study limitation is the lack of consideration for potential confounding variables. While efforts were made to control for known factors, variables beyond the scope of this research could influence outcomes. Future studies should address these variables to provide a more comprehensive understanding of the phenomena under investigation.

5. Conclusions

Professionals have assessed that the nurse-physician relationship environment is relatively good overall. However, disruptive behaviors have been observed in clinical practice, which can have a negative impact on the safety climate and clinical outcomes.

Age and type of service were the most relevant socio-occupational variables for the perception of the impact of disruptive behavior in the nurse-physician relationship. The factors most associated with disruptive behavior and influencing the safety environment included stress and frustration, reduced communication, and problems in the nurse-physician relationship. Nurses expressed significantly more negative perceptions of losing concentration and reducing information transmission.

Regarding the impact of disruptive behaviors on the nurse-physician relationship and clinical outcomes, physicians have a more unfavorable perception of quality of care, patient safety, and even mortality rate. In addition, disruptive behaviors negatively influence patient, physician, and nurse satisfaction.

We have observed that professionals do not yet understand the taxonomy of patient safety incidents, but they have a relatively high perception of incidents associated with disruptive behaviors. In addition, a cultural perception persists that generates fear and “low credibility” with respect to the reporting system as a tool for learning and

improvement. Changing culture is not an easy challenge, but it significantly impacts other countries and remains a priority in improvement strategies.

The bullying of nurses by patients, doctors, and employees is common in the healthcare industry. Nurses who are bullied are more likely to experience burnout, and nurses who experience burnout are more likely to intend to quit. However, few studies investigate how leadership can mitigate workplace incivility and nurse bullying as a way to improve nurse retention. A cross-sectional study was conducted using a sample of 216 nurses recruited from various regions across the United States from different specialties. A moderated mediation model using path analysis was used to examine the relationships between bullying, burnout, and ethical leadership in predicting intentions to stay. Bullying significantly and positively related to burnout ($\beta = 0.22, p = 0.02$), and burnout significantly and negatively related to intent to stay ($\beta = -0.18, p = 0.01$). Perceived ethical leadership predicted intentions to stay ($\beta = 0.62, p = 0.00$), and ethical leadership moderated the effect of bullying on burnout ($\beta = 0.20, p = 0.03$). The results of our study also suggest that nurses are less likely to quit when ethical leadership is present, and ethical leadership weakens the effect of bullying on burnout.

Keywords: burnout; ethical leadership; turnover intentions; United States; workplace bullying

1. Introduction

Nurses are a key part of the healthcare system; they have the majority of direct interactions with patients, and it is estimated that by the next decade over 13 million nurses will be needed worldwide [1]. In the United States, there will be a national shortage of 63,720 full-time registered nurses for nursing roles by the year 2030 [2]. Additionally, the health systems of all 63 countries of the World Health Organization European Region have been adversely affected [3], and a shortage of more than 100,000 nurses is expected in Australia by the year 2025 [4]. This shortage is, in part, due to a variety of factors including a decline in nursing faculty, an aging population, an aging nursing workforce, burnout, staffing ratios, and verbal abuse in healthcare settings [4]. Many new nurses graduating and beginning their careers are not staying in the profession as a whole for long [5]; in

addition, fewer nurses are becoming certified [6–8]. Additional factors contributing to this shortage include workplace environment, team dynamics, leadership style, organizational commitment, and turnover [7]. As this historical shortage persists in the United States [9, 10], patient care suffers, and the remaining nurses tend to be overworked, which leads to more negative experiences for those remaining.

In recent years, events such as the introduction of the Affordable Health Care Act in the U.S. have resulted in a substantial increase in potential patients testing the capacity of healthcare providers [11]. Coupled with global health pandemics such as SARS, Ebola, and Covid-19 over the past few decades, first responders in healthcare have encountered additional strain that leads to burnout [12] and lower job engagement worldwide [13, 14]. For example, during the time of the COVID-19 pandemic, nurses in

Australia and New Zealand experienced more stress and greater workloads [15, 16]. More than half of the 351 nurses in a study conducted in Oman during the pandemic reported high levels of job burnout [13]. This resulting burnout among nurses is high [17, 18], and it is an important variable that affects employee turnover intentions [19]. Therefore, it is critically important to assess the level of burnout among nurses and identify factors that can reduce it.

Turnover can be costly for organizations monetarily [20], but turnover among nurses has even greater implications for healthcare organizations because it negatively impacts patient outcomes [21] and healthcare resources [22]. Nursing shortages lead to negative outcomes including an increase in mortality, staff violence, accidents, and injuries [8], rates of nosocomial infections, patient mortality, patient falls, pressure ulcers, prolonged average hospital stay lengths, and additional healthcare costs [23], further validating the need for solutions to ameliorate it.

Prior research has shown that some main psychological predictors of turnover include job satisfaction [24, 25], organizational commitment, and intent to stay [24, 26], value attainment, and mood [25]. Being bullied at work [27], burnout [19, 28], and leadership style [29] have also been shown to influence employees' turnover intentions. In the context of nursing, inadequate staffing is another important predictor of turnover because it leads to greater physical exhaustion by nurses managing heavy workloads [28].

Bullying is one way in which experienced nurses control new nurses to meet objectives, but verbal abuse can be traumatic for new nurses [30] and lead to outcomes that are psychologically, physically, and emotionally harmful [31]. In prior research, bullying is "considered as the most chronic issue in the health-care sector" [32]: 2, and being placed in stressful and unethical situations such as this can lead to job burnout [33]. Moreover, nurses who experience bullying at work may leave the nursing profession altogether [34–36]. Although bullying and burnout can negatively affect outcomes for nurses and their patients, scant research addresses strategies to reduce bullying incidents, especially related to nursing [37].

Some research results suggest that leadership styles of nursing managers can impact nurse behavior [29]. Unfavorable leadership styles, such as toxic leadership, are positively related to turnover intentions [29] while favorable leadership styles, such as transformational leadership, are negatively related to turnover intentions [38]. Despite the call from scholars to redirect attention to ethical leadership to improve nursing and patient outcomes [39], empirical investigations on how it can impact a culture of workplace incivility and burnout are limited. Because ethical leadership can model ethical performance [37], we propose that ethical leadership will ameliorate workplace incivility, and possess a buffering effect on burnout that stems from bullying behavior.

In this study, we examined perceived ethical leadership among nurses working for various types of healthcare provider institutions, and the consequences of bullying and burnout on intentions to stay. Our aim is to understand some understudied causes of turnover intentions in nursing.

Our study makes a significant contribution to the literature in the following ways. First, given the turnover crisis in the nursing profession [4, 8], we fill a void in the turnover intentions literature by investigating how an ethical leadership style can mitigate the effect of bullying on burnout. Furthermore, because ethical leadership is understudied in the nursing literature [32, 37], and bullying is prevalent among new nurses [40], we examine its effect on intentions to stay among nurses who experience burnout as a result of experiencing or observing bullying in the workplace. In line with prior research, we contend that bullying and burnout have negative effects on intentions to stay, and further the literature by proposing that perceptions of ethical leadership influence this relationship.

As shown in Figure 1, we hypothesize that bullying is directly related to job burnout of nurses. Further, we propose that job burnout is negatively related to intentions to stay. Also depicted by our model, we contend that leadership perceived to be ethical by nurses ameliorates the effect that bullying has on job burnout. Lastly, we propose the interaction effect between perceived ethical leadership and bullying on job burnout is indirectly related to intentions to stay resulting in a moderated mediation model.

1.1. Predictors of Turnover Intentions. Turnover intention refers to when an employee's motive is to leave a specific organization [41] and is a predictor of the actual act of turnover [42]. Job turnover among nurses has been an ongoing concern for many years [43] with the national average total hospital turnover rate being 19.5% as of 2022 [44]. In general, four types of variables have been studied extensively as predictors of turnover which include job training, job involvement, positive affectivity, and negative affectivity [45]. Positive and negative affectivity refer to dispositional states of pleasurable or unpleasurable engagement, respectively [46]. Justice, stress, and social support are variables associated with positive and negative affectivity used to research determinants of turnover [45], which include, but are not limited to, dimensions of supervisory support, role overload, role conflict, and perceptions of fairness [45]. Specific to the field of nursing, job turnover is exacerbated when nurses' have negative experiences in their work environment [47]. For example, other factors contributing to turnover include pandemic-related pressures [48], inadequate nurse staffing [49, 50], dealing with toxic leadership [29], and workplace violence [51]. In line with research on perceptions of fairness, bullying in the workplace is associated with high turnover intentions [52–54]. Viewed as a form of stress, burnout is also linked to intentions to quit and actual turnover [33]. As of recent, nurses specifically are leaving the nursing field due to emotional exhaustion brought on by high job demands, low job control, and role overload due to caring for COVID-19 patients [55], that also contributes to lower overall psychological well-being among nurses [48]. Besides dispositional effects on turnover intentions, perceptions regarding the nursing profession and the negative public image of their organization also affects nurses' job satisfaction which in

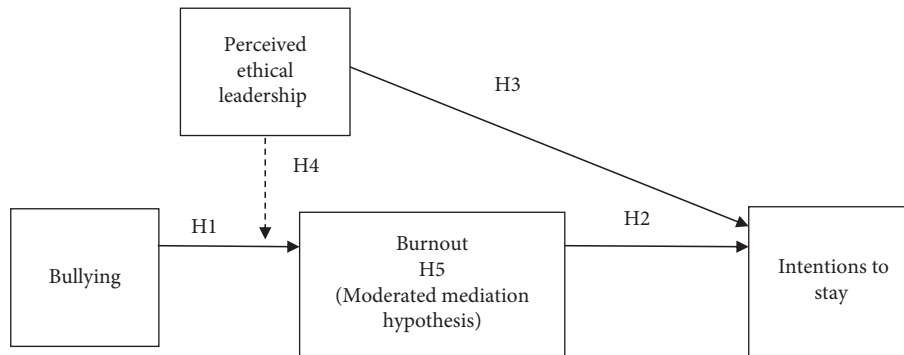

FIGURE 1: Conceptual model.

turn influences their decision to quit their job or the profession entirely [51, 56].

1.2. Nursing Context. For our study, we focus on bullying and how it leads to both burnout and nurse intentions to stay because healthcare organizations are especially susceptible to bullying behaviors [30, 57]. There is evidence to suggest this may be because nurses are taught to bully others as an organizational cultural norm [58], and that healthcare systems traditionally operate using paternalistic styles of leadership that can lead to the oppression of nurses [58], exacerbated by authoritarian management practices [59]. Bullying is the act of aggressive behavior toward an individual repeatedly over time [60] which may also violate employees' civil rights [61]. Due to both the nature of their work environments and hospital group dynamics, nurses work under unique conditions that can be tied to turnover, including the experience of both physical and psychological effects. Physical conditions experienced by nurses from doctors, patients, and co-workers include "invasion of personal space, shoving and blocking the way, threat of violence, physical abuse, or actual abuse" [57]: 140. Patients in facilities where nurses are bullied can also receive poor nursing care or experience adverse events [62, 63]. We suggest that the nurse manager can play a key role in mitigating these bullying behaviors as a way to increase nurse retention and improve patient outcomes. Specifically, we study the effect that the ethical leadership of the nurse manager has on these scenarios.

1.3. Bullying and Job Burnout. Job burnout occurs when employees experience chronic stress resulting from their job [64] and is caused by various stressors which may include a number of physical or psychological issues nurses experience in their workplaces [65]. A key dimension of burnout is exhaustion [33], which is defined in the nursing literature as a common feeling of physical and emotional overload experienced by nurses stemming from interactions with co-workers and patients [66]. A work environment where bullying occurs is a stressful environment where employees feel intimidated, abused, or insulted, resulting in a stressful work experience [32]. Workplace bullying among nurses can lead to a number of psychological and mental health

outcomes and work behaviors such as quiet quitting [67], depression, suicidal ideation, post-traumatic stress disorder, deterioration in the quality of their work life [68], job dissatisfaction [51], and burnout [69]. Physical health symptoms experienced by bullied nurses include headaches, eating disorders, onset of chronic diseases, and sleep disturbances [40].

Emotional exhaustion, a dimension of burnout [33], can be exacerbated by bullying, which could have a greater effect on intent to leave than any other factor [35]. Bullying can manifest itself in unfair treatment or any sort of verbal or physical harassment and may greatly influence whether or not nurses stay with an organization [61]. Examples of bullying include, but are not limited to, verbal attacks, intimidations, and withholding support [70] and its effect on employees shares similar characteristics to symptoms of burnout including anxiety and depression symptoms [33, 71, 72]. Further, prior research has shown that nurses experience burnout in climates where workplace bullying occurs [73]. In line with prior research, we contend that bullying is another prevalent factor that explains intentions to quit as it influences feelings of burnout.

Hypothesis 1. Bullying is positively related to burnout.

1.4. The Effect of Burnout on Intentions to Stay. Some of the global nursing shortage can be attributed to burnout, as increasingly more countries report how it has directly impacted turnover across their health systems [50]. Since nurses are likely to experience job burnout [74], the relationship between burnout and turnover must be further explored, especially since nurses have ongoing interaction with patients and their visitors, and frequent encounters with work stressors [75]. Burnout is considered a stress phenomenon, linked to lower job performance and poor health outcomes [33, 76], physical and mental health outcomes including psychological and physiological fatigue [75], impaired short-term memory and cognitive decline [77], alcohol and drug use [76], and disintegration of family and social relationships [74, 78, 79]. Under stressful circumstances associated with burnout, employees are less committed to the organization [80], become exhausted, and struggle to continue working. Some recent examples of stressful circumstances that relate to burnout and turnover

among nurses include, but are not limited to, inadequate staffing [50], anxiety, and fear stemming from caring for patients during the COVID-19 pandemic [81]. Consequently, nurses experiencing burnout seek other jobs [82] and are more inclined to quit [75]. Not only is nurse burnout related to greater turnover [51, 83], burned-out nurses may no longer communicate effectively with others, engage in behaviors of workplace incivility [83], and experience physical and mental health challenges. Burned-out nurses will also express indifference toward patients [84] which can jeopardize their safety [21].

Hypothesis 2. Burnout is negatively related to intentions to stay.

1.5. The Effect of Ethical Leadership on Employees and Organizations. The type of leadership employees receive can greatly influence performance, especially in an environment like that of nursing. Ethical leadership is an observable expression from leaders of support for behavior deemed appropriate for followers that may be enacted through relationship building [85], communication, decision-making, and reinforcement [86]. Various studies have shown that ethical leadership creates an ethical environment conducive for reducing moral distress, thereby improving job satisfaction and absenteeism [87]. However, among the few studies on ethical leadership in the nursing literature that do exist, the number of quantitative studies is lacking [88].

Leaders in an organization set the tone for employees in terms of establishing a support system, the work environment, and acceptable behaviors. In fact, one of the most powerful methods to promote ethics in healthcare and the nursing practice is to role model ethical performance on the managerial level [37]. Leaders, through displaying and modeling ethical leadership, foment an ethical environment for nurses. Working in an ethical environment is especially important in a healthcare environment; especially at the nurse level, given that they interact the most frequently with patients.

1.6. Ethical Leadership and Turnover Intentions. In environments where nurses are “faced with obstacles that force them to act against their ethical beliefs, they feel discomfort, dissatisfaction, and frustration” [89]: 5, which can increase intentions to quit. An ethical environment allows nurses to feel supported and operate in an environment that is conducive to a higher quality of patient care. Moreover, ethical leadership influences the behavior of employees through its influence on the work climate [90]. However, many nurses report that they feel unsupported by their leaders [37] and some nurse leaders admit that ethical practice should be emphasized more as a part of organizational support [39]. However, the literature regarding the role of ethical leadership in nursing has recently been sparse [37]. For these reasons, we expect ethical leadership to be immensely important in the nursing field, which can prove beneficial for healthcare systems via increased job satisfaction for nurses and better patient outcomes [39]. Medical practices may

receive outsized gains for attracting and developing ethical leaders throughout their organization due to the difficult work climate that nurses face on a day-to-day basis [91]. Furthermore, results from prior research suggest that a climate perceived as ethical helps prevent burnout [92] and strengthens organizational commitment [92–94], and job satisfaction [95–97], both predictors of turnover intentions [56]. For this reason, we expect to find that strong ethical leadership has a direct relationship with intention to stay.

Hypothesis 3. Perceived ethical leadership is positively related to intentions to stay.

1.7. The Interaction Between Perceived Ethical Leadership and Bullying. While we suggest that bullying [27] and burnout [98] will increase employees’ intentions to leave an organization, we propose that the employment and development of ethical leaders in the organization can mitigate those intentions. Ethical leadership in place decreases employee anxiety about their job and increases employee behavior aligned with ethical principles [99]. Ethical leaders are both moral persons and moral managers [100]. Not only do they need to be moral individuals, but also they must apply that morality in the workplace. Brown and colleagues [86] define ethical leadership as “the demonstration of normatively appropriate behavior through personal actions and interpersonal relationships, and the promotion of such conduct to followers through two-way communication, reinforcement, and decision-making (p. 120).” Prior research has utilized social learning theory to explain how ethical leadership can mitigate negative workplace environments [101, 102]. This is welcome news for healthcare providers and nurses in particular because work environments in healthcare organizations have been shown to create a climate that leads to burnout [103].

Ethical leaders set a standard for what moral behavior is like in the workplace [104]. Employees with ethical leaders learn what is and what is not appropriate behavior in the organization through their leaders. In addition to the likelihood that bullying would decrease under ethical leaders due to an increased ethical climate [105], employees reporting to ethical leaders will be much less likely to assume bullying behavior is normal and appropriate workplace behavior. Evidence suggests that employees with ethical leaders will develop the ability and willingness to confront and address the conflict behavior [106] rather than assuming that exiting the organization is their only way out. For example, Islam and colleagues [32] found that the presence of ethical leadership positively influenced employee voice behavior and negatively affected bullying. In addition to the ethical role modeling and increased psychological safety that employees feel when working for ethical leaders, these ethical leaders have also been found to increase employees ability to deal with relationship conflict situations in the workplace by increasing employees’ ability to create resolution [101]. In addition to social learning, the way that leaders design the work environment has been found to be a key mechanism for ethical leaders to decrease workplace

bullying [107]. Prior research indicates that ethical leaders influence both the work climate that an employee works in and influences the behaviors and abilities of employees directly. For these reasons, we expect ethical leadership to moderate the effect that bullying has on employee burnout.

Hypothesis 4. Perceived ethical leadership moderates the effect of bullying on burnout such that nurses will experience less burnout from bullying when ethical leadership is high compared to when it is low.

Thus far we have proposed that bullying is positively related to job burnout (i.e., Hypothesis 1 above), and that this relationship is moderated by perceived ethical leadership (i.e., Hypothesis 4 above). We also proposed that perceived ethical leadership is positively related to intentions to stay (i.e., Hypothesis 3 above). As prior research suggests that job burnout predicts turnover intentions, we contend that perceived ethical leadership signals to nurses messages of support regarding bullying prevention which, in turn, improve their feelings of job burnout, and ultimately intentions to stay. Thus not only do we propose that job burnout is related to intentions to stay (i.e., Hypothesis 2 above), we also propose that a conditional indirect effect exists for bullying and perceived ethical leadership on intentions to stay through job burnout. Based on prior research regarding the mediating role of burnout [79], this type of model is a moderated-mediation model [108, 109] resulting in our final hypothesis (full model shown in Figure 1).

Hypothesis 5. Bullying is related to intentions to stay via conditional indirect effects, such that its relationship with intentions to stay is moderated by perceived ethical leadership and mediated by job burnout.

2. Materials and Methods

2.1. Participants. A total of 216 nurses from various regions across the United States were recruited from different specialties to participate in the current research study in exchange for modest compensation. One hundred were identified through an email listserv managed by the Association of Women's Health, Obstetric, and Neonatal Nurses (AWHONN) and followed by nurses in obstetrics and women's health as their primary field. The remaining 116 were recruited using an online surveying agency (Turk-Prime's Prime Panels platform: <https://www.turkprime.com/LaunchedSurvey/PrimePanels>) that commissions large-scale stratified samples. By recruiting participants from a wide array of online sources, this service allows researchers to set a priori demographic quotas for sampling. The panel was set to ensure the recruitment of participants from the nursing field.

2.2. Measures. All of the scales of measurement used for the current study were adapted from those published in peer-reviewed journals and have a reliability Cronbach's alpha coefficient greater than 0.80.

2.2.1. Intentions to Stay. The dependent variable intentions to stay were measured using a four-item five-point Likert scale [110] used to measure intent to stay. For the current study $\alpha = 0.89$. Sample items include "I would like to leave my present employer" and, "I plan to stay with my present employer as long as possible."

2.2.2. Bullying. The workplace incivility/bullying culture scale [111] was adapted to measure the independent variable bullying. It includes 12 items and uses a five-point Likert scale. The scale yielded a coefficient $\alpha = 0.96$ for the current study. The survey begins with the following incomplete question to be completed by the 12 listed items to total 12 questions: "During the past year were you ever in a situation in which any of your supervisors or coworkers. . ." Sample items used to complete the question asked of participants include "Gave you hostile looks, stares, or sneers" and, "Made jokes at your expense."

2.2.3. Burnout. Malach-Pines' [112] short version of burnout measure was used to measure the mediating variable job burnout of participants in the current study. It includes 10 items using a seven-point Likert scale and yielded a coefficient $\alpha = 0.92$. Participants are asked an introductory question "When you think about your work overall, how often do you feel the following?" Sample items that follow the introductory question for participants to answer include "Hopeless", and "Difficulties sleeping."

2.2.4. Perceived Ethical Leadership. We measured perceptions of ethical leadership using the 10 item five-point Ethical Leadership Scale that Brown and colleagues [86] developed. For the current study $\alpha = 0.96$. Sample items include, "Conducts his/her personal life in an ethical manner," and "Sets an example of how to do things the right way in terms of ethics."

2.2.5. Controls. Age, race and organizational tenure were originally entered as control variables, and because they significantly did not have an effect on the primary variables of interest we removed them from the main statistical analysis.

2.3. Procedures. Online surveys were used to collect the data for this study. Participants replied to a link sent to their email address after having signed up to be a part of the research study either through their listserv announcement or as part of the Prime Panels platform. Upon clicking on the link, participants were redirected to an introductory web page where they provided consent before completing a battery of questions including surveys that measured the primary variables of interest in the current study dispersed among other surveys that measured various work attitudes, perceptions, beliefs, and basic demographic information.

2.4. Statistical Analysis. A moderated mediation model using path analysis in Mplus v.8 was conducted to examine proposed relationships [113] as seen in Figure 2. A moderated mediation path model is a statistical technique used to

FIGURE 2: Graphed interaction effect between bullying and perceived ethical leadership on burnout.

examine how the relationship between two variables (independent and dependent variable) is influenced by a third variable (moderator) through a mediating variable [114, 115]. In this model, the mediator (burnout) lies between the independent and dependent variables and explains part of the effect of the independent variable on the dependent variable. The moderating variable (ethical leadership) influences the strength or direction of the relationship between the independent variable and the mediator, ultimately affecting the indirect effect on the dependent variable. The current model examined the interaction between bullying, burnout, and ethical leadership in predicting intentions to stay. The primary purpose of the model was to examine how job burnout mediated the relationship between bullying and intentions to stay. In addition, the interaction effect between bullying and perceived ethical leadership on job burnout was tested to examine the mediation effect further.

3. Results and Discussion

3.1. Results. Participants with missing data related to the variables being investigated were removed resulting in 184 valid responses ($N = 184$); a response rate of 85.2%. Respondents were 92% female with an average age of 40.2 years ($SD = 11.95$), and most were White (84%), followed by Black (7.4%), Hispanic/Latinx (6.8%), and American Indian (1.9%).

Table 1 shows the means, standard deviations and bivariate correlations for all study variables. It should be noted that the path model was just-identified, thus, model fit indices were not useful (i.e., $RMSEA = 0.00$, CFI and TLI = 1.00). Our first and second hypotheses were supported as expected indicating that bullying significantly and positively relates to burnout ($\beta = 0.22$, $p = 0.02$), and burnout significantly and negatively relates to intent to stay (i.e., intentions to quit) ($\beta = -0.18$, $p = 0.01$), respectively.

TABLE 1: Descriptive statistics and bivariate correlations.

Variable	Mean	SD	1	2	3
1 Bullying	1.58	0.79			
2 Burnout	3.10	1.17	0.30**		
3 Ethical leadership	0.13	1.10	-0.39**	-0.42**	
4 Intentions to stay	3.60	1.10	-0.36**	-0.46**	-0.61**

Note: $N = 184$.

Abbreviation: SD, standard deviation.

** $p < 0.01$.

Hypothesis 3 which proposed that perceived ethical leadership predicts intentions to stay was also supported with significance ($\beta = 0.62$, $p = 0.00$), and our fourth hypothesis proposing that ethical leadership moderates the effect of bullying on burnout was supported ($\beta = 0.20$, $p = 0.03$). The graph of the interaction in Figure 2 indicates the direction hypothesized with perceived ethical leadership mollifying the effect of bullying on burnout. Our fifth and final hypothesis proposed a moderated mediation model. Although there were significant paths from bullying to burnout and from burnout to intent to stay, and the interaction term was significant, the indirect effect of bullying on intentions to stay was not significant; hence Hypothesis 5 was not supported ($\beta = -0.04$, $p = 0.08$). Table 2 presents the results and coefficients for the observed variables.

3.2. Discussion. There is an ongoing shortage of skilled nurses across many high income countries. The key components of nursing work of providing care are challenging and emotionally trying, which have an impact on the shortage and the ability of the industry to attract and retain nurses [116], and the resulting quality of patient care [28]. Prior research has established that bullying relates to burnout [23, 69, 116–118], yet there is limited research that examines solutions to mitigate this relationship, and how nurse leaders, specifically, can address this cultural phenomenon. There is limited research that investigates the effect of ethical leadership on nursing outcomes [37], and scant research in the nursing literature addresses how various styles of leadership can mitigate the effect of bullying on burnout and turnover intentions, specifically. The results of the current study contribute to the literature and to solutions for mitigating burnout and turnover among nurses in a number of ways.

The results of the current study align with prior research suggesting that bullying relates to burnout, and that burnout relates to turnover intentions [23, 118]. The results also suggest that bullying has a main effect on turnover intentions. However, we found no indirect effect for bullying on turnover intentions through burnout in the present study, compared to prior studies with nurses working in Taiwan [23] or Korea [118]. This could be due to cultural differences and how workplace culture is perceived differently by nurses in the United States compared to nurses from other countries. For example, based on Hofstede's dimension of national cultures [119], the United States ranks lower than Taiwan and Korea on the dimensions of power distance and higher on the dimension of individualism. Power distance is defined as the

TABLE 2: Summary of path analysis predicting intentions to stay.

Path	R ²	β	SE
Burnout on	0.23*		
Perceived ethical leadership		0.39***	0.09
Bullying		0.22*	0.09
Perceived ethical leadership X			
Bullying		0.20*	0.09
Intentions to stay on	0.52***		
Perceived ethical leadership		0.62***	0.06
Burnout		-0.18*	0.07

Note: N = 184.

Abbreviation: SE, standard error.

* $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$.

degree to which employees prefer a consultative or participative style of leadership (i.e., low ranking) versus an autocratic style of leadership (i.e., high ranking) [119]. Individualism refers to the degree in which a person views their connection to their society on a spectrum of either having loose ties to others and looking after one's self (i.e., high ranking), or valuing strong bonds with their community and having a great sense of loyalty to their society (i.e., low ranking) [119]. Employees in the U.S. who prefer a consultative style of leadership (i.e., low power distance) may be less apprehensive about expressing their opinions, attitudes, and beliefs with leadership compared to employees in other countries where a more autocratic style of leadership is preferred (i.e., high power distance). Also, employees in the U.S. who are more likely to hold individualistic ideals (i.e., high individualism) may be more likely to challenge the "status quo" compared to employees from countries where collectivism ideals (i.e., low individualism) are the norm. We posit that this perspective may weaken or eliminate the indirect effect that bullying has on turnover intentions. This is because their perceived ability to express concern about bullying may serve as a coping mechanism for reducing burnout, thereby weakening the relationship. More research about the relationship between bullying, burnout, and turnover intentions among nurses in the U.S., and its comparison across multiple countries may offer a more comprehensive understanding of this phenomenon.

Suggestions for mitigating the effects of bullying and burnout on turnover have been proposed in prior research [23, 118], but there is limited empirical evidence that these solutions work. Although prior research has investigated the relationship between leadership, bullying, burnout, and turnover intentions, not all leadership styles have been empirically examined as a means to mitigate the negative effects of this relationship. Laschinger and colleagues [120] conducted a study with results to suggest that authentic leadership negatively affects workplace bullying. Another study, qualitative in nature, suggested that transformational leadership attributes are important for establishing a positive hospital work environment [121]. We responded to the call for a greater examination of ethical leadership as an effective tool to manage nursing outcomes in healthcare [37, 118], and specifically the call to propose interventions to mitigate the effect of bullying on burnout [69]. Not only did the current study results suggest that ethical leadership has

a positive main effect on intentions to stay, the results also show that ethical leadership ameliorates the effect of bullying on burnout. Providing ethical leadership training and employing nurses who demonstrate ethical leadership may be a useful strategy for mitigating the effect of bullying on burnout, two important predictors of turnover.

4. Limitations and Future Research

It is important to note a few limitations of this study. The current study used self-report measures where social desirability may have affected the results of the data in addition to mono-method bias as a result of common method variance [122]. Cross-sectional designs such as the kind used for our study also poses limitations on causal inferences regarding the relationships between the observed variables. Online data collection also can pose limitations for controlling environmental factors. However, prior research has established there is equivalence between the results of online survey methods and results produced using paper-and-pencil formats [123].

Although our study yielded significant findings, qualitative studies may offer additional explanations to why ethical leadership mitigates the effect of bullying on burnout and increases intentions to stay in the nursing field. The current study used the survey method to measure participants' perception about the ethical leadership of their nurse manager, which can limit the richness of the data collected. Research questions that address how followers identify ethical leadership in healthcare settings are warranted. For example, does it matter if perceived ethical leadership communication is verbal instead of written? Are there any effects for gender based on the identity of leaders or nurse managers? Building on prior research [124], should we investigate whether any effects exist for race based on the identity of leaders or nurse managers perceived as ethical? Future researchers should address these questions to explain the effect of different circumstances under which ethical leadership influences the behavior and attitudes of nurses.

5. Conclusions

The aim of the current study was to investigate the relationships between perceived bullying, burnout, perceived ethical leadership, and turnover intentions. In line with prior research, the results suggest that nurses who get bullied are more likely to experience burnout, and nurses who experience burnout are more likely to intend to quit. Furthering this line of research, the results of our study also suggest that ethical leadership weakens the effect of bullying on burnout, and nurses are less likely to quit when ethical leadership is present [125–130].

5.1. Implications for Nursing Management Research. Our path analysis findings align with and extend previous research on workplace mental health outcomes in nursing. The significant relationship we found between bullying and burnout ($\beta = 0.22$, $p = 0.02$) supports prior studies showing that workplace incivility and bullying contribute to emotional exhaustion and burnout among nurses [73, 116]. The moderating effect of

ethical leadership on this relationship ($\beta = 0.20$, $p = 0.03$) builds on work by Laschinger et al. [130] on authentic leadership, suggesting that multiple positive leadership styles may help buffer against the negative effects of bullying.

Furthermore, our results highlighting the importance of ethical leadership in predicting intentions to stay ($\beta = 0.62$, $p = 0.00$) complement research on the nursing work environment. Studies have shown that supportive practice environments and ethical climates are associated with lower turnover intentions among nurses [96, 131]. Our findings suggest that ethical leadership may be a key factor in creating such positive work environments.

5.2. Implications for Nursing Management Practice. Developing a better understanding of ethical leadership's role in nursing has major implications for strategies to increase retention. There are instances when organizations go through periods of rough transitions when trying to improve their climate or culture. As leaders remove bully employees from their organization, ensuring there is ethical leadership in place may mitigate the degree of burnout experienced by nurses who are bullied. The first implication of our study is for healthcare administrators to recognize the importance of training nurse managers about ethical leadership principles and strategies. The study results suggest that this will help improve nurses' intentions to stay, and thereby reduce turnover in the field of nursing. Second, nurse managers who are perceived as ethical leaders have the effect of weakening the impact of workplace incivility on burnout. This should translate into better work outcomes for nurses and, in turn, improve health outcomes for patients. In line with prior recommendations for improving the nursing work environment [132], our results suggest that healthcare organizations should prioritize developing ethical leadership skills among nurse managers. This aligns with calls for creating positive practice environments to enhance nurse retention [133].

Aim. To assess the efficacy of a low-cost haemorrhage-control task simulator integrated in a high-fidelity simulation scenario to facilitate knowledge and practical skills acquisition, as well as self-efficacy in haemorrhage control among nursing students. **Design.** A quasi-experimental before-after design was conducted at the University of Almería. **Methods.** A one-group preintervention, immediate postintervention, and a third assessment at three months were performed, with the Stop the Bleed Education Assessment Tool used to evaluate knowledge of haemorrhage control, as well as a 5-point Likert scale used to evaluate perceived self-efficacy. The success of controlling exsanguinating bleeding was determined by quantifying the millilitres lost during the intervention and calculating the time required to control the haemorrhaging. The data were reported using the TREND guidelines. **Results.** One hundred and three final-year nursing students participated in this study. Significant improvements ($p < 0.001$) were observed in pre- and posttest total scores on knowledge of bleeding control, self-efficacy, as well as time is taken and volume loss to control the haemorrhage. Similar results were observed between preassessment and three months postassessment with significant improvements ($p < 0.001$) in all measures. **Conclusions.** The use of a haemorrhage-control task simulator within a high-fidelity simulation scenario resulted in noteworthy improvements in nursing students' practical skills, knowledge retention, and self-efficacy. After three months, performance decreased but remained greater than pretraining levels. Thus, broadening the use of this task-training simulator would be of great value to further develop a first responder training approach with healthcare professionals and other laypersons, allowing for greater knowledge distribution and reaching a larger audience. **Implications for Nursing Management.** The findings underscore the potential efficacy of this simulator as a valuable resource for nursing educators and supervisors to train nursing students and professionals in terms of practical skills, knowledge retention, and self-efficacy in haemorrhage control, fostering a train-the-trainer cascade approach to reach a wider audience and enhance bleeding control proficiency among professionals.

1. Introduction

Haemorrhagic shock is a severe form of hypovolemic shock that occurs when significant blood loss leads to insufficient oxygen delivery at the cellular level and, if ignored, may

culminate in death within minutes [1]. Indeed, only haemorrhage is the cause of death in 55.1% of patients aged 1 to 46 [2], thereby being the primary cause of intrahospital mortality within 48 hours after admission and the second highest cause of prehospital death in both military and

civilian trauma patients, accounting for 40–45% of all fatalities [3–6]. In this context, managing patients with haemorrhagic shock remains difficult and complex, with a high mortality rate [7–9]; hence, early recognition and prompt action to halt bleeding are critical, as the condition is time-dependent [4, 10].

Moreover, 34.5% of traumatic accident patients die from preventable bleeding-related causes, either in the prehospital setting or within an hour of being admitted to the hospital [11, 12]. While strengthening hospital and prehospital care seems to be essential for reducing trauma-related mortality, further bleeding control training needs to be provided to ensure such successful interventions [13–15]. The World Health Organisation and numerous consensus groups recommend first responder training programmes, for instance, as the first step in formalising emergency medical services in areas where no prehospital services have yet been created [16–18]. In this vein, one of the most effective and well-established training programmes for adequate bleeding control worldwide is the Stop the Bleed (STB) campaign, a basic short educational programme for both laypeople and healthcare professionals, that aims to provide education on wound compression, wound packing, and the use of emergency tourniquets [19]. According to certain research, even a single 2-hour STB training course could significantly increase self-confidence and competence among healthcare students instructed in bleeding control measures [20, 21].

Aside from the STB programme, there are a number of additional training programmes available that have similar objectives, which include Haemorrhage Control Course [22], Tactical Combat Casualty Care, and Advanced Trauma Life Support [23]. These programmes all share an agreed-upon aim of providing individuals with the knowledge and skills to effectively manage haemorrhage, with tourniquets standing as the primary device used to control time in exsanguinating haemorrhage in extremities [24, 25]. Although different methods can be employed for this training, simulation-based education, ranging from low-fidelity simulation (LFS) to high-fidelity simulation (HFS), has been shown as one of the most successful teaching-learning approaches for these scenarios [26–28]. In this manner, high-fidelity simulation (HFS) stands as the most popular and effective approach for incorporating realism and authenticity into the educational experience for demanding scenarios [29]. Notably, nursing students demonstrate superior outcomes in both technical and nontechnical skills when employing HFS during their emergency environment training [30]. This may not only foster self-confidence but also help in lowering anxiety levels among students [29, 31]. However, recent evidence suggests that its use in haemorrhage control training programmes such as STB appears to be currently limited and costly due to the nature of the specialist simulators and personnel skillset required [32].

Notwithstanding self-efficacy in bleeding control is paramount in successfully performing the intervention, and specialised training for first responders and healthcare professionals has shown improvement in confidence across all domains, thereby increasing the ability to manage severe active bleeding and pack a bleeding wound, and there is still

scant evidence regarding the use of cost-effective HFS for haemorrhage education. For these reasons, the aim of this study was to assess the efficacy of a low-cost haemorrhage-control task simulator, recently patented by our research team (ES-1294309_U [33]) and integrated into an HFS scenario to facilitate knowledge and practical skills acquisition, as well as self-efficacy in haemorrhage control among nursing students.

2. Material and Methods

2.1. Design and Participants. A quasiexperimental one-group before-after design was conducted at the University of Almeria from February to July 2022, following the recommendations of the Transparent Reporting of Evaluations with Nonrandomized Designs statement (TREND) guidelines [34]. The study participants were selected through purposive sampling from final-year nursing students who met the following inclusion criteria: (1) were enrolled in clinical placement 6 and 7 modules, (2) attended the bleeding control training, and (3) signed the required informed consent forms prior to participation.

2.2. Clinical Simulation. An HFS scenario was designed using a low-cost haemorrhage-control task simulator developed by our research team (ES-1294309_U) and based on the INACSL of Best Practise Standards: SM Simulation Design framework [35]. This simulator comprises a first container, means for pressurizing the infusing liquid, a venepuncture member with a flexible conduit leading to a second collecting container, and pressure control means for the user to regulate the pressure on the venepuncture member. The simulator is calibrated to measure the millilitres exsanguinated and includes a timer to record the time taken to control the haemorrhage. Specifically, the device replicates a haemorrhage in a limb within a closed circuit, using a fluid simulating blood, pressurized at a constant pressure chosen by the user-trainer, optionally through a manual or automatic sphygmomanometer. Proper and effective tourniquet placement is essential for haemorrhage control, requiring the application of the appropriate pressure.

The clinical setting was intended to simulate an exsanguinating haemorrhage scenario in which the participant was only able to control the condition using a tourniquet, without prior training (PRE). The exsanguinating haemorrhage was caused by a 6-millimetre incised wound on the anterior surface of the simulator's forearm. Table 1 summarises the required elements used to lead the simulation-based experience.

Following the collection of PRE data, the clinical simulation started with an initial 90-minute briefing in which participants were presented with the purpose of the intervention and the scenario they were facing. The nursing students received training on the proper management of exsanguinating haemorrhages using a tourniquet. This training was provided by experienced military nurses in the field and was based on the first-care provider model. After

TABLE 1: Simulation training session of bleeding control.

PRE	Prebriefing	HFS components	Simulation	Debriefing	IPA	POST
Knowledge questionnaire (SBEAT)	Military nurses provide 90-minute specialised training based on the first-care provider model	Modality (exsanguinating haemorrhage simulator) Fidelity (realism through simulation equipment, setting, and scenario)	Haemorrhage-control task simulator integrated into a traumatic multiple-incident scenario (including an exsanguinating haemorrhage) Standardised emergency equipment (including tourniquet)	Plus-delta approach using double-barrelled questioning (problem-solving and critical thinking through informed learner self-assessment, and managing perception mismatches)	Knowledge questionnaire (SBEAT) Self-efficacy questionnaire (5-point Likert scale)	Knowledge questionnaire (SBEAT) Self-efficacy questionnaire (5-point Likert scale) Practical skills (time, exsanguinated volume)

3M: 3-month assessment; HFS: high-fidelity simulation; IPA: postassessment; PRE: preassessment; POST: postassessment; SBEAT: Bleed Education Assessment Tool.

the initial briefing, the simulation stage began, in which the students attempted to control the haemorrhage with the tourniquet (POST), applying the training received during the clinical simulation by the military. This was followed by a 30-minute debriefing stage in which critical thinking and perceptions were shared collectively. Additionally, three months (3M) later, a third assessment of each study parameter was performed to assess the short- to medium-term retention of knowledge and practical skills for bleeding control.

2.3. Instruments. The sociodemographic data were collected using an ad hoc questionnaire created expressly for this purpose. The gender, age, and total amount of previous training in bleeding control were all questions on this questionnaire. The level of knowledge in bleeding control, success in haemorrhage control with tourniquet application, and students' training self-efficacy were measured as outcome variables pre- and postintervention.

Pre- and postintervention student knowledge was assessed using a nonvalidated modified version of the Stop the Bleed Education Assessment Tool (SBEAT) [36], a standardised assessment instrument for evaluating cognitive components of first aid for potentially life-threatening haemorrhages. The tool used incorporates 34 items into 20 survey questions. The questionnaire score ranged from 0 to 100, with a higher score indicating more knowledge in the field. In a Rasch model, the mean infit statistics were 1.00 and the outfit was 0.99, showing a reasonable level of fit [37].

Conversely, student self-efficacy was measured using a 5-point Likert scale, which was applied to 23 questions in the developed questionnaire. The responses to each of the questions were totalled up at the end of the questionnaire and shifted so that the maximum score was 100 points; a higher score on the questionnaire was interpreted as a greater perceived self-efficacy by the student. Cronbach's alpha reliability levels for this instrument were 0.99 (PRE), 0.99 (POST), and 0.98 (3M).

Lastly, the success of controlling exsanguinating bleeding was determined by quantifying the millilitres lost during the intervention and calculating the time required to control the haemorrhaging. The blood lost quantification was carried out by instructors directly observing the simulator's collection bag, which was graduated in 20-millilitre increments. When the amount of exsanguinated blood did not exceed 800 millilitres and the time did not exceed 120 seconds, the intervention was deemed successful.

2.4. Data Analysis. All statistical analyses of the data were conducted using the IBM SPSS Statistics v.27.0 software. A significant value of $p < 0.05$ was considered for all statistical tests performed. First, a descriptive analysis was performed on sociodemographic variables. The frequencies and percentages of qualitative variables, and the mean and standard deviation of quantitative variables were calculated. The Kolmogorov–Smirnov test was used to determine the normal distribution of the data. The chi-square test was then

used to analyse the differences between qualitative variables. The Student's t -test or Mann–Whitney U test, ANOVA, or Kruskal–Wallis test were used for quantitative variables, depending on whether the variables matched normality conditions or not. Depending on the distribution, Pearson's or Spearman's correlation was used to relate quantitative variables.

2.5. Ethical Considerations. The study proposal was approved and authorised by the Ethics Committee of the Department of Nursing, Physiotherapy and Medicine at the University of Almeria (EFM 99/2021) and in accordance with all of the ethical aspects of the Declaration of Helsinki. All participants were informed and signed informed consent forms prior to participating in the study, as well as had the option to withdraw at any time. Added to that, participants were advised that their participation in the clinical simulation training would have no influence on their grades.

3. Results

One hundred and three final-year nursing students participated in the study, with women accounting for 78.64% ($n = 81$) and men for 21.36% ($n = 22$). In terms of age, the mean age was 23.34 years (5.81), with a range of 21 to 56 years. Baseline characteristics are summarised in Table 2.

Table 3 and Figure 1 provide a comparison of the variables knowledge, self-efficacy, time, and volume pre- and postintervention. These phases correspond to the initial evaluation (PRE), the immediate evaluation after the intervention (POST), and the three-month (3M) late evaluation.

In terms of participant knowledge, statistically significant differences were found between the PRE and POST findings ($Z = -5.84$; $p < 0.01$), as well as at 3M when compared to the PRE phase ($Z = -4.82$; $p < 0.01$). The mean questionnaire score in the PRE phase was 70.58 (10.24), increasing to 79.51 (8.53) in the POST phase and 76.70 (8.95) at 3M (Figure 1(a)).

PRE-intervention self-efficacy was significantly different from POST self-efficacy ($Z = -8.53$; $p < 0.01$) and self-efficacy findings at 3M ($Z = -8.23$; $p < 0.01$). The mean score in the PRE phase was 45.83 (21.69), 77.50 (15.24) in the POST phase, and 68.50 (15.19) at 3M (Figure 1(b)).

The time required for controlling bleeding differed statistically between the three phases: PRE-POST ($Z = -6.65$; $p < 0.01$), PRE-3M ($Z = -5$; $p < 0.01$), and POST-3M ($Z = -2.48$; $p < 0.05$). Prior to training, the mean time (s) to stop simulated haemorrhaging was 76.38 (41.28), which was reduced to an average of 41.69 (27.13) following the intervention and 47.13 (28.88) after three months (Figure 1(c)).

The difference in the amount of exsanguination (mL) in the simulator between the PRE and POST phases was statistically significant ($Z = -6.98$; $p < 0.01$) as was the difference between the PRE and 3M ($Z = -5.23$; $p < 0.01$) and between the POST and 3M ($Z = -2.84$; $p < 0.01$). The mean loss was 573.30 (246.01) in the PRE phase, 325.15 (179.83) in the POST phase, and 387.38 (199.10) at 3M (Figure 1(d)).

TABLE 2: Baseline demographic characteristics of participants.

Variable	N/M	%/SD
Gender		
Male	22	21.36
Female	81	78.64
Age (years)	23.34	5.83
Knowledge (0–100)	70.58	10.24
Self-efficacy (0–100)	45.83	21.69
Time (s)	76.38	41.28
Volume (mL)	573.30	246.10

TABLE 3: Comparison of the variables knowledge, self-efficacy, time, and volume pre- and postintervention.

Variable	PRE (M (SD))	POST (M (SD))	3M (M (SD))	PRE-POST sig. (Z)	PRE-3M sig. (Z)	POST-3M sig. (Z)
Knowledge (%)	70.58 (10.24)	79.51 (8.53)	76.70 (8.95)	0.000 (–5.84)	0.000 (–4.82)	0.011 (–2.55)
Self-efficacy (%)	45.83 (21.69)	77.37 (15.36)	68.50 (15.19)	0.000 (–8.53)	0.000 (–8.23)	0.000 (–5.92)
Time (s)	76.38 (41.28)	41.69 (27.13)	47.12 (28.88)	0.000 (–6.65)	0.000 (–5.00)	0.013 (–2.48)
Volume (mL)	573.30 (246.10)	325.15 (179.83)	387.38 (199.10)	0.000 (–6.98)	0.000 (–5.23)	0.005 (–2.84)

4. Discussion

The aim of our study was to assess the efficacy of a low-cost haemorrhage-control task simulator integrated into an HFS scenario to facilitate knowledge and practical skills acquisition, as well as self-efficacy in haemorrhage control among nursing students. While there have been a few studies in this field to date, the current study emphasises training utilising a low-cost simulator to improve clinical skills and knowledge retention in the nursing student training process, which is created from generally available materials, requiring a minimal economic investment.

According to the findings of our study, final-year nursing students had a very poor success rate in haemorrhage management. At baseline, only half of the study participants demonstrated effective control prior to the intervention using a tourniquet. Likewise, the time required and the number of millilitres of blood lost during the pre-intervention phase were inadequate. This supports previous

findings employing certified training manikins as simulators [38, 39]. They found that the success rate in haemorrhage control among healthcare students was less than 66% and less than 24%, respectively, and the mean time taken was more than 75 seconds, and the amount of blood lost was more than 500 mL. Following the educational intervention, however, significant improvements in the level of knowledge, self-efficacy, and bleeding control skills among nursing students were observed, suggesting that the intervention was effective in improving the students' abilities to manage haemorrhages using a tourniquet. The present findings seem to be consistent with other research. Goralnick et al. [40] found that laypersons can successfully apply tourniquets following a one-hour course. Their study utilised various training methods, including an audio kit with visual aids on the device (audio kit) and instructional flashcards. Similarly, Stadeli et al. [41] reported improvements in knowledge and self-efficacy after participants received theoretical exposure with English slides followed by practical interpretation

without an apparent simulator. Furthermore, Muret-Wagstaff et al. [42] observed that participants achieved a proficiency level in controlling bleeding after four sessions. Their training consisted of in-person instruction following the Peyton 4-stage model and simulation-based mastery learning with deliberate practice on certified simulators of amputated limbs [42]. While earlier research has noted the importance of educational interventions in the domain of self-efficacy in bleeding control training [43, 44], our findings have important implications for developing similar results in self-confidence and self-efficacy among nursing students utilising a low-cost simulator. In this vein and as mentioned in the literature, participants are able to attain nearly flawless competency scores and appropriately assist a bleeding victim by applying direct pressure [45], particularly when HFS or more realistic models are being used, with no major financial expenditure [46]. The study by Orlas et al. [45] was conducted through a master class followed by a practical component, employing Z-Medica's training kits, which include certified manikins. Additionally, the study by Villegas et al. [46] also employed manikins as simulators.

Regarding the limitations of the study, it should be noted that the intervention was a pre-post design with expected improvements after the training and a late assessment at three months. Nonetheless, this is the first study to incorporate a low-cost simulator with regular nursing faculty materials in an HFS scenario, which demonstrated reliability and validity in evaluating advancement in knowledge level, self-efficacy, and haemorrhage control. Although our results demonstrate reliability and validity, it is important to note that the study design has several limitations and is not adequate for establishing causality. Therefore, in future studies, it would be desirable to perform a randomised trial that measures the retention of this training for a longer period than three months and expand the sample to other populations such as medical students, other healthcare professionals, civilian populations, or laypeople. Finally, another limitation of this study to consider was the use of tourniquets solely as haemorrhage control methods; hence, it might be worthwhile paying attention to other approaches such as pressure, wound packing, and others.

5. Implications for Nursing Management

In general, it seems that educating and training healthcare professionals and students is effective in promoting self-efficacy, knowledge retention, and ensuring patient survival while controlling and managing haemorrhages [47–51]. However, both laypeople and healthcare professionals continue to lack the necessary knowledge and expertise to utilise tourniquets properly [52], and thus, our findings may help healthcare educators and supervisors to find a suitable approach to foster training among their professionals and students in effective bleeding control. As previously stated in the literature, it may be worth noting that this basic training could serve as the initial step in a train-the-trainer cascade, allowing for more knowledge distribution and reaching a broader audience [20, 53].

6. Conclusion

The effectiveness of a low-cost task simulator within an HFS scenario for haemorrhage control training in nursing students was evaluated in this study, which revealed a significant improvement in the practical skills and knowledge retention of the students who used the simulator. This was evidenced by a reduction in the time required to apply a tourniquet and the millilitres of blood lost in the simulator, whereas knowledge and perceived self-efficacy were increased. Although a decrease in the performance of the students was observed after three months, they still maintained higher results than those obtained before the training and close to those obtained immediately after the high-fidelity clinical simulator training. Overall, these findings indicate that using a low-cost task simulator within an HFS can be a valuable resource for training nursing students in haemorrhage control, with effects that are comparable to additional simulators and persist over time, though reinforcement of its application may be required in the future.

Objectives. To examine the effectiveness of a patient-family (carer) partnership intervention on the BP control, self-care and self-efficacy for hypertensive people, and dyadic-relationship quality, depressive and anxiety symptoms, and health-related quality of life for the family dyads (hypertensive people and family carers) in rural communities of mainland China. **Design.** A randomised controlled trial. **Methods.** A total of 110 family dyads were randomly recruited from village clinics and randomly allocated to the intervention group ($n = 55$) or control group ($n = 55$). Family dyads in the control group received usual care. In addition to the usual care, family dyads in the intervention group received the individual-based, five-session patient-family (carer) partnership intervention. The primary outcomes included SBP, DBP, and the proportion of people with normal controlled BP. EuroQol five-dimensional-five-level (EQ-5D-5L) was adopted to evaluate participants' health-related quality of life. Data were collected at the baseline (T0), one-month (T1), and three-month postintervention (T2). Generalised estimating equation model was adopted to test the study hypotheses on all study outcomes. **Results.** Compared with the control group, hypertensive people in the intervention group had a greater reduction in SBP by 10.10 mmHg and DBP by 4.66 mmHg and a larger proportion of people with normal BP at T2, as well as statistically significant improvements at T1 and T2 in dyadic relationship, self-care, antihypertensive drug-titration rate, anxiety symptoms, and health-related quality of life. The intervention also had statistically significant positive effects on family carer's dyadic relationship and health-related quality of life at T1 and T2. **Conclusion.** The patient-family (carer) partnership intervention has the potential to improve hypertensive people's BP control and family dyad's dyadic-relationship quality and mental health at short-to-medium term follow-ups. **Implications for the Profession and/or Patient Care.** This study provided evidence and direction to support healthcare providers in developing and implementing patient-family (carer) partnership intervention for hypertension care in rural areas. This trial is registered with ChiCTR1900027087.

1. Background

Cardio-cerebrovascular disease is the leading cause of death and disability-adjusted life-year worldwide [1]. Hypertension is a major risk factor for cardio-cerebrovascular disease, and it is a major challenge for chronic illness management, with high prevalence and poorly controlled blood pressure

(BP) [2]. Hypertension prevalence in rural and urban areas could be similar, but the control rates were statistically significant lower in rural areas in China and worldwide, that was, about 9.8% versus 14.5% worldwide [3] and 9.5% versus 14.0% in China [4].

The health disparities in rural areas can contribute to the lower treatment and control rates of hypertension [5]. In

rural areas, the health disparities are considerably related to the healthcare system, socioeconomic condition, geographical distance of seeking healthcare services, strength and competence of healthcare providers, and individual characteristics such as education level and physical activity pattern, as well as the differences in cultural practices and living habits [6]. One of the largest health disparities presented in China is the inequality of resources and accessibility to healthcare services between rural and urban areas [7]. The percentages of hypertensive people receiving treatment provided by physicians in the recent two weeks are 11.29% in urban areas and 6.77% in rural areas [8].

Hypertension management interventions for populations in rural areas should consider specific sets of important sociodemographic characteristics of hypertensive people, the healthcare service/system, and their living districts/areas as needed. Families serving as an important source of social support for people with hypertension in rural areas can facilitate their compliance with the recommended treatment regimen [9]. Notably, Chinese family culture and values place high emphasis on the responsibilities and obligations of family members in caring for sick family members, considering them to be moral obligations and norms of Chinese societies [10]. These cultural specificities can influence family members' and carers' responses to the needs of their patients, the self-efficacy of an ill relative, and the relationship of the family dyad in daily care [11, 12].

Establishing a positive family-dyad (patient and the family carer) partnership is essential in family-oriented care at home [13]. Family care intrinsically involves the patients and their family carers (i.e., the family dyad) in close interactions and relationships. Family-dyad partnership is the supportive and collaborative relationship in illness management. A review of systematic reviews demonstrated that involving family members in chronic illness care can benefit patients and families [14]. However, there were research results showed that family care can be stressful for the patients and family carers during the caregiving process because of criticisms [15], family conflicts [16, 17], and overcontrolling or protective behaviours [18, 19], which can negatively affect the relationship between family dyad, as well as their physical and psychological health. Most family carers especially those living in rural areas often have lower levels of education and health literacy and may not be equipped or prepared for engagement and facilitated hypertension management. Interventions directed at improving family carers' ability and confidence and family-dyad partnership in providing care for hypertensive people are needed [20, 21]. Therefore, this study aimed to test a family-dyad partnership programme on BP control for people with hypertension in rural communities of mainland China.

1.1. Intervention Development. The development of the patient-family (carer) partnership intervention (PFPI) for people with hypertension and their family carers living in the rural areas of mainland China was (1) based on the findings of a systematic review and (2) guided by a theoretical framework-shared care model (SCM).

We conducted a systematic review to evaluate the effects of different approaches to psychoeducational intervention for family dyads in hypertension care and to examine the optimal structure, format, and components of effective interventions [22]. Synthesised evidence of the 15 (RCTs and quasiexperimental) studies demonstrated a small to medium effect of family dyad-oriented psychoeducational intervention on BP control. Several main intervention components among the effective psychoeducational interventions were identified, including education for lifestyle modification and medication adherence, home BP monitoring, and group education for family carers. In addition, interventions using a mixed-teaching approach (a combination of didactic and participatory learning) can be more effective for these family dyads than other methods. Also, several research gaps have been identified. First, very few interventions were developed to improve patient-family (carer) communication and cooperation in daily hypertension care. In addition, only two of the 15 studies adopted a theoretical framework to guide the intervention. Second, none of the included studies reported the effects of psychoeducational interventions for family dyads/family carers focused on health outcomes of family carers. Third, RCTs with high-quality methodology on psychosocial intervention for hypertension care are lacking. Well-designed RCTs of family-oriented psychoeducational intervention with commonly accepted health outcomes for the Chinese hypertension population are recommended. Finally, only two studies on hypertension care were conducted in rural areas; thus, the effects of psychoeducational intervention for hypertensive patients residing in rural areas are uncertain and inconclusive. Considering the low percentage of well-controlled hypertension and health disparities (e.g., lack of healthcare providers) in rural communities such as remote districts or villages in mainland China, there is a strong need or demand for a well-prepared family carer to facilitate and support daily care, lifestyle change, and health management for their hypertensive relatives. Therefore, a family-dyad psychoeducational intervention with didactic and participatory learning strategies (e.g., family dyadic communication, decision-making, and action planning) for hypertension care in rural communities can be designed for further testing among the population of family dyads of people with hypertension.

SCM was adopted to guide the intervention used in this study. SCM provides a structure on how to involve a family carer in caring for a patient with chronic illness. Figure 1 presents the theoretical framework of the current study. In the SCM, shared care is defined as an interpersonal process used by patients and family carers (family dyad) in home care to exchange support and manage a chronic illness [23]. Shared care is a dyadic process in which each participant affects and is affected by the other(s) [24]. The SCM hypothesises and anticipates that shared care can improve the effects of providing and receiving a family member's (carer's) assistance on improving the quality of the dyad's relationship and therefore positively affects the self-care and promotes the physical and mental health of the family dyads [23, 25]. Shared care elements (communication, decision-

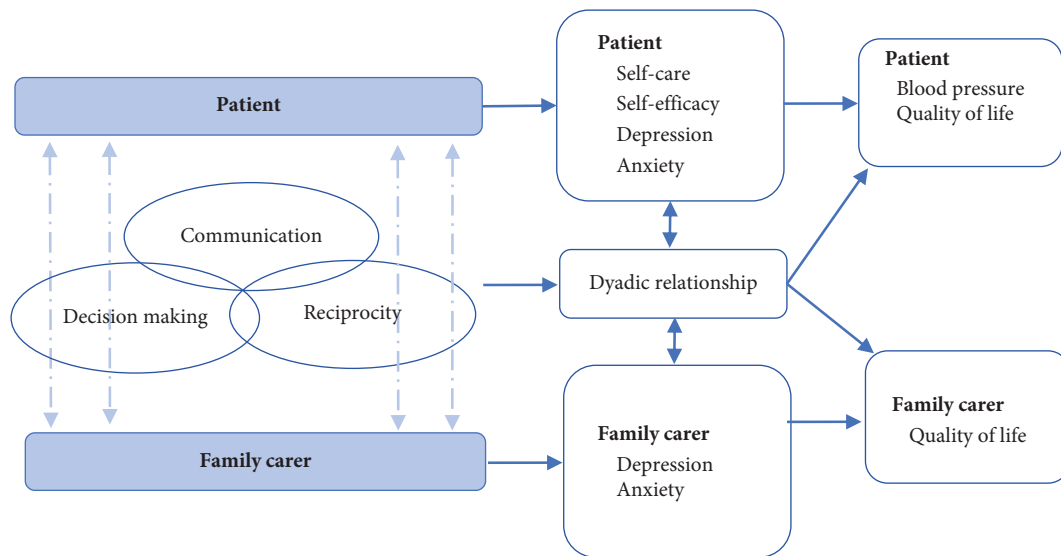

FIGURE 1: Theoretical framework of this study.

making, and reciprocity) have substantial positive associations with the self-care, depressive symptoms, dyadic-relationship quality, and health-related quality of life of patients with heart diseases and their family carers [26–28]. The elements or components of shared care also have inverse relationships with the strain and depressive symptoms of patients and their family carers (family dyads) [25]. Therefore, the SCM provided a practical and structured framework for developing the patient-family carer partnership intervention for the current study. The three main elements of shared care (communication, decision-making, and reciprocity) were used to guide intervention development.

2. Method

2.1. Study Design. This study adopted a single-blinded RCT with a parallel control (usual care) group and repeated measurements at one- and three-month postintervention. The study is reported in line with the Consolidated Standards of Reporting Trials 2010 Statement. We registered the study in the Chinese Clinical Trial Registry (registration number: ChiCTR1900027087) in October of 2019.

This study hypothesised that the participants in the intervention group would show statistically significant greater improvements at one-month and three-month postintervention, when compared with those in the control (usual care) group, on the followings:

- (1) The patients' SBP and DBP levels and proportion of patients with normal controlled BP (primary outcomes), self-care, self-efficacy, antihypertensive drug-treatment rate, antihypertensive drug-titration rate, dyadic-relationship quality, depressive and anxiety symptoms, and health-related quality of life
- (2) Family carers' dyadic-relationship quality, depressive and anxiety symptoms, and health-related quality of life

2.2. Participants and Setting. Hypertensive patients receiving home visits and care at two village clinics in Liuyang City, Hunan Province, China, were the potential eligible participants of this study. The eligibility of participants was identified according to the study criteria by the researcher in home visit. People with hypertension and their family carers (dyads) were randomly enrolled in this study.

These two adjacent rural villages are located in Liuyang City, which is the most populous county-level division in the easternmost part of Hunan Province of mainland China. Meanwhile, Hunan Province is located in the south-central part of China, with over 69 million population. Liuyang city (covering an area of around 5,000 km²) comprises 1.5 million residents. The villages under study are Gaoping and Longquan villages in Gaoping county, which are remote villages on the east side of Liuyang, being 20–30 km distance from Liuyang City. Each village has over 2,000 residents. Owing to the distance from the city, the village residents usually receive healthcare services provided by doctors at the village clinics. The public village clinics have only one medical staff (village doctor) in each clinic who provides primary health care to all residents there, such as home visits and medical consultations for people with hypertension, diabetes, and other chronic illnesses in the village(s).

Random sampling was used to recruit the eligible participants. The researcher reviewed the hypertensive people's medical records in the two village clinics under study and created a list of potential participants in alphabetical order of their family names after screening. The people on the list were randomly selected using a random number table and approached by the researcher during home visits to confirm the study eligibility and ask for consent for participation. The block randomisation with a block size of four or six and sealed opaque envelopes labelled with group (number) were adopted to ensure the randomisation and allocation concealment, respectively. An independent research assistant prepared the randomisation schedule and sealed opaque

envelopes. The randomisation sequence was generated from an online randomisation programme (<https://www.sealedenvelope.com>). After baseline measurement, participants opened the sealed envelope and were allocated to either the intervention or the control group, which was concealed from the outcome assessors, as well as the clinic staff. The inclusion criteria for people with hypertension were as follows:

- (1) Those aged 18 years or above.
- (2) Having essential hypertension without adequate BP control (SBP \geq 140 mmHg and/or DBP \geq 90 mmHg). Essential hypertension was confirmed by examining the patient's medical records in the village clinics. When "essential" was not clearly marked, the village doctor would check against the patient's medical information in the clinic for interpretation and confirmation.
- (3) Living with one or more family members.
- (4) Speaking Mandarin or local dialect.

People were excluded if they were as follows:

- (1) Diagnosed with a terminal illness (e.g., cancer, end-stage renal disease, and severe heart failure)
- (2) Diagnosed with a mental disorder, including dementia, schizophrenia, etc.
- (3) Diagnosed with stroke or COPD
- (4) Having physical disability, which was defined as needing assistance with or inability in any of the six activities of daily living (e.g., toilet, feeding, dressing, grooming, physical ambulation, or bathing) in the Physical Self-maintenance Scale [29]
- (5) Living alone
- (6) Participating or having participated recently in a structured hypertension management programme in the last six months

A family carer is a member of a family with a kinship, marital, or coresidence relationship involved in a patient's daily health care [30]. Each person nominated one family carer for participation by asking two questions in the sociodemographic datasheet: (1) "Do you have family member(s) who get involved with your health care in helping with medications, blood pressure monitoring, clinic visits, smoking cessation, alcohol control, weight loss, healthy diet, sodium restriction, or physical activity?"; and (2) "How long do you two spend together every day on average"? The family member who provided more assistance and stayed longer time was selected as the family carer to be enrolled in this study.

The family carers were included if they were as follows:

- (1) Aged 18 years or above
- (2) Blood, by-marriage, or coresidence relatives of the patient
- (3) Contactable by phone or WeChat

Conversely, the carers were excluded if they were as follows:

- (1) Having a severe mental disorder such as dementia, schizophrenia, acute or severe depression/anxiety disorders, and/or learning disorder
- (2) Taking care of two or more patients in the family
- (3) Diagnosed with hypertension

2.3. Sample Size. The sample size was estimated with reference to the effect sizes on the primary outcomes (change in SBP, DBP, and proportion of normal controlled BP) in similar studies. In our previous systematic review [22], the Cohen's effect size (d) of family dyad-oriented psycho-educational intervention for hypertensive people on changes in SBP and DBP was 0.59 and 0.57, respectively, at short-term (immediately to three months) postintervention. From the results, the sample size could be 94 and 100, respectively, with a two-group comparison test such as *t*-test (two-tailed) with 80% power at the statistically significant level of 5%, by using G*Power [31]. Moreover, the results of our previous systematic review reported attrition rates between 0% and 19.77%, and most studies had an attrition rate below 10% (13 out of the 15 included studies) [22]. Furthermore, the pilot study of this RCT indicated an attrition rate of 4.55% [32]. Therefore, an attrition rate of 10% was used, and the final sample size was 110 family dyads (i.e., 55 for each group).

2.4. Intervention Group. The people with hypertension and their family carers received the patient-family (carer) partnership intervention (PFPI), which were five individual-based, biweekly face-to-face training sessions. We conducted a pilot study to test the feasibility, acceptability, and preliminary effect of the patient-family (carer) partnership intervention for people with hypertension in a Chinese rural community. The findings of this pilot study indicated that the PFPI was a feasible and acceptable programme, as reflected by its high recruitment and intervention and study-completion rates, as well as positive feedback and perceived benefits from the participants. The results of the pilot study and the structure, content, format, and components of the PFPI have been published somewhere [32]. Improvements in the intervention in current RCT were made based on the findings of pilot study. Table 1 outlines the protocol of the PFPI.

In this study, the PFPI was delivered by the first author, who is a registered nurse and has research experience in chronic disease management (e.g., cardiovascular disease, stroke, and diabetes) in rural communities. Moreover, the researcher could speak the local language of the participants and was familiar with their local culture. This familiarity could facilitate the researcher-participant communication in the delivery of the intervention and in sample recruitment.

2.5. Control Group. Participants in the control and intervention groups received usual care delivered by a village doctor during home visits every three months following government regulations: the village doctor monitored BP, provided advice on hypertension self-care, and responded to people's questions about hypertension management during

TABLE 1: Protocol of the patient-family carer partnership intervention (PFPI).

home visits. The BP values collected were uploaded to the hypertension follow-up system managed by the Health Bureau of Liuyang City. The village doctors did not prescribe antihypertensive drugs during home follow-up. Patients who needed prescriptions were referred to visit the village clinic or other regional clinics/hospitals for medical care.

2.6. Instruments

2.6.1. Demographic Data Form. The demographic data form was developed and used to collect the sociodemographic and clinical characteristics of people with hypertension and their family carers. The sociodemographic and clinical information of people with hypertension included age, gender, marital status, employment status, education level, body mass index (BMI), smoking status, alcohol status, physical exercise, medical insurance, annual family income, family structure/unit, duration of hypertension, and comorbidities. The family carers' age, gender, marital status, employment status, education level, BMI, smoking status, alcohol status, medical diseases, and the relationship with patient were also collected.

2.6.2. Measure for Outcomes Variables

(1) BP Measurement. The method and procedure for measuring BP followed the Chinese hypertension management guideline [33]. Before starting to measure BP, the patients sat quietly in a chair, feet on the floor, and back supported, for at least 5 minutes; exercise and smoking were avoided for at least 30 minutes before measurement; the bladder was emptied; and the patient's arm was supported (resting on a desk). The middle of the cuff was placed on the patient's upper arm in the same horizontal position as the right atrium which is at the midpoint of the sternum. The correct cuff size adhering to Whelton et al. [34] recommendation was used. An electronic upper-arm sphygmomanometer (OMRON HEM-752) with a validated measurement protocol and the results have been published in a peer-reviewed journal was used to measure BP [35]. BP was measured in both arms, and the arm with a higher BP reading was used for all subsequent BP measurements. BP measurement was repeated at an interval of 1 min, and the mean value of two readings was recorded. If the difference between two readings of SBP or DBP was more than 5 mmHg, it was measured again, and the average value of three readings was recorded [33].

(2) Proportion of People with Normal BP. The number of hypertensive people with normal BP at each assessment divided by the total number of hypertensive people enrolled in the group resulted in the proportion of people with well-controlled or normal BP at that time of measurement. According to the Chinese hypertension management guideline [33], the normal BP level of Chinese adults was below 140/90 mmHg (i.e., both SBP and DBP should achieve this norm-based standard); for patients aged 65 years or

above, a normal BP should be less than 150/90 mmHg; and for patients with diabetes, it should be less than 130/80 mmHg. The determination of normal BP control was based on the current BP reading taken by the researcher/data collector in T0, T1, and T2.

(3) Antihypertensive Drug-Treatment Rate. The assessor asked participants a single question (e.g., "Have you taken any antihypertensive drugs prescribed by your doctor in the past two weeks?") to collect data about the antihypertensive drug usage in the past two weeks. The antihypertensive drug-treatment rate refers to the percentage of total number of patients took antihypertensive drugs (in the past two weeks) among the hypertensive patients who participated in this study.

(4) Antihypertensive Drug-Titration Rate. The assessor asked participants the question "Have your antihypertensive drugs prescription been adjusted by your doctor in the past two months?" to collect data about the titration of the antihypertensive drug. The antihypertensive drug-titration rate refers to the percentage of the total number of patients who had drug titration (in the past two months) among the hypertensive patients who participated in this study.

(5) Hypertension Self-Care Profile (HBP SCP). Three scales are included in HBP SCP (behaviour, motivation, and self-efficacy), which can be used together or independently. In this study, the Behaviour and Self-efficacy subscales in the HBP SCP were used to measure hypertensive people's self-care behaviour and self-efficacy, respectively. Each subscale contains 20 items rated on a four-point scale; a higher score indicates a high level of self-care behaviour or self-efficacy. The Chinese version of HBP SCP revealed good psychometric properties in the Chinese hypertensive population. Cronbach's alpha coefficients of the Behaviour and Self-efficacy subscale were 0.86 and 0.93, respectively. Moderate correlations were identified between HBP SCP subscales and Treatment Adherence Questionnaire for Hypertension (TAQPH) scales ($r=0.45, 0.61, 0.65$, all $p<0.001$) [36].

(6) Dyadic Relationship Scale (DRS). A Chinese version of the DRS was used to measure the family dyad's partnership quality. It comprised two separate versions, namely, the Patient and the Caregiver version, to evaluate both the patients' and caregivers' perceptions towards the impacts of family care on positive and negative (dyadic strain) interactions [37]. The Patient and Caregiver versions of the DRS were rated on a four-point Likert scale, from 0 (strongly agree) to 3 (strongly disagree). A lower score of the two versions indicated better perceived dyadic relationships by patients and their family carers, respectively. The Chinese versions were tested with 132 hypertensive people and their family carers in China, with good internal consistency (Cronbach's alphas=0.82 and 0.83 for the Patient and Caregiver version, respectively), positive correlations with the self-efficacy subscale of the Hypertension Self-Care Profile and Zarit Burden Interview schedule (Pearson's $r=0.70$ and 0.79 , respectively; both $p<0.001$), and test-

retest reliability (ICC = 0.97 and 0.96, both $p < 0.01$) (Zeng, Yang, and Chien, 2022).

(7) *Patient Health Questionnaire-9 (PHQ-9) and Generalised Anxiety Disorder Scale-7 (GAD-7)*. The PHQ-9 and GAD-7 are efficient tools for measuring perceived depressive and anxiety symptoms, respectively. Items in PHQ-9 and GAD-7 are rated on a four-point Likert scale from 0 “never” to 3 “almost every day;” and the higher scores of both scales indicated more severe symptoms of depression and anxiety, respectively. Cronbach’s alpha coefficient of the Chinese version of PHQ-9 was 0.82 in Chinese rural elderly [38]. The GAD-7 has been translated into a Chinese version and validated in general hospital outpatients, with a Cronbach’s alpha coefficient of 0.90 and test-retest reliability of 0.86 [39].

(8) *EuroQol Five-Dimensional-Five-Level (EQ-5D-5L)*. EQ-5D-5L, including the descriptive system and the EQ visual analogue scale (EQ-VAS), was adopted to evaluate participants’ HRQoL. Five dimensions of individual health condition (e.g., mobility, self-care, usual activities, pain/discomfort, and anxiety/depression) were measured by the descriptive system using five items with a five-point Likert scale from 0—“No” to 5—“Extreme”. The mainland China set value of EQ-5D-5L was used to convert the ratings on five dimensions into a single value, in which a higher score represented poorer HRQoL [40]. The EQ-VAS was a 20 cm vertical, visual analogue scale rating on one’s overall health, with an endpoint between 0 (worst imaginable health state) and 100 (best imaginable health state). In Chinese patients with chronic illnesses, Cohen’s kappa for the test-retest reliability of the self-classifier ranged from 0.41 to 1.00. Validity was demonstrated using known-group construct validity: seven of 10 priori hypotheses relating the EQ-5D dimensions to SF-36 dimensions were fulfilled [41].

2.7. Process Evaluation. A checklist of all items of the intervention protocol to check/monitor the intervention fidelity was used by the researcher during each session to monitor the intervention implementation (see supplementary file 1). The family dyads’ adherence to the partnership techniques in daily hypertension care is difficult to assess. In this study, strategies, such as behaviour observation during sessions and reporting and the feedback sought from the participants (dyads), were used to assess the family dyad’s adherence to the learned partnership and related techniques in daily hypertension care. For example, the researcher asked the family dyad to provide examples of the communication, decision-making, and reciprocity used in hypertension care [28] and observed the dyad’s communication styles and patterns during the training sessions. The identified partnership issues were recorded in the “checklist of partnership skills implementation during training sessions and daily life.” Each identified partnership issue was listed and marked as “implemented” or “non-implemented/inappropriately implemented” by the researcher. Further training was implemented in the next or subsequent sessions to address the “non-implemented/inappropriately implemented” skills.

2.8. Data Collection. The researcher reviewed a total of 702 patients’ medical records in two village clinics (387 and 315 records per clinic) under study at Liuyang City, Hunan Province, China, between July and August 2020 and created a list of 530 potential participants in alphabetical order of their family names. There were 180 (33.96%) patients on the list, who were randomly selected and approached during home visits to confirm the study eligibility and ask for consent for participation. After visiting 137 patients, 110 eligible family dyads (patients and their family carers) agreed to participate in the study. The 110 dyads were randomly assigned to either the intervention or control group in equal total numbers in each group, that is, with 55 dyads per group. The recruitment was conducted by the researcher.

Written informed consent was obtained from the participants who agreed to participate in this study. Then, the researcher collected the baseline data (T0). For the participants who could not read and understand the items/contents in instruments, the researcher/assessors read and explained the items and recorded participants’ responses to each item.

The researcher delivered the ten-week PFPI from August to October 2020. Postintervention data collection was conducted through home visits at 1-month (T1, November 2020) and 3-month (T2, January 2021) postintervention by a retired village doctor who was blinded to the group allocation. The retired village doctor was trained (in the village clinic) by the researcher to develop skills in data collection. Five hypertensive people were invited to participate in the training session. Peer assessments were performed on these five people with hypertension to ensure BP measurement consistency between the researcher and the assessor. An explanation of the instruments was provided during the assessor training. Considering some of the participants in the rural communities were illiterate, the assessor practiced reading and interpreting each item in the instruments to the participants. The practices for data collection were conducted in the training session until the assessor was competent to collect the data independently.

2.9. Data Analysis. IBM SPSS version 25.0 (IBM Corp. Armonk, NY, USA) was used for data analysis. Data cleaning was adopted to ensure data quality and study validity. All statistic tests involved were two-sided with the statistically significant level set at 0.05. Descriptive statistics were used to summarise the participants’ demographic and clinical characteristics and outcome variables. The assessment of normality for the continuous variables was conducted using Q-Q plot, skewness, and kurtosis statistics.

Chi-square tests and independent *t*-tests were adopted to test the homogeneity of the sample at baseline measurement. Chi-square test or Fisher’s exact test was used for categorical variables. Independent *t*-tests were applied for the continuous variables that followed a normal distribution.

Intention-to-treat (ITT) analysis was used for data or outcome analysis. ITT analysis method could preserve the sample size and statistical power, thereby resulting in a more accurate, unbiased estimation of the effectiveness of an

intervention [42]. The generalised estimating equation (GEE) model was adopted to analyse the group and time differences of individual outcome variables. In the current study, the data collected at three different time points within the same subject were usually auto-correlated. Therefore, the AR(1) model was selected as working matrices in GEE analyses. The GEE model can be applied when the data missing completely at random (MCAR) [43]. In this study, the results of Little's MCAR test ($\chi^2 = 108.949$, $DF = 148$, $p = 0.993$) supports the MCAR and GEE can be used.

In the GEE analyses, the interaction (group \times time) treatment effects were included in the GEE model to examine the changes in each outcome between the intervention and control groups across the three time points. When the interaction treatment effect was statistically significant in the GEE analysis, pairwise contrast tests were used to identify any statistically significant mean score differences in each outcome measure between groups at postintervention time points (T1 and T2).

Incorporating covariates into the GEE model could minimise the bias of confounding variables and safeguard the statistical power of the intervention effects [44]. In this study, potential covariates were identified based on the results of comparisons for sociodemographic and clinical characteristics and outcome variable scores at baseline between the intervention and control groups. Variables with $p < 0.1$ were considered as potential covariates and adjusted in the GEE model [45].

2.10. Ethical Considerations. This study was conducted in compliance with the principles outlined in the Declaration of Helsinki. Approvals for this study were obtained from the University Cluster Clinical Research Ethics Committee (CREC Ref. No.: 2019.375). Access permission for this study from the village clinic under study was also obtained. Participant recruitment was followed the voluntary principle. Each potential participant (hypertensive people and their family carers) received a detailed introduction about the study. Informed written consent was obtained from all individual participants before collecting any data. All participants had the right to refuse to participate or withdraw from the study without any influence on usual care services provided by clinical doctors. All data collected were anonymous, kept confidential, and used for research purposes only. The participants were not in any way identifiable in the research reports.

3. Results

110 eligible family dyads (patients and their family carers) participated in the study. Within one month after the intervention (T1), one person with hypertension in the intervention group died after baseline data collection; one family dyad from the control group moved to the city to live with their son. Therefore, the two groups shared the same attrition rate of 1.82% at T1. At three months post-intervention (T2), one person with hypertension died after T1 in both groups; one dyad in the intervention group and

two dyads in the control group were out of villages at the time-point of T2. Therefore, the attrition rates at T2 were 5.45% ($n = 3$) for the intervention group and 7.27% ($n = 4$) for the control group; hence, the attrition rate of the study was 6.36% ($n = 7$) at T2. Figure 2 illustrates the flowchart of participants' recruitment, group allocation, and number and reasons for withdrawals.

3.1. Demographic and Clinical Characteristics. Table 2 presents the demographic and clinical characteristics of people with hypertension. The mean age was 67.65 years ($SD = 11.53$). The majority of them were female (60.91%, $n = 67$), married (72.73%, $n = 80$), and farmers (93.36%, $n = 106$). 30.00% of the people with hypertension were illiterates ($n = 33$). The mean BMI was 23.52 kg/m² ($SD = 3.61$). About 15% ($n = 17$) and 35% ($n = 39$) were currently drinking and smoking, respectively. More than half of the people with hypertension (54.55%, $n = 60$) took part in farm work. Their average duration of hypertension was 6.25 years ($SD = 3.64$). About two-thirds of people with hypertension had at least one comorbidity (60.91%, $n = 67$), from whom one-third of them were diagnosed with diabetes (29.09%, $n = 32$). No statistically significant differences were observed in the demographic and clinical characteristics of people with hypertension between the two groups (p values ranged from 0.06 to 1.00).

The demographic characteristics of family carers are summarised in Table 3. About two-thirds of the family carers were spouses of people with hypertension (67.27%, $n = 74$). The average age of family carers was 59.51 years ($SD = 9.53$), and nearly two-thirds of them (61.82%, $n = 68$) were male. The majority of them completed at least primary school education (66.36%, $n = 73$) and farmers (89.09%, $n = 98$). Their average BMI was 24.91 kg/m² ($SD = 2.78$). About half of them (49.09%, $n = 54$) had one or more medical illnesses. Neither the Chi-square tests nor t -tests identified statistically significant differences in the demographic and clinical characteristics of family carers between the two groups.

3.2. Outcome Variables at Baseline. The mean scores or frequencies/percentages of the outcome variables are summarised in Table 4. At baseline (T0), the mean SBP values for both study groups were above the normal level of SBP (90–140 mmHg), and the mean DBP values were normal (60–90 mmHg). People with hypertension in the two groups had similar mean score of DRS-C-PT, 12.60 ($SD = 3.45$) for the intervention group and 12.22 ($SD = 3.90$) for the control group. The results of independent t -tests showed no statistically significant differences between groups in the outcome variables of people with hypertension, including SBP, DBP, dyadic-relationship quality, self-care, self-efficacy, depressive symptoms, anxiety symptoms, and health-related quality of life at T0, with p values ranging from 0.29 to 0.89; the Chi-square tests did not identify any statistically significant differences in antihypertensive drug-treatment rate ($p = 0.70$) and the rate of hypertensive drugs titration ($p = 0.54$) at T0.

Note. OR, odds ratio; DRS-C-PT, Chinese version of Dyadic Relationship Scale (patient version); DRS-C-PT, Chinese version of Dyadic Relationship Scale (caregiver version); HBP SCP-Behaviour, Behaviour scale of Hypertension Self-Care Profile; HBP SCP-self-efficacy, Self-efficacy of Hypertension Self-Care Profile; PHQ-9, Patient Health Questionnaire-9; GAD-7, Generalised Anxiety Disorder Scale-7; EQ-5D-5L, EuroQol five-dimensional five-level; EQ-VAS, EuroQol Visual Analogue scale. [#]Presented as *n* (%). *Presented as median (lower quartile, upper quartile).

All the outcome variables of family carers were computed using independent *t*-tests. There were no statistically significant differences between groups in family carers' dyadic-relationship quality, depressive symptoms, anxiety symptoms, and health-related quality of life at T0, with *p* values ranging from 0.44 to 0.98.

3.3. Effects of PFPI on People with Hypertension. The results of outcome variables for people with hypertension and family carers at T0, T1, and T2 are presented in Table 4. Most

of the outcome variables were normally distributed with standard skewness and kurtosis scores between –1.96 and +1.96 and the data points were approximately located on the diagonal line of the Q-Q plot. However, the scores of PHQ-9 and GAD-7 for patients were not normally distributed. The normality of the PHQ-9 and GAD-7 scores across the three data collection time points was met with logarithm transformation. The effect sizes for patients' continuous outcome variables at T1 were small to medium, with Cohen's *d* values ranging from 0.33 to 0.77; at T2, Cohen's *d* values ranged from 0.31 to 0.92. Regarding the

categorical outcome variables of patients, the odds ratio ranged from 1.49 to 11.81 at T1 and 1.51 to 9.91 at T2. For the outcome variables of family carers, the effect sizes were small, with Cohen's *d* values ranging from 0.18 to 0.44 at T1 and 0.20 to 0.44 at T2.

The results of GEE test (Table 5) indicated statistically significant interaction (group \times time) treatment effects on the study outcomes, including SBP, DBP, proportion of people with normal BP, DRS-C-PT, HBP SCP-Behaviour, HBP SCP-Self-efficacy, PHQ-9, GAD-7, EQ-5D-5L index score and EQ-VAS of people with hypertension with *p* values ranged from <0.001 to 0.04, between the two groups over three-month follow-up. Regarding the effects of PFPI on family carers, the results of the GEE test (Table 5) indicated statistically significant interaction treatment effects on GRS-C-CG, GAD-7, EQ-5D-5L index score, and EQ-VAS between groups over the three-month follow-up, with the *p* values ranged from <0.001 to 0.03.

Pairwise contrast tests in the GEE (Table 5) indicated that, compared with the control group, the people with hypertension in the intervention group reported statistically significant greater improvements in SBP, DBP, DRS-C-PT, HBP SCP-Behaviour, hypertension drug-titration rate, GAD-7, EQ-5D-5L index score, and EQ-VAS at T1 and T2; and in the proportion of people with normal BP, HBP SCP-Self-efficacy at T2. When compared with the control group, the family carers had statistically significant greater improvements in GRS-C-CG and EQ-5D-5L index score at T1 and T2, and in GAD-7 and EQ-VAS at T1.

4. Discussion

4.1. Effects on the Outcomes of People with Hypertension. We supported the study hypotheses that people with hypertension in the intervention group would show statistically significant greater improvements in SBP and DBP values, dyadic relationship, self-care, hypertensive drug-titration rate, anxiety symptoms, and HRQoL at both T1 and T2 and on the proportion of patients with normal BP and self-efficacy at T2, when compared with those in the control (usual care) group. However, the hypotheses concerned with statistically significant greater improvements on the proportion of people with normal BP and self-efficacy at T1 and on antihypertensive drug-treatment rate and depressive symptoms at both T1 and T2 were not supported.

4.1.1. SBP and DBP Values and the Proportion of People with Normal BP. The effect sizes of PFPI on SBP were medium (Cohen's *d* = 0.77) at T1 and large (Cohen's *d* = 0.92) at T2, whereas those on DBP were small at T1 and T2, with Cohen's *d* = 0.44 and 0.47, respectively. The findings of BP control are consistent with and more effective (in SBP and DBP reduction) than the results of our previous systematic review in which eight included RCTs of family dyad-oriented psychoeducational interventions reported that the SBP and/or DBP of people with hypertension statistically significant decreased at less than three months postintervention (medium pooled effect sizes of 0.59 and 0.57, respectively)

[22]. Furthermore, PFPI significantly improved the proportion of people with normal BP across the study period, from zero at baseline to 23.64% at T1 and 41.82% at T2. Among the studies included in our previous systematic review [22], four reported the effects of family support interventions on the proportion of people with normal BP. The improvements in the proportions of people with normal BP in these studies (15.8%–44.90%) were similar to those in the current study (23.64% at T1 and 41.82% at T2). The overall rate of well-controlled hypertension (SBP <130 mmHg and DBP <80 mmHg) in the USA in 2017–2018 was 39.64% [46]. Therefore, PFPI could be useful in improving the proportion of people with normal BP across rural areas, bringing it to the same level in developed countries.

People with hypertension in rural communities could not receive adequate healthcare services [7, 8]. In the current study, the clinic doctor (the only staff in the clinic) needs to provide nearly 300 home visits each month to all patients with hypertension and/or diabetes in the village. The large workload is not conducive to providing complete and effective hypertension care services. The family carers in the PFPI group were trained to supervise and assist in patients' medication intake, BP monitoring, and problem behaviour change and to record BP values and medication adherence in the booklet provided for reference to healthcare providers. Therefore, they were employed as surrogates for formal healthcare providers [47]. This assistance in hypertension care could alleviate the effect of the shortage of healthcare providers on hypertension management in rural areas [48]. Moreover, compared with the previous studies on family-oriented or family support intervention [48, 49], PFPI was delivered in face-to-face individual (for family dyad) sessions during home visits. The scattered living status and underdeveloped transportation in rural areas could prevent patients from actively seeking healthcare services. The healthcare service (e.g., PFPI) delivery format of home visits addresses the health disparities in seeking healthcare service for rural community residents due to long geographical distance.

The construct of SCM, which was adopted for PFPI development in this study, could interpret the statistically significant effect of PFPI in BP control. The three main components (communication, decision-making, and reciprocity with family dyad) in SCM were committed to building an effective patient-family carer (dyadic) partnership in daily hypertension care. The conflicting beliefs, difficulty in talking about an emotional topic, and lack of skills in handling conflict negatively affected the care partnership [15, 16]. PFPI provided dyadic communication skill training improving dyadic communication led to reductions in depressive symptoms for the patients and/or family carers and a positive value for the family. Systematic reviews demonstrated that family-dyadic partnership-/relationship-focused interventions were more likely to lead to reductions in depressive symptoms for patients with chronic illness and their family carers than the family interventions only directed at increasing knowledge and skills for managing the disease [47]. The exchange of values and prefers about self-management strategies between the dyad

TABLE 5: Generalised estimating models for comparing the outcomes across time between the intervention and control groups.

members is the basis of decision-making and action in hypertension care; it could improve the self-care (e.g., medication intake and problem behaviour change) of patients with hypertension [50]. Implementing the action plan with mutual support is highly emphasised in the SCM and PFPI [28]. In the PFPI sessions, the family dyad was guided to identify problem behaviour and set goals; discuss the influence of behaviour change; discuss difficulties in behaviour changes and effective coping strategies; identify ways to seek information, professional help, and community support whenever needed; and formulate an action plan. The family dyad applied these decision-making techniques in daily hypertension care situations when needed to make decisions. Research has demonstrated that the improved decision-making skill of stroke survivor-caregiver dyad was positively associated with survivors' depressive symptoms, dyadic relationship, and survivor coping skills [51]. Dyadic partnership is also a process of giving and accepting physical and emotional help with appreciation [52]. For example, in the PFPI sessions, the family dyads discussed the assistance provided by the family carer and received by the patient in behaviour modification. They also discussed the difficulties and challenges throughout the process of giving and receiving assistance and the strategies to overcome them and express gratitude and appreciation. These reciprocity skills facilitate the family dyad's mutual cooperation in BP monitoring, medication adherence, and behaviour change at home.

Another feature of PFPI is cultural sensitivity. Interventions taking the culture into account are more likely to lead to more positive behavioural changes [53]. In the rural areas of China, family culture and values highly emphasise the responsibilities and obligations of family members in caring for sick family members [10]. Therefore, in PFPI, the family carer was treated as a partner in hypertension care. Each family dyad worked together to promote treatment adherence and lifestyle modification through effective dyadic communication (to avoid conflicts and over-protection) and decision-making in health care.

4.1.2. Dyadic-Relationship Quality. In this study, the dyadic relationship significantly improved for the intervention group at T1 ($p = 0.004$) and T2 ($p < 0.001$) with medium effect sizes (Cohen's $d = 0.52$ and 0.65 , respectively). As the dyadic relationship quality was seldom measured as an outcome in previous studies [47], limited information about the effect of interventions on dyadic relationship quality among people with hypertension could be found. Seber and Woda [28] developed a shared care dyadic intervention based on SCM for patients with heart failure and used a dyadic relationship measure as one of the patient outcomes in their pilot study. However, noticeable differences were found in the participants, sample size, study design, and times of outcome measurements between two studies, which may have led to the difference in their effect sizes on the dyadic relationship quality, with a Cohen's d of 0.65 at three-month postintervention in the current study and 0.25 immediately postintervention in Seber and Woda's study [28].

In an RCT study, a family partnership intervention was effective in improving perceived confidence and motivation for self-care and reducing dietary sodium among heart failure patients. Other RCT study also demonstrated the effectiveness of family-focused dyadic psychoeducational intervention on the dyadic relationship of stroke survivors and their family caregivers [51]. Therefore, family-dyad partnership intervention may be feasible and effective in improving self-care and self-efficacy for patients with chronic illnesses.

4.1.3. Self-Care and Self-Efficacy. PFPI significantly improved hypertensive people's self-care and self-efficacy in hypertension management with medium and small effects, respectively (Cohen's $d = 0.65$ and 0.31 , respectively). In our previous systematic review [22], three studies reported the results of self-care, all of which revealed statistically significant improvements. Similar to this study, educating family dyad jointly in the educational sessions on knowledge and skills of lifestyle modifications through discussion and goal setting and encouraging family carers to supervise patients' behavioural changes were used in previous studies. These intervention components/contents were also demonstrated (in a systematic review) to be effective in improving self-management for patients with uncontrolled type II diabetes mellitus [54]. PFPI also adopted participatory learning strategies to improve the family dyads' skill in identifying the problem behaviour and making decisions and action plans for behaviour change. The participatory learning strategies encourage more active involvement of participants in the learning process, improve the dyadic communication and cooperative techniques of family dyad in health care, and facilitate changes in their lifestyle behaviour [55].

4.1.4. Antihypertensive Drug-Treatment Rate and Antihypertensive Drug-Titration Rate. In the current study, the hypertensive people in the intervention and control groups had improved antihypertensive drug-treatment rates. However, the difference between groups was nonsignificant ($p = 0.17$ and 0.18 , respectively) at T1 and T2. In the home visit service (usual care), the village doctor monitored the BP of people with hypertension (every three months) and encouraged them to intake hypertensive drugs for those who had uncontrolled BP, which may lead to an improvement in antihypertensive drug treatment [56]. On the other hand, people with hypertension in the intervention group had significantly improved antihypertensive drug-titration rate at T1 and T2 ($p = 0.01$ and <0.001 , respectively). Although usual care (with or without PFPI) revealed effect on improving antihypertensive drug-treatment rate, the PFPI together with usual care for the intervention group had a much better effect on the antihypertensive drug-titration rate.

Evaluating the efficacy of antihypertensive drugs in BP control (e.g., BP monitoring) promptly is a prerequisite for drug titration [34]. However, only 24.5% to 34.3% of people with hypertension living in China rural communities

conducted weekly BP measurements [57]. People with hypertension receiving the PFPI had more frequent BP monitoring (e.g., measured BP at each session) than those in the usual care group, which may lead to a higher antihypertensive drug-titration rate. A recent systematic review examined the effects of family involvement in hypertension care on managing medications of older patients with chronic illnesses [56]. The findings indicated that family carers' participation in conveying information about patients' medication adherence and BP values to healthcare providers and receiving feedback and decision-making in managing medications could lead to drug titration more effectively. The intervention combining BP self-monitoring and self-titration to adjust antihypertensive medication could lead to the reduction of 9.2 mmHg in SBP and 3.4 mmHg in DBP for people with hypertension compared with the usual care group [58]. In the current study, we did not collect the data on dose and types of antihypertensive drugs, and the BP values changed after the drug titration. Therefore, the effect of drug titration on BP change remains unknown. Further studies should collect the data of doses and types of antihypertensive drugs used and changed over time, and the BP values changed after the drug titration, to identify the trajectory of BP change.

4.1.5. Depression and Anxiety Symptoms. The findings of this study revealed that PFPI reduced depressive symptoms, but the effect was nonsignificant between groups. However, anxiety symptoms were significantly reduced at T1 and T2 compared with the control group, with medium and small effect sizes (Cohen's $d=0.52$ and 0.48 , respectively). Inconsistent with the findings on depressive symptoms of hypertensive people in the current study, systematic reviews in chronic illness care have provided evidence of the positive effects of family involvement in illness management programs for adults with different chronic illnesses (e.g., stroke survivors and patients with cancer) [59, 60]. The inconsistency may be due to the low level of people's depression at baseline (mean PHQ-9 score was 4.00), where a PHQ-9 score below 10 is considered to be mild in depression symptoms. Such flooring effect of low depressive symptoms at baseline might cause difficulty in showing treatment effects by making statistically significant changes or improvements in their scores. Patients with serious illnesses (e.g., stroke and cancer) often experience more depressive symptoms [47]. The effect of PFPI on reducing hypertensive people's depressive symptoms should be further studied.

Increasing evidence of the association between anxiety and hypertension exists [61, 62], and anxiety could negatively affect medication adherence [63]. A significant correlation between anxiety, family function, and QoL was found, and anxiety had a partial mediating effect on the relationship between family function and QoL of older adults with hypertension in low-income communities [64]. The effects of family involvement in hypertension care on anxiety could not be found in previous studies. In other chronic illnesses, such as heart diseases, the effect of family dyad intervention on anxiety in patients with coronary heart

disease and family partners was evaluated in a systematic review; the authors could not find significantly lower anxiety levels for patients who received interventions focusing on disease counselling and improving social support than the control group [65]. By contrast, another systematic review demonstrated that interventions targeting the relationship between patients with cancer and their family carers could significantly improve anxiety, depression, and/or distress in both [59]. The potentially effective components of these included studies were education and training about disease knowledge, problem-solving skills, and counselling and discussions in a dyadic manner, similar to the PFPI in the current study. Therefore, even though the evidence of family-dyadic partnership interventions on anxiety symptoms of hypertension and other chronic illnesses (e.g., hypertension, diabetes, and stroke) was limited, the findings of this study supported that family-dyadic partnership intervention could be a promising intervention in improving the anxiety symptoms of people with chronic illness.

4.1.6. Health-Related Quality of Life, HRQoL. PFPI significantly improved the HRQoL of people with hypertension at T1 and T2, with medium and small effects (measured by EQ-5D-5L index: Cohen's $d=0.66$ and 0.49 , respectively; measured by EQ-VAS: Cohen's $d=0.61$ and 0.51 , respectively). An effective family-dyadic partnership was beneficial for QoL of people with hypertension in low-income communities [64]. The structure of SCM also supports a positive relationship between self-care, dyadic relationship, and HRQoL [24]. Similarly, Reid et al. reviewed [63] psychological interventions for patients with coronary heart disease, and their partners demonstrated improvements in the HRQoL of patients at 6 to 13 months post-intervention. The main components of the interventions in the reviewed studies were similar to those in this study, including information giving and counselling in 2 to 8 dyadic sessions within 1.5 to 4 months.

4.2. Effects on the Outcomes of Family Carers

4.2.1. Dyadic Relationship Quality. With no available evidence for the family's perceived dyadic relationship in hypertension care, the GEE test identified statistically significant interaction effects of PFPI on the family carers' perceived dyadic relationship at T1 ($p=0.04$) and T2 ($p=0.049$) with small effect sizes (Cohen's $d=0.36$ and 0.31 , respectively). In two pilot studies (with small sample sizes of four and 10 only), shared care interventions developed based on SCM were tested among patients with heart failure and their family carers. These studies reported improvements in the quality of dyadic relationship (also measured by DRS-CG) immediately post-intervention [27, 28]. Dyadic communication and reciprocity in healthcare were the main contents of PFPI in the current study, leading to significant improvements in dyadic relationship. Family-dyadic partnership-focused intervention had positive effects on improving the dyadic relationships in their verbal feedback, such as knowing each other better, expressing suggestions and assistance positively, exchanging

views on illness experiences, and clarifying perceptions [50]. The findings could support further research to employ the patient-family (carer) partnership model of intervention to improve the dyadic relationship of family carers and patients with hypertension.

4.2.2. Depressive and Anxiety Symptoms. The PFPI has positively improved the family carers' depressive symptoms, but the GEE test results did not indicate statistically significant effect between groups. None of the studies reviewed in our previous systematic review provided evidence about the family carers' depressive symptoms in hypertension care. The result of a systematic review and meta-analysis demonstrated that a stronger perception of filial obligation was associated with increased depressive symptoms among family carers, especially in Chinese culture [66]. Family dyadic relationship-focused interventions can significantly improve family carers' depression of patients with stroke, cancer, and arthritis [59]. Since patient and family carer depression influences patient self-care and family carer's contribution to self-care, healthcare providers should assess and treat depression in both members of the dyad to improve self-care [67]. However, caring for seriously ill patients (e.g., stroke and cancer) can bring more caregiving burden and pressure to family care. As discussed above, the low level of family carers' depression at baseline might cause difficulty in showing treatment effects by making statistically significant changes or improvements.

In the current study, family carers' anxiety symptoms were significantly improved at T2, with a small effect size (Cohen's $d=0.28$). The improved dyadic partnership is conducive to lowering anxiety symptoms, as declared in SCM [24]. No information on anxiety symptoms of family carers for people with hypertension could be obtained from previous studies. The positive effect of interventions involving the family in treatment of the anxiety of family carers has been demonstrated in systematic reviews of patients with other chronic physical diseases, such as cardiovascular disease, arthritis, and diabetes [68]. An "umbrella" review also found that dyadic relationship-focused family interventions could improve the mental health of adult patients with chronic illness and their family carers [47]. Therefore, family-dyadic partnership/relationship intervention may positively affect the family carers' anxiety symptoms, and further research is needed to support the positive effect of PFPI in improving the anxiety symptoms of family carers in hypertension care.

4.2.3. Health-Related Quality of Life (HRQoL). PFPI significantly improved the HRQoL of family carers at T1 and T2 ($p = 0.03$ and 0.02 , respectively), with small effects when measured using EQ-5D-5L index (both Cohen's $d=0.44$). However, the difference in HRQoL measured using EQ-VAS was statistically significant at T1 only ($p = 0.04$) with a small effect size (Cohen's $d=0.33$). The symptoms, mood, knowledge, and behaviour of people with hypertension towards hypertension management and the family carers' caregiving burden were significantly related to the HRQoL

of the family carer [69]. The results of a systematic review and meta-analysis that showed lower poststroke cognitive performance were associated with poorer caregivers' quality of life [68]. In the current study, with the positive effects of PFPI in improving patients' self-care, anxiety symptoms, and family carers' perceived dyadic relationship, the improvement of HRQoL could also be statistically significant and positive. Similar to other family outcomes used in this study, limited evidence was available in previous hypertension care studies. Further research is suggested to confirm the effect of PFPI on improving the carer's HRQoL.

4.3. Limitations. Several limitations should be acknowledged. First, the participants in this study were recruited in only two villages in Hunan Province in Southern China, thus limiting the representativeness of the participants and the generalisability of this study to other rural areas in China. Second, this study examined the short-term (one- and three-month postintervention) effects of PFPI on the outcome variables of people with hypertension and their family carers. The longer-term (e.g., six months or above) effects of PFPI on these outcomes remain unknown, and they need to be tested in further studies. Third, although a checklist of all items of the intervention protocol was used to monitor the intervention fidelity by the researcher during each session, this study lacked sufficient process evaluation. Future studies are recommended to adopt a process evaluation to thoroughly understand the intervention implementation, compliance of participants, and successful features of the programme [70]. An independent observer or audio and video recording could be used to measure implementation fidelity. Lastly, as an individual's BP values could fluctuate throughout the day, the BP values obtained from measuring at a one time point on the data collection day may not comprehensively reflect the patient's BP controls. A 24-hour ambulatory blood pressure monitoring could be adopted in future research to obtain more accurate BP values.

4.4. Implications. This study provides evidence on integrating the PFPI into hypertension management programmes for rural communities in China. This study also reveals its potential application to a wider hypertensive population in the rural and urban areas of China. Several suggestions were provided to facilitate the implementation of PFPI in practice. First, the study findings could help health policymakers and government administrators realise the importance of patient-family (carer) partnership as the model of intervention in hypertension management in communities, particularly in rural areas with very limited healthcare service. They could also promote the related health regulations or policies to emphasise the adoption of patient-family partnership models of care in community-based hypertension management or services. Second, hypertension care stakeholders need to discuss the barriers and facilitators of integrating PFPI into the current hypertension management service. Third, the village doctors and/or social workers, who are the common healthcare workers in rural areas, should be trained to conduct PFPI.

5. Conclusion

We evaluated the effectiveness of PFPI on people with hypertension and their family carers in rural communities in China. The findings demonstrated statistically significant positive effects of PFPI on the majority of the outcomes of participants. These findings supported integrating PFPI into the current hypertension care programmes/services as it could be a more feasible and effective approach to hypertension management in rural areas of China. Further studies are recommended to apply a mixed-method research design and recruit participants with diverse clinical, sociodemographic, and ethnic backgrounds to evaluate the longer-term effects of PFPI in different China regions.

Data Availability

The datasets used to support the findings of this study are available from the corresponding author upon request.

Additional Points

Reporting Method. The study is reported in line with the Consolidated Standards of Reporting Trials 2010 Statement. Patient or Public Contribution. Eligible hypertensive people receiving home visits and care at two village clinics and their family carers were randomly enrolled in this study. The researcher reviewed the hypertensive people's medical records in the two village clinics under study and created a list of potential participants (those aged 18 years or above and having essential hypertension without adequate BP control) in alphabetical order of their family names after screening. The people on the list were randomly selected using a random number table and approached by the researcher during home visits to further confirm the study eligibility (living with one or more adult family members, speaking Mandarin or local dialect, and without terminal and mental illness, etc.). The researcher introduced the study to the participants and the benefits, risks, participants' rights, and confidentiality when participating in this study. Written informed consent was obtained from the participants who agreed to participate in this study. The researcher delivered the intervention to participants in the intervention group. A retired village doctor was trained to collect data. What Does this Paper Contribute to the Wider Global Clinical Community? (i) The patient-family (carer) partnership intervention has the potential to improve hypertensive people's BP control in rural areas. (ii) The intervention also helps to improve hypertensive people's and family carer's dyadic-relationship quality and mental health at short-to-medium-term follow-ups. (iii) This study provides evidence on integrating the patient-family (carer) partnership intervention into hypertension management programmes for rural communities worldwide. Trial Registration. This study was registered in the Chinese Clinical Trial Registry <https://www.chictr.org.cn> (registration number: ChiCTR1900027087) in October 2019, and the first participant was recruited in July 2020.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

This research received grant from the President's Funding of Southern University of Science and Technology Hospital (2022-C3) and the Science and Technology Project (Medical and Health) of Shenzhen Nanshan District (NS20230010).

Supplementary Materials

Supplementary material 1: a checklist of intervention fidelity. The checklist consisted of all items of the intervention protocol. It was used by the researcher during each intervention session to monitor the intervention fidelity. At the end of each session, the researcher checked the completion of each item on the list with family dyad and marked as "completed" or "uncompleted." The "uncompleted" intervention item was made up in time. Supplementary material 2: hypertension management booklet. The booklet comprised four sections, including the goal of BP control, risk assessment for cardiovascular disease, criteria of healthy behaviours and worksheets for identifying behavioural problems, and hypertension self-care. (*Supplementary Materials*)

Background. Most frontline nurses lack sufficient readiness for effective disaster response. Therefore, designing a disaster management training program (DMTP) to promote nurses' readiness for disaster response is imperative. **Aim.** This study aimed to evaluate the effectiveness of a structured DMTP on nurses' readiness for response to disasters. **Methods.** A randomized controlled trial was conducted. One hundred eligible nurses, recruited using convenience sampling from a medical centre in northern Taiwan, were randomly assigned to either the experimental (EG, $n = 50$) or control (CG, $n = 50$) group. Both groups received regular continuous nursing education. The EG received an extra two-day (16 h) structured DMTP delivered by transdisciplinary collaborations through multiple teaching strategies (lectures, simulations, problem-solving lessons, demonstrations, tabletop exercises, discussions, group presentations, and reflections). Readiness for disaster response, consisting of four subscales (emergency response, clinical management, self-protection, and personal preparation), was assessed at baseline and 12 weeks after the intervention. Generalized estimating equations were used as the primary method of data analyses to evaluate the intervention effects. **Results.** Ninety-four nurses (94%) completed the study, and 100 nurses were included in the intention-to-treat analysis. While participants in the EG had increased readiness for disaster response after training and at the 12-week follow-up, those in the CG exhibited no differences between baseline and 12-week follow-up. When the group \times time interaction was examined, the EG had a greater increase in readiness for disaster response and its four domains, including emergency response, clinical management, self-protection, and personal preparedness after 12 weeks, than the CG. **Conclusion.** A two-day structured DMTP utilizing multiple teaching strategies through transdisciplinary collaborations is recommended to enhance hospital nurses' readiness for disaster response. **Implications for Nursing Management.** Nursing leaders should consider incorporating such a structured DMTP into ongoing nursing training as a critical component of professional development programs, thereby strengthening nurses' disaster readiness in hospital settings.

1. Introduction

Disasters have engendered significant repercussions characterized by extensive damage, destruction, and loss of life, property, or livelihoods in communities and societies [1]. Worldwide, nations face potential threats from a wide array of disasters, including natural disasters such as earthquakes,

hurricanes, floods, landslides, and wildfires, and anthropogenic catastrophes such as terrorist attacks and warfare. These disasters have profound impacts on both individuals and nations, leading to severe consequences [2, 3].

Taiwan, situated in a geographically vulnerable region, faces a wide spectrum of natural disasters and associated hazards. Among these, earthquakes, typhoons, landslides,

floods, and industrial accidents have historically affected island nations. Over the past few decades, earthquakes have been one of the most devastating events in Taiwan. Previous disaster epidemiology studies related to the 1999 Chi-Chi earthquake in Taiwan, which claimed 2,415 lives and caused injuries to 11,305 people, revealed that the demand for medical care peaked 12 hours after the earthquake and remained elevated for up to three days [4]. These findings highlight the critical significance of timely disaster response for healthcare in Taiwan.

Disasters can result in a range of adverse outcomes, including infrastructure damage, economic consequences, physical injuries, psychosocial impacts, environmental ramifications, and deprivation of essential services such as water, sanitation, and healthcare, forcing people to leave their homes and communities temporarily or permanently and even lose their lives [3, 5]. Therefore, efforts to decrease the unexpected consequences of disasters and develop strategies to mitigate their impacts remain an imperative research focus. However, to minimize the impact of a disaster and ensure timely and effective responses, a robust frontline medical workforce, particularly nurses, is crucial in disaster areas and local hospitals near the affected sites [6, 7]. Frontline nurses must efficiently assess the severity of patients' injuries and prioritize care based on the level of urgency during a disaster when there may be a high volume of patients in need of care. In addition, nurses are responsible for stabilizing patients experiencing a medical emergency with initial treatment, transferring patients to hospitals or medical facilities, offering coordinated care to patients with other healthcare professionals, and providing emotional and psychological support to patients and their families during disasters [8].

Considering the continuous occurrence of disasters and the negative impacts they entail, nurses' readiness to respond is crucial for mitigating the adverse consequences on affected individuals. Recently, the COVID-19 pandemic has highlighted the necessity of having a national nursing workforce prepared with the knowledge, skills, and abilities to respond [9]. Disaster management is the effort to reduce unexpected consequences and disaster risks [10]. Therefore, to ensure effective and efficient disaster management, it is crucial to enhance frontline nurses' readiness for disaster response, thereby saving lives and mitigating adverse health impacts on affected populations [10, 11].

According to the World Health Organization, most disaster-related deaths occur in healthcare facilities that are unprepared for emergency situations [12]. Adequate preparation and disaster readiness of healthcare personnel, especially nurses who often serve as first responders, can significantly reduce fatalities [8, 13]. Moreover, building resilient health systems through better-prepared medical staff is fundamental [8, 11]. The readiness of nurses not only impacts the immediate effectiveness of disaster response but also significantly affects the overall resilience of health systems and predicts the nurses' willingness to engage in these situations [7] and their capacity to deliver adequate care within a disaster environment [14]. Comprising the largest segment of the healthcare workforce, nurses play

a pivotal role in shaping community health outcomes during disasters [15] and managing emergency or disaster medical situations, thereby forming the backbone of the health system. Therefore, it is crucial that nurses possess the requisite knowledge, skills, and competencies, especially readiness, to respond effectively to disasters [16].

However, a significant concern is that many hospital nurses report a lack of readiness for disaster response [15, 17]. Disaster readiness varies significantly across countries, influenced by factors such as economic status, governance, infrastructure, and historical disaster experience [18–21]. For instance, high-income countries like Finland exhibit a proactive approach by incorporating a disaster readiness mindset into governmental strategies [21]. This approach involves identifying potential disaster risks and implementing measures to mitigate them effectively, ensuring a well-coordinated response when disasters occur [21]. In contrast, many countries face challenges in disaster preparedness due to limited resources and infrastructure. Previous studies have highlighted that nurses, especially undergraduate nursing students in these regions, often lack sufficient training and education in disaster management, which is crucial for effective emergency response and clinical management [18, 20, 22]. This gap is evident in regions such as Southeast Asia and parts of Africa, where the frequency of natural disasters like floods and cyclones is high, yet preparedness levels remain inadequate [20, 22]. In Taiwan, a cross-sectional study involving 311 registered nurses at a military hospital found that the majority of nurses demonstrated poor readiness and lacked adequate preparation for disaster situations [11]. Studies have also highlighted that nurses and nursing students with prior disaster-related training and experience in disaster response demonstrate higher readiness and competencies [11, 18]. In India, nurses display moderate levels of preparedness, influenced by various factors such as education, prior disaster experience, mental health, and especially disaster self-efficacy, a vital factor that determines an individual's behavior and performance during disaster situations [23]. In Japan, nurses' disaster readiness has been significantly shaped by the country's frequent exposure to natural disasters. A study examining the disaster preparedness of nurses following the Great East Japan Earthquake found that while they demonstrated moderate levels of overall preparedness, there were notable deficiencies in handling specialized scenarios, such as chemical or biological incidents, and in their psychological preparedness [14]. Thus, the availability and quality of emergency and disaster management training for health professionals vary widely, with many countries offering little to no formal training [14]. Therefore, it is essential to develop structured and effective educational programs to enhance hospital nurses' readiness for disaster response [17].

Disasters also have significant adverse effects on the mental well-being of frontline nurses, who are a high-risk and vulnerable group of medical responders to adverse psychological outcomes [13]. In the context of surging demand, providing high-quality care during disasters is a daunting task. Such situations detrimentally affect the

health of healthcare professionals, especially their psychological well-being, owing to the repetitive exposure to traumatic events inherent in their work. Adapting preventive interventions and mitigation strategies targeted specifically at high-risk hospital nurses would be beneficial in decreasing negative outcomes [13]. The lack of adequate training for healthcare providers is a risk factor for adverse psychological health outcomes after disasters [24]. Therefore, designing and incorporating a well-structured disaster management training program into continuous clinical nursing education can mitigate the negative impacts on the mental well-being of hospital nurses who experience disaster events.

Curricula related to disaster training using multidisciplinary methods of simulation and human factor training have been proposed for implementation by organizations such as the Association of American Medical Colleges in the USA, the Government of the Federal Republic of Germany, and the Research Centre in Emergency and Disaster Medicine and Computer Science Applied to Medical Practice in Italy [17]. However, it is currently recognized that there is brief or nonexistent exposure to disaster training within current clinical training curricula worldwide, which may leave hospital nurses unprepared for an intimidating and unfamiliar setting if assisted in the healthcare workforce. Given that various nursing programs have provided education and training in disaster management in recent decades [17, 25–27], most research has focused on nursing students, and most frontline nurses have also reported insufficient readiness or preparedness in responding effectively to disasters [15, 28]. According to a recent study conducted in Greece that evaluated the effects of disaster education on hospital nurses' knowledge, skills, and expertise through evidence-based interventions, the educational intervention resulted in improved knowledge and self-confidence levels among nurses but did not lead to changes in their behavioral intentions [27]. In addition, most existing disaster programs focus on triage skills during disaster response instead of addressing the full spectrum of disaster management, including preparedness, clinical management, emergency response, and self-protection [11, 17]. Tzeng et al. delineated four critical domains of nurses' readiness for disaster response: emergency response, self-protection, clinical management, and personal preparation [11]. These domains align with the International Council of Nurses (ICN) Core Competencies in Disaster Nursing, outlined in 2019, which emphasizes the necessity for nurses to possess both theoretical and practical understanding of disaster preparedness to respond effectively to emergencies [29]. Emergency response entails managing large-scale emergencies through triage, initial stabilization of patients, incident management, medical evacuation, and transportation [8, 11, 19]. Self-protection focuses on the use of protective clothing; handling chemical, biological, radiological, and nuclear decontamination; infection control; and ensuring safety of both patients and nurses [8, 11, 17, 19]. Clinical management involves performing physical assessments, operating equipment in austere environments, and providing specific medical care such as trauma care, management of burn or

explosion injuries, first aid, and handling toxic substance injuries [8, 11, 19]. Personal preparation includes acquiring basic survival skills; making physical, psychological, and social plans (law/ethics) prior to engaging in disaster response; communication; recovery; and fostering confidence in collaboration with multidisciplinary teams or peer care [8, 11, 19].

Designing educational programs to enhance frontline nurses' disaster readiness without considering the above key domains of disaster management may not only result in the depletion of manpower and material resources but also fail to achieve the expected outcomes. Given that the ICN's core competencies in disaster nursing and the disaster readiness for response to emergencies and disasters are diverse and extensive, enhancing these competencies and readiness inevitably relies on a variety of teaching strategies. In addition, improving learning effectiveness requires the development of skills across different learning dimensions [30]. Therefore, designing disaster curricula or training programs may require multidisciplinary methods and innovative strategies. However, the development of comprehensive disaster management training programs remains limited, particularly in Taiwan, a region that urgently requires a well-prepared disaster nursing workforce.

This study examined the effectiveness of a two-day structured disaster management training program with multiple teaching strategies to promote hospital nurses' readiness for disaster response. We assume that providing such a well-organized disaster management training program delivered by transdisciplinary collaboration through multiple teaching strategies may enhance nurses' readiness for disaster response, possibly increasing their willingness to respond to disasters and mitigating the negative impacts on hospital nurses' mental well-being in the face of future disaster events. Therefore, the practical purpose of this study was to achieve two outcomes: (1) to improve nurses' readiness for disaster response, enabling them to provide timely and efficient care during disasters and (2) to strengthen nurses' resilience, helping them cope with the trauma associated with disaster response, and empowering them with the skills to take on key roles in disaster management teams.

2. Materials and Methods

2.1. Study Design. A two-parallel, randomized controlled trial was conducted at a medical centre in northern Taiwan. Eligible hospital nurses were randomly assigned to either a control group (CG), which received regular continuous nursing education, or an experimental group (EG), which participated in an additional two-day (16-hour) structured disaster management training program (DMTP). The readiness for disaster response including four domains (emergency response, clinical management, self-protection, and personal preparedness) was assessed as outcome measures.

2.2. Participants. Initially, potential participants from a military medical centre in northern Taiwan, affiliated with the national government and responsible for dispatching personnel to disaster-affected areas in Taiwan or overseas,

were recruited by a research assistant. Inclusion criteria were (1) hospital nurses with at least three months' work experience at the local medical centre; (2) aged 20–65 years; (3) full-time employees; (4) able to speak and understand Mandarin; and (5) agreed to participate in the research and to be randomized to one of the two groups. The exclusion criteria were (1) trainee nurses without nursing licenses; (2) new nurses lacking signed contracts because of their inability to work independently; (3) individuals not providing direct care; and (4) those unable to complete the intervention.

Sample size estimation using G* Power (Germany, version 3.1.9) software was based on previous studies with a medium-to-small effect size of 0.15 for the outcome of the expected increase in readiness for disaster response [19, 31, 32], an alpha set at 0.05, number of measurements 2, and a power of 0.80, and each group required 45 hospital nurses [33]. Fifty estimated participants from each group were recruited to account for a 10% loss to follow-up.

2.3. Study Cohorts and Interventions. Eligible hospital nurses were randomly assigned to the EG or CG using sealed opaque envelopes following computer-generated random serial numbers by the project investigator. All recruited participants underwent monthly continuous nursing education sessions (30–60 minutes/session) in their workplace units/wards. The participants in the EG received an extra two-day structured DMTP through multiple teaching strategies, such as lectures, simulations, problem-solving lessons, demonstrations, tabletop exercises, discussions, and reflections.

Before implementing the DMTP, we assembled a team of 17 transdisciplinary professionals, including a wilderness survival expert with over 10 years of experience, three nursing specialists in disaster nursing education with more than 10 years of experience, an emergency physician with over 20 years of experience, and 12 clinical practice experts. Among the 12 clinical practice experts, six had experience as nurses supporting disaster events, while the other six were nurse leaders with expertise in emergency/critical care, involving the project investigator/corresponding author. This team held consensus meetings to discuss program content and determine effective teaching strategies for a total of 16 hours, with 2 hours/session weekly for eight weeks. The DMTP, implemented following the consensus protocol developed by the consensus/research team, was structured based on four major domains/themes—emergency response, clinical management, self-protection, and personal preparation [11]—to ensure the validity and veracity of the delivered DMTP.

The outline of the two-day (16-hour) DMTP, as presented in Table 1, included a 2-hour lecture and a 14-hour workshop. The 2-hour lecture covered the concepts of disaster nursing, special concepts of disaster, effects of disasters on health, disaster management and its stages, assessment of possible hazards and vulnerabilities, and stages of planning in disasters. The 14-hour workshop consisted of (a) emergency response: mass casualty and triage, medical evacuation, and delivery; (b) clinical

management: trauma care, burn/explosion injury management, first aid treatment, and toxic substance injury management; (c) self-protection: nuclear and biochemical pollution disposal, protective equipment—wear and remove skills—and infection control; and (d) personal preparation: water survival training and rappelling training. In addition, disaster situational responses involve determining the magnitude of a disaster event, planning disaster response, evaluating the health needs of the affected groups, establishing priorities, identifying actual and potential public health problems, determining the resources needed to respond to the needs identified, and collaborating with other professional disciplines and governmental and non-governmental agencies. Additionally, communication skills were incorporated into the workshop to achieve goals such that the participants could better understand the challenges and complexities of responding to disasters through engagement in hands-on training exercises, role-playing scenarios, and simulations [8, 11, 17].

2.4. Measures. Sociodemographic characteristics and readiness for disaster response were collected by a separate research nurse who was blinded to the group assignments. Data on sociodemographic characteristics (age, sex, marital status, and educational level), length of nursing work, position (military or civilian nurse), nursing leader (yes or no), work unit/specialty (critical care units/emergency, general/medical-surgical ward, or others such as outpatient department and operation room), previous disaster training (yes or no), and previous disaster nursing experience (yes, no, or not yet but on list) were collected using self-administered questionnaires. Participants, including head and assistant head nurses of hospitals responsible for overseeing nursing staff, coordinating patient care, and managing resources, were categorized as nursing leaders. The EG was invited to assess their readiness for disaster response at the end of the training program. Both the EG and CG completed the evaluation of readiness for disaster response at 12 weeks. Prior to the study, the tool was reviewed by a panel of experts in disaster management, including five disaster-related experts (content validity index: 0.91), to ensure content validity. A pilot test was also conducted with 10 nurses (2 males and 8 females) to assess the tool's clarity, relevance, and ease of use. Furthermore, quality checks were conducted regularly to ensure the integrity and reliability of the data throughout the study period.

2.5. Readiness for Disaster Response. Nurses' readiness for disaster response was assessed using a 40-item self-administered scale with well-established reliability and validity (acceptable convergent validity with 0.84–0.97), including four domains: emergency response (6 items), clinical management (7 items), self-protection (11 items), and personal preparedness (16 items) [11]. The internal consistency reliabilities of the entire questionnaire and its four subscales (emergency response, clinical management, self-protection, and personal preparedness) were 0.96, 0.86, 0.85, 0.88, and 0.97, respectively. Each item was scored from

TABLE 1: The disaster management training program content in the experimental group.

Content	Teaching strategy	Domain	Time
(1) Concept of disaster nursing, special concepts of disaster, and effects of disaster on health	Lecture	—	2 hr
(2) Disaster management and its stages			
(3) Assessment of possible hazards and vulnerabilities			
(4) Stages of planning in disasters			
(1) Mass casualty and triage	1st-day workshop, six concurrent sessions: lectures, simulations, and problem-solving lessons	<i>a, b</i>	3 hr. (30 min/each topic or session)
(2) First aid treatment, bone injury, and wound care			
(3) Medical evacuation and delivery/transport			
(4) Childbirth care at disaster sites			
(5) Burn/explosion injury management and fluid infusion			
(6) Management of multiple trauma care			
Emphasizing personal safety and protection measures for responders and affected individuals during disasters	Lectures and demonstrations	<i>c, d</i>	4 hr. (2 hr./each topic or session)
(1) Water survival training			
(2) Rappelling training	2nd-day workshop: lectures, simulations, problem-solving lessons, demonstrations, discussions, and reflections	<i>a, b, c</i>	3 hr. (30 min/each session)
(1) Detection/triage and treatment of nuclear, biological, and chemical contamination/pollution			
(2) Decontamination practice and treatment for nuclear, biological, and chemical substances			
(3) Protective equipment—wear and remove skills			
(4) Infection control in the disaster environment			
(5) Toxic substance injury management			
(6) Management of nuclear, biological, and chemical pollution disposal	Tabletop exercises, simulations, problem-solving skills, group presentations, group discussions, and debriefing	<i>a, b, c, d</i>	3 hr
Scenario simulation exercises: Conducting simulated emergency scenarios to provide hands-on experience in managing crises, determining the magnitude of the disaster event, planning disaster response, evaluating health needs of the affected groups, establishing priorities, identifying actual and potential public health problems, determining resources needed to respond to the needs identified, and collaborating with other professional disciplines, governmental and nongovernmental agencies, and communication skills			
Comprehensive discussions	Group discussions and reflections	—	1 hr

Note. ^aEmergency response, ^bclinical management, ^cself-protection, and ^dpersonal preparation.

1 (strongly disagree or very low readiness), 2 (disagree or low readiness), 3 (neutral or average readiness), 4 (agree or high readiness), to 5 (strongly agree or very high readiness) on a five-point Likert scale, with scores ranging from 40 to 200. Each subscale score ranged from 6 to 30, 7 to 35, 11 to 55, and 16 to 80, in emergency response, clinical management, self-protection, and personal preparedness, respectively. Higher scores represented greater readiness for disaster response. The percentage of total scores was categorized into readiness levels: a score percentage above 75% indicated "highly competent or very good," 50% to 75% indicated "moderately competent or good," 25% to 50% indicated "low competent or fair," and below 25% indicated "incompetent or poor." In addition, the Cronbach's alpha for the scale and its four subscales (personal preparedness, self-protection, emergency response, and clinical management) in this study were 0.92, 0.94, 0.90, 0.82, and 0.76, respectively.

2.6. Ethical Consideration. Approval from the institutional review board was obtained (Reference number: 2-103-05-018) from a local medical centre in Taiwan. Participation in the study was entirely voluntary, and the participants could withdraw from the study at any time.

2.7. Data Analysis. The study employed SPSS version 16.0 (SPSS Corp., Armonk, NY, USA) for all statistical analyses. Descriptive statistics including means with standard deviations (SDs) and numbers with percentages (%) were utilized to present the characteristics of the study participants. The last observation-carried-forward method of data imputation was used for the intent-to-treat analysis. Baseline characteristic comparisons between groups were conducted using the independent *t*-test or chi-square test. Differences between the groups, both pre- and postintervention, as well as the mean difference between pre- and postintervention within the two groups, were compared using independent *t*-tests. To assess the intervention effects over time, the generalized estimating equations (GEEs) analysis for longitudinal data was applied, considering the significant interaction of group and time (group \times time) [34]. All statistical analyses were two-tailed, and significance was set at $p < 0.05$.

3. Results

3.1. Baseline Characteristics of Participants. Initially, 399 hospital nurses were screened. Of these, 264 nurses declined to participate, and 35 nurses did not meet the inclusion criteria (six had not yet signed contracts with the hospital, four were trainee nurses without nursing licenses, two did not provide direct care, and 23 reported not being able to complete the study intervention). The remaining 100 participants who met the inclusion criteria were randomly assigned: 50 (50%) to the EG and 50 (50%) to the CG.

Of the 100 eligible hospital nurses, 94 (94%) completed the study. The reasons for missed visits, including withdrawal from the study due to absence on the second day of the training program ($n = 4$) and loss in follow-up due to

leaving the nursing job at the hospital ($n = 2$) at the 12-week assessment, are presented in the flow diagram (Figure 1). However, 100 participants were included in the data analysis.

The sociodemographic characteristics, working units, experience of previously received disaster training, and personal participation experience in disaster events of the EG and CG are presented in Table 2. The baseline scores of readiness for disaster response and its four subscales (emergency response, clinical management, self-protection, and personal preparedness) for the two groups are shown in Table 3.

3.2. Outcome Evaluation. Table 3 presents the descriptive and univariate analyses of the outcome evaluations. Nurses in the EG had increased readiness for disaster response and its three subscales—emergency response, self-protection, and personal preparedness—immediately after the program and at the 12-week follow-up. However, there were no significant changes in the readiness or its four subscales in the CG. The EG had a remarkably greater increase in the mean differences between pre- and postintervention in readiness for disaster response and its four subscales than the CG.

The effectiveness of the two-day DMTP on readiness for disaster response and its four subscales, including emergency response, clinical management, self-protection, and personal preparedness, assessed through GEE analyses, is shown in Table 4. The analysis revealed a significant interaction between group and time (group \times time) regarding readiness for disaster response, indicating that the EG experienced a greater increase at 12 weeks than the CG ($\beta = 27.3$, $p < 0.001$). Specifically, the EG demonstrated significant improvements in emergency response ($\beta = 3.7$, $p = 0.002$), clinical management ($\beta = 3.7$, $p = 0.012$), self-protection ($\beta = 8.4$, $p < 0.001$), and preparedness ($\beta = 10.5$, $p = 0.003$), compared to the CG.

4. Discussion

4.1. Summary of Findings. Our study demonstrates the effectiveness of a two-day, structured disaster management training program provided by transdisciplinary professionals via multiple teaching strategies in improving hospital nurses' readiness for disaster response, including four domains: emergency response, clinical management, self-protection, and personal preparedness. The program significantly enhanced hospital nurses' disaster management readiness. These findings contribute substantively to the existing literature by confirming that active participation in a structured and comprehensive disaster management training initiative can substantially bolster hospital nurses' preparedness, increasing their confidence and willingness to engage in effective disaster response [17, 35]. Moreover, our results align with previous research, emphasizing the importance of a well-structured training program delivered through collaborative efforts across disciplines and employing varied

teaching strategies, ultimately improving response readiness in complex disaster scenarios [17].

The effectiveness of this disaster management training program offers compelling evidence for an optimal educational approach geared towards improving nurses' readiness for disaster response, encompassing emergency response, clinical management, self-protection, and personal preparedness. In light of the steady rise in the availability of disaster training programs over the past two decades, our hypothesis was that creating a structured disaster management training program, delivered by transdisciplinary professionals utilizing multiple teaching strategies, would enhance individuals' knowledge and skills. Furthermore, as previously reported, we believe that it can also enhance their motivation to overcome perceived barriers and indecisive thinking and, most importantly, strengthen their willingness to actively participate in complex disaster situations [17, 35]. The primary focus of the program was to promote readiness for disaster response through a transdisciplinary professional-delivered approach. In addition, the utilization of diverse teaching strategies in the program served as a valuable model for evidence-based nursing education in clinical settings, specifically for hospital nurses.

4.2. Comparison with Previous Research. Our study findings highlight that transdisciplinary collaboration brings together experts from various professional fields, such as emergency management, public health, education sciences, and nursing, and ensures a holistic understanding of disasters and their impacts. This collaborative approach allows the design of a comprehensive educational training program for disaster response [17, 36]. Diverse experts foster innovative thinking and problem solving by providing various perspectives, ideas, and solutions, leading to more effective and well-rounded disaster preparedness, response, and management plans [17]. For example, during a consensus meeting before the training program, the invited experts shared diverse perspectives on the program's design. Transdisciplinary professionals collectively identified the vulnerabilities and risks associated with various types of disasters, aiding the development of targeted mitigation strategies and risk reduction measures [17]. In addition, our transdisciplinary teams analyzed resource requirements across multiple sectors and identified efficient allocation strategies, optimizing the use of limited resources and prioritizing critical needs during disasters to simulate real-world scenarios. A recent report stated that the emerging trends in disaster research

over the past 20 years, marked by increased international cooperation and the transdisciplinary nature of disaster science, have gained popularity [36]. This demonstrates that valuable lessons can be learned from catastrophes and that these emerging trends serve as a scientific foundation for a clearer understanding of progress in disaster science, providing a reference for rapidly identifying frontier issues in disaster science.

Adopting various teaching approaches such as competency-based, all-hazard, and interprofessional approaches, flipped classrooms, simulations, tabletop exercises, virtual reality, and telenursing care in simulated conditions is the current trend in the design of disaster training programs [17, 37]. Therefore, our study employed multiple teaching strategies, including lectures, simulations, problem-solving lessons, demonstrations, tabletop exercises, discussions, group presentations, and reflections, through transdisciplinary collaborations in designing the disaster management training program for hospital nurses. This program aimed to enhance learning outcomes because individuals have different learning styles and preferences. In addition, participants accommodated various learning styles and engaged in training more effectively, increasing their chances of understanding and retaining information and enhancing learning outcomes. Different teaching strategies promoted active participation and engagement among the participants. Instead of passive learning, participants were actively involved in the learning process through discussions, group activities, and practical exercises. This active engagement facilitates better comprehension, critical thinking, and knowledge application, making training more effective and impactful. In addition, given the rapidly changing nature of disasters, the effectiveness of disaster response remains uncertain, particularly due to the challenges in ensuring the timely arrival of professional rescuers. Therefore, telehealth will play an important role in disaster management. A recent study demonstrated that the quality of telenursing care under simulated conditions was satisfactory during the response phase to disasters at Kerman [37]. Therefore, implementation of telenursing care would be helpful in future disasters; however, more evidence is recommended to support the use of telenursing care training under simulated conditions as an alternative teaching strategy.

Disaster management training requires the development of practical skills such as emergency response procedures, risk assessment, communication protocols, and coordination techniques. Therefore, incorporating hands-on

TABLE 3: Comparison of readiness for disaster response between groups at baseline and 12 weeks.

	Baseline				12 weeks				M.D. between pre- and post-test			
	EG (n = 50) Mean (SD)	CG (n = 50) Mean (SD)	t	P	EG (n = 50) Mean (SD)	CG (n = 50) Mean (SD)	t	P	EG (n = 50) Mean (SD)	CG (n = 50) Mean (SD)	t	P

exercises, simulations, and real-life case studies provides opportunities for participants to apply their knowledge and practical skills to make decisions in realistic scenarios. This practical approach helps bridge the gap between theory and practice, building competence and confidence in hospital nurses, thus ensuring their readiness for disaster response. Therefore, using multiple teaching strategies in a disaster management training program not only enhances learning outcomes but also promotes active participation and engagement, facilitates varied perspectives, develops practical skills, improves knowledge retention, fosters collaboration, encourages adaptability, and provides a holistic understanding of the field [17, 36]. These benefits contribute to the overall effectiveness of the training program and equip hospital nurses with effective disaster management strategies.

A recent systematic review reported that, among 23 studies, the majority assessed knowledge (78.3%), attitude (60.9%), or skills (43.5%) following disaster training [35]. This highlights the need for further research on the assessment of readiness for disaster response after such training. Most of the reported disaster programs focused on triage skills during disaster response instead of addressing the full spectrum of disaster management [11, 17]. In addition, the length of disaster training programs ranged from 1 to 28 days, with a median duration of two days [35]. Therefore, we developed and evaluated the effectiveness of a two-day structured DMTP covering the full spectrum of disaster management, including emergency response, clinical management, self-protection, and personal preparedness. Overall, our study found that the DMTP improved hospital nurses' readiness for disaster response, which could be attributed to the enhancement of participants' attitudes, knowledge, and skills in disaster response [35]. In addition, most studies investigating the effectiveness of disaster training programs have used pre- and posttest measures [17]. Therefore, the strength of our study lies in the fact that we conducted a randomized controlled trial to prove the effectiveness of DMTP.

Medical responders are at a high risk of experiencing a wide range of negative psychological health conditions following a disaster. Notably, depression and posttraumatic stress disorder are the most commonly diagnosed conditions among medical responders. A recent report documented that the prevalence of posttraumatic stress disorder among medical workers involved in the earthquake response was 16.4%, highlighting that medical workers involved in responding during disasters should undergo screening for mental health disorders before and after disasters and receive the necessary training regarding stress management and psychological resilience [38]. Particularly, nurses have higher levels of adverse outcomes than physicians and other medical professionals [13]. In addition, when organizations are exposed to disasters, staff members are often unprepared for the potential psychological impacts that can negatively affect their well-being. Fortunately, predisaster training can improve employees' confidence in their ability to cope with disasters [28, 39] and contribute to improving their psychological health [40]. Furthermore, combining

reinforcement of emotional intelligence with predisaster training can also facilitate learning outcomes, since emotional intelligence has a significant positive relationship with various components of learning strategies, namely, self-efficacy, rehearsal, critical thinking, cognitive self-regulation, time and study environment management, peer learning, and help seeking [40]. Therefore, lack of structured and comprehensive training is an important risk factor for negative psychological outcomes across all types of disasters [13].

Personal preparedness and self-protection are critical for disaster response management. In challenging disaster environments, emergency services may not be readily available or may become overwhelmed. Individuals who are self-prepared and have basic self-reliance skills are more likely to survive, recover quickly, and be in a position to help others, reducing the risks of injury or death. Therefore, preparedness for self-rescue or self-protection is one of the most important elements of organized and timely emergency response to disaster events [41]. Personal preparedness and self-protection also enable swift responses in the immediate aftermath of a disaster, which is crucial for survival. Additionally, having individuals well-prepared for self-protection during a disaster can alleviate the burden on emergency services, allowing first responders to prioritize those in greatest need [11]. Therefore, personal preparedness and self-protection not only increase individuals' chances of survival and recovery but also contribute to an effective disaster response.

Readiness for disaster response, an important component of disaster management, encompasses the capacity to manage disaster impact quickly and efficiently. Therefore, responding quickly and appropriately to disasters is crucial and depends on frontline nurses' preparedness. Nurses' readiness for disaster response and competencies can vary depending on factors such as their specialty or work area of practice, individual interests, prior experience in in-service training programs, and exposure to deployments in disaster sites [18]. For example, nurses working in emergency departments or critical care settings may have more training and experience in disaster response than those working in other areas of healthcare [28]. However, nurses' readiness for disaster response includes not only clinical management and emergency response but also personal preparedness and self-protection ability [11]. During a disaster event, nurses not only provide first aid and advanced clinical care, monitor physical and mental health needs, allocate resources, conduct efficient communication, and provide crisis leadership [17] but also oversee the use of personal protective equipment, maintain personal emergency supply, prioritize their own safety, utilize appropriate personal protective equipment, and practice infection control measures to minimize exposure to hazards. In addition, according to our previous findings, nurses with prior disaster training were associated with greater readiness for disaster response, including its four major domains: emergency response, clinical management, self-protection, and personal preparedness, after adjusting for potential covariates such as sociodemographics (marital status and educational level), length of nursing

work, nursing position, nursing leaders, work unit/specialty, and previous disaster nursing experience [28]. Therefore, the current study aimed to develop a two-day structured disaster management training program that addresses the full spectrum of disaster management, including preparedness, clinical management, emergency response, and self-protection. Fortunately, we discovered the effectiveness of the training program in increasing hospital nurses' readiness for disaster response, both immediately after the program and at the 12-week follow-up.

4.3. Limitations and Strengths. There are some limitations in this study that should be considered. First, the geographic region in which this study was conducted may limit its generalizability to other cultural groups. Therefore, the current research findings must be interpreted with caution; more rigorous sampling strategies from multiple sites or hospitals are recommended. Second, although the 12-week follow-up effects after intervention are important, evaluation of long-term follow-up might be necessary. While acknowledging these limitations, it is crucial to recognize the strengths of our study as well. These strengths include the random allocation design, provision of a well-structured disaster management training program with multiple teaching strategies, and a high rate of study completion by the participants (94%).

4.4. Contributions and Future Directions. Notably, our study is the first trial to test the effectiveness of a two-day (16-hour) structured disaster management training program that includes four major domains/themes (emergency response, clinical management, self-protection, and personal preparation) through multiple teaching strategies (i.e., lectures, simulations, problem-solving lessons, demonstrations, tabletop exercises, discussions, group presentations, and reflections by transdisciplinary collaborations on readiness for disaster response among hospital nurses). Future studies could apply this training program to confirm its effectiveness across different cultures and focus on investigating competencies, combining knowledge, attitude, skills, readiness, and self-efficacy. This might help to elucidate how the training program improves readiness for disaster response in this population. Moreover, further more studies can (1) conduct longitudinal studies to provide insights into the long-term retention of disaster response skills and identify necessary intervals for refresher training; (2) integrate modern technologies like virtual simulation to potentially elevate training efficacy; (3) explore whether the program not only increases readiness for disaster response but also empowers hospital nurses; and (4) employ focus groups or qualitative methods to examine hospital nurses' perceptions regarding the most helpful aspects of the training. In addition, the feasibility of implementing the intervention in hospitals, educational institutions, and schools is an important next step.

4.5. Implications for Nursing Management. In light of our study findings, which reveal that structured disaster management training programs (DMTPs) utilizing

multiple teaching strategies and transdisciplinary collaborations significantly enhance nurses' readiness for emergency and disaster response, nursing leaders or managers should actively integrate such DMTPs into ongoing professional development curricula to fortify hospital response readiness and capabilities. Specifically, nursing leaders are encouraged to prioritize these training modules, ensuring they are recurrent and updated regularly to reflect the latest in disaster response protocols and technology. Moreover, it is recommended that these programs be tailored to the specific needs and challenges of the nursing staff within individual healthcare facilities, considering factors such as existing skill levels and potential disaster risks pertinent to geographical locations. Nursing management could also benefit from establishing a feedback loop where participants in these programs contribute insights and suggestions for improvements. This approach fosters a culture of continuous learning and adaptation, thereby improving individual nurse preparedness and enhancing the overall institutional resilience to disasters.

5. Conclusions

A two-day structured disaster management training program, delivered by transdisciplinary professionals using multiple teaching strategies, can serve as an effective approach to improve hospital nurses' readiness for disaster response. Such disaster training programs might include innovative methods such as virtual reality and be integrated into ongoing nursing education and future curricula to strengthen disaster readiness across healthcare settings. In addition, continuous educational efforts and periodic refresher training are recommended to maintain and update these critical skills. Nursing leaders or managers should consider incorporating such a structured disaster management training program as a critical component of professional development programs, thereby strengthening nurses' disaster readiness in hospital settings, fostering a culture of continuous learning and adaptation, and enhancing overall institutional resilience to disasters.

Aims. This umbrella review aims to comprehensively synthesize and analyze the findings of available systematic reviews on the effectiveness of individual-based strategies for reducing nurse burnout occurring in hospital-based settings. **Methods.** Following JBI guidelines, an umbrella review was conducted to integrate the effectiveness of various strategies to reduce burnout. Systematic reviews were searched in the Embase, MEDLINE (Ovid), Cochrane Library, CINAHL (EBSCO), Scopus, and WOS databases. Inclusion criteria included studies published in any language from database inception to April 2023. Eligibility assessment involved two independent reviewers who evaluated titles, abstracts, and full texts. The systematic reviews were critically evaluated using JBI SUMARI. The results were narratively synthesized and grouped by strategy. **Results.** Eleven systematic reviews were included, covering the years 2012 to 2021. The appraisal tools varied, though all included reviews were of high quality. The strategies were categorized into three domains: mental health (51%), physical activities (26%), and professional competence (13%). The interventions most identified were mindfulness-based stress reduction for mental health, yoga for physical activities, and professional competence education. These individual-based strategies were shown to effectively eliminate emotional exhaustion (72.7%), depersonalization (44%), and occupational stress (78%) among nurses in hospital-based settings. **Conclusion.** Mental health, physical activities, and professional competence are strategies to reduce nurse burnout. Implementing these approaches in healthcare settings can improve emotional exhaustion, depersonalization, and occupational stress of nurses.

1. Introduction

Globally, nurse burnout is a critical issue impacting on the healthcare workforce which is reported as 11.23% of burnout symptoms [1] and continuously spreading out within the healthcare sector [2].

Indeed, nurse burnout is amplified during the COVID-19 pandemic, given their increased vulnerability to the virus and the multifaceted challenges encountered in providing care [3, 4]. Nurses constitute a large proportion about 60% in hospitals, and an increasing number of nurses are required to assist critical and general patient care during the COVID-19 pandemic [5].

Burnout in nurses has numerous detrimental effects on individuals, organizations, and patient care. It significantly affects the health and well-being of nurses by emotional exhaustion, depersonalization, and low personal accomplishment. These symptoms can have adverse consequences for nurses, including the development of physical and mental health problems such as depression and anxiety [6, 7]. Nurse burnout is linked to poor outcomes such as quality of care and patient satisfaction [6]. Burnout can be detrimental to patient care quality, leading to an increase in medical errors that compromise patient safety [8]. Addressing nurse burnout becomes imperative to uphold quality patient care and sustaining the healthcare system. Improving nursing burnout requires interventions at various levels, including national and organizational policy such as creating a positive work environment and healthy workforce strategies, as well as individual-based approaches. While national and organizational strategies to reduce burnout are generally directed towards the majority, individual-based strategies are needed to be designed for nurses to choose according to their preference.

Numerous interventions have been suggested to assist nurses in practicing self-care with the aim of mitigating or preventing burnout and various individual health-related outcomes [9–13]. For example, physical activities such as yoga, Qigong, and Tai Chi have been proposed to improve sleep quality and alleviate post-shift stress [10]. Emotion-focused tactics and psychosocial programs have been implemented to enhance mental health and prevent burnout [12]. A variety of mindfulness-based interventions (MBSR) have been advocated to enhance nurse well-being. These interventions have shown positive impacts on sleep quality, anxiety, depression, and overall resilience [13–15]. Interventions such as team-based training, communication skills enhancement, cognitive coping mechanisms, and problem-solving techniques have demonstrated efficacy in reducing nurse burnout and maintaining effectiveness [9, 11]. Multicomponent interventions have also positively affected physical and mental health and job satisfaction [12].

Recent research on nursing burnout has increasingly focused on multifaceted interventions with promising potential. These interventions often combined physical or psychological methods, yet researchers are interested in wide range of outcome indicators [16, 17]. Numerous original studies employing different approaches to reduce burnout have yielded varying results due to differences in study design and implementation [17, 18]. Systemic review and

meta-analysis on the topic of burnout have emerged prominently since the 1990s and have been essential to integrate the best evidence while evaluating research biases [19]. However, differing criteria for research inclusion and exclusion, search terms, timeframes, language, and type of article have contributed to varied outcomes and interpretations on the efficacy of nurse burnout strategies. The increasing number of such reviews can be overwhelming for those seeking clinical application. Furthermore, while numerous interventions are frequently used, their comprehensive evaluation in many meta-analyses remains lacking [20].

An umbrella review, alternatively known as an overview of reviews, represents a unique literature review format that aggregates findings from multiple systematic reviews or meta-analyses on a specific subject [21]. Unlike traditional systematic reviews that examine primary studies, an umbrella review analyzes evidence from existing reviews to provide a more comprehensive overview of the research area. This method is particularly apt for a comprehensive synthesis of varied strategies and outcomes across a multitude of reviews, providing a more integrated understanding of effective interventions in a thoroughly researched domain [20, 21]. By compiling data from various reviews, an umbrella review yields clearer, more substantial, and elevated insights into the efficacy of individual-based strategies for mitigating burnout among nurses. This type of review facilitates a thorough assessment of current evidence, pinpointing both consistencies and discrepancies in the findings [22]. Therefore, the objective of this umbrella review is to comprehensively synthesize and analyze selected systematic reviews which have evaluated the effectiveness of individual strategies implemented to reduce burnout among nurses.

2. Methods

This umbrella review aims to synthesize the impact of individual-based strategies on reducing nurse burnout within hospital-based settings. The methodology adhered to the guidelines developed by the Joanna Briggs Institute [23] and the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) reporting standards. The umbrella review was registered in the PROSPERO system (Number: CRD42022330618).

2.1. Search Strategy. Six databases, from inception to April 2023 were searched: Embase, MEDLINE (Ovid), Cochrane Library, CINAHL (EBSCO), Scopus, and WOS. The PICO framework guided this umbrella review with the question: Are individual-based strategies effective in reducing burnout among front-line nurses in hospital settings? Language was not restricted. The MeSH and free-text terms related to individual-related strategies for burnout in nurses were searched. The syntax was listed as [(nurse* OR (staff* OR employee* OR officer* OR personnel* OR practitioner* OR profess* OR provider* OR specialist* OR worker*)) NEAR/6 (nurs* OR health* OR hospital* OR medical))] AND

[(burnout* OR "burn out*" OR exhaustion* OR (extreme* ADJ 4 fatigue*))]. The SR filter formula used the BMJ Best Practice syntax (<https://bestpractice.bmj.com/info/toolkit/learn-ebm/study-design-search-filters/>).

2.1.1. Inclusion and Exclusion Criteria. The selection process applied the following inclusion criteria: (1) studies specifically targeting nurses, (2) interventions that were individual-based and aimed at reducing burnout, (3) primary outcomes related to burnout and their dimensions, such as emotional exhaustion, depersonalization, and reduced personal accomplishment, (4) the context as hospital-based setting, and (5) type of systematic reviews was intervention-based. Studies were excluded if (1) participant data were combined with other healthcare disciplines, (2) no provided data to address the effectiveness in the systematic reviews, and (3) insufficient information to appraising methodologic quality.

2.1.2. Selection of Articles. Articles meeting the inclusion criteria were uploaded to EndNote X9 (Clarivate Analytics, PA, USA) for article screening. Two independent reviewers assessed eligibility by titles and abstracts followed by full text review of eligible studies. Reasons for the exclusion of papers that did not meet the inclusion criteria were recorded. Any disagreements between the two reviewers were resolved through discussion with a third reviewer. After relevant studies were retrieved, the JBI system for the unified management, assessment, and review of information (JBI SUMARI) (JBI, Adelaide, Australia) was applied to integrate findings.

2.2. Quality Appraisal. The methodology's quality was evaluated using the JBI SUMARI's systematic review instruments, consisting of the JBI Critical Appraisal Checklist for Systematic Reviews and Research Syntheses (JBI CACSRRS) [24]. The appraisal of systematic reviews or meta-analyses is guided by 11 questions. The answers are rated as "yes," "no," "unclear," "or not applicable." Two independent reviewers used the instruments to appraise eligible studies. A third reviewer was consulted to facilitate discussion and resolve any issues.

2.3. Data Extraction. The JBI SUMARI was used to extract data from the included reviews. The information extracted included first author's name and country, published year, and review objectives. The details of included studies in each review were extracted and included the number of studies, number of included participants, country, study design, strategies, outcome measurement, and conclusions.

3. Results

3.1. Search Process. A total of 2424 articles were retrieved from six databases. After removing duplicate records ($n=1130$) and screening by title and abstract, 52 full-text articles were reviewed. Articles were excluded due to the following: the outcome did not include burnout ($n=10$), subjects included non-nursing staff ($n=25$), and the article did not present a systematic review ($n=8$). Nine articles

from six databases were retained. Two additional articles were obtained using a citation search. Eleven articles were included in the analysis (Figure 1).

3.2. Characteristics of Included Articles. The articles were published between 2012 and 2021, with two of the eleven systematic reviews including meta-analyses (Table 1). The number of studies synthesized with the systematic review ranged from 6 to 25, encompassing a total of 467 to 6,055 subjects. Researchers were represented from Germany ($n=4$), Canada ($n=2$), and one each from Taiwan, Korea, Australia, Malaysia, and Iran. The included studies in the review encompassed a global perspective, covering Europe (with countries such as the Netherlands, Spain, Italy, Germany, Ireland, the UK, Portugal, Denmark, Sweden, Norway, Greece, and France), the Americas (the USA, Canada, and Brazil), the Middle East (Iran and Israel), Asia (India, Japan, Turkey, China, Taiwan, Malaysia, Hong Kong, and Korea), and Oceania (Australia). The RCT was the most researched design within the reviews. The outcome indicators represented three categories: mental perception (e.g., stress, burnout, depression, and life satisfaction), physical symptoms (e.g., muscle pain and insomnia), and work-related (e.g., patient care and job satisfaction).

3.3. Quality Appraisal. The quality of the eleven included articles was evaluated using the JBI CACSRRS. In the eleven systematic reviews, 10 (90.9%) achieved a yes score on 8 of the 11 questions (Table 2). All articles met of 100% for questions 1, 7, 8, 10, and 11. Four questions (Q2, Q3, Q4, Q5, and Q6) were met between 64% and 91%. Question 9, "the likelihood of publication bias," was answered for only one review due to the low number of studies in the other reviews. All eleven systematic reviews were included for qualitative integration.

3.4. Effectiveness of Strategies and Interventions

3.4.1. Strategies and Interventions for Reducing Burnout. Among the 11 selected systematic reviews, a total of 145 studies were included. After removing duplicates, 131 remained, of which 64 studies discussed the three strategies for the outcome indicators of burnout or occupational stress. Within these 64 studies, the strategies employed included combinations in 6 studies (four mental health + physical activities and two mental health + professional education) and single strategies in 59 studies (25 for mental health, 24 for physical activities, 9 on professional education).

Among the 64 studies, the distribution of strategies applied was as follows: mental health ($n=31$, 44%), physical activities ($n=28$, 40%), and professional competences ($n=11$, 16%). In the 31 studies focused on mental health strategies, three types of interventions were included: mindfulness-based stress reduction (MBSR), stress and relaxation management, and resilience and cognition training. Two studies combined two approaches (stress and relaxation management + resilience and cognition training; MBSR + resilience and cognition training). Thus, in these 31

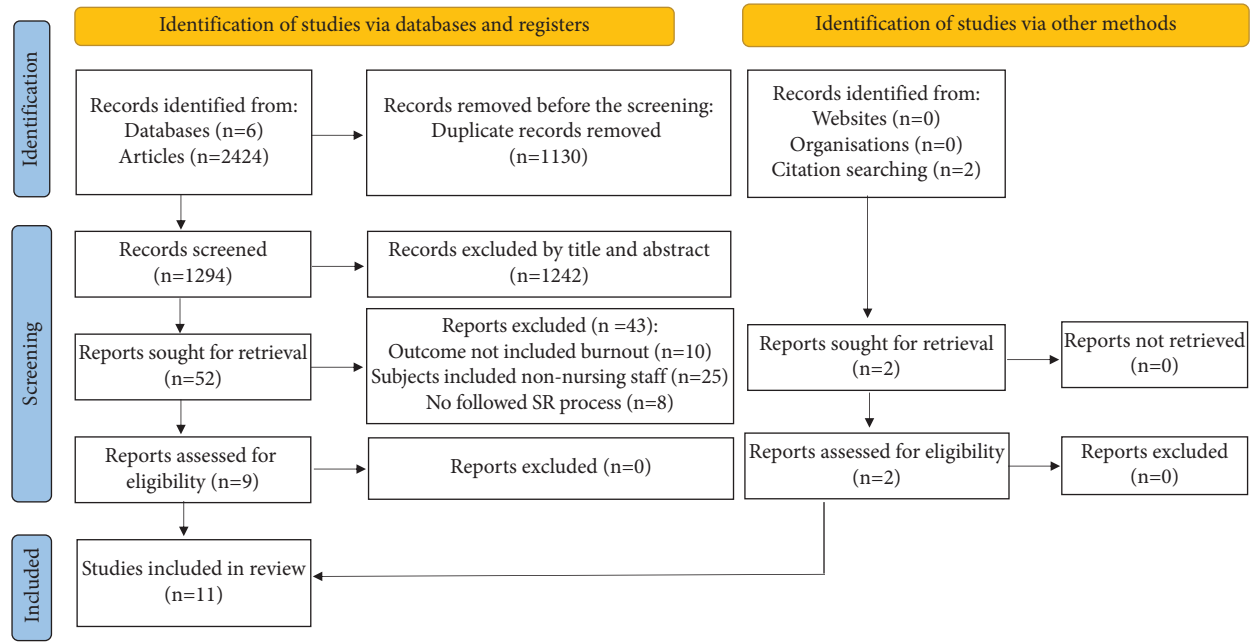

FIGURE 1: Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow diagram. From: Page MJ, McKenzie JE, Bossuyt PM, Boutron I, Hoffmann TC, Mulrow CD, et al. The PRISMA 2020 statement: an updated guideline for reporting systematic reviews. *BMJ* 2021; 372: n71. doi: 10.1136/bmj. n71.

mental health strategy studies, the distribution of the interventions was MBSR (48%), stress and relaxation management (27%), and resilience and cognition training (24%). In the 28 studies related to the strategies of physical activities, two types of interventions were yoga and general physical exercise, with their distribution being yoga (71%) and general physical exercise (29%). Among the 11 studies on professional competences strategies, two types of interventions were competence education (73%) and coworker supervision (27%) (Figure 2).

3.4.2. Effectiveness of Interventions for Reducing Burnout. Among the 64 studies reviewed, 23 mentioned the effectiveness of interventions on emotional exhaustion (EE), with 17 (74%) reporting a significant reduction in EE. Among these 17 studies, the interventions most frequently effective in reducing EE included MBSR mentioned 5 times, competence education 4 times, resilience and cognition training 3 times, stress and relaxation management 2 times, coworker supervision 2 times, and yoga once. 19 studies addressed the impact of interventions on depersonalization (DP), with 11 (58%) reporting effective reductions. The most frequently effective measures for reducing DP included MBSR 4 times, resilience and cognition training 3 times, competence education 2 times, stress and relaxation management once, coworker supervision once, and yoga once. 20 studies discussed intervention effects on low personal accomplishment (LPA), with 10 (50%) achieving significant reductions. The interventions most effective in reducing LPA were MBSR, resilience and cognition training, and competence education, each mentioned 3 times, followed by coworker supervision 2 times, stress and relaxation management once,

and yoga once. 42 studies examined the effectiveness of interventions on work stress, with 32 (76%) noting substantial stress reductions. The most frequently effective strategies to reduce work stress were yoga 17 times, MBSR 6 times, stress and relaxation management 5 times, competence education twice, and general physical activities twice (Figure 3).

4. Discussion

An umbrella review included a comprehensive evaluation of evidence derived from eleven systematic reviews of 131 different research studies focused on reducing nurse burnout. Strategies formed three main categories: mental health, physical activity, and professional competence. The interventions which positively contributed on burnout were MBSR, resilience and cognition training, and stress and relaxation as well as yoga in occupational stress.

4.1. Enhancing Mental Health. MBSR is the most frequent mental health strategy applied to reduce burnout based on the study findings. Nurses face a high workload and poor working conditions [29] and are at risk of developing psychological distress [30]. Many studies have documented the effectiveness of MBSR in reducing stress [13, 14]. For physical mechanism, MBSR practices can be crucial for the body's defense against infections and improving health [31, 32]. MBSR practices cultivate self-compassion, helping individuals to face adversity without succumbing to self-criticism or negative self-evaluation, which are key factors in burnout [33]. When conducted in group settings, mindfulness practices strengthen interpersonal connections

Note. Met appraisal question (O)/not meet appraisal question (X)/unclear (U)/not applicable (N/A); Question of checklist: (1) Is the review question clear and explicitly stated? (2) Were the inclusion criteria appropriate for the review question? (3) Was the search strategy appropriate? (4) Were the sources and resources used to search for studies adequate? (5) Were the criteria for appraising studies appropriate? (6) Was critical appraisal conducted by two or more reviewers independently? (7) Were there methods to minimize errors in data extraction? (8) Were the methods used to combine studies appropriate? (9) Was the likelihood of publication bias assessed? (10) Were recommendations for policy and/or practice supported by the reported data? (11) Were the specific directives for new research appropriate?

FIGURE 2: The strategies and interventions for reducing nurse burnout.

among nurses, providing a network of emotional support that is vital for managing work-related stress and reducing the risk of burnout [34].

A typical MBSR program consists of two to three hours of instruction per week for eight weeks and requires regular practice to reap its full benefits. However, some factors should be considered for the individuals [35, 36]. (1) Time commitment: a typical MBSR program consists of two to three hours of instruction per week for eight weeks; it may be challenging for some individuals to commit this amount of time. (2) Requires practice: MBSR requires regular practice to reap its full benefits; a busy schedule may make this difficult for some individuals. (3) Not a substitute for professional help: the MBSR program should not be regarded as a substitute for professional medical or

psychological care. In cases involving mental or physical illness, it is essential to seek professional assistance.

4.2. Increasing Physical Activity. Increasing physical activity was the second most frequently strategy for mediating nursing burnout, with yoga being the most common activity. Physical activity influences hormone levels, including the stress hormones. Maintaining physical activity provides a positive contribution to human psychoneuroimmunology and improved mental health [37]. The systematic review of Dutta et al. [38] described the physical and psychological benefits of yoga. However, yoga practitioners must be cautious of (1) musculoskeletal injuries: injuries to the musculoskeletal system are caused by the improper position,

FIGURE 3: The effectiveness of interventions for reducing emotional exhaustion, depersonalization, low personal accomplishment, and occupational stress.

which can lead to muscle, bone, and joint problems [39]; (2) overstretching: an individual who overstretching their body or pushes it beyond its limits can lead to both pulled muscles and torn ligaments as a result of overstretching or pushing the body beyond its maximum ability [40]; and (3) physical exhaustion: for beginners or individuals with underlying health conditions, intense yoga sessions can sometimes result in physical exhaustion [41].

4.3. Improving Professional Competence. Professional competence was the third strategy, and professional competence education and coworker supervision were the important interventions in the current systematic reviews. The nurses' professional competence is reflected in their attitudes, knowledge, and psychosocial and psychomotor skills [42]. Nursing professional competence refers to the ability of nurses to demonstrate various abilities such as personal characteristics, professional attitudes, values, knowledge, and skills as they carry out their professional responsibilities [43]. Some researchers emphasized the significance of professional values on nursing competence and found the negative relationship between professional values and burnout [44, 45]. On the other hand, work-related stress occurs when people are expected to perform tasks beyond their abilities which requires coping mechanisms. Improving professional competence can provide confidence which can lead to a sense of mastery and control. Situational control reduces the stress associated with uncertainty and ambiguity for a decrease in burnout [45, 46]. Nurses possessing high levels of professional competence are typically well-equipped with the necessary knowledge, skills, and experience to adeptly handle challenging situations and workloads [47].

Additionally, nurses with higher levels of professional competence reported stronger relationships with their colleagues, likely because they are more likely to be seen as competent and trustworthy [48]. Many research studies have indicated that good interpersonal relationships are an important factor in combating burnout [49, 50]. Therefore, higher professional competence can positively contribute to good interpersonal relationships and self-confidence at work, which can then reduce stress and burnout.

4.4. Implications for Managers. The umbrella review highlighted the importance of manager facilitation in addressing nursing burnout through individual-based strategies. Key recommendations include routine assessment of burnout level, offering MBSR and yoga programs, fostering workplace social support networks, and organizing professional competence development programs.

First, regular assessment of the burnout level is necessary because the effectiveness of interventions would be ineffective after 6 months [11]. Managers can tailor the schedule for burnout assessments to align with the organization's culture and the individual characteristics of employees. This approach allows for a thorough evaluation of burnout levels, taking into account differences across various professional nursing tiers and considering significant occurrences like hospital accreditation or personal milestones. Second, managers can arrange the MBSR and physical activities such as yoga or general physical exercise training for nurses. Before the nurses practice the MBSR or yoga activities by themselves, well-trained instructors can provide comprehensive training and prevent the adverse events of MBSR and yoga. On the other hand, the instructors can suggest the appropriate period of MBSR or skill of yoga according to individual

characteristics. Third, resilience improvement is also an important factor. Studies indicate that resilience can combat burnout [15, 26]. Health organizations need to improve the well-being of nurses and the managers can implement training courses such as resilience training to prevent the incidence of cumulative burnout [51]. Fourth, nurse leaders can mitigate the negative impact of burnout on their professional values by strengthening and improving their professional value education through seminars and nursing in-service education programs [52]. In addition, nurse managers can provide continuing education opportunities based on the working unit or level of professional capacity to enhance professional competence among nurses [53]. The competence improvement education can teach nurses to determine for themselves how to handle their problems and how to improve their situation through meaningful dialog and engagement with nurse leaders concerning their work-life issues. Finally, the peer support and supervision system is necessary. A network fosters a sense of belonging and security, enhancing individuals' ability to cope with stress and burnout. Designing leisure activities for nurses can contribute to interpersonal relationships and decrease stress [54].

5. Strengths and Limitations

An umbrella review systematically compiled and synthesized evidence on individual-based strategies for reducing stress and burnout among nurses in hospital-based settings. The review marks a significant step in collating evidence and identifying the research on the most frequently used strategies. The review was limited by only including published systematic reviews and omitted grey literature or unpublished studies. Overlapping sources across the systematic reviews led to inconsistent outcomes and may have rendered burnout metrics inaccurate. Additional mental health indicators, such as anxiety or depression, may have confounded burnout findings. The umbrella review revealed that while numerous interventions are commonly used, many have not been thoroughly tested. More research is needed for in-depth analysis of these interventions.

6. Conclusion

Strategies for reducing nurse burnout are focused on mental health, physical activity, and professional competence. Nurses can adopt personal preference strategies and self-help interventions to reduce burnout.

Data Availability

Data are available upon request.

Additional Points

What Is Already Known about the Topic? (1) Nurse burnout is a widespread and global problem. (2) Nurse burnout has been associated with negative individual and work-related outcomes. (3) Various strategies have been implemented to reduce nurse burnout. *What This Paper Adds.* (1) Strategies to reduce burnout can be categorized into three domains:

mental health, physical activities, and professional competence. (2) The interventions most applied were mindfulness-based stress reduction, yoga, and competence education. (3) Individual-based strategies were shown to effectively eliminate emotional exhaustion, depersonalization, and occupational stress.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

We appreciate the librarian, Ching-Ju Fang, for the article search suggestions for the manuscript. This study was funded by the National Science and Technology Council (NSTC 112-2314-B-006-044).

Aim. To explore the status of job crafting, leisure crafting, and burnout among nurses and to examine the impact of job crafting and leisure crafting variations on burnout using machine learning-based models. **Background.** The prevalence of burnout among nurses poses a severe risk to their job performance, quality of healthcare, and the cohesiveness of nurse teams. Numerous studies have explored factors influencing nurse burnout; however, few involved job crafting and leisure crafting synchronously and elucidated the effect differences of the two crafting behaviors on nurse burnout. **Methods.** Multicentre cross-sectional survey study. Nurses ($n = 1235$) from four Chinese tertiary hospitals were included. The Maslach Burnout Inventory-General Survey, the Job Crafting Scale, and the Leisure Crafting Scale were employed for data collection. Four machine learning algorithms (logistic regression model, support vector machine, random forest, and gradient boosting tree) were used to analyze the data. **Results.** Nurses experienced mild to moderate levels of burnout and moderate to high levels of job crafting and leisure crafting. The AUC (in full) for the four models was from 0.809 to 0.821, among which the gradient boosting tree performed best, with 0.821 AUC, 0.739 accuracy, 0.470 sensitivity, 0.919 specificity, and 0.161 Brier. All models showed that job crafting was the most important predictor for burnout, while leisure crafting was identified as the second important predictor for burnout in the random forest model and gradient boosting tree model. **Conclusion.** Even if nurses experienced mild to moderate burnout, nurse managers should develop efficient interventions to reduce nurse burnout. Job crafting and leisure crafting may be beneficial preventative strategies against burnout among nurses at present. **Implications for Nursing Management.** Job and leisure crafting were identified as effective methods to reduce nurse burnout. Nurse managers should provide more opportunities for nurses' job crafting and encourage nurses crafting at their leisure time.

1. Background

Nurses constitute the largest proportion of the healthcare workforce worldwide and play an essential role in clinical treatment, illness prevention, and health promotion. However, because of extensive job demands, scarce resources, work-family conflicts, and complex clinical work environments, nurses experience several burnout symptoms, such as emotional exhaustion, cynicism, and reduced professional efficacy [1, 2]. These phenomena adversely affect the quality of care, patient safety and satisfaction, job

performance, turnover rate, and the physical and mental health of nurses [3, 4]. According to a nationwide survey conducted in the United States of America, 16.6%–30.0% of nurses (3,957,661 samples) reported experiencing burnout and 31.5% of them listed burnout as a contributing factor to their decision to leave their positions [5]. A cross-sectional survey in 12 European countries showed that 10%–78% of nurses had burnout symptoms [6]. In the mainland China, the burnout rate is also high; for example, in Shanghai, it is 45.1% [7], and in Hunan, it is at 34.9% [8]. Given the current high levels of burnout among nurses worldwide, it has

become critical for hospital administrators, nurse managers, and nurses themselves to gain a deeper understanding of the factors that contribute to burnout to enhance the quality of clinical care, stabilize nurse retention, and improve the physical and mental health of nurses.

Job crafting is defined as the actions employees take in modifying their tasks and work relationships to promote their cognitive understanding of the job meaning and attain a greater person-job fit [9]. Previous studies have highlighted that job crafting is not only beneficial to employees' health (e.g., well-being and general health) [10, 11], work attitude (e.g., job satisfaction and organizational commitment) [12], and behavior (e.g., work engagement and creativity) [13] but is also conducive to organizational performance (e.g., quality of care and group innovation) [14, 15]. Literature review shows that increasing research had investigated the relationship between job crafting and burnout in nurses. Cumulative evidence has shown that job crafting can maintain a proactive balance between job demands and resources by fostering self-driven work behavior, consequently alleviating nurse burnout [16]. Several studies have found a moderate-to-high influence of job crafting on burnout [16, 17], whereas others have reported a rather small effect of job crafting on burnout [18]. Because the effect sizes of these studies were inconsistent, further investigation is required to provide new evidence.

Leisure crafting is a novel strategy for dealing with depleted resources and was firstly defined by Petrou and Bakker [19]. This strategy refers to individuals' proactive and self-initiated pursuit of off-job life to fulfill their goals, interpersonal connections, learning, and personal growth. Unlike job crafting, leisure crafting motivates individuals' passions and satisfies their psychological requirements by shaping their leisure activities in a proactive, deliberate, and serious manner [20, 21]. Existing studies indicated that leisure crafting can reshape the task and relational bounds of individuals' leisure, improve their sense of mastery, and help them acquire resources [22, 23]. Leisure crafting is believed to address individuals' needs and values and improve their ability to handle workplace stressors, thereby averting the negative effects of job demands [24]. Few studies have explored the effects of leisure crafting on work-related attitudes and behaviors, particularly burnout issues. Moreover, little is known about whether job crafting and leisure crafting have similar effects on burnout.

Conservation of resources' theory assumes that individuals have the motivation to invest their resources for accumulating additional resources to protect their health and well-being [25]. Based on the conservation of resources' theory, an excessive workload is a persistent threat to nurses' valued resources, which results in burnout [26]. While nurses' accumulation of resources can sustain and protect additional resources, which greatly alleviate burnout among nurses, several studies supported that both job crafting and leisure crafting play vital roles in acquiring and adjusting resources [10, 27]. Job crafting and leisure crafting represent resource gain processes as nurses cope with stressful job demands and enrich their leisure time that motivate them and enhance their ability to perform well [28]. Resources

gained from job crafting can improve nurses' ability to better fulfill their work obligations, which is conducive to reduce burnout [29]. Resources activated and replenished from leisure crafting can spill over to the work domain to improve nurses' work engagement and hence lighten nurse burnout [27]. Therefore, based on theoretical basis and the empirical studies, the study puts forward hypothesis 1: job crafting and leisure crafting are negatively influencing nurse burnout.

At present, most studies have investigated the factors influencing burnout using multiple linear regression models, which have high requirements for data features (including normal distribution and homoscedasticity). Machine learning, a common artificial intelligence-driven technology, has been successfully integrated into the field of health risk assessment. Unlike traditional statistics, machine learning models do not have any rules for data distribution and learn from provided samples to explore the complex and non-linear relations among measured variables [30]. Several studies have applied machine learning to test predictors of burnout and achieved good findings. However, most of them only used one type of machine learning model (e.g., convolutional neural network, multitask learning technique, and decision tree) [31, 32], which does not avoid bias caused by the model and confirms the most significant predictors of burnout.

The main objectives of this study were to provide a comprehensive description of job crafting, leisure crafting, and burnout among nurses from Chinese tertiary hospitals. We also aimed to evaluate the effects of job crafting and leisure crafting on burnout by developing and validating four machine learning-based models.

2. Methods

2.1. Study Design. The cross-sectional multicenter study design was employed to describe the status of job crafting, leisure crafting, and burnout among nurses and explore the associations among these variables.

2.2. Participants. There are 107 tertiary hospitals in Shandong Province, China (<https://www.doc88.com/p-11461558491027.html>). A convenience sampling method was used to recruit hospitals from the 107 tertiary hospitals. Nurses from the included hospitals, who met the inclusion and exclusion criteria, were required to participate in the online survey. The inclusion criteria included registered and licensed practical nurses who directly cared for patients. Nurses on sick leave or those in the process of turnover were excluded from the study.

A total of 1,754 nurses from the four tertiary hospitals were invited to complete the online questionnaires, and 1,235 responses were included in the final analysis (Supplementary file "Participation rate and sample size").

2.3. Measures. A personal demographic form, the Maslach Burnout Inventory-General Survey (MBI-GS), the Job Crafting Scale (JCS), and the Leisure Crafting Scale (LCS) were used for the online survey.

The personal demographic form included 10 questions to investigate nurses' sociodemographic information, such as sex, age, years of service, academic degree, marital status, do they have a child/children, professional qualifications, specialty area, monthly income, and shift work.

The MBI-GS was used to assess the nurses' burnout status. This 16-item seven-Likert scale was developed by Maslach and Jackson [33]. The Chinese version was translated by Li and Shi [34]. Three dimensions of the MBI-GS are "emotional exhaustion," "cynicism," and "reduced professional efficacy." A seven-point Likert scale (0 = never, 6 = every day) was used to score the items. The following equation, developed by Kalimo et al. [35], was used to calculate the total MBI-GS score. Total score for burnout = score for "emotional exhaustion" \times 0.3 + score for "cynicism" \times 0.3 + score for "reduced professional efficacy" \times 0.4. The minimum and maximum scores for burnout range from zero to six, with higher scores indicating severe levels of burnout. Cronbach's alpha coefficients for the MBI-GS were 0.88 in the study.

The JCS used to measure job crafting was developed by Tims et al. [36]. The Chinese version's validity and reliability were tested by Liao [37]. This 21-item scale has four dimensions (increasing structural job resources, increasing social job resources, increasing challenging job demands, and reducing obstructive job demands) and scores on a five-point Likert scale. The score for job crafting is the average score of the total items. Higher scores indicated greater job crafting experienced by nurses. In this study, Cronbach's alpha coefficients for the JCS were 0.95.

The nine-item LCS, developed by Petrou and Bakker [19], measured nurses' crafting during their leisure time. The validity and reliability of the Chinese version were examined by Guo et al. [38]. A five-point Likert scale (1 = not at all, 5 = very many) was used to score each item. The LCS score is the average of nine items. The LCS had good validity and reliability, with Cronbach's alpha coefficients of 0.95 in the current study.

2.4. Data Collection. This study was conducted at four tertiary hospitals between June 3 and October 31, 2022. The Wenjuanxing-Enterprise edition (Changsha Ranxing Information Technology Co., Ltd., Changsha, China) was used to develop the online survey. Two research assistants were recruited from each hospital. All research assistants were given a three-hour investigation training session before conducting the survey. Research assistants delivered an online questionnaire link and explanatory statements to the nurses via e-mail, WeChat, and other communication apps. Nurses who met the inclusion criteria were asked to complete the survey. Two push notifications (Dear participants, please remember to complete the online survey. Thank you.) were sent to nurses. The survey took 10–15 minutes to complete.

2.5. Ethical Considerations. Ethical approval (Human Sciences Ethics Committee of School of **, one University No. 2020-R-030) and hospital permissions were obtained for this study. Nurses who submitted the online survey were considered to have provided informed consent.

2.6. Data Analyses. Data were analyzed using SPSS 24.0, with descriptive analysis, *t*-tests (to compare burnout scores between two groups), ANOVA (to compare burnout scores' differences among three or more groups), and correlation tests (to evaluate the correlations among the measured variables). Kurtosis and skewness were used to describe the normal distribution of measured variables. Values for kurtosis were from -0.237 to 1.002 , and values for skewness were between -0.724 and 0.392 , indicating that, generally, the data were normally distributed. According to the Harman single-factor analysis, 36.7% of the variance could be explained by one factor, which suggests that no significant common method variance was found in the study. K-means clustering analysis was used to divide burnout into a low burnout group and a high burnout group.

A computer-generated random number sequence divided the data into training (70%) and validation (30%) cohorts. Python 3.9 was employed to conduct four machine learning algorithms (logistic regression model, support vector machine, random forest, and gradient boosting tree) to obtain models for predicting nurse burnout. The logistic regression model is one kind of generalized linear regression categories. Support vector machine employs kernel functions to map linearly indivisible data to a multidimensional feature space, which could deal with complex data such as high dimensional, nonlinear, and small sample size. Random forest is an integrated algorithm which uses decision trees as the main classifier. Random forest is applied to issues of classification and regression. Gradient boosting tree includes decision tree and gradient boosting. It can deal with tasks of classification and regression via additive model and forward distribution algorithms.

The burnout prediction models included 16 variables (independent variables: job crafting and leisure crafting; covariates: significant demographic characteristics; dummy variables: eight variables). Five repetitions of the 10-fold cross-validation were conducted to optimize the model parameters. The area under the receiver operating characteristic curve (AUC), accuracy, sensitivity, specificity, and Brier were calculated to compare the predictive performance of the models. Brier represents the average-squared distance from the predicted probability of the model to the actual probability. The lower the Brier scores, the better the model performance. A two-sided *p* value ≤ 0.05 was considered statistically significant.

3. Results

3.1. Demographic Characteristics and Burnout of Nurses. Most nurses were women (95.8%), married (80.9%), held bachelor's degrees (85%), and had a child/children (76.2%). Over half were 30–39 years old, had temporary employment, had worked less than 11 years in medical and surgical departments, and had shift work more than four times per month. Of these, 46.4% were lead nurses, and only 23.3% of the nurses' income was higher than 9000 Yuan (1,231 \$ USD) (Table 1).

The results of the bivariate statistical analysis showed that nurse burnout levels were significantly different according to age, years of service, marital status, child/children status, professional qualifications, specialty area, and shift work (each $p < 0.01$).

3.2. Descriptive and Correlation Analyses among Burnout, Job Crafting, and Leisure Crafting. The burnout level for nurses was 2.02 ± 1.05 , indicating that nurses experienced mild-to-moderate levels of burnout. The average score for job crafting was 4.05 ± 0.56 . The average score for leisure crafting was 3.84 ± 0.78 , suggesting that nurses had moderate-to-high levels of job and leisure crafting (Table 2).

The correlation analysis showed that burnout was significantly negatively correlated with job and leisure crafting (each $p < 0.01$) (Table 2). Nurses who experienced high burnout generally engaged in less job and leisure crafting.

3.3. K-Means Clustering Analysis for Burnout. According to the K-means clustering analysis, two clusters for burnout were found: the low-burnout group (final cluster center 1.24, $n = 678$) and the high-burnout group (final cluster center 2.97, $n = 557$) (Table 3).

3.4. Model Performance. The binary logistic regression analysis showed that job crafting, age, medical department, paediatric department, and shift work significantly influenced nurse burnout. Nurses who had lower job crafting, were younger in age, worked in medical and paediatric departments, and shifted work had a higher risk of experiencing severe burnout. Supplementary Files eTable 1 and eFigure 1 present the regression model results.

Support vector machine (SVM), random forest, and gradient boosting tree were employed to evaluate significant factors influencing burnout. The importance of the permutation features was calculated using the three machine learning algorithms. In the SVM model, the top five predictors were job crafting, age, child/children status, years of service, and leisure crafting (Supplementary file eFigure 2). In the random forest and gradient boosting tree models, the top five predictors were job crafting, leisure crafting, age, years of service, and professional qualifications (Supplementary file eFigures 3 and 4).

The performance of each model is summarized in Table 4. The receiver operating characteristic (ROC) curves for the validation cohort are shown in Figures 1(a) and 1(b). The

gradient boosting tree model performed the best, with an AUC of 0.821, accuracy of 0.739, sensitivity of 0.470, and specificity of 0.919. The Brier score for the gradient boosting tree was the lowest (0.161), indicating that the model was reliable.

4. Discussion

This study aimed to explore the status of job crafting, leisure crafting, and burnout among Chinese nurses and exam the effects of job crafting and leisure crafting on burnout using four machine learning algorithms. This study is one of the first investigations on this topic. We found that nurses experienced mild-to-moderate levels of burnout and moderate-to-high levels of job and leisure crafting. Furthermore, compared with leisure crafting, job crafting played a greater role in predicting burnout in SVM, random forest, and gradient boosting tree models. These important findings suggest that nurses plan their efforts to promote their job and leisure crafting and that nurse managers should adopt effective strategies to reduce burnout symptoms among nurses.

In the current study, nurses had mild-to-moderate levels of burnout. These results are supported by previous studies conducted in other countries [39, 40]. As nurses experience mild-to-moderate burnout, both nurse managers and nurses pay less attention to this chronic, persistent syndrome, which leads to severe outcomes in nurses' physical and mental health, job performance, and organizational commitment [41, 42]. Accordingly, raising managers' and nurses' concerns about burnout is vital, especially in mainland China. Furthermore, effective personal-oriented, organizational-oriented, and personal-organizational combined interventions should be implemented to reduce burnout among nurses.

In this study, the nurses experienced moderate-to-high levels of job crafting. This finding is consistent with the studies of Alharthi et al. [43] and Harbridge et al. [44]. A qualitative study revealed that nurses had passion and strengths in job crafting. They were actively job crafting in all aspects via activities, such as techniques' training, participating in working teams and committees, and being involved in programs [45]. Nurses proactively initiated and altered clinical tasks to address the requirements of their vulnerable patients, which could promote the quality of care and achieve more meaning in their jobs [46].

We found, quite interestingly, that nurses experienced moderate-to-high levels of leisure crafting. Studies have indicated that leisure crafting is an individual's adaptive behavior in leisure life, which can positively benefit work engagement, personal achievement, and organizational performance [47, 48]. Several leisure activities were believed to enhance individuals' leisure crafting, such as hobby participation, enjoying activities, and seeking a sense of purpose during leisure time [49]. Therefore, nurses are encouraged to pursue their hobbies and engage in leisure activities to produce crafting behaviors outside their work.

In the present study, four machine learning models were used to evaluate the effects of differences in job and leisure crafting on burnout among nurses. Although the predictive

TABLE 1: Demographic characteristics and burnout among nurses ($n = 1,235$).

Characteristics	n (%)	Burnout ($M \pm SD$)	Test statistics

capacity of the models was less satisfactory (AUCs ranged from 0.803 to 0.821), they can help nurse burnout management and their prediction can be improved by including more influencing variables. The sensitivity of the four models ranged from 0.128 to 0.470, indicating a low capacity to target nurses at a high risk of burnout. A possible reason is that some important predictors were not included in the models; as a result, the models could not sensitively include nurses with burnout. The specificity of the four models (ranging from 0.919 to 0.995) was good in the study,

indicating that the models specifically distinguished burnout from similar syndromes. Among the four models, the gradient boosting tree exhibited the best performance, with good sensitivity and calibration efficacy. The performance of the SVM model was similar to that of the random forest model, whereas that of the logistic model was far from satisfactory.

In this study, job crafting was the most important predictor of burnout in the four models. In contrast, the effect size of job crafting on burnout was small in the logistic

regression analysis (odds ratio = 0.123). Martinez et al. [50] reported that job crafting can explain 15.7%–19.7% of the variance in burnout in four dimensions (personal impact dimension, job dissatisfaction, motivational abandonment, and social climate dimension) among male nurses. Roskova and Faragova [18] reported that job crafting combined with age and position explained 14% of the variability in burnout among full-time employees. According to the Job Demands-Resources model, overwhelming job demands and limited job resources lead to burnout and job crafting is one of the mediating factors in this relationship. High job crafting encourages individuals to reframe their perceptions of work, engage in more workplace relationships, and change the nature of their tasks, which could decrease burnout and increase job satisfaction and well-being [51]. Considering the mild but significant effect of job crafting on nurse burnout, nurse managers and nurses must foster nurses' crafting behaviors in their clinical work through several typical interventions (e.g., job crafting workshops and job crafting exercises) [52, 53].

In the study, we creatively revealed the predictive value of leisure crafting on burnout using four machine learning models. Leisure crafting was the second or fifth most important feature for burnout in the SVM, random forest, and gradient boosting tree models. However, leisure crafting was not included in the final logistic regression model. Studies have reported that off-job crafting enables individuals to learn new things, expand existing hobbies, and have new personal connections, which can help them overcome severe challenges, promote personal growth, and achieve a good balance between job and leisure [54, 55]. Ugwu [56] demonstrated that leisure crafting alleviates the negative effects of counterproductive work behaviors caused by high job demands. Therefore, nurse manager and nurses should be aware of the importance of leisure crafting in burnout. Various leisure activities should be organized in establishing new interpersonal relationships, developing new skills, and learning new meanings in work and life [57].

Despite the fact the correlations between job crafting, leisure crafting, and burnout had been tested in the study, several limitations in this present study need to be considered. First, data were collected from four Chinese tertiary hospitals. Data from other hospital levels were lacking, which might have influenced the performance of the model in the external dataset. We suggest collecting sufficient data from different hospitals to validate the model. Second, regarding the cross-sectional study design, the effects of job and leisure crafting on burnout did not present a cause-and-effect relationship. Therefore, a longitudinal study is needed to better understand the predictions of job and leisure crafting on nurse burnout. Third, the study focused only on limited characteristics of nurses, such as demographic, job crafting, and leisure crafting. This might be the primary reason for the low sensitivity of the models. Therefore, several significant factors influencing burnout (e.g., job stress, job resources, work-family conflict, collegial support, and leadership) should be investigated and analyzed in future studies. Fourth, 52 male nurses were included in the study. Generalization of the model for male nurses should be

done with caution, and further surveys of this demographic are needed to clarify the model found in the study. Finally, nurses who were on sick leave and in the process of turnover were excluded from the study. Nurses in these conditions may experience high levels of burnout. Therefore, further studies could recruit nurses in these conditions to promote the generalization of the studies.

5. Conclusions

Burnout is a serious issue among nurses worldwide, raising great concerns among hospital administrators and nurse managers. In this study, nurses experienced mild-to-moderate levels of burnout; moreover, they had moderate-to-high levels of job and leisure crafting. These findings indicate that despite nurses having some burnout symptoms, they tend to apply crafting activities to increase their clinical skills and confidence and promote their interpersonal relationships and self-development. According to the machine learning-based predictive models, job crafting and leisure crafting were significant predictors of burnout, and job crafting was the most important predictor of burnout in the four models. Therefore, nurse managers are encouraged to create a casual crafting environment and take effective measures to improve nurses' crafting behaviors, ultimately reducing their burnout and promoting their clinical performance and organizational commitment.

6. Implications for Nursing Management

Burnout is a critical risk factor for the organizational health (e.g., organizational commitment and development) of hospitals and physical (e.g., inflammation, pain, and sleep disorder) and mental health (e.g., anxiety and depression) of nurses. Therefore, hospital administrators and nurse managers should pay more attention on this severe problem and take effective measures to alleviate burnout among nurses. According to the findings of this study, routine assessment of burnout among nurses should be added in health management strategies for nursing team.

In this study, job crafting was the most significant influencing factor for nurse burnout. Nurse managers should realize the positive effects of job crafting on nurse burnout. Several effective interventions (including job crafting training workshop, job crafting e-learning, and career crafting training) can be selected as training courses to meet the job crafting needs of nurses [58, 59]. Furthermore, nurse managers are encouraged to create a positive working environment and provide more organizational resources and opportunities for nurses to help them successfully deal with work challenges and achieve self-growth. In addition, several kinds of mutual-aid groups should be organized by nurse managers to support nurses find help from colleagues.

Leisure crafting is another new influencing factor for nurse burnout. According to this interesting finding, nurse managers are suggested to support nurses to cultivate personal hobbies and learn new knowledge via several group activities. Nurses are encouraged to fully use their leisure

time to keep good personal relationships, develop new skills, and obtain a different experience. Setting achievable goals and keeping active thinking in leisure activities are also beneficial to nurses work attitude and performance.

Background. According to projections based on current trends, it can be anticipated that from 2024 onward, approximately 70% of all cancer cases will be diagnosed in individuals 65 years and older. Given this complex intersection between population ageing and cancer incidence, it is of great importance to address this issue from a comprehensive care perspective. Here comes the importance of advanced practice nurse into play. However, this figure is still not sufficiently valued in many countries. Its roles are also not clearly defined at the international level. For this reason, a systematic review of the scientific literature was carried out to analyze the impact of advanced practice nurse on the quality of life of older adults with cancer. **Methods.** Searches were carried out in PubMed, Web of Science (WoS), Scopus, CINAHL, LILACS, and ScienceDirect databases. They were limited to studies conducted in the last 7 years. Only open-access articles were selected. To analyze the chosen articles and assess their quality, the criteria of the PRISMA and CASPe statements were applied. All authors participated in both the selection of the articles and their analysis. **Results.** Of the initial 58 articles selected, a total of 10 articles were finally included, as they met the eligibility criteria established after further analysis. The results show a positive relationship between the advanced practice nurse intervention and quality of life in older adults with cancer. **Conclusions.** Advanced practice nurse (APN) plays a key role in the care of older adults with cancer, significantly improving their quality of life and contributing to the comprehensive care of these patients. The findings evidenced in this work support the integration of APNs in cancer care teams to improve patient experience and overall well-being.

1. Background

A major challenge is being grappled with modern society: the intertwined issues of population growth and rising life expectancy. Life has been expanded by advances in healthcare, but a complex scenario has been created by declining fertility rates. From 1950 to 2015, the population over 60 quadrupled, and it is projected to be 2.1 billion by

2050 [1]. Public health worldwide is being transformed by demographic changes due to evolving factors, with significant impacts on both health and social aspects [2].

An important concern in this context is the growing prevalence of chronic diseases related to age, including cardiovascular problems, degenerative conditions, dementia, and notably, cancer [1]. From the analysis of the most current statistics, it can be seen that around 20 million

new cases of cancer were reported worldwide in 2020. Among these, breast, lung, colon, prostate, and stomach cancers are noted as standing out, being currently recognized as some of the diseases with the highest incidence rates on the international scene [3]. By 2024 and beyond, around 70% of cancer cases are expected to be diagnosed in people 65 years and older, driven by ageing-related biological changes and a higher likelihood of comorbidities. This poses a significant risk to the quality of life for older individuals [4, 5].

To tackle the challenges of ageing and increased cancer rates, a holistic strategy is essential. Nursing plays a crucial role by adopting a comprehensive perspective, considering individual differences, and tailoring personalized solutions for better elderly life quality [6].

Quality of life in cancer patients is a key concept in nursing, encompassing general well-being in various dimensions. Its understanding has evolved since its origin in the post-World War II in the United States [7]. Originally, quality of life in cancer patients was assessed through objective measures such as survival and physical function. However, psychologists found that these could not fully explain variations. Subjective interpretations, such as happiness and life satisfaction, became crucial. These subjective factors often have a more significant impact on the quality of life of patients than objective factors alone [7].

In this context, the concept of health-related quality of life (HRQoL) emerged to capture the interaction between health and quality of life in a more holistic way [7]. To measure the HRQoL in cancer patients effectively, it is essential to consider multiple components such as functional, cognitive, emotional, spiritual, social, and economic aspects. Assessing specific problems and symptoms, such as pain and fatigue, is crucial. This comprehensive approach not only aids in clinical decision-making but also identifies vulnerable patient groups that need personalized care. It helps to evaluate the impact of treatment on quality of life, tolerability, and adherence. Nursing plays a key role in providing complete care and improving the overall quality of life for cancer patients [4].

In January 2018, the Andalusia Health Quality Agency (Spain) presented a professional competency manual for advanced practice nurses (APNs) in cancer care that includes competence in complex care coordination, such as in the case of the elderly with cancer [8, 9]. In Spain, there is a distinction between generalist and specialist nurses. However, with the increasing demand for health services and the need for highly specialized care, the new role of APNs has arisen. This model draws inspiration from Anglo-Saxon countries such as the United Kingdom, Canada, Australia, and New Zealand, adapting to the evolving complexity of health systems [5]. In the international context, advanced practice nurse is increasingly gaining momentum in different countries. However, there is a common denominator which is the need to provide clarity about this role in the provision of health services [10].

The concept of the APN originated in the United States during the 1960s and was later adopted in other countries, including the United Kingdom, Canada, and Australia.

Following the National Cancer Act of 1971, which established a comprehensive framework for cancer prevention, diagnosis, and treatment in the U.S., APNs initially focused on cancer management and research. As treatments grew more complex, the need for improved coordination across cancer care facets became evident, leading to stronger interdisciplinary collaboration and integrated care. The United Kingdom's Calman-Hine's report recommended specialized multidisciplinary teams and oncology care networks, reflecting these needs. Similarly, in other countries such as Portugal, this role is fulfilled by specialized nurses who, although they may not carry the same title, perform comparable functions in providing expert care and coordinating healthcare services in their areas of specialization [8].

An APN is a highly skilled nursing professional who has obtained advanced educational credentials and clinical training beyond the basic nursing education and licensing required of a registered nurse (RN). APNs are prepared through a postgraduate degree, such as, a master's or doctoral program, which enables them to provide a higher level of care and take on roles that include direct patient care, consultation, education, research, and administration [8].

ICN emphasizes that APNs should conduct direct healthcare practices within their focus population. These nurses can play a crucial role in assessing and diagnosing the needs of senior oncology patients using theories such as the theory of unpleasant symptoms and the symptom management theory. Their expertise helps identify clusters of symptoms and assess their impact on patient's quality of life and functionality [11].

APNs play a multifaceted role in the care of elderly patients diagnosed with cancer, functioning across various capacities that directly impact patient outcomes. As consultants, they provide crucial guidance to healthcare professionals, patients, and families, ensuring personalized and understandable care plans. Their educational responsibilities are profound, with a focus on disseminating advanced nursing practices to clinical nurses in primary care settings and sociohealthcare residences, areas critical to the elderly population. APNs also engage in research, contributing to the development of innovative, evidence-based approaches that enhance cancer care. Furthermore, through transformational leadership, APNs implement significant changes in healthcare practices, advocating for improvements that optimize the treatment and recovery processes for senior oncology patients. These roles exemplify the APNs' integral contribution to a holistic healthcare approach, emphasizing their importance in both direct patient care and broader healthcare improvements [8].

Although the APN role is recognized globally, there is a scarcity of studies examining its impact on the quality of life of senior oncology patients. Updated information is crucial, especially postpandemic, to understand the quality of service perceived by the patient and academic variables related to proper training in this role. Older patients are a heterogeneous population ranging from those who are frail and dependent to those who are extremely active. Therefore, it is necessary to provide adequate geriatric care. Currently,

there is not enough evidence on whether nursing staff apply adequate and comprehensive care to senior oncology patients. APNs could have a relevant role in this comprehensive care, which is why it is important to know the experiences that already exist with these professionals [12].

Therefore, the objective of this research was to conduct a systematic review of the scientific literature to identify research studies that analyze the impact of APNs on the quality of life of older adults with cancer. This study further examines evidence of the effectiveness of advanced practice nurse roles in meeting the healthcare needs specifically the quality of life of senior oncology patients.

2. Materials and Methods

In this study, a systematic review of the scientific literature was carried out in which studies analyzed the relationship between APN interventions and the quality of life of older adults with cancer. PRISMA statement criteria were applied [13] for systematic reviews by comprehensively analyzing the selected articles. The study was carried out according to the guidelines of the Declaration of Helsinki. This research is registered in PROSPERO (International Prospective Register of Systematic Reviews) with the registration number 488680.

The PICO framework is a structured approach that helps in formulating precise clinical research questions. In the proposed study, the focus is on senior oncology patients (population), investigating the effects of advanced practice nurse care (intervention) in comparison to standard nursing care (comparison). The main goal is to determine the benefits of such specialized nursing interventions in terms of improved health outcomes (outcome). Accordingly, the research question formulated is as follows: "What are the benefits of advanced practice nurse care in improving health outcomes compared to standard nursing care among senior oncology patients?" This question aims to capture the specific impacts of advanced practice nurse on the care quality and health results in this vulnerable group, thereby guiding potential improvements in clinical practices.

2.1. Selection Criteria. The systematic review was carried out between February and March 2023 in PubMed, Web of Science (WoS), SCOPUS, CINAHL, LILACS, and ScienceDirect databases. The investigation focused on literature published within the past seven years, specifically from January 1, 2016, to March 31, 2023, and exclusively included open-access documents. Our aim was to derive recent and well-supported findings from a range of documentary materials, leading to the decision to incorporate both research studies and reviews, whether systematic or bibliographic in nature.

2.2. Search Strategy. The search strategy was approached by selecting the following search criteria: for PubMed ((“Advanced Practice Nurse” [Mesh]) AND “Aged” [Mesh]) AND “Neoplasms” [Mesh]; ((“Advanced Practice Nurse” [Mesh]) AND “Neoplasms” [Mesh]) AND “Quality of Life” [Mesh]; for WOS ((ALL=(advanced practice nurse)) AND

ALL=(neoplasms)) AND ALL=(quality of life); ((TS=(advanced practice nurse)) AND TS=(neoplasms)) AND TS=(quality of life); ((ALL=(advanced practice nurse)) AND ALL=(aged)) AND ALL=(neoplasms); for SCOPUS (TITLE-ABS-KEY (“advanced practice nurse”) AND TITLE-ABS-KEY (neoplasms) AND TITLE-ABS-KEY (aged)) AND PUBYEAR >2016 AND PUBYEAR <2023; (TITLE-ABS-KEY (“advanced practice nurse”) AND TITLE-ABS-KEY (neoplasms) AND TITLE-ABS-KEY (“quality of life”)); for CINAHL advanced practice nurse AND quality of life AND older adult AND cancer; advanced practice nurse AND neoplasms AND aged AND quality of life; for LILACS (advanced practice nurse) AND (cancer) AND (older adult) AND (quality of life); (advanced practice nurse) AND (aged) AND (neoplasms) AND (quality of life); for ScienceDirect advanced practice nurse AND quality of life AND cancer AND older adult.

2.3. Inclusion and Exclusion Criteria. The following inclusion criteria were used: (a) studies in which APN was analyzed, (b) consideration of quality of life and cancer variables, (c) studies in which the sample was an adult population, and (d) articles published in scientific journals. All articles included in this review had to meet the four criteria detailed above.

Exclusions from this study encompassed various document types, such as editor letters, commentaries, opinions, perspectives, guidelines, standards, and case series. To ensure the reliability and accuracy of our process, three authors (C.U.-G., F.-J.G.-V., and E.C.) independently assessed the relevance of the selected articles to the study’s objectives and adherence to the inclusion criteria. When the title, abstract, and keywords of the article were in doubt for inclusion, two other authors were included (R.C.-B.; M.-d.-l.-A.M.-G. and E.-M.B.-M.) to arbitrate the decision on their inclusion or exclusion.

The process of identifying and choosing articles, including those that were ultimately included or excluded, as well as the rationale behind their exclusion during the screening and selection stages, is depicted in the flowchart in Figure 1. This representation aligns with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, which are aimed at enhancing the thoroughness in the reporting of systematic reviews and meta-analyses [14].

2.4. Data Extraction. The data extraction process was carried out through extensive trials and postsearch proceedings. This started by reviewing, primarily and meticulously, the title, abstract, method, results, and conclusions of each article. Data were extracted as found in their respective studies at the time of review and were inserted into Table 1

In this systematic review, the selection of variables was guided by the PICOS framework [25], encompassing participants, interventions, comparisons, outcomes, and study design. With this strategy, it was possible to delimit the inclusion criteria and, based on them, carry out a qualitative analysis of the results. In addition, the research incorporated other pertinent variables such as the authors, year of publication, country, reference article, study objectives,

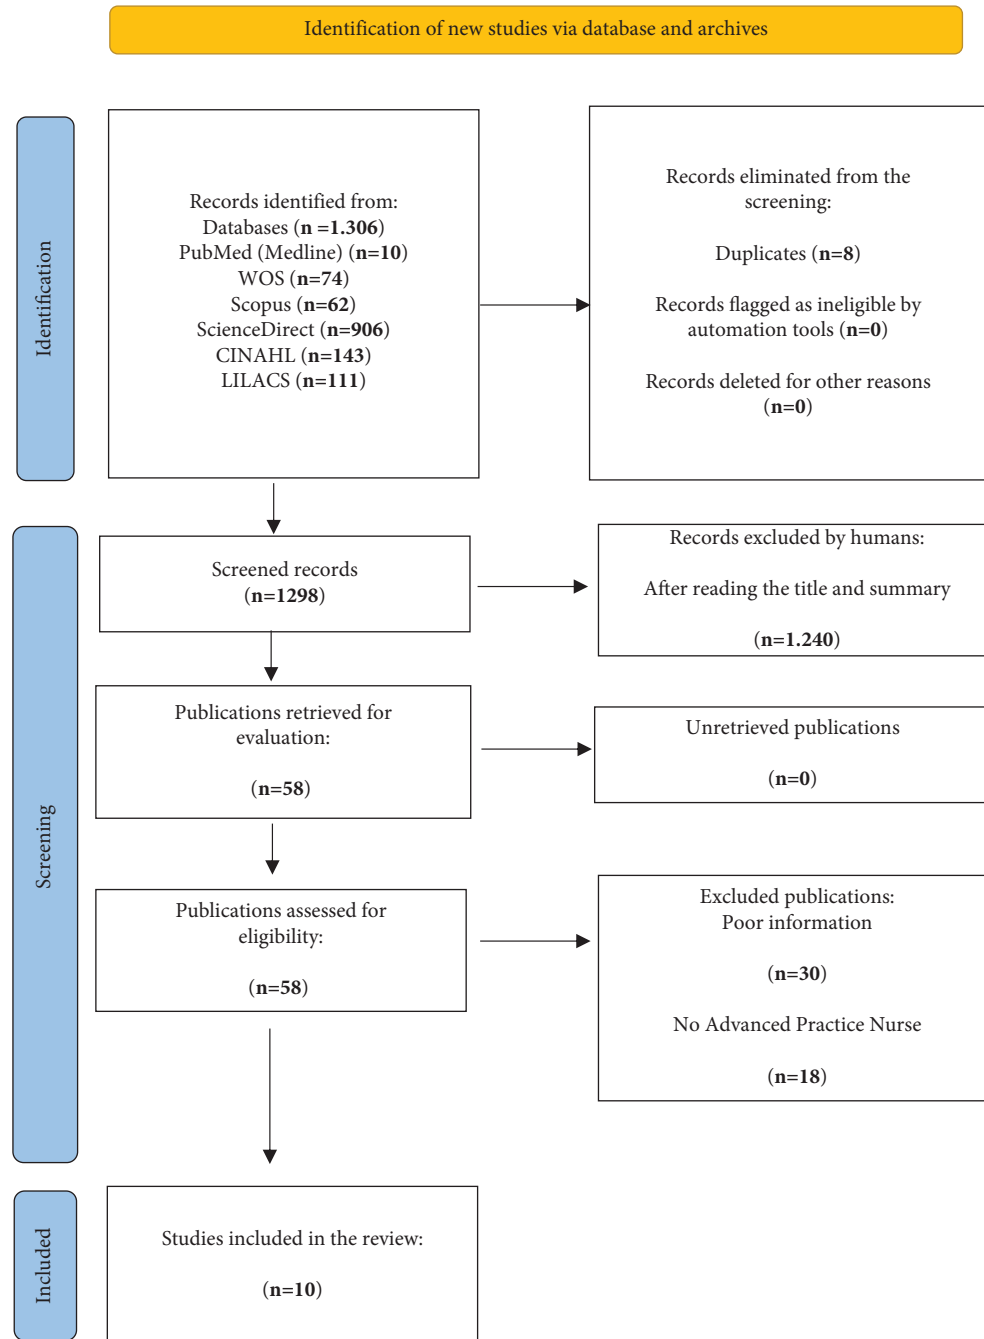

FIGURE 1: Flowchart of the systematic review process according to the statements of the PRISMA protocol.

participant details, variables measured, and the scales used. With data extraction, a document was created with a set of data and was hosted in the Arias Montano Institutional Repository [26].

2.5. Presentation of the Results: Adherence to Quality Initiative (PRISMA). The results of the primary studies, obtained through a systematic and reproducible methodology, were presented qualitatively and quantitatively (Figure 1).

2.6. Quality Evaluation. In selecting articles for this review, we conducted a quality analysis using the criteria of the EPHPP tool [27]. This tool assigns an overall quality rating to each study based on the assessment of six key components. Studies are rated as “strong” if they have no weak components and at least four strong ones. Those with fewer than four strong components and one weak component are deemed as “moderate.” Studies receiving two or more weak component ratings are categorized as “weak” [27].

TABLE 1: Characteristics of the studies included in the systematic review.

Author (year) country (reference)	Study design	Comparisons	Objectives of the study	Participants	Measured variable and scale	Interventions	Results
Raphaelis, et al. (2018), Switzerland, Austria [15]	Longitudinal, multicentre, randomized phase 2 study	Written information group and counselling group with an advanced practice nurse	To determine whether written information and/or counselling reduces disease-related uncertainty in women with vulvar neoplasia	N = 49 women with vulvar neoplasia from four Swiss hospitals and one Austrian hospital	The German adult form of the Mishel uncertainty of illness scale (MUJIS-A)	Written: two booklets during the time from diagnosis to surgery. Counselling: five consultations with APN for 10–50 minutes	Overall, the counselling group showed a better trend of improvement on all uncertainty scales throughout the study. Within the counselling group, uncertainty, ambiguity, inconsistency, and unpredictability decreased significantly over six months
Westman et al. (2019), Sweden [16]	Cross-sectional study including two cohorts of patients	All patients with gynecological, hematological, head and neck CA and upper GI before and after the intervention of a new nursing figure in a region of Sweden	To compare patients’ perceptions of care before and after the introduction of a new advanced nursing role, the coordinating contact nurse (CCN), in a region of Sweden	N = 1872 [patients with gynecological (n = 598), hematological (n = 461), upper gastrointestinal (n = 418) and head and neck cancers (n = 395)]	The validated Swedish versions of the European Organization for Research and Treatment of Cancer (EORTC) quality of life questionnaire, QLQ-C30 and QLQ-INFO25, and also a study-specific questionnaire	Interventions were carried out by the new nursing staff. Data were collected in April–May 2015 (baseline) and April–May 2017 (follow-up)	In relation to health-related patient information (overall mean EORTC QLQ- INFO25 score increased from 41.23 to 44.16, $p = 0.0006$), statistically significant improvements were found related to the availability of supportive care resources, e.g., increased informed access to the contact nurse and individual written care plans

TABLE 1: Continued.

Author (year) country (reference)	Study design	Comparisons	Objectives of the study	Participants	Measured variable and scale	Interventions	Results
Serra-barril et al. (2023), Spain [17]	Qualitative phenomenological study	A group of patients and a multidisciplinary group of professionals	To know the lived experience of cancer patients and multidisciplinary professionals in relation to the care provided by the advanced practice nurse	18 professionals and 11 patients	Experiences related to advanced practice nurse, most relevant functions/ characteristics/care offered by this figure, benefits of the care provided, and most relevant aspects of care. The instrument used was self-developed interviews	The study took place from March to December 2021 in four highly complex public university hospitals in Catalonia. Individual interviews with professionals (45–60 minutes each) were conducted online from March to May 2021, using the Microsoft teams platform. From October to December 2021, patient interviews were conducted in person, in a quiet and comfortable hospital room, and lasted approximately 30–45 min	Advanced practice nurses play a critical role in cancer care, making positive contributions to the patient experience and to the work of the multidisciplinary team
Serena et al. (2018), Switzerland [18]	Qualitative descriptive	A multidisciplinary group of professionals and a group of patients	To explore the acceptance of a new role, the advanced practice lung cancer nurse (APNLC), from the perspective of patients and healthcare professionals in a country that lacks regulatory oversight of advanced practice nurse (APN) roles	Multidisciplinary healthcare team, including physicians ($n = 6$), oncology nurses ($n = 5$), the social worker, and the APNLC. Patients ($n = 4$)	The measurement variables were identification of the role of the CLNPA, specific contributions of the role of the CLNPA, and flexibility of the CLNPA service. Semistructured interviews with self-developed items and a self-developed guide for conducting focus group discussions were used for this purpose	Two focus group discussions were conducted with members who had worked closely during the last 6 months with the ANPLC: G1 nurses and social workers and G2 physicians. Semistructured interviews were conducted for ANPLC and patients (lung cancer patients who had received care from ANPLC)	Three main themes were found: identification of the role of the CLNPA, specific contributions of the role of the CLNPA, and flexible service of the CLNPA. Clinicians and patients clearly recognized the role of the CLNPA, noting contributions to continuity of care, psychosocial support, and facilitation of self-management of symptoms

TABLE 1: Continued.

Schneider, Kempfer, and Backes (2021) Brazil [19]	Systematic review	—	Seeking evidence on the education of advanced practice nurses through clinical practice and nursing care with cancer patients	A total of 12 experimental studies were identified	The variables that the studies had to address were educational guidance, control of pain or other symptoms related to the disease and/or treatment, and satisfaction and improvement in the quality of life of cancer patients. All of them in studies in which advanced practice nurses had been involved	The searches were carried out in the following electronic data: PubMed, LILACS, Institute for Scientific Information (ISI) Web of Knowledge via Web of Science, Scopus, CINAHL-EBSCO, and Cochrane Central Register of Controlled Trials (CENTRAL). The timeframe was from 15 July 2018 to 15 December 2019	The analysis of these studies showed that advanced practice nurses were adequately trained. This fact was objectified through the conclusions of the experimental studies analyzed, since, through the good practice of advanced practice nurses, an improvement in the control of pain or other symptoms related to the disease and/or the treatment, satisfaction, and improvement in the quality of life of cancer patients was identified
Muñoz et al. (2023), Spain [20]	Cross-sectional, descriptive study with a quantitative approach	Intervention without a control group	To identify the competency profile of advanced practice nurses involved in the care process of oncology patients	N = 35 nurses caring for cancer patients at the Hospital del Mar, Barcelona	The variables analyzed were the educational standards required by ICN for advanced practice nurse and postgraduate academic qualifications. The instrument for defining the role of the advanced practice nurse (IDREPA) was used	The data were recorded between February and March 2021 through the completion of the instrument by the professionals	Nine (31%) nurses were identified as meeting the standard in all 6 domains on the IDREPA scale to be considered as advanced practice nurses. Of these 9, 31% met the educational standards required by ICN, 7 (24.1%) with an official master's degree and 2 (6.9%) with a doctorate

TABLE 1: Continued.

Geese et al. (2020), Switzerland [21]	Qualitative analysis study	A single experimental group with two subgroups, one of the patients and one of the relatives of patients	To explore the experience of prostate cancer patients undergoing radical prostatectomy and their partners from diagnosis through to follow-up care and the APN support program	$N = 18$ participants, patients ($n = 10$) spouses ($n = 8$)	The study variables were perceptions of empathetic, trusting, informed, open behaviours, and quality of information received in terms of diagnoses and symptoms, offered by the advanced practice nurse. A series of self-developed semistructured interviews were used as an instrument	Between September 2015 and January 2016, 10 patients with PCa and eight spouses agreed to participate in the study. A series of semistructured interviews were conducted to explore patients' and their partners' experiences from diagnosis to discharge	Patients appreciated the EPA's support program. They noted that the EPA was empathetic, trustworthy, knowledgeable, and open. Patients received specific information about PCa, including related symptoms and postoperative side effects
Alotaibi and Al anizi, (2020), Saudi Arabia [22]	Systematic review	—	To determine how advanced practice nurses (APNs) can contribute to cancer care	$N = 5$ items that met the established criteria	The variables taken into account in this work were support for elderly patients, stress relief, improvement of quality of life, and help in symptom management	A series of systematic searches of research studies conducted from 2005 to 2018 were carried out in the following databases: MEDLINE, CINAHL, PubMed, and AMED	The selected studies showed that EPAs provide support to elderly patients, which helps to relieve stress and improve the quality of life of cancer patients. In addition, it was found that EPAs can help patients with symptom management

TABLE 1: Continued.

Author (year) country (reference)	Study design	Comparisons	Objectives of the study	Participants	Measured variable and scale	Interventions	Results
Kim and Yoo (2022), South Korea [23]	Quasiexperimental study with a pretest-posttest nonequivalent control group	Experimental and control groups	To investigate the effects of an advanced practice nurse-led psychoeducational program on distress, anxiety, depression, cancer coping, health-promoting behaviour, and quality of life among colorectal cancer survivors	N = 39. 19 in the experimental group and 20 in the control group	Distress, anxiety, depression, cancer coping, health promotion, and QOL (quality of life) were investigated	A psychoeducational program was implemented by an advanced practice nurse. The program included interventions on anxiety, depression, distress, coping and health-promoting behaviours, and quality of life. Variables were measured before, immediately after, and 4 weeks after the intervention	The psychoeducation program had a positive effect on reducing stress and anxiety in colorectal cancer survivors, improving their coping with cancer and their quality of life
Morgan et al. (2016), USA [24]	Bibliographic review article	—	Describe how the advanced practice nurse (APN) is uniquely suited to meet the needs of older adults across the cancer continuum	N = 82. The information detailed in this paper is based on 82 articles found in searchable databases	Cancer care through: (1) preventive care, screening, and early diagnosis; (2) oncology and gerontology-specific care in geriatric oncology clinics and beyond; and (3) throughout survivorship	A series of searches were carried out in the following databases: Google Scholar, PubMed, and CINAHL. Search terms included the following: "Gero-oncology," "geriatric oncology," "advanced practice nurse," "nurse practitioner," "older adult," "elderly," and "cancer". The papers included in this review range from 2002 to 2015	APNs have made great strides in the care of older adults with cancer through prevention, screening and diagnosis, evidence-based geriatric oncology, and throughout the disease process and are well positioned to help understand the complex relationship between risk factors, geriatric syndromes, and frailty and translate research into practice

The findings of this analysis are shown in Table 2. Of the various articles analyzed, 14% had a strong overall score [23], 57% a moderate overall score [15, 16, 20, 21], and 29% a weak overall score [17, 18].

However, although the percentage of strong scores was the lowest proportion, all papers had strong internal components compared to the percentage of participants who made it to the end of the intervention. In addition, most studies showed strength in terms of the instruments used for data collection and the risk of bias [15, 16, 20, 23]. These internal components with a strong score are relevant and can be prioritized with respect to others, as they are more closely related to the objective of the study in this systematic review. Therefore, although the presence of other internal components with weak or moderate score is evident, since the most relevant internal components were strong, all these studies were included in this research. Another aspect to highlight is that the studies with a moderate overall score only presented one weak internal component out of the six evaluated [15, 16, 20, 21]. Similarly, those with a weak overall score had only two weak internal components [17, 18].

3. Results

3.1. Selection of Studies and the Data Extraction Process. After conducting a comprehensive search and applying the controlled terms (DeCS and MeSH) together with Boolean operators as specified in the search strategy, a total of 1306 relevant articles were collected. The first search was conducted in Web of Science (WoS), where 74 articles were found; the second search was conducted in the Scopus database, gathering a sum of 62 articles; the third search was conducted in PubMed, obtaining a total of 10 articles; subsequently, different searches were conducted in ScienceDirect, CINAHL, and LILACS, obtaining a total of 906, 143, and 111 studies, respectively. Eight duplicate articles were eliminated, resulting in a total of 1298 papers.

The criteria detailed in the data extraction were applied. The first level of screening involved examining the titles and abstracts of articles in all databases, retaining those that looked promising for a full-text review. This stage left a pool of 58 articles for further analysis.

Subsequently, inclusion and exclusion criteria were applied to these 58 articles, resulting in the elimination of 48 of them. The reasons for excluding these 48 articles in the context of this review were based on several considerations: insufficient information ($n = 30$) and insufficient discussion of the topic of APN ($n = 18$).

Finally, after this selection process, a total of 10 articles were identified and retained that met the relevance and quality criteria established for this research. To reduce the selection bias, each article was independently reviewed by three of the researchers (C.U.-G., F.-J.G.-V., and E.C.), who decided whether each article met the criteria. If these researchers did not reach a consensus on the inclusion of a paper, the other two researchers (R.C.-B.; M.-d.-I.-A.M.-G. and E.-M.B.-M.) mediated the decision.

3.2. Characteristics of the Studies: Result Synthesis. Table 1 provides exhaustive details of the main data related to each of the studies included in this review. These data include relevant information such as names of authors, year of publication, country of origin, type of study, comparisons examined, study objectives, participant population, variables considered, measurement instruments used, interventions, and, finally, the results obtained.

Of the ten research articles included in this review, one (10%) was a longitudinal, multicenter, randomized phase 2 study [15]; one (10%) a cross-sectional study involving two cohorts of patients [16]; three (30%) were qualitative studies [17, 18, 21]; two (20%) were systematic reviews [19, 22]; one (10%) a descriptive cross-sectional study with quantitative approach [20]; one (10%) a quasiexperimental study [23]; and one (10%) a literature review study [24].

In terms of the countries in which the work was carried out, three (30%) were carried out in Switzerland [15, 18, 21], one (10%) in Sweden [16], two (20%) in Spain [17, 20], one (10%) in Brazil [19], one (10%) in Saudi Arabia [22], one (10%) in South Korea [23], and one (10%) in the USA [24].

Concerning the area of study topic addressed by the different articles, five (50%) investigated patients' perceptions of the APN [15, 16, 22–24] two (20%) investigated perceptions of both patients and professionals of the multidisciplinary team [18, 20], two (20%) on the adequacy of APN education [19, 20], and one (10%) on perceptions of patients and family members [21].

Regarding the perceptions of APNs in relation to adult oncology patients, satisfactory results were obtained from patients and other professionals in the multidisciplinary team, with direct clinical practice, coordination, consultation, advice, and education being the most important [17]. In addition, the figure of obtaining information and applying advice on self-management of physical symptoms is positively valued [18]. Similarly, relatives of senior oncology patients also showed their appreciation for this professional, which is considered a valuable resource in the counselling about the disease [21].

From the ten studies analyzed, the following conclusions are drawn regarding the role of advanced practice nurses and the adequacy of their training: They play an essential role in assessing and diagnosing the needs of senior oncology patients by performing a comprehensive geriatric assessment. It also collaborates in the promotion of regular cancer screening and detection [24]; plays a crucial role in the early detection of complications and toxicities related to cancer treatment, contributing to a more accurate diagnosis and more effective care planning [17, 22]; contributes to the assessment and diagnosis of the needs of older patients with colorectal cancer by providing a comprehensive assessment of patients' needs, as well as continuity of care, psychosocial support, and facilitation of self-management of symptoms [18, 23]; and promotes care and facilitates the transition process from diagnosis to end of life. It also plays an important role in education and collaboration with multidisciplinary teams [19]; influences the improvement of patient variables such as uncertainty, ambiguity, inconsistency, and unpredictability, and increases the safety and confidence of

TABLE 2: Quality assessment components and ratings for the EPHPP instrument.

Articles	Components**						Overall score*
	1	2	3	4	5	6	
Raphaelis et al. [15]	S	S	M	W	S	S	M

patients and relatives [15, 21]; and improves the acquisition of information related to supportive care resources [16]; their training in most cases meets the training standards required by ICN and this is evidenced by their clinical and care practice [19, 20].

3.3. Association between the Different APN Interventions with the Quality of Life of Senior Oncology Patients. APNs prioritize and effectively manage pain, providing vital emotional and psychological support during cancer treatment. Through empathetic communication and family participation, they improve both quality of life and patient ability to self-manage their health [19]. In certain cases, the APNs called patients after initial chemotherapy sessions to assess symptoms and provide advice, addressing both physical and psychological aspects of quality of life. This approach was proven to be more effective than interventions that focus solely on targeting quality of life [16]. Emotional and psychological support, with the use of active listening by APNs, also led to improvements in quality of life through reduced stress and anxiety [16]. Another key element was advance care planning in gerontological end-of-life care. People involved in this type of care are more likely to know and fulfill their wishes at the end of life, which improves patient and family satisfaction [24].

The groups with APN counselling showed a better trend of improvement on all uncertainty scales [15]. On the other hand, the reviewed studies have also shown how APNs can provide support to senior oncology patients through external means. The provision of telephone support facilitated access to the system and provided a rapid response to patients' problems and needs [16, 17]. Finally, it was also observed how APNs can make referrals to support services for patients and their families, such as support groups or counselors and mental health services, as they can identify signs of depression or emotional distress and collaborate with other mental health professionals when necessary. All of this had an impact on improving the quality of life of patients and families [15, 19, 24].

4. Discussion

The aim of this systematic review was to identify research papers that analyzed the impact of APNs on the quality of life of older adults with cancer.

Cancer care has become increasingly complex due to an ageing population and the growing need for comprehensive and personalized approaches to cancer treatment [1]. This review highlights multiple findings that underscore the essential contribution of APNs in enhancing quality of life and providing comprehensive care to senior oncology patients.

APN collaborates with the multidisciplinary team to carry out a comprehensive geriatric assessment, achieving a substantial change in treatment decisions in more than 40% of patients. With the intervention of this professional, great advances in prevention, detection, and diagnosis are achieved [24]. To grasp the significance of this finding, it is essential to appreciate the role of the global geriatric assessment in adults. Older people undergo a transformation in their health, affecting their functional, psychological, and social aspects. A dependable global geriatric assessment that is valid, feasible, and simple aids in diagnosing health problems across all dimensions. It streamlines medical care and improves the overall quality of life for the elderly [28].

Early implementation of palliative care with APN in cancer treatment significantly improves patient's quality of life, reduces depression, and minimizes the need for intensive care. This approach may also contribute to increased survival, as demonstrated in postoperative patients who received home APN intervention compared to those who did not [15, 19]. These findings emphasize the vital role of APNs in end-of-life care, where their advanced clinical decisions and specialized knowledge in cancer care directly contribute to improved quality of life. This ensures that older adults receive optimal treatment, leading to longer survival in most cases [20].

Nurses are increasingly taking on new roles in different countries. Health education is becoming one of its key functions. There is a significant improvement in patients' perception of the health-related information they receive [16]. All this makes a positive contribution to the patient's experience and to the work of the multidisciplinary team [17].

The health education provided by APNs goes beyond providing general information to senior oncology patients. It plays a crucial role in the ongoing dialogue with patients, offering guidance and education on managing reported side effects during medication treatment [18, 29–31]. Similarly, these nurses work closely with social workers, pharmacists, and physicians. This interdisciplinary and coordinated

approach can have a significant impact on the quality of life of senior oncology patients by providing a smoother and more effective transition from the hospital setting to outpatient or home care [16].

On the other hand, it has also been observed that with the intervention of APNs in psychoeducational programs for cancer survivors, their coping improves, as well as their quality of life. This is due to the positive effect on the reduction of stress and anxiety [23]. Patient-centered care, which includes both physical and psychological aspects of quality of life, produces more effective results than interventions that focus solely on quality of life. APNs, with their knowledge and experience, play a crucial role in achieving this, contributing to the reduction of chemotherapy-related symptoms [22, 23]. However, it should be kept in mind that an intervention directed only towards health education is unlikely to lead to a complete behavioural change. To improve the level of behavioural change in senior oncology patients, it is also necessary to implement regular physical activity and dietary practices [32]. Physical activity is an important factor that affects the prognosis and psychosocial adjustment of senior oncology patients [33].

One of the most distressing things for senior oncology patients is the uncertainty they experience. The disease process they are going through has many variables that are completely unknown to them [34]. Raphaelis and collaborators' [15] findings indicate that APN counselling reduces uncertainty related to vulvar neoplasia in adult women. Personalized counselling by APNs showed a significant decrease in uncertainty measures in six months, while written information did not produce significant decreases over time in another group [21]. This corroborates what has already been evidenced in other research, where participants stated that APNs were a key point of support: people who were there for any concerns that were difficult to discuss with a social network or other healthcare providers [35].

In terms of perception of the multidisciplinary team, Serena and collaborators [18] detailed promising results in their research. Physicians perceived APNs as adding value in facilitating access to care, supporting symptom management, providing psychosocial support, and improving continuity of care [18]. These results are consistent with other studies, which emphasize the concurrent empowerment of medicine and nursing. The specialization of nursing roles, such as APNs, contributes significantly to the overarching goal of healthcare, improving patient well-being. Medical professionals recognize and value this nursing role as a valuable complement to their clinical work [36].

Families' perceptions of the APNs were also identified in several studies as favorable [18, 21]. Families noted that, after the intervention, they and their ill relatives received targeted information about cancer, its symptoms, and side effects. In addition, APNs referred them to support services, including self-help groups, sex therapy, and psycho-oncology [18]. However, despite the results, Hart and colleagues [37] estimated in their study that only 65% of patients were willing to be seen by an APN for the first time.

All the scientific literature reviewed agrees that it is necessary to provide individualized, multidimensional and multidisciplinary care to senior oncology patients. For this, the figure of APNs is fundamental, as it is a specialization that requires formal training and education [38, 39]. Currently, there are multiple training initiatives in Spain, such as organizing symposiums, conferences, and courses, although it would still be necessary to include this training and specialization in the curricular training of both geriatric nurses and oncology specialists [9].

This study has limitations, including the heterogeneity of incorporated works due to methodological variations, participant characteristics, intervention specifics, and outcomes. It is difficult to extrapolate conclusions with qualitative studies or systematic reviews; however, in this research, there are also several studies with a control group, a cohort study, and a randomized study, which present greater control of bias [40] and therefore the possibility of extrapolating their conclusions. Despite these limitations, the research addresses a contemporary question in the context of recent global challenges, especially the pandemic. There is a scarcity of studies on the influence of APNs on the quality of life of cancer patient's postpandemic, making this investigation novel. Furthermore, it is a work in which the PRISMA declaration criteria [13] for systematic reviews have been rigorously followed through the exhaustive analysis of the selected articles. However, future research with various interventions and randomized trial designs by APNs is recommended to further advance knowledge in this area, taking into consideration a greater margin of years regarding the publication date for database searches. It would also be appropriate in future research to carry out a meta-analysis after making the systematic review.

5. Conclusions

Carrying out systematic reviews such as those in this study is a challenge due to the lack of recognition that currently exists for these professionals. However, the evidence reflected represents relevant conclusions for the profession in particular and for public health in general.

APNs play a crucial role in the care of older adults with cancer, significantly improving their quality of life and contributing to comprehensive patient care. The research conclusions in this review highlight various aspects of the work of APNs in oncological care for the elderly, including comprehensive geriatric assessment, early detection of complications, personalized care planning, emotional support, educational guidance for patients and families, and vital collaboration within multidisciplinary teams. It is evident that advanced practice nurse (APN) is an emerging practice that improves the care of older people.

In summary, the findings presented in this paper endorse the inclusion of APNs in oncology care teams for a better patient experience and overall well-being. It is crucial to acknowledge and appreciate the significant contribution of APNs in oncology. Advocacy for greater recognition and regulation of its role in the care of senior oncology patients, along with its participation in clinical trials, is essential. The

work of APNs not only enhances the quality of life of these patients but also positively influences clinical outcomes and the health workforce.

6. Implications to Nursing Management

The study highlights the critical role of advanced practice nurses (APNs) in enhancing the care of senior oncology patients, suggesting significant implications for nursing management and leadership. APNs lead multidisciplinary teams effectively, advocating for shared leadership to improve decision-making and care execution. Nursing management should leverage APN expertise in policy advocacy, particularly in expanding their roles within oncology, which is essential for enhancing patient care and operational efficiency.

APNs' ability to manage early complications and provide personalized care underscores the need for ongoing professional development and involvement in quality control measures. Nursing leaders should prioritize continuous education for APNs and empower them to initiate care plan adjustments, ensuring high standards of patient safety and care quality.

Furthermore, establishing robust feedback mechanisms for APNs can enhance the effectiveness of nursing practices. This feedback is crucial for refining patient care strategies and advancing nursing leadership, aligning with the goals of improving clinical outcomes and the overall patient experience in healthcare settings.

Background. Emotional intelligence (EI) is an instrumental quality for effective management in the changing landscape of healthcare leadership, specifically among female nursing leaders. **Aim.** This study aims to assess the EI among female nursing leaders in Saudi Arabian hospitals and to examine its connection with leadership and effectiveness of decision-making during a transformational period. **Methods.** This study applied a correlational descriptive cross-sectional methodology to gather data from 232 female nursing leaders. The data were collected via an online survey using convenience sampling. The study incorporated demographic data as well as a 16-item EI scale. Approval was granted by the ethics committee, and the participants' privacy was appropriately ensured. **Results.** The majority of the participants were experienced professionals aged 25 years and above, with a significant proportion holding a bachelor's degree or higher, and over five years of leadership experience. The study revealed a positive connection between EI and self-leadership (self-awareness, self-reflection, and self-motivation), especially among leaders with more experience. An investigation considering many variables revealed a noteworthy model that explains 55.2% of the variation in EI scores. This model portrays that higher self-leadership scores, as well as longer experience, are predictors of higher levels of EI. **Conclusions.** This study has found that EI is widespread among female nursing leaders, and it is meaningfully and positively associated with their aptitude for self-leadership. The fact that more leadership experience correlated with higher EI signifies the need for focused EI development programs in the nursing leadership curriculum. These insights are instrumental for developing leadership that can effectually manage the intricacies of the evolving healthcare transition.

1. Introduction

All nurse leaders must possess a comprehensive range of skills to effectively lead in this transformational era [1]. The transformational era of healthcare refers to a period of significant changes and advances in the industry, such as technological advances, new treatment modalities, and shifting patient demographics [2]. Emotional intelligence (EI) is particularly important for female nursing leaders in this era as it equips them with the skills to navigate these changes, inspire their teams, and foster a culture of continuous learning and growth. By incorporating EI into their mindset, female nursing leaders can effectively lead their teams through the challenges and complexities of healthcare

transformation, ultimately ensuring the delivery of high-quality patient care and to maintain a positive work environment [2]. To be effective, it is essential for female nursing leaders to be aware of their emotions and manage them. Female nursing leaders often face unique challenges in the workplace, such as gender-based discrimination and pay inequality [3].

As a result, it is important for female nursing leaders to be aware of their own emotions to manage their stress and stay emotionally healthy [1]. By understanding their emotions, female nursing leaders can develop strong coping strategies and be better equipped to navigate the challenges they may face in the workplace. This awareness of their emotions can also help to better empathize with and support

their colleagues, regardless of gender. Moreover, the literature supports that EI has significant influence on authentic leadership [4]. EI stems from the concept of social intelligence, which refers to the ability to understand and influence other people [5].

For instance, a female leader with high EI would recognize when a team member is feeling overwhelmed and provide support to that team member rather than reprimanding them for not achieving a goal. In addition, several studies have demonstrated that EI can also be used to foster team spirit, create a culture of mutual respect and trust, manage staff effectively, and make decisions based on empathy and understanding [4]. Female leaders tend to have a stronger awareness of their emotions and are better able to recognize and empathize with their colleagues' emotions. This often leads to better communication and problem-solving skills, which can be beneficial when working with male colleagues. In addition, females may be more likely to offer emotional support and be more understanding of their colleagues' needs [5]. EI analogous to a compass that guides decisions and actions, helping leaders to stay on course and guide the team in achieving its goals.

Gender and leadership have, in recent times, been at the center of controversy [6]. As more females occupy leadership roles in many countries, questions arise as to whether they should lead in specific areas and whether both males and females exhibit similar leadership traits [7].

The literature shows that gender differences do exist and affect leadership roles in certain circumstances [5, 6]. For example, a report by the Pew Research Center indicates that females only account for 24% of the total members of national legislative bodies globally [8].

Furthermore, a meta-analysis by Lopez-Zafra et al. on transformational leadership, EI, and gender stereotypes revealed that females exhibited higher charisma, transformational characters, and EI skills than males, despite traditional stereotypes of females in leadership [5]. For example, women are often stereotyped as not aggressive enough for leadership positions. They are viewed as caregivers, where men are viewed as assertive. According to a recent report, the unemployment rate for Saudi females has declined to 15.4% in the fourth quarter of 2022 from 2021, 2020, and 2019, with the leading indicators of the Women's Labor Force Survey showing a marked improvement [9]. The percentage of employed females increased to 30.4% from 27.6% in the fourth quarter of 2021, due to the decline in female unemployment, the expansion of their economic participation, and the growth of their employment in a variety of fields. It increased slightly from 35.6% in the fourth quarter of 2021 to 36% in the fourth quarter of 2022 [9]. Leadership styles are essential variables that may explain gender differences in leadership. Different leadership styles require different skillsets, and females may be more likely to have the necessary skills to lead effectively [4, 5]. For example, females may be more likely to have empathy and interpersonal skills, which are important in leading a team. In addition, females may be more likely to make decisions based on the best interests of the team rather than on

personal gain. Yet, different leadership styles may require different skills, such as the ability to motivate and inspire others [5], which are typically associated with males. Females who are successful in leadership roles may have developed these skills through different experiences and methods than males.

An effective leadership style includes demonstrating higher EI. EI influences an individual's establishment as a role model, which helps to gain the trust of team members [4]. EI is an inherent attribute, regardless of gender or sex. However, the level of EI varies among individuals and can often be the difference between influential leaders and less successful ones. Multiple studies show that females score higher than males in EI and are generally more expressive than males [3, 5]. This means that females tend to be more supportive and can effectively manage emotions. Characteristics such as femininity and emotional clarity are essential predictors for transformational leadership [5]. Emotional clarity, specifically, is an important predictor of intellectual stimulation and inspirational charisma in the workplace. Emotional clarity is the ability to identify, understand, and communicate emotions accurately and effectively. It involves self-awareness, self-regulation, and self-expression and is an important skill for leaders to be successful [6, 7].

According to the literature, EI has become a key characteristic of female nursing leaders in the current healthcare transformation landscape [8, 9]. The purpose of this study is to assess the EI of female nursing leaders in the healthcare sector. The results of the study provide insight into how EI can be improved among female nursing leaders to foster better decision-making and enhance leadership skills. As a result of strengthening these skills, patient care and outcomes are likely to improve.

2. Methods

2.1. Study Design and Participants. A correlational descriptive cross-sectional design was conducted using online survey questionnaires.

2.2. Sampling and Data Collection. A total of 232 female nursing leaders working in government and nongovernment hospitals in Saudi Arabia were selected using convenience sampling. Using power analysis to determine the sample size to achieve a significance level of 0.05 and power of 0.80, the minimum requirement was 143 subjects. Data were collected through the online survey questionnaires and the responses were confidential. The survey questionnaires were designed to be short and easy to complete to encourage participation.

2.3. Eligibility and Exclusion Criteria. A nurse with a leadership experience of five years or more (head/charge or equivalent, administrator or equivalent, and supervisor or equivalent) was eligible to participate in the study. Nurses without leadership experience and male nurses were excluded.

2.4. Instruments/Measurements. To gather information to assess the EI among female nursing leaders in the healthcare sector during the transformation era, the Wong and Law Emotional Intelligence Scale (WLEIS) five-point Likert scale with categories of 1–5 (1 = strongly disagree; 5 = strongly agree) was used in this study [10]. The WLEIS contains 16 items based on the ability model. It has four dimensions: self-emotional appraisal, other emotional appraisal, using emotions, and regulating emotions. The total EI score is equal to the mean of the items 1–16. The total self-emotions appraisal is based on the mean of items 1–4. The total regulation of emotions is equal to the mean of items 5–8. Total use of emotion is equal to mean of items 9–12. Total others emotion appraisal is equal to the mean of items 13–16. Increased levels of EI correspond to higher scores on the scale. The scale's factor loadings represent different sub-constructs of EI, and each factor has items that measure specific facets of EI. The correct interpretation of scores calls for the reflection of the highest and lowest possible scores on the scale and the knowledge of the meanings of each factor loading [10]. This measure has been cited over 1300 times by Google Scholar citation searches, demonstrating its popularity among researchers [11]. Based on an earlier study conducted in Saudi Arabia, the final scale had an overall Cronbach's alpha of 0.81, adequate construct validity, and a high content validity index, which indicates excellent internal consistency [12]. There was also a section on demographic characteristics including age, nationality, years of experience, level of education, work experience, workplace, sector, current position, and training courses in the past year.

2.5. Statistical Analysis. The statistical data were coded and entered into the statistical package of social science (SPSS), version 23. Descriptive statistics were generated for all study variables. Pearson correlations, polyserial correlations, and regression analysis were computed to examine the intercorrelations among study variables.

2.6. Ethical Considerations. Ethical approval for this study was obtained from the Institutional Research Ethics Committees (IRB number: HAP-01-R-059). Written consent from study subjects was obtained. Confidentiality of the data and privacy of the study subjects was maintained. Subjects were assured they had the right to withdraw from the study.

3. Results

3.1. Participants' Characteristics. A total of 232 female nursing leaders completed the survey; their demographic characteristics are summarized in Table 1. The majority of participants were aged 25 years and above (88.8%). Majority were Saudi nationals (64.2%) and had more than 5 years of leadership experience (61.6%). A majority of the participants held a bachelor's degree or higher (85.4%). Participants had a variety of workplace expertise. A majority of the participants did not provide a specific designation, choosing the option of "others" (52.2%). A majority of the participants

TABLE 1: Characteristics of female nursing leaders in transformational era.

Characteristics	Mean ± SD/number (percentage)
Age (in years)	
<25 years	26 (11.2%)
25–35 years	94 (40.5%)
36–45 years	73 (31.5%)
>45 years	39 (16.8%)
Nationality	
Saudi	149 (64.2%)
Expatriates	83 (35.8%)
Years of experience	
<5 years	89 (38.4%)
6–15 years	53 (22.8%)
16–25 years	25 (10.8%)
>25 years	65 (28.0%)
Educational level	
Diploma/ADN	34 (14.7%)

Private	31 (13.4%)

SD: standard deviation.

had taken self-development courses in the previous year (73.7%) and a majority worked in the government sector (80.6%).

3.2. EI and Its Factor Scores in Female Nursing Leaders. The mean values of EI total score and factor scores of self-emotions appraisal, regulation of emotions, use of emotion, and other emotions appraisal were 4.00 ± 0.56 ; 4.03 ± 0.69 ; 4.03 ± 0.71 ; 4.12 ± 0.65 ; and 3.84 ± 0.70 , respectively (Table 2). These results suggest that participants generally had moderate to high levels of EI, as indicated by the mean scores falling within the four-point range. The highest mean score was observed for the factor of regulation of emotions, indicating that participants were particularly skilled at managing and controlling their emotions. In addition, the high

TABLE 2: Emotional intelligence and its factor scores in female nursing leaders.

	Minimum	Maximum	Mean	SD
Total self-emotions appraisal	1.00	5.00	4.03	0.690
Total regulation of emotions	1.00	5.00	4.033	0.709
Total use of emotion	1.00	5.00	4.123	0.649
Total other -emotion appraisal	1.25	5.00	3.843	0.699
Total emotional intelligence	1.13	5.00	4.003	0.559
Valid N (listwise)				

SD: standard deviation.

standard deviations indicate variability in the participants' responses, highlighting individual differences in EI within the study cohort.

3.3. Self-Leadership Scale and Its Factor Scores in Female Nursing Leaders. The mean values of self-leadership scale total score and factor scores of behavior awareness and volition, task motivation, and constructive cognition were 36.67 ± 4.93 ; 12.65 ± 1.87 ; 11.99 ± 2.05 ; and 12.03 ± 1.94 ; respectively (Table 3). These findings suggest that, on average, participants had moderate levels of self-leadership, with higher scores in behavior awareness and volition. Task motivation and constructive cognition scores were also relatively high, indicating a strong sense of motivation and cognitive strategies for self-leadership among the participants.

3.4. Multivariate Analysis: Multiple Linear Regression-Associated Factors of EI. The multiple regression model was statistically significant, $F(17, 217) = 17.451$, $p < 0.001$, $R^2 = 0.552$ (Table 4). For every unit change in the self-leadership score, the EI level increased by 0.72 ($p < 0.001$). The highest level of experience category (>25 years) showed a higher level of EI 0.205 ($p = 0.021$). These findings indicate a significant positive relationship between self-leadership and EI, with a 0.72 increase in EI for every unit change in the self-leadership score. Furthermore, the highest level of experience category (>25 years) was associated with a statistically significant higher level of EI, suggesting that years of experience may contribute to higher levels of EI. These results highlight the importance of self-leadership and experience in fostering EI.

4. Discussion

The findings of this study demonstrate the interconnected nature of EI among nursing leaders during a transformation period. It is indicated that female nursing leaders who have high EI scores have great potential to be effective leaders since they are likely to practice EI in their leadership style. Subsequently, EI leadership guides the formation of highly cohesive groups. There is an abundance of empirical findings supporting the relationship between EI and effective leadership styles [1, 4, 5, 10, 13]. The study findings clarified this association. Specifically, there are two key components of EI: emotional clarity and emotional regulation. For example, the findings indicate that female

nursing leaders who are aware of their team members' emotions are better leaders because they promote optimal participation by the team members.

According to research by Mysirlaki and Paraskeva, females demonstrate EI in their leadership more than males [14]. Furthermore, individuals with higher EI are more likely to adopt an effective leadership style that is required in the current transformational era [14, 15]. Yet, a study has shown that females tend to possess higher levels of EI than males, making them more attuned to the emotions and needs of others [16]. This heightened EI can greatly benefit female nursing leaders in healthcare, allowing them to effectively connect with and support their teams, as well as navigate the complex and evolving challenges of the organization. These findings help explain the evidenced higher levels of EI among female nursing leaders who were subjects in this study. The correlation between higher levels of EI and nursing leadership is underlined by the four elements of leadership styles, which include idealized influence, inspirational motivation, intellectual stimulation, and individual consideration. These elements collectively contribute to the effectiveness of leaders who possess high EI [17].

Nursing leaders are required to demonstrate to their staff that they are hands-on in the directives they propose [18]. This attribute encourages commitment among the team and allows nursing leaders to put their advocacy into practice. In this transformative era, female leaders need to demonstrate idealized influence whereby they act as exemplary role models. This approach to leadership means acting as a role model—a strategy that further contributes to higher levels of trust and confidence from the rest of the team [17–20]. An emotional relationship created between the leader and the team because the leader applies emotional support and spreading their individual emotions concerning how they expect their followers to behave. A mutual scenario of emotional manifestation is also created, such that the followers also demonstrate emotional commitment that fosters collaboration in a team [18, 19].

EI also helps nursing leaders demonstrate certain nonverbal emotional cues that create the perception of a charismatic and effective leader. For instance, simple cues such as eye contact go a long way in establishing healthy working relations between a leader and the team [1, 4]. One of the scores' findings that demonstrated effective teamwork and collaboration in the study participants was "others emotion appraisal." As the participants achieved high scores in this category, one can infer better levels of interpersonal functioning because these nursing leaders are likely to

TABLE 3: Self-leadership questionnaire and its factor scores in female nursing leaders.

	Minimum	Maximum	Mean	SD
Behavior awareness and volition	4.00	15.00	12.65	1.87

display appropriate reactions to the various personalities on the team. By understanding and tailoring reactions to the different emotional presentations that various individuals demonstrate, a nursing leader generates the emotional knowledge of how to gain optimum productivity and cooperation from staff members [10].

Effective female nursing leadership includes streamlining the staff toward attaining a common goal. This involves monitoring not only the usual protocol measures but also challenging scenarios, such as change implementation [10–12]. During change implementation, a significant number of staff may demonstrate resistance to change, which can lead to frustration and negative emotions on the

part of the leader. Even so, nursing leaders realize that attaining their envisioned goal requires optimum input from every stakeholder. Such challenging scenarios are significant determinants of a nursing leader's ability to maintain optimum functionality amid stressful conditions, which is why emotional regulation is a significant attribute of a successful leader [12–15].

EI can assist nursing leaders navigate the challenges of implementing change and working under pressure. Leaders with EI create a work environment marked by enthusiasm and flexibility, which, ultimately, supports their key goal of implementing innovation and optimizing productivity [13]. Such leaders are better equipped to create this work

environment because they have immersed themselves in the activities they are proposing to their team. This scenario was evident in the study as the female nursing leaders achieved high scores of self-leadership. An ability such as this implies that the leader proposes expectations on which she can also deliver and understands if some members of the team find the challenge difficult to achieve.

EI is an integral aspect of maintaining group cohesiveness so that members work toward a common goal despite individual differences [13–15]. Building group cohesiveness, therefore, leads to high levels of individual and team engagement. There is an abundance of the literature demonstrating improved performance and relationships among cohesive groups [16]. Members of a cohesive team also display higher satisfaction levels with their performance because they feel they have been given the opportunity to provide an optimum contribution to the course of leadership. In the transformative era, leaders achieve this goal when they not only act as role models but also foster intellectual stimulation to the group members [12].

Research on effective leadership styles has demonstrated improved group outcomes when more inclusive leadership styles are employed, as opposed to those that bestow all the power on the leader [12, 13]. It is crucial for a leader to encourage feedback from individual team members as they may have useful insights derived from their specific experiences in their roles [14]. In as much as a leader may hold a vision for a given course, maximum contribution from the rest of the team is necessary to determine the effectiveness with which the goal is realized. Accepting input from team members makes them feel that their contribution is valued [11]. EI allows leaders to fuel individual team members' contribution through task motivation, as indicated by the high scores achieved in the study cohort. One method to attain task motivation is through valuing members' contributions and feedback because this allows members to generate a self-driven desire for intellectual stimulation [12]. As such, the female nursing leader's initial vision becomes the team members' challenge to explore every method of achieving the goal.

EI enables leaders to foster innovation and creativity among the team members because they are free to develop a critical approach toward the status quo and apply problem-solving techniques to challenges [13]. The high scores achieved by the participants' task motivation imply that the cohort possessed the skills necessary to motivate team members toward a given course. Leaders with high task motivation ability demonstrate skills such as active listening, encouraging team members to communicate and participate, adaptability, and being supportive.

Effective leadership skills are among the several clinical competence areas built by experience [13]. As such, transitioning from a novice to an experienced nurse comes with the benefit of progressively gaining competence in leadership. As nurses spend many years in a clinical area, they become better at establishing cohesion and collaboration in the workplace, with a leader's perspective [14].

The study findings showed higher levels of EI in female nursing leaders who had more years of workplace experience (>25 years). The clinical area can be challenging in terms of applying theoretical knowledge in practice. It often takes time to attain practice competence, even for a nurse who demonstrates excellence in theoretical knowledge. The advent of nursing theories such as Patricia Benner's theory of transition from novice to expert nursing provides sufficient proof of the journey a nurse undertakes to attain optimum competence levels in clinical roles [15]. Evidence from studies also demonstrates nurses' improved competence and confidence levels in their clinical skills, such as catheterization, injection, and sample collection [16].

Similarly, the area of nurse leadership is largely built by years of clinical experience. This concept has also introduced the vital role of nurse mentors in fostering professional growth for novice nurses. Nurse mentors aid novice nurses in avoiding specific errors that are common among new graduates [17]. They also provide insightful guidance on strategies of successful nurses in clinical areas such as workflow management, networking, and workplace collaboration [18]. Experience gives nurses hands-on skills with improved efficiency and the confidence to handle even challenging scenarios, such as ethical dilemmas [19]. This evidence implies that nurse leadership skills will also improve progressively with time and experience.

Through the study by Benner, significant findings were discovered that are related to the relationships between years of experience, EI levels, and the demonstration of leadership skills among nurse leaders. It is noteworthy that nurses with at least five years of experience have exhibited more comprehensive nurse leadership competence compared to novice nurses. This remark illustrates the importance of practical experience to develop leadership skills in the nursing field. Nurses with many years of experience are given an opportunity to hone essential skills such as decision-making, communication, and team management, which are key to good leadership. In addition, it was found that nursing leaders with over 25 years of work experience were those who had higher levels of EI. This reveals that prolonged professional tenure contributes to the maturing and perfecting of emotional regulation and awareness skills, which are crucial to successful leadership. The sense that more time is spent in different types of clinical environments and interpersonal relationships increases the EI that nurse leaders with lengthy experience possess. Overall, these findings reinforce the need to pay attention to and utilize the complementary nature of experience, EI development and leadership proficiency in the process of building a cadre of skillful nurse leaders able to lead healthcare organizations through their complexity [20]. For instance, effective communication is a crucial aspect of nurse leadership that helps establish better relationships and succinctly present ideas [21].

More experienced nursing leaders also possess better decision-making and critical thinking skills that enable them to analyze complex situations and evaluate options to

determine the best course of action [22, 23]. Furthermore, having analytical and problem-solving abilities assists seasoned nurses respond to situations more effectively by adopting novel approaches and putting into practice tried-and-true tactics that are supported by data and experience. For example, evidence-based practice is a strategy designed to ensure nurses provide high-quality care [23].

In addition, for experienced nurses, the application of evidence-based practice includes the adoption of leadership styles, qualities, and skills that have evidence indicating quality outcomes. These nurses also have strongly established EI that has been activated by prolonged durations of self-awareness as well as the knowledge of how different people react [24]. There is also strong literature backing the positive impact EI has on effective conflict resolution, team inspiration, and maintaining a supportive work environment [25–27].

Therefore, apart from gaining knowledge on effective leadership strategies, practical experience assists nurses to become great leaders through team management and operational decision-making. In this transformative era, female nursing leaders must acquire skills beyond balancing costs, monitoring productivity, and maintaining high levels of patient and staff satisfaction [28]. They also need to act as role models and influence processes at not only the organizational but national levels as well. A strong nursing leader motivates team members, creates a safe and collaborative work environment, and ultimately boosts morale and job retention [12].

4.1. Limitations. A significant limitation of the study is that the study participants were only selected from Saudi Arabian hospitals. This sampling method represents subjects from a specific region. Considering leadership skills are influenced by factors such as culture, the sampling process may have been biased in this regard. Therefore, the findings cannot be generalized to participants from other regions with different cultural backgrounds. The sample size was also relatively small for the generalizability of the findings to larger settings. Another limitation of the study was that only female participants were included. This prevented a comparison of females to males, as leaders who are just as effective as or more effective than men. This finding would have assisted in demystifying the misconception of the inability of females to lead that has led to leadership stereotyping based on gender.

4.2. Recommendations. To display their mastery of leadership abilities in this transformative period, leaders must receive training in EI. Leaders also must embrace leadership styles that encourage team members. Building EI is an inner motivation that passionate nurses should cultivate since it greatly enhances cohesiveness and participative leadership. There is a need for leaders to not only understand and control their own emotions but also understand other people's emotions. To apply these findings to the clinical setting, hospitals must create EI models that can include specific personality assessments, behavioral evaluations, and other relevant factors to ensure that the chosen leaders

possess the necessary emotional stability for the clinical setting. Hospitals may start putting the results into practice by launching leadership development programs designed specifically for nursing leaders; these programs should emphasize resilience in terms of managing one's own emotions as well as comprehending those of others. To reinforce EI in nursing leaders, hospitals can also develop slogans that frequently remind leaders of the importance of this quality. Examples of such slogans could include "Empathy is Essential," "Lead with Compassion," "Leading with Emotional Intelligence," "Creating a Caring Culture," or "Empowering through Understanding." These slogans can be printed and mounted at strategic locations to serve as vital tools of communication tool to this course.

4.3. Implications to Nursing Management. The research on EI in the transformational era among female nursing leaders has several implications for nursing management. Firstly, it highlights the importance of nurturing EI skills in nurses, as it can positively impact their leadership abilities and the overall quality of patient care. Secondly, it emphasizes the need for healthcare organizations to prioritize the recruitment and development of emotionally intelligent leaders who can effectively navigate the complexities of the healthcare landscape. Lastly, the findings suggest that incorporating EI training into nursing leadership programs can be a valuable investment in enhancing the effectiveness and success of nursing management. By understanding and addressing these implications, nursing management can foster a more inclusive and empowering environment for female leaders, ultimately enhancing the overall quality of patient care.

5. Conclusion

By assessing EI levels in female nursing leaders, this study sought to establish EI as a forerunner to a transformational leadership style. As established from the study's findings, participants showed high levels of manifestation of transformational behavior. It has also been established from the literature that EI is critical in predicting transformational leadership based on the key components of emotional clarity and emotional regulation. The findings have also challenged the common misconception that females are not effective nurse leaders. As established, individual behavior is determined by factors that are not limited to gender but also to other determinants such as environment, personal experiences, culture, and heredity. The study's findings point to the necessity of creating instruments to raise the EI of nursing leaders to achieve transformational leadership. Furthermore, after receiving sufficient training in EI, leaders, male and female alike, can demonstrate EI in their leadership style to achieve greater levels of employee satisfaction and organizational performance.

Aims. This study examined nurse managers' conflict resolution styles, tranquillity and patience levels, and their relationships. **Background.** Managers are supposed to know how to manage conflict to reduce the destructive effects of conflict and create constructive effects. **Methods.** The study was a descriptive cross-sectional study and in a city centre in Karadeniz region, in May 2022. It was aimed to reach all executive nurses but was completed with 41 executive nurses. The data were collected face to face using a Sociodemographic Questionnaire, the Rahim Organizational Conflict Inventory, the Patience Scale, and the Tranquillity Scale. **Results.** 51.2% experienced conflict with colleagues and 46.3% with other employees. In conflict management, the most commonly used style was integrating and the least was dominating, respectively. The Patience Scale score (39.15 ± 6.09) and Tranquillity Scale score (3.70 ± 0.70) were moderate. At the same time, long-term (10.19 ± 2.18), short-term (8.90 ± 2.54), and total patience scores were significantly lower in case of conflict with nurses. Interpersonal patience levels were significantly lower in case of conflict with other employees. There was a negative correlation between working as a manager and compromising style. **Conclusion.** It was concluded that executive nurses used the integrating style more, and their patience and tranquillity levels were moderate. In addition to using the integration style more, the fact that nurse managers have moderate levels of patience and calmness will reflect positively on the quality of patient care. It will also increase employee satisfaction. Increasing the level of peace in health institutions will support patience, happiness, and a sense of belonging among employees.

1. Introduction

Conflict is a disagreement or incompatibility between two or more people or groups, a clash of interest, power, and status [1] and occurs when conflicting activities happen [2]. Conflict is a contestation of interests, power, and status between two or more individuals or groups and occurs when conflicting activities occur. The differences in values, ideas, and attitudes, communication and coordination disorders, uncertainties about the management field, and sometimes the poor functioning of the management process can be considered the root causes of conflict in hospitals [1, 3, 4]. Conflict is not always positive or negative; it can signify danger or a harbinger of new opportunities. Whether

conflict outcomes are positive or negative is related to how it is managed [1]. Constructively worked conflict is said to bring about healthy competition, strengthen team participation, and bridge the communication gap [5]. Therefore, conflict management is one of the skills managers require [6].

Conflict resolution is the method used to resolve conflicts in social situations [7]. Different strategies such as integration, obliging, dominating, compromising, and avoiding are used in conflict management. The "integration" strategy adds up to a high interest for self and others, plus involves preciseness, information exchange, and questioning. As for the strategy of "compromising," the individual neglects his self-interest to satisfy the other party's anxiety,

resulting in the situation's characterisation as obedience and compliance with the requests of the opposite party. In addition, it is used when the protection of relations with the other party is more important than the satisfaction of needs. Contrary to the strategy of "integration," "domination" adds up to a high interest for oneself and a low interest for others. The dominant person will do anything to win, resulting in their ignorance of the other party's needs and expectations. Conflict is viable unless it is between the superior and the subordinate, but it can lead to a stalemate when both sides are on equal footing. The "avoiding" strategy involves low interest, both for oneself and others. In other words, an avoidant cannot satisfy both his anxiety and others. Instead of resolving the conflict, postponement can be used to gain time for one of the parties. The "obliging" strategy involves both parties giving up on something to reconcile mutually. Therefore, it is unsuitable for dealing with complex problems requiring a problem-solving approach. However, it is useful when building a consensus is impossible and both parties need a temporary solution to a complex issue [1, 8, 9].

Nurse managers experience conflict daily and are central to conflict management [10]. A study revealed that 61.4% of the nurses in charge of the service had conflicts with the nurses they worked with, most of which were caused by organisational reasons (61.5%) [11]. The leading causes of conflict between physicians and nurses are ambiguity in job descriptions, communication problems, rude and destructive behaviours of physicians, perception of the profession [12], and differences in doctors' demand for power and nurses' demand for influence [13]. In addition, other studies have found moderate to high levels of stress [14–16], job burnout [17], low job satisfaction [15, 18–21], and occupational fatigue [22] in nurses. Factors affecting stress and job satisfaction, such as high workload, shift work and overtime, staff shortage, job uncertainty, workplace violence, and managers' attitude [15, 16, 22–24] can also be considered as factors that cause conflict.

The reasons for the conflict among the executive nurses were affected by variables such as the hospital, age, and professional experience. In addition, the job description and workload caused the conflict [25]. Regarding conflict management, it was determined that the service managers used the integration strategy the most and avoidance the least [11]. Accordingly, nursing students mostly used the strategy of obliging and least domination [26]; in addition, the conflict strategies of university students did not differ according to gender [27]. Different strategies were used to resolve the conflict between doctors and nurses; the most used strategies were integration, compromising, and avoidance, whereas the least used one was dominating [12]. While determining the appropriate strategy in a conflict, considering its contribution to organisational effectiveness, satisfying social needs, and meeting members' ethical and moral needs are crucial. However, excessive integration and obliging strategies help solve strategic problems [1].

Patience, which is among the characteristics expected in managers [28, 29], is defined as a person's tendency to stand calmly in the face of disappointment, distress, or suffering [30]. The concept of patience gives the manager purpose, tolerance,

openness to change, and empathy. It is expected by employees to be more compassionate, open-minded, and willing to manage any situation [29]. Patience has long been recognised as a human strength and a critical component of moral excellence [31]. Its structure saves the individual from negative emotions and increases life satisfaction [32]. The demonstration of true patience depends on both behavioural and emotional components [30]. Patience is positively related to subjective well-being, positive coping, and success [31]. It also includes powerful virtues, such as balance and justice. Patients have less negative affect, lower depression, fewer health problems, and increased life satisfaction [32]. Nurses' patience levels were above the average [33], and it was determined to be a component that affects nurses' resilience in Iran [34].

On the other hand, tranquillity reflects feelings such as comfort, calmness, and serenity, expressed by the characteristics of [35] individuals, such as harmony, balance, comfort, confidence, and inner peace [36]. When there is no threat in daily life, feelings of satisfaction, tranquillity, and well-being emerge, and people generally express their expectations from life in two different ways: tranquillity and happiness [35]. Although studies on patience and tranquillity in the healthcare field are limited, tranquillity and employee performance are positively associated [37]. In this respect, it is thought to be a pioneering study.

Conflicts can frequently emerge due to the complex structure of health services, which are also areas where different disciplines work together. They can happen between health personnel, resulting in medical errors with severe consequences if they are not resolved [38, 39]. Since all conflicts in health institutions will affect cooperation and the delivery of quality health services, managing the conflict with a positive outcome is crucial. Therefore, it is necessary to determine the use of conflict resolution strategies by executive nurses. In addition, nurses work in extraordinary situations such as pandemics. Also, these processes cause nurses to experience depression, stress, and anxiety [40]. These negative emotions can affect the level of patience and peace of mind of nurses. Patience and peace levels of nurse managers will be reflected on the working environment and nurses and will affect the quality of service. The level of patience and peace affected may also influence the choice of conflict resolution strategy. Therefore, this study aims to determine executive nurses' conflict resolution strategies, tranquillity, and patience levels and examine their relationship.

Research Questions.

- (1) Which conflict resolution strategies is the most used by nurse managers in conflict resolution?
- (2) Which levels of tranquillity and patience the nurse managers need?
- (3) Is there a relationship among conflict resolution strategies, tranquillity, and patience levels?

The hypotheses of this study are formulated as follows.

Hypothesis 1. There is a relationship between the patience levels of nurse managers and their conflict resolution styles.

Hypothesis 2. There is a relationship between the serenity levels of nurse managers and their conflict resolution styles.

Hypothesis 3. Patience level and serenity level are related to each other.

2. Methods

2.1. Population and Sample of the Study. This study was conducted as a descriptive cross-sectional study. The study population comprised 60 executive nurses working in the Education and Research Hospital and the State Hospital in a city centre in Karadeniz region. It was aimed to reach all administrative nurses without dealing with the sample determination process. The study was completed with 41 executive nurses who agreed to participate and obtained consent in May 2022. 68% of the research population has been reached.

Inclusion criteria were as follows:

Working as an executive nurse

Volunteering to participate in the study

2.2. Sampling Strategy. The questionnaires were distributed to the executive nurse and collected after they were filled out.

2.3. Data Collection Tools. The data were collected face to face using the Sociodemographic Questionnaire, the Rahim Organizational Conflict Inventory Scale, the Patience Scale, and the Tranquillity Scale.

2.3.1. Sociodemographic Questionnaire. The questionnaire developed by the researcher consists of 11 questions, including age, gender, marital status, educational status, working time in the profession, working time in the current institution, working time as a manager, condition of a conflict with nurses, condition of a conflict with other employees, and state of finding oneself patient and peaceful.

2.3.2. Rahim Organizational Conflict Inventory (ROCI-II). This scale was developed by Rahim in 1983 to identify five different conflict management strategies. It was adapted into Turkish by Gumuseli and Taymaz and consisted of three forms. Form A includes conflict management strategies used by subordinates in conflicts with superiors. Unlike form A, form B holds strategies superiors use in conflicts with subordinates. Form C consists of strategies organisation members use in conflicts with their peers. In this study, form B, also called ROCI II, was used. The scale, which was designed in a 5-point Likert type, consists of 28 items and has options such as always (5), often (4), sometimes (3), rarely (2), and very rarely (1). It reveals individuals' use of five conflict management strategies to what extent. Also, it has the following five subdimensions: integration, compromising, dominating, avoiding, and obliging. Items "1, 5, 12, 22, 23, and 28" are related to the "integration" strategy, items "2, 11, 13, 19, and 24" to "compromising," "8, 9, 18, 21,

and 25" to "dominating," "4, 7, 10, 14, 15, and 20" to "obliging," and items "3, 6, 16, 17, 26, and 27" to the "avoiding" strategy. The score intervals of 4.20–5.00 (always), 3.40–4.19 (often), 2.60–3.39 (sometimes), 1.80–2.59 (rarely), and 1.00–1.79 (very infrequently) are used in grading and interpreting the weighted averages obtained from the scale. A high score from any subdimension indicates that that specific conflict management strategy is used more than others. In contrast, a low score from any subdimension shows that that particular strategy is used less than different strategies [8, 41]. Cronbach's α of the scale subscales was calculated as 0.81 [41]. In this study, Cronbach's α values of the scale were found in the range of 0.66–0.89.

2.3.3. Patience Scale. The Patience Scale was developed by Schnitker, and its validation study in Turkish was conducted by Dogan and Gulmez. There are three subdimensions on the scale, namely, interpersonal patience: 1, 4, 7 (*r*), 9, 11; long-term patience (patience in life hardships) 2, 5, 8; and short-term patience (patience in daily life) 3, 6, 10 (*r*). It was designed in a 5-point Likert type with 11 items and covered the options between "strongly agree" and "strongly disagree." Also, it contains nine positive and two opposing statements. Items 7 and 10 are reverse scored. The highest score on the scale is 55, and the lowest is 11 points. The highest and lowest score ranges that can be obtained from the subdimensions of the scale are interpersonal patience "5–25," long-term patience "3–15," and short-term patience "3–15." A high score obtained from the scale indicates that the patience levels of the individuals are high, whereas a lower score shows a lower level of patience [30, 42]. Cronbach's α of the scale was found to be 0.78 [42]. The Cronbach's α value was found to be 0.68 in the study.

2.3.4. Tranquillity Scale. The Tranquillity Scale developed by Demirci and Eksi is an 8-item one-dimensional scale. Items 5 and 6 are reverse scored. It was designed in a 5-point Likert type, including options such as not at all suitable for me (2), not suitable for me (3), somewhat suitable for me (4), fairly suitable for me (5), and completely suitable for me. The highest score on the scale is 40, and the lowest is 8 points. A high score obtained from the scale indicates that the tranquillity levels of the individuals are high, whereas a lower score shows a lower level of tranquillity. The Cronbach's α internal consistency coefficient of the scale was calculated as 0.78 [35]. Also, its Cronbach's α value was found to be 0.84 in the study.

2.4. Statistical Analysis. For the statistical analysis of the data, the SPSS Statistics 22 software was used. Elements such as percentage, mean, and standard deviation were used to analyse descriptive data. In addition, the Student t-test, Mann-Whitney *U* test, one-way ANOVA, Kruskal-Wallis test, pairwise comparisons, Tukey's HSD post hoc test, and the Pearson correlation analysis were used according to the normal distribution of quantitative data. In the correlation

analysis, 0–0.39 was considered a weak correlation, 0.40–0.69 a moderate correlation, 0.70–0.89 a strong correlation, and 0.90–1.00 a powerful correlation [43]. The level of significance was accepted as $p < 0.05$.

2.5. Ethical Considerations. The study data were collected by obtaining the Ethics Committee’s permission of the university numbered 2022/89 and institutional permissions from the relevant units. Participants agreed to participate voluntarily.

3. Results

37 (90.2%) of the executive nurses participating in the study were women, 38 (92.7%) were married, and their age average was 37.90 ± 7.35 . If we look at their educational status, 27 (65.9%) of them have a bachelor’s degree, 8 (19.5%) have an associate’s degree, 4 (9.8%) are postgraduates, and 2 (4.9%) are high school graduates. Their working hours in the profession are 14.5 ± 7.31 , in the current institution 11.8 ± 7.23 , and as a manager 5.69 ± 5.07 . 21 (51.2%) of the participants stated that they had conflicts with their colleagues, 19 (46.3%) had conflicts with other employees, 38 (92.7%) were patient, and 29 (70.7%) were peaceful. When the reasons stated by those who have conflicts with their colleagues are classified, we develop six themes. The highest cause of conflict is due to working conditions such as lack of personnel and heavy workload, as shown in Figure 1.

When we group the themes as per the literature, 8 (44.4%) of the conflicts are happening due to individual reasons (lack of love and respect, not taking responsibility, lack of empathy, and personal problems), 10 (55.6%) of them due to organisational reasons (working conditions and health policies).

Observations revealed that executive nurses always used the integration strategy, mostly the obliging and compromising strategies and, occasionally, the avoidance and domination strategies. The average score of the Patience Scale is considered moderate with a value of 39.15 ± 6.09 , and its subdimension scores were determined as 9.88 ± 2.42 for short-term patience, 18.02 ± 2.98 for interpersonal patience, and 11.24 ± 2.35 for long-term patience, respectively. Participants’ level of tranquillity is considered moderate, with a score of 3.70 ± 0.70 . In addition, their average scores from the scales are shown in Table 1.

Accordingly, executive nurses’ long-term, short-term, and total patience levels were significantly lower in case of conflict with the nurses ($p = 0.002$, $p = 0.007$, and $p = 0.001$). Their interpersonal patience levels were also substantially lower in case of conflict with other employees ($p = 0.037$). There was no significant difference in the Patience Scale according to gender, marital status, educational status, and being patient and peaceful. No significant difference was found in the Tranquillity Scale by the independent variables. (Table 2).

According to the analysis in Table 3, there was a significant difference in terms of using the strategies of integration and obliging as conflict resolution methods as to

FIGURE 1: Reasons for conflict of executive nurses with colleagues.

TABLE 1: Participants’ Patience Scale, Rahim Organisational Conflict Inventory Scale, and Tranquillity Scale scores.

Scales	n	Minimum	Maximum	χ	Sd.
Patience Scale					
Interpersonal patience	41	11	21	18.02	2.98
Long-term patience	41	5	15	11.24	2.35
Short-term patience	41	4	15	9.88	2.42
Total patience	41	27	47	39.15	6.09
Rahim Organizational Conflict Inventory (ROCI II)					
Integration	41	19	30	4.40	0.52
Compromising	41	8	25	3.61	0.79
Dominating	41	6	25	2.56	0.83
Avoiding	41	6	30	2.93	0.82
Obliging	41	18	30	4.04	0.55
Tranquillity Scale	40	16	40	3.70	0.70

the educational status of the executive nurses ($p = 0.040$, $p = 0.049$). While this difference was observed between postgraduates and high school and undergraduates regarding the integration strategy, it was only seen between postgraduates and undergraduates in the obliging strategy. The table also reveals that postgraduates use the integration and obliging strategies less often. There was no significant difference between conflict resolution strategies by gender, marital status, conflict with nurses and other employees, and state of being patient and peaceful variables. (Table 3).

The correlation analysis revealed that a weak negative correlation was determined between the variable of working time in the institution and both compromising ($r = -0.34$) and obliging ($r = -0.37$). There was a weak negative ($r = -0.37$) correlation between the working time as

a manager variable and the obliging strategy. A weak positive ($r=0.35$) correlation was determined between short-term patience and the level of tranquillity.

Then again, a moderate positive correlation was found between the strategies of integration and compromising ($r=0.66$), a strong correlation with obliging ($r=0.77$), and a weak positive correlation with the level of tranquillity ($r=0.31$). The correlation analysis is shown in Table 4.

4. Discussion

This study, which investigated the strategies of nurses working in managerial positions in two different hospitals in conflict management and their levels of patience and tranquillity, revealed that 51.2% of the participants had conflict with their colleagues and 46.3% with other employees. In similar studies, 61.4% of the nurses in charge of the service stated that they had conflicts with the other nurses [11], and conflict was experienced by all critical care nurses, with 42.5% of the studied nurses having had moderate conflict [44]. This can be explained by the fact that different professional members work together in the health sector, working conditions are complex, and the workload is high. As per the study, the participants mostly used the "integration" strategy in conflict management, the second most "obliging," and the least "dominating." Similar to this study, in other relevant studies, it was stated that the strategies of integration and compromising [11, 12, 25, 45–48] were used the most, and the domination [12, 25] strategy was used the least. In addition, some studies indicate the least used strategy was avoidance [11, 45, 46]. The fact that the nursing students mainly used the compromising strategy and least the domination strategy shows similarity with our results [26]. According to the literature, strategic solutions can be solved by integrating and obliging [1]. Consistent with this information, executive nurses use the strategies desired in conflict resolution more. Although administrative nurses and nursing students use the compromising strategy more often in conflict resolution, the data show that conflict continues at high rates in hospitals. Therefore, it is crucial to attempt to solve the individual and organisational factors that are considered to be the cause of this situation. In a study, it was shown that by using tele-nursing application, it can improve the delivery of health services by increasing access to specialised services where mutual communication and interaction are well established [49]. Similarly, tele-nursing application can be tried in conflict resolution.

According to our study, postgraduate executive nurses used "integration" and "obliging" strategies less than high school and undergraduate nurses. While it was similar in one study that undergraduates used the compromising strategy less than other strategies [46], the educational status variable did not make a significant difference in conflict resolution strategies in other studies [11, 45, 47]. This difference may be due to the different grouping of the educational status variable. The fact that postgraduates are positioned in senior management is not unexpected. On the other hand, executives are more likely to resolve strategic

conflicts involving differences in planning and objectives, and the literature suggests using the strategies of integration and obliging in strategic conflict resolution. Integration and compromise styles allow all employees to adopt the organisation's goals and objectives. So, the reason for the decrease in integration and generous strategies, which were widely used by students and postgraduates, should be investigated in other studies.

As the duration of work in the profession and the hospital increases, the usage of the strategies of compromising and obliging decreases. Similarly, one study found that the compromising strategy decreased as the experience and seniority increased, which supports our study results [46]. This study has also revealed that the compromising strategy decreased as the working time as a manager increased. According to another study, while the generous strategy was used more in those who worked as a manager for 20 years or more, avoidance was used more in those who worked for 6–10 years [45]. Working as a long-term manager can increase organisational commitment and the use of a compromising strategy. The difference in this study may be that nurses have less managerial experience. Besides, there are studies in which these variables do not make a difference [47].

In this study, the age average was 37, and no significant relationship was found between age and conflict resolution strategies. There are other supporting studies with the same results [47]. However, as a result of this study, the compromising strategy was used significantly more by employees over 45 [45]. The majority of the young population in this study, which showed a positive correlation between age and experience, may explain the difference from the other research.

In the study, similar to the literature, the gender [27] and marital status [45] variables did not make a significant difference in conflict management strategies. Unlike this study, there are studies where males prefer to use the generous [46] or avoidance [47] strategies more, while females prefer to use the integration strategy more [47].

92.7% of the participants think that they are patient. When we look at the scale scores, their patience levels are above average in total and subdimensions, similar to a study [33]. Also, it was observed that although executive nurses' long-term, short-term, and total patience levels decreased during a conflict with the nurses, their interpersonal patience levels did not change. These results suggest that executive nurses maintain communication with nurses by looking at events situationally to ensure the continuity of their work. Their interpersonal patience levels decrease during a conflict with other employees. This may suggest that they individualise the events more. The literature shows a positive relationship between patience and decision-making skills [50]. Therefore, the decrease in the interpersonal patience levels of executive nurses may affect their problem-solving skills and create new clash environments. In this case, it may lead to communication loss with other employees. The study found no relationship between patience level and conflict resolution. In this case, hypothesis 1 is rejected.

TABLE 4: The correlation between independent variables, the Patience Scale, the Tranquillity Scale, and the Rahim Organisational Conflict Inventory Scale.

Variables	Working time in the profession	Working time in the current institution	Active time as a manager	Interpersonal patience	Long-term patience	Short-term patience	Total patience	Integration	Compromising	Dominating	Avoiding	Obliging	Tranquillity level

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.

70.7% of the participants in the study stated that they were peaceful, and their tranquillity levels were found to be moderate according to the scale. Also, there was a positive correlation between their tranquillity and short-term patience levels. This finding supports hypothesis 3. During a conflict with nurses whose short-term patience levels are low, there is expected to be a decrease in the tranquillity levels of executive nurses. The fact that their tranquillity level could have been higher in this study may be the fact that they always use the integration strategy. Considering this study, a positive correlation was found between the integration strategy and the level of tranquillity. This relationship supports hypothesis 2.

4.1. Limitations and Strengths. Including only public institutions in the study and the small number of managers may be a limitation. However, it is a strength that the issues of patience and peace of mind are addressed together. What makes this work powerful is that no studies have been found in the healthcare field in which conflict management strategies are being studied together with tranquillity and patience. In addition, the fact that studies on patience and tranquillity in nurses are limited in general makes this study vital.

5. Conclusion and Recommendations

Accordingly, the participants used all conflict management strategies, mostly “integration” and frequently “obliging” and “compromising.” Also, their educational status was influential in their conflict management strategy preferences. In addition, the patience and tranquillity levels of the participants were moderate. While their long- and short-term patience levels decrease in case of a conflict with nurses, their interpersonal patience levels decrease in a conflict with other employees in the hospital. This study has also revealed that the level of tranquillity increases as the integration strategy is used in conflict resolution. On the other hand, no relationship was found between patience and conflict management strategies. This finding indicates that executive nurses maintain professionalism and exhibit the same attitude in the face of events.

Due to its nature, health services have a complex structure, and it is an area where different disciplines work together, so conflicts are inevitable. They need to be managed in a way that will result in a positive outcome as it will affect cooperation and quality of health service delivery. For tranquillity, activities such as in-service training are recommended to increase the use of “integration” by all managers. It is crucial to draw attention to this issue, especially in the postgraduate education process. A unit can be established within the organisation for staff only, where nurses can receive support when they feel that their level of patience and peace of mind has decreased. It is recommended that similar issues be studied with nurses and other health professionals in future studies. In addition, qualitative research methods can be used to examine the issues in depth.

Aim. This study investigated the role of cultural, organizational, and managerial support, workplace fun, affective commitment, innovative behavior with innovative output, and also the mediating role of innovative behavior in the framework of a causal model. **Background.** Innovation is the driving force of development in hospitals, and the quality of healthcare is closely related to hospital innovation. Today, nurses with innovative behaviors are the biggest asset of any hospital because they are involved in any improvement and progress. **Methods.** This descriptive cross-sectional correlational study was conducted using causal modeling methods, including path analysis and structural equation modeling. Using the proportional stratified sampling method, 321 nurses from Ardabil teaching hospitals were included in the study. Data were collected by standard demographic characteristics, innovative behaviors, innovative support, workplace fun, and affective commitment questionnaires. Partial least square structural equation modeling (PLS-SEM) was used to test the conceptual model using PLS-SMART 2 software. **Results.** Cultural support had a positive and significant effect on innovative behavior by affecting organizational support and then managerial support. In addition, workplace fun had a positive and significant effect on innovative behavior directly and indirectly through the mediating role of affective commitment. Finally, innovative behavior also had a positive and significant effect on nurses' innovative output. **Conclusion.** Supervisors and managers can adopt the organizational and managerial support approach to improve the nurses' innovative behaviors. Workplace fun will also improve nurses' innovative behaviors and affective commitment, thereby increasing their innovative output. **Implications for Nursing Management.** By adopting organizational and managerial support for nurses' innovative behaviors, managers should take measures that promote workplace fun and affective commitment to improve nurses' innovative output by encouraging innovative behaviors.

1. Introduction

To provide quality healthcare, hospitals must adopt innovative practices [1]. With the constantly evolving health technology and increasing demand for healthcare services, hospitals need to improve their efficiency, creative thinking,

and value [2]. Innovative behavior involves generating, cultivating, and implementing new ideas within an organization or workgroup [3]. Implementing innovative nursing practices in hospitals directly influences their performance [1, 4]. The particular area where a hospital implements innovative nursing practices has a significant

impact on its overall performance [1, 4]. Continuous innovation of nurses not only fulfills their developmental needs but helps managers improve their work performance [1]. One strategy that managers can employ to encourage innovation is to create a fun work environment [4].

Workplace fun includes socializing with colleagues, celebrating at work, personal freedoms, participating in challenges, performance-based competitions, and generally fun activities at work [5]. Workplace fun affects the attitudes and working behaviors of employees and strengthens their creativity of employees. The effects of workplace fun on innovation have been mentioned in studies [1]. Tews et al. reported that a fun work environment is more attractive to employees than their salary and promotion [6].

Employees usually pursue their affective needs after meeting material needs [7]. Affective commitment describes the employee's emotional dependence on identification and participation in the organization and the individual's emotional orientation towards the organization. Affective commitment is revealed when employees accept that initiative is necessary to maintain the image and reputation of the organization, promote the organization, work hard for the development of the organization, and have high trust and loyalty to the organization [1]. In addition, the role of organizational commitment in the emergence of innovative behaviors has also been seen [8]. For people's innovative behaviors to be transformed into new and effective products and methods, more efforts of employees are needed, and the support of managers and some influential organizational variables are also required [3]. Different leadership styles affect organizational innovation [7].

The more supportive the leadership style, such as transformational leadership, the more innovative behaviors will be in that organization. In the studies conducted on nurses, the cultural climate supporting innovation in the organization and managerial support for innovation has had a positive relationship with the innovative behaviors of nurses [9]. Despite the abovementioned cases, employees have often shown that their managers still deny them from having a fun workplace [10].

The effect of a supportive work environment on employee innovation is significant, but it is often neglected in Iranian hospitals. Despite the importance of recreational activities in promoting innovative behaviors, more research needs to be done in this field, especially among nurses in Iran. To fill this gap, a pioneering study was conducted in Ardabil City, which examined the relationship between innovative behavior, workplace fun, support for innovation, and affective commitment among nurses. These findings illuminate the benefits of a positive work culture and inform future efforts to foster innovation in healthcare settings.

2. Literature Review

Numerous factors can affect innovation, including individual and contextual factors. Three factors that influence employees' innovation are cultural, managerial, and organizational support [3, 11]. Among these factors, some, such as the direct manager's influence, support, and leadership

style, can have more significant effects than cultural factors. Innovation is a managerial process that requires approval from the organization and its managers [12]. However, the national culture governing the society can affect the leadership style of managers and the organizational support provided [3]. According to Sönmez et al.'s study [4], leadership support has a positive impact on increasing innovative behaviors and ultimately leads to an increase in the innovative output of employees. In Yang et al.'s study [13], it was found that humble leadership fostered innovative behaviors in nurses. Based on these findings, we hypothesized that innovative support positively correlates with innovative behaviors.

Over the past few years, the importance of having a fun work environment and its impact on employee behavior and performance has been recognized [14]. Creating a pleasant and humorous atmosphere in the workplace encourages positive behavior among employees [15]. A fun-filled workplace can lead to a reduction in stress levels and increase enjoyment, resulting in better engagement with the team, colleagues, and the organization as a whole. In addition, having fun at work has a positive effect on creativity, work performance, and the affective commitment of employees [16]. By incorporating fun activities into the work environment, employees can show more innovative behaviors and improve the overall work environment [1]. Managers offer their care and support for employees by creating exciting conditions in the work environment, and employees show more organizational behaviors, such as innovation, to return it to managers [17]. The results of Jing et al.'s study [1] showed that nurses who had fun in the work environment showed more innovative behaviors, and this mechanism could be due to the effects of affective commitment created in employees seeking fun in their work environment. When the organization creates a calm environment through entertainment for nurses, they will be more active and creative in terms of thinking [1]. Therefore, the following hypothesis was developed: workplace fun positively correlates with innovative behaviors.

Affective commitment is the psychological identification of employees with the goals and values of the organization and the level of belief and support for it [18]. Affective commitment is revealed when employees take the initiative to maintain the image and reputation of the organization, inform the public about the organization, strive for the development of the organization, and have high trust and loyalty to the organization [1, 15]. Such people show more ability to participate in the activities of an organization. They are always ready to try beyond their duty to achieve the organization's goals [12, 18]. Affective commitment can predict employees' feelings, such as trust and stress, or organizational behaviors, such as absenteeism from the workplace or organizational innovation [19]. It has been observed that employees with a higher level of commitment to their organization continually develop creative solutions to work-based problems and, thus, show a greater tendency to engage in innovative behaviors [20]. Therefore, we hypothesized that affective commitment positively correlates with employees' innovative behaviors.

One of the most critical issues that define a person's behavior in an organization is affective commitment. Affective commitment shows the individual's identity and participation and enjoyment in the organization. People who have an affective commitment to the organization go beyond simply staying in the organization. One of the factors that can create affective commitment in a person is fun at work. Putri et al.'s study [19] showed that fun at work through employees' work participation can lead to affective commitment in employees. Also, Al Bazzal's study [21] also showed that fun in the work environment directly leads to affective commitment in people. Other studies show that having fun at the workplace by creating a happy atmosphere for employees leads to the creation of teamwork spirit and thus leads to an increase in affective commitment in the individual [22]. The existence of such arguments led us to create the following hypothesis: workplace fun has a positive relationship with affective commitment.

There have been few studies conducted to examine the relationship between innovative behavior and workplace fun, affective commitment, and support for innovation. To fill this gap in research, it is important to study all the influential variables proposed in the structural model of innovation in the hospital and the treatment environment. This includes examining the importance of these variables and refining the relationships between them through the inclusion of other structures such as workplace recreation and affective commitment. By doing so, we can gain a more accurate theoretical explanation of the behavior and ultimately the innovative output of nurses in the workplace.

Therefore, the purpose of this study is to examine the indirect role of the hierarchies of cultural, organizational, and managerial support, as well as the direct and indirect effects of workplace entertainment, through the mediation of affective commitment. This study aims to examine the relationship between innovative behavior and the output variable, while also exploring the potential mediating role of affective commitment and managerial and organizational support on innovative behavior. The study will focus on nurses and test a conceptual model using the structural equation modeling method. The model was developed based on existing theoretical and research background. The study hypotheses are displayed in Figure 1.

3. Methods

3.1. Aims. Although there are studies related to the issues raised above, the effect of workplace fun on the innovative behavior of nurses in the working environment of Iranian hospitals is a topic that has not been sufficiently researched and its mechanisms have not been revealed well. Therefore, this study is the first to investigate the relationship between innovative behavior and workplace fun, innovation support, and affective commitment among nurses in Ardabil City, Iran.

3.2. Design. This descriptive cross-sectional research was conducted using causal modeling methods, including path analysis and structural equation modeling.

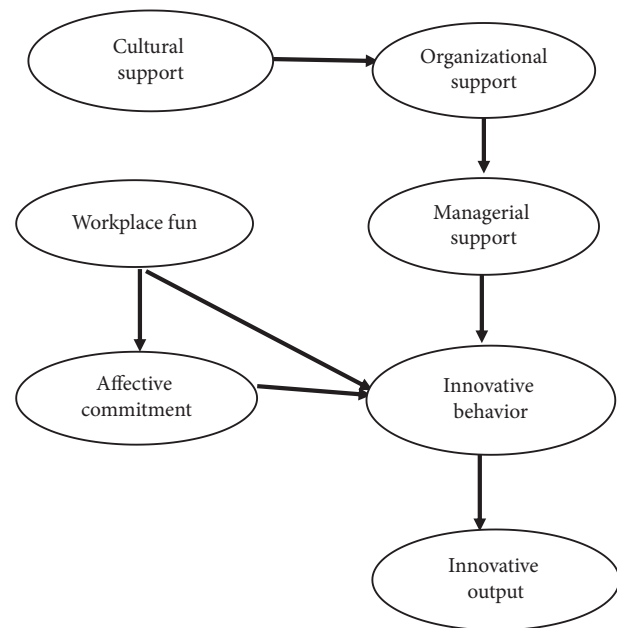

FIGURE 1: A graphical model highlighting the hypothesized relationships.

3.3. Participants. The statistical population included all nurses ($n = 1284$) of five teaching hospitals in Ardabil, a city located in the northwest of Iran. The inclusion criteria were nurses who worked in clinical settings and had at least 6 months of nursing experience. They also reported that they had no history of physical or mental illnesses. Nurses who had continuous leave of absence for more than three months and nursing supervisors and managers were excluded from the study.

3.4. Data Collection. A study was conducted on 291 nurses to determine an appropriate sample size using Krejcie and Morgan's [23] table. This method is used when the entire study population is known. For studies using the structural equation method, the minimum sample size should be 20 times higher than the number of subscales. There were 16 subscales in this case, so the minimum sample size required was 320. Assuming a 10% attrition rate, the final sample size estimated was 321 participants.

The Vice Chancellor of Nursing at the University of Medical Sciences was contacted to determine the appropriate number of healthcare professionals required in Ardabil City based on the population. The study included 140 nurses from Imam Khomeini Hospital (out of 560 individuals), 65 from Fatemi Hospital (out of 260 individuals), 40 from Alavi Hospital (out of 160 individuals), 35 from Imam Reza Hospital (out of 140 individuals), and 41 from Bu Ali Hospital (out of 164 individuals) using proportionate stratified sampling. Simple random sampling was used within each stratum. After obtaining the code of ethics, the researchers introduced themselves to the nursing offices of the teaching hospitals. Then, before sampling, they referred to different departments, introduced themselves to the nurses, and provided

explanations about the research design and objectives and completing the questionnaires. Data were collected from January to March 2023.

3.5. Measures

3.5.1. Social Demographics, Workplace Fun, Affective Commitment, Innovative Behavior and Innovation Support Questionnaire. The sociodemographic questionnaire included age, gender, marital status, education, work sector, experience, professional level, monthly income, shift type, and overtime.

3.5.2. Workplace Fun. Workplace fun was measured using fourteen items adopted from Tews et al. [6]. This questionnaire has 14 items and three subgroups of socializing with colleagues, manager's support for fun, and attachment. Each item is rated on a five-point Likert scale, including completely disagree = 1, disagree = 2, neutral = 3, agree = 4, and completely agree = 5(6). The overall Cronbach's alpha coefficient of this questionnaire was reported to be 0.90 in the study of Tews et al. [6] and 0.86 in this study.

3.5.3. Affective Commitment. The organizational commitment questionnaire was developed by Allen and Meyer [24]. It has three affective [1–8], continuous [9–16], and normative [17–24] dimensions. In this study, only the affective dimension of this questionnaire was used. Responses are scored on a five-point Likert scale, from completely disagree = 1, disagree to completely agree = 5; the lowest score is 8 and the highest score is 40. A higher score indicates more affective commitment. The Cronbach's alpha of the affective dimension was computed to be 0.85 in Allen and Mayer's study [24] and 0.73 in this study.

3.5.4. Innovative Behavior Scale. This scale was prepared by Lukes and Stephan [3] by examining other innovative behavior scales. While reviewing the other scales, they deleted or modified some of the items in those scales. Innovative behavior scales include 23 questions and six dimensions. The six dimensions of innovative behavior include idea generation (3 items), idea search (3 items), idea communication (4 items), application (3 items), involving others (3 items), and overcoming obstacles (4 items). The overall mean score of the six subscales constitutes the overall score of the innovative behavior scale. The innovation output dimension consisting of three items is evaluated separately. Participants respond to questions on a five-point Likert scale, from strongly disagree = 1 to strongly agree = 5. An increase in the overall score of the innovative behavior scale and the subscale score of innovation output indicates an increase in innovative behavior and innovation output. The Cronbach's alpha values in the subscales of innovative behavior ranged from 0.60 to 0.88 in Lukes and Stephan's study [3] and from 0.79 to 0.96 in this study.

3.5.5. Innovation Support Inventory. This scale was also developed by the same authors [3]. It includes 12 items and three dimensions, including managerial support,

organizational support, and cultural support. The items are rated on a 5-point Likert scale, and increased scores of subscales indicate increased innovation support. Cronbach's alpha values of innovation support subscales varied from 0.77 to 0.82 in Lukes and Stephan's study [3] and from 0.91 to 0.93 in this study.

To use the workplace fun, innovative behavior, and innovation support questionnaires, after obtaining permission from the original designers, these instruments were subjected to forward-backward translation. First, they were translated into Persian by two expert translators who were blinded to each other. Then, both translations were merged into one by choosing the best words from each. Next, this selected Persian text was again translated into English by two translators who were fluent in English and did not know each other and the original text of the questionnaire. It was also ensured that the translated text matched the original text of the questionnaire. Then, before collecting the data, the content validity and face validity of the questionnaire were evaluated. For this purpose, the desired tool along with a list was provided to 14 nursing education experts and professors at Ardabil University of Medical Sciences, and they were asked to rate the items as necessary, useful but unnecessary, and unnecessary. Finally, the content validity indices of the workplace fun, innovative behavior, and innovation support questionnaires were calculated to be 0.89, 0.92, and 0.88, respectively. Then, to measure the reliability of the questionnaires, Cronbach's alpha coefficients were calculated for the questionnaires and their dimensions, whose values were above 0.79. These results showed that the questionnaires and their subscales had an acceptable level of reliability.

4. Data Analysis

This research implements variance-oriented partial least squares (PLSs) to conduct structural equation modeling. PLS is preferred due to its flexibility and reliability in handling complex models with smaller sample sizes. Two software, SmartPLS, and LISREL, adopt different approaches to evaluate the model fit. SmartPLS focuses on indicators related to the adequacy of the model in predicting dependent variables. Internal consistency, convergent validity, and predictive power are crucial indicators utilized to determine the model's goodness of fit.

The current research is of the type of structural equations in which the partial least squares method of the variance axis type is used. The difference between the variance-based method (partial least squares such as SmartPLS) and the covariance-based method (such as LISREL) is that this method does not require special distributional assumptions and is compatible with any number of samples, especially in more complex models with the number of variables is greater, even with a lower sample number, the results are still reliable. Also, this method has fewer limitations and is especially suitable in cases where predictive properties between variables are needed. In general, the power of this method is much higher than covariance-based modeling. This method has many validity indices that are used for

composite structures. Also, at the alpha level of 0.01 and below, the statistical t-values higher than 1.96 are also considered significant.

In this research, the model of the relationships of workplace fun variables, affective commitment to innovation support, and innovative behavior as second-order and hierarchical constructs was tested in the form of a conceptual model through structural equation modeling, and the partial least squares method was used to test the measurement model. In testing the measurement model, convergent validity and average variance extracted (AVE) indices were used to assess validity [25]. To evaluate reliability, Cronbach's alpha (α) and composite reliability [26] were used. In the structural model section, the R^2 and Q^2 indices were used, the coefficient of determination or R^2 for dependent variables shows the amount of explanation of the variable by the developed model [27, 28]. The Q^2 index or Stone Geissler coefficient ($(sse/sso)-1$), which is the quality index of the structural model, examines the predictive power of the structural model [28, 29]. The f^2 index also shows the effect size of the independent variables. SPSS (version 14) and SmartPLS (2nd version) were used for data analysis.

5. Ethical Considerations

This study was approved with the ethical code IR.AR-UMS.REC.1401.153 by the Research Ethics Committee of Ardabil University of Medical Sciences. After obtaining the necessary permits, data collection was carried out from January to March 2023. Written informed consent was obtained from all participants. It was explained to the participants that the data would be kept anonymous and confidential. This survey was conducted on healthcare professionals who voluntarily agreed to participate in the study.

6. Results

6.1. Descriptive Statistics. In this research, 321 nurses in five hospitals in Ardabil received the set of questionnaires. All questionnaires were fully answered and analyzed. Table 1 presents the descriptive indices, including mean, standard deviation, median, mode, skewness, and kurtosis related to each of the research variables.

6.2. Correlation Matrix. The correlation matrix, the relationship between constructs, and their significance are reported in Table 2(a-c).

The study focuses on the measurement model's reliability and validity using convergent validity and AVE. Convergent validity measures how well a hidden variable is understood by its items. Fornell and Larcker [25] established a criterion for the variance of this validity, where a value above 0.5 is deemed acceptable. For convergent validity, AVE values should be at least 0.5, and CR values should be at least 0.7. According to SmartPLS, all constructs in this study had a CR higher than 0.7, indicating convergent validity.

Divergent validity is checked by using a construct's square root (e), which should be higher than the correlation of that construct with other constructs [28]. This indicates

that the correlation of that construct with its indicators is higher than its correlation with different constructs. Tables 2(a-c) presents the validity check results on the correlation matrix's diameter, showing the appropriate validity of the constructs.

6.3. Research Model Indicators. The study also evaluated the measurement model's reliability using Cronbach's alpha value of at least 0.7, which was considered acceptable. Another criterion called composite reliability was introduced by Werts et al. and is also used in the partial least square method. The values in Table 3(a-c) are more significant than 0.7, indicating that the measurement models possess good internal consistency. In addition, Section 6.3 [26] specifies the research model indicators. The reliability of the innovative behavior structure was 0.946 (Cronbach's alpha), and the convergent validity (AVE) and discriminant validity (AVE) were 0.495. The reliability of emotional commitment was 0.755, and the convergent and discriminant validity was 0.464. Lastly, the reliability for workplace fun was 0.982, and the convergent and discriminant validity was 0.451.

After verifying the validity of the constructs, it was found that the AVE index in three constructs, namely, innovative behavior (AVE = 0.495), affective commitment (AVE = 0.464), and workplace fun (AVE = 0.451), was below the recommended acceptable range suggested by Fornell and Larcker. Specific questions with a lower factor load in each structure were removed from each scale to address this issue. Specifically, questions 1, 4, 13, and 14 were removed from the Workplace Fun scale, question 17 was removed from the Innovative Behavior scale, and question 8 was removed from the Affective Commitment scale. Following this, the AVE index was re-examined, and it was found to be 0.506, 0.543, and 0.503 for Innovative Behavior, Affective Commitment, and Workplace Fun, respectively. All three values were above 0.5 and considered acceptable. The model was then rerun, and the values of the indices, relationships between variables, and factor loadings were updated in Figure 2.

In addition, as per the referee's request, the hidden variables of the second order, i.e., workplace fun and innovative behavior, were run in separate models (Figures 3 and 4). The indices of convergent validity, divergent validity, and reliability of the subscales in these two models are presented and reported in Tables 2(b-c) and 3(b-c). All the reliability and validity indices for these two hidden variable subscales were within the acceptable range.

6.4. Factor Load Coefficients Significance of Each Model Paths. In examining the structural model, the coefficient of determination or R^2 for dependent variables showed the degree of explanation of the variable by the developed model [27]. As shown in Table 3(a-c), the developed model was able to explain 48% of the variance of the innovative output variable, 35% of the variance of innovative behavior, 58% of the variance of managerial support and affective commitment, and 49% of the variance of organizational support, indicating that the structural model fit was moderately and strongly confirmed. The results of Table 3(a-c) show the Q^2

TABLE 1: Descriptive statistics of research variables.

Noticeable: $P < 0.001^{***}$ and $P < 0.01^{**}$. (a) 1 = innovation outputs; 2 = cultural support; 3 = innovative behavior; 4 = managerial support; 5 = affective commitment; 6 = organizational support; 7 = workplace fun. (b) 1 = involve others; 2 = overcome obstacles; 3 = start affectivity; 4 = idea relation; 5 = idea search; 6 = ideation. When interpreting the Fornell and Larcker matrix, compare the values. The bold values indicate the square roots of the Average Variance Extracted (AVE) values. Ensure that the values along the main diagonal are greater than the other values in the corresponding column, as this confirms the structure's validity.

index of 0.291 for innovative output, 156.0 for innovative behavior, 401.0 for managerial support, 200.0 for affective commitment, and 371.0 for organizational support, which indicates the moderate and high predictive power of the structural model. The f^2 index also showed that the effect size of the independent variables was in the medium and high range. Finally, since the numbers on the main diameter of the Fornell and Larcker matrix (Table 2(a-c)) were more than the numbers below it, the validity of the research model was confirmed. The structural model of the research is reported as standard coefficients (PLS algorithm) and significant coefficients (bootstrapping) in Figure 2. Path coefficients (Beta) were used to determine the contribution of each of the predictor variables in explaining the variance of the criterion variable, and the significance of the path coefficients was also determined (Figure 2). According to the findings presented in Table 4 that shows factor loading of the studied variables, it can be inferred that workplace fun (WF) has a significant and positive impact on all the variables studied. In addition, innovative behavior (IB) also has a high

impact on most of the variables. Lastly, affective commitment (AC) demonstrates moderate factor loadings on certain variables.

6.5. Direct paths Model. Considering the confirmation of the goodness of fit of the model, the model fitted to the data can be presented. Next, the significance of the direct paths was examined. The path of cultural support to organizational support was statistically significant ($\beta = 0.705$, $p < 0.05$). Assuming that other variables are constant, if cultural support increases by one unit, organizational support will increase by 0.705 standard deviations. Also, the paths of organizational support to managerial support ($\beta = 0.762$, $p < 0.05$), managerial support to innovative behavior ($\beta = 0.192$, $p < 0.05$), innovative behavior to innovation outputs ($\beta = 0.678$, $p < 0.05$), workplace fun to innovative behavior, ($\beta = 0.278$, $p < 0.05$), workplace fun to affective commitment ($\beta = 0.467$, $p < 0.05$), and affective commitment to innovative behavior ($\beta = 0.248$, $p < 0.05$) were statistically significant and positive (Table 5).

6.6. Indirect Paths Model. After examining the direct paths of the model (Table 6), the indirect paths were examined. For the path of cultural support to managerial support through organizational support, a significance level was reported ($p < 0.001$), indicating that cultural support has a significant effect on managerial support through the mediator variable organizational support. Assuming that other variables are constant, if cultural support increases by one unit, managerial support will increase by 0.537 standard deviations through organizational support. Also, the organizational support and managerial support variables were able to play a mediating role in the impact of cultural support on innovative behavior. Furthermore, for the path of cultural support to innovation outputs through the mediating variables innovative behavior, managerial support, and organizational support, a significant level of p value was reported ($p = 0.05$) (Table 6), which shows that innovative behavior, organizational support, and managerial support could play a mediating role in the impact of cultural support on innovation outputs. Workplace fun had a significant effect on innovation outputs through the mediator variable innovative behavior. Finally, affective commitment and innovative behavior could play a mediating role in the impact of workplace fun on innovation outputs (Table 6).

7. Discussion

Rapid changes in global competition and the increasing demand for services from consumers make innovation essential for the survival of any organization. Due to the competitive environment of today's organizations, creating distinctive and continuous innovation by encouraging employees to generate ideas and implement ideas and innovations is one of the requirements for the success of organizations. There are effective factors for promoting the innovative behaviors of nurses in hospitals; the most effective ones are workplace fun, affective commitment, and innovative support. The main purpose of this study was to determine the relationship among workplace fun, affective commitment, innovation support, and innovative behavior. In other words, it aimed to find out how workplace fun, affective commitment, and innovation support influence innovative behavior.

Cultural support was related to organizational support and indirectly influenced managerial support through organizational support. This result was in line with the findings of Sonemz et al. [4]. Culture in organizations is the result of the relationships and interaction of the prejudices and assumptions of the founders of that organization, i.e., the sum of the common meanings and concepts between the

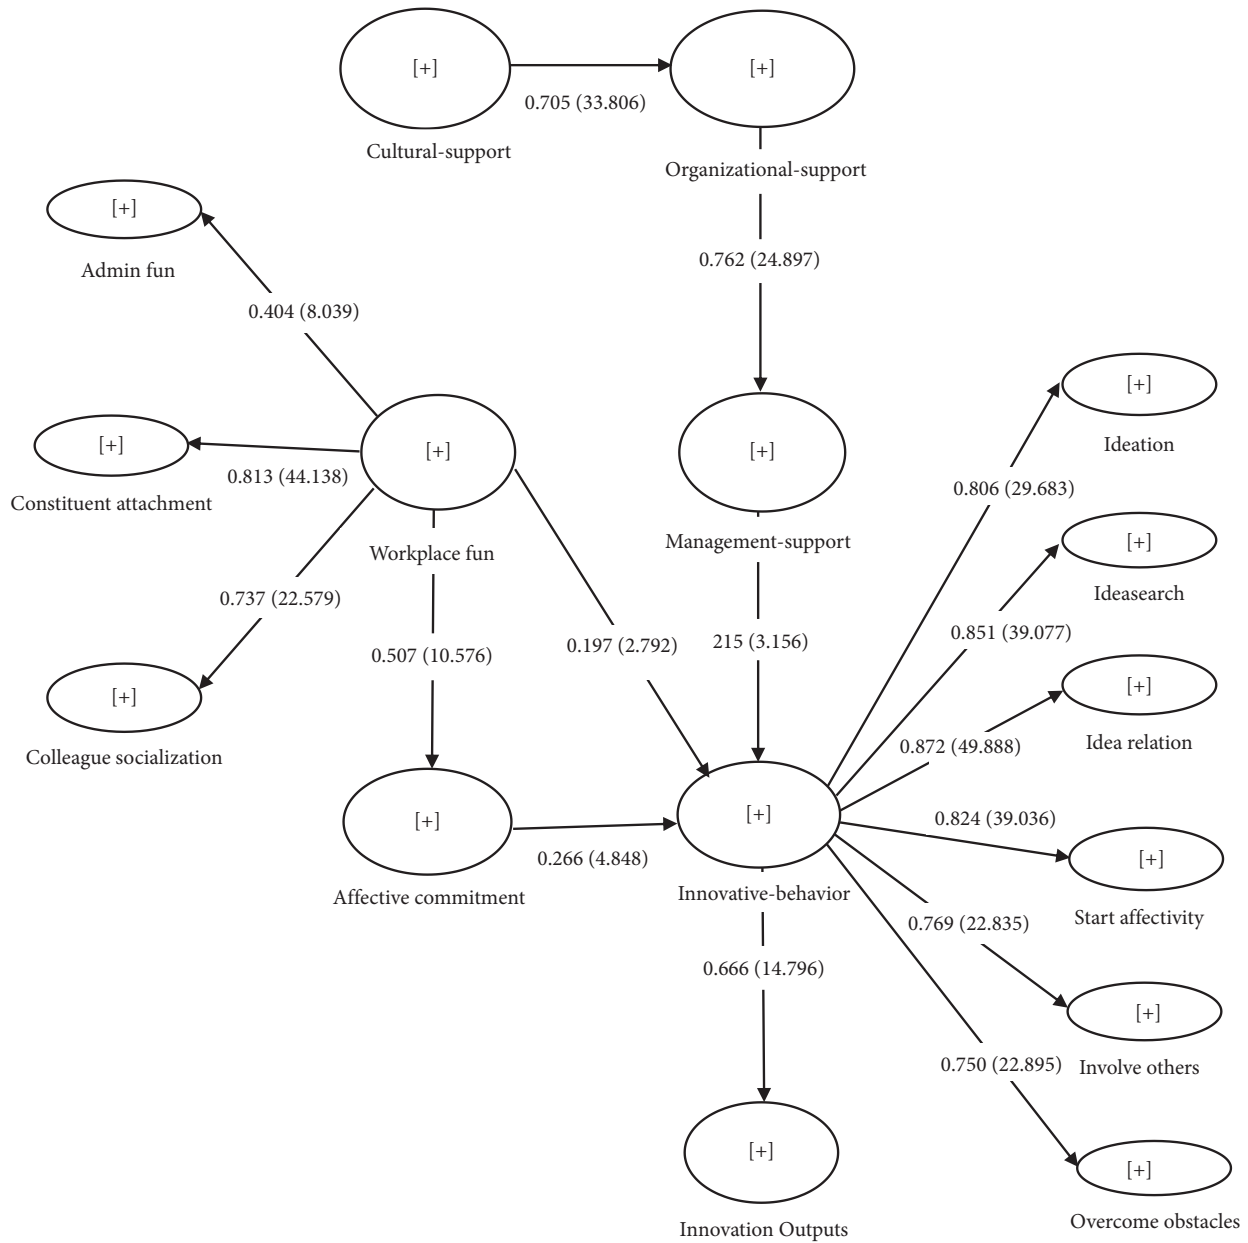

FIGURE 2: Factor-load coefficients significance of each model paths.

members of the organization. One of the dimensions of culture in organizations is giving authority and support to employees to develop their capabilities, including innovation [30]. It can be argued that cultural support in organizations means the support of the members of the organizations for governing meanings. The organizational support theory assumes that organizational support fulfills the important socioaffective needs of employees at work, such as the need for affiliation or approval, which itself leads to self-enhancement processes in them [31]. Moreover, organizational support was associated with managerial support, which confirms the results of Sonmez et al.'s study [5]. Employees who receive more organizational support, in addition to organizational commitment, show more satisfaction, productivity, and creativity, which in turn can

attract more attention and support from managers [32]. On the other hand, studies have shown that the more the employees receive better and more supportive leadership from their managers, the more organizational support they receive [33].

The results of the present study showed a relationship between managerial support and innovative behaviors, which was consistent with the study of Emiralioglu et al. [9] Managers and their support have direct and indirect effects on the culture and innovative behaviors of employees; they can exert this effect in different ways, including the effect of evaluation and reward system on innovation [34]. With the support of managers, employees can think more creatively about work-related issues and problem-solving [5]. In general, it can be said that managerial attitudes are

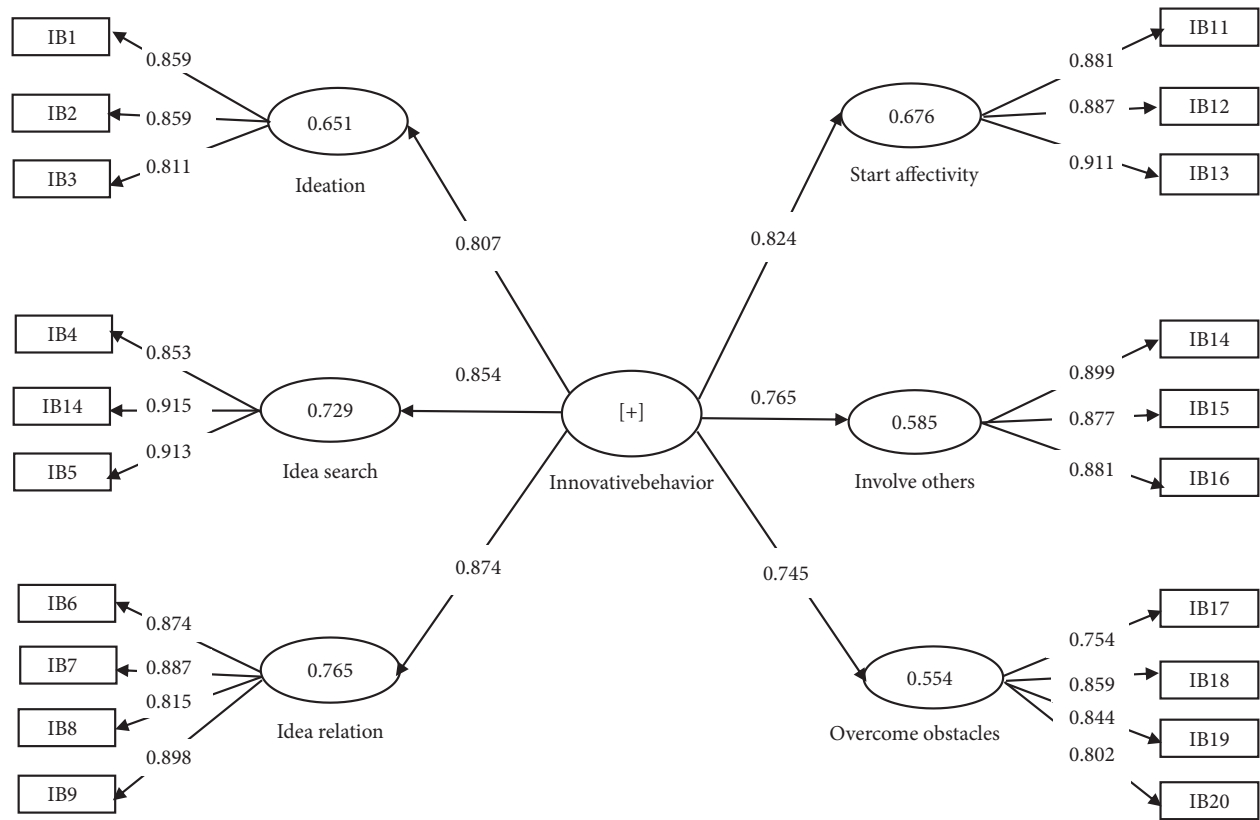

FIGURE 3: Factor-load coefficients significance of each innovative behavior's model paths.

significantly linked to innovation, and managers who encourage their employees to find new sources of knowledge inside and outside the organization experience a higher rate of innovation in their unit [34].

The results also indicated that cultural support significantly affected innovative behavior through the mediating role of managerial support and organizational support. This result was in line with the results of previous studies [3]. The results of these studies showed a relationship between managerial support and nurses' innovative behaviors. The results of other studies have revealed that the leadership style of nursing managers has a positive effect on behaviors [35, 36]. In this regard, the results of Sonmez et al.'s study [4] confirmed that nurses' innovative behaviors are influenced more by managerial innovation support, where cultural support affects organizational support and organizational support exerts an indirect effect on innovative behavior by influencing managerial support [4]. Organizations can improve innovation performance by motivating employees' innovative behavior and improving their wellbeing. They can also encourage innovation by developing innovation management systems, thereby creating a favorable environment for innovation and improving innovation performance [37].

The results also showed that cultural support significantly affected innovation outputs through the mediator variables managerial support, organizational support, and innovative behavior, which was consistent with the results of Lucas et al.'s study [3]. Through organizational support,

managers and organizations can provide support or resources to facilitate employees' efforts to create positive changes, new ideas, or innovative behaviors [38]. At the organizational level, innovation performance refers to the successful implementation of original ideas. Zhang et al. [36] confirmed that organizational culture, organizational care, and social context affect employees' innovation performance. The results of these studies confirm that organizations can improve innovation performance by encouraging employees' innovative behavior and improving their wellbeing. They can also encourage innovation by developing innovation management systems, thereby creating a favorable environment for innovation and improving innovation performance. It can be said that innovative behavior is the most effective variable involved in nurses' innovation outputs. Hence, by improving and promoting innovative behaviors, innovative outputs can be directed in positive directions.

There was a relationship between innovative behaviors and innovative output, which was in agreement with the results of Sonmez et al. [4] and Emiralioglu et al. [9]. Although employees may show many innovative behaviors, these innovative behaviors do not always show themselves as innovative output, which can also affect employees due to the work environment [9]. Therefore, managers should always try to create an environment that can bring innovative behaviors closer to innovative output in employees.

Based on the results of this research, workplace fun directly and significantly predicted innovative behaviors. It

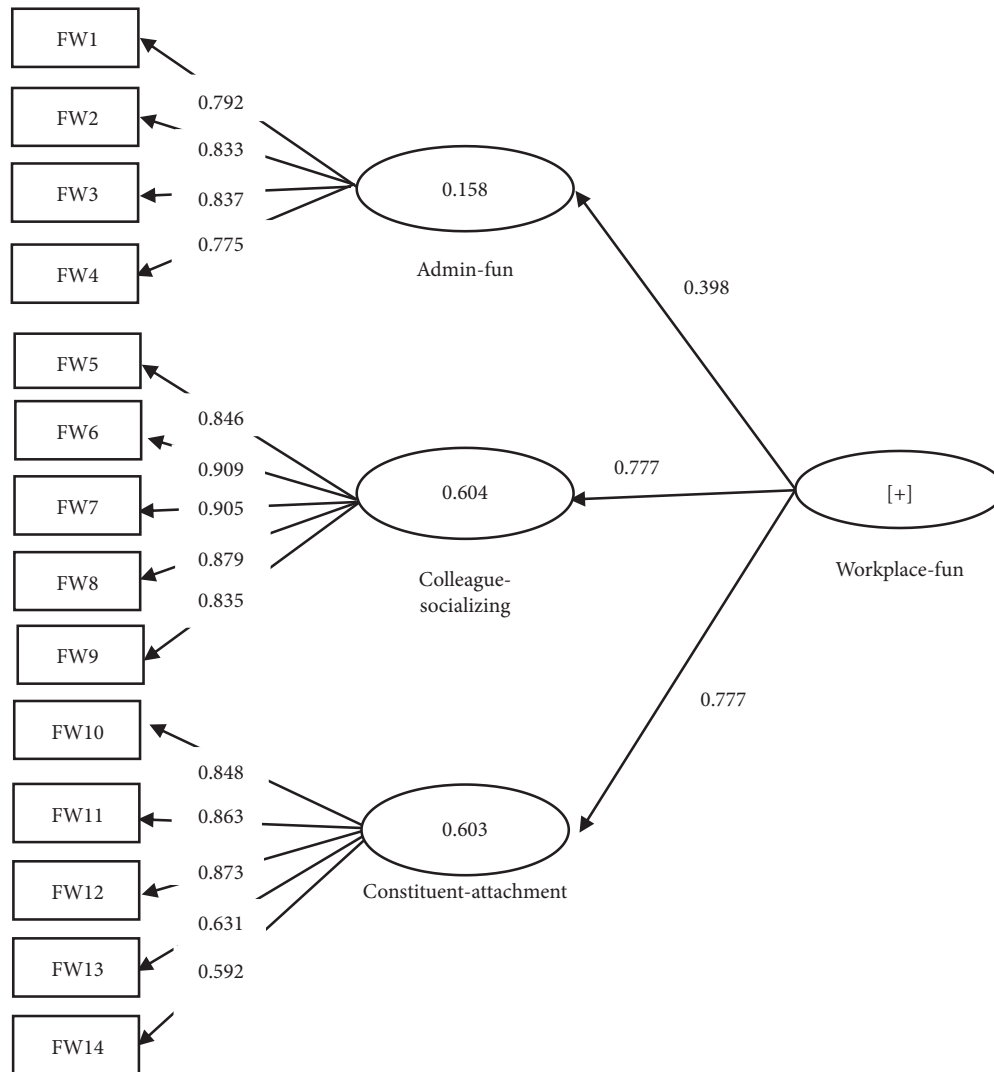

FIGURE 4: Factor-load coefficients significance of each work-place fun's model paths.

also indirectly had a significant impact on innovation outputs through innovative behavior, which was consistent with the results of Jing [1] and Michel [15]. People feel happy when they participate in fun environments, which give them the necessary motivation to face challenges. Workplace fun can also create a kind of optimism and strengthen work values for a person [39]. Employees are more committed to their jobs when they have workplace fun because it can create an atmosphere that motivates them to invest their time and energy in work and stimulates their involvement in innovative work [9].

Furthermore, fun activities can effectively improve the working environment of employees and help them show more innovative behaviors [1]. Fun is always associated with joy and happiness and can create a kind of enthusiasm and mental flexibility for employees to be at work, which in turn leads to the creation of innovative behaviors in employees. The joy of workplace fun makes employees want to do useful and productive work, use all their abilities to the fullest, and even enjoy helping others. Creating positive emotions maximizes people's energy for the development of

physical, intellectual, and social resources and helps them make efforts to create new behaviors. Finally, improving nurses' innovative behaviors will increase the quality of services provided to patients and promote more appropriate innovative outputs.

The results indicated a significant and direct relationship between workplace fun and affective commitment and between affective commitment and innovative behaviors, which was consistent with the results of Jing's study [1]. Studies have reported that unpleasant and stressful factors in the workplace, such as violence and bullying, can have direct effects on reducing the affective commitment and mental health of employees [40]. Based on the affective events theory, work events can directly lead to affective reactions and contribute to judgment-oriented behavior. People's affective orientations affect their efforts to achieve occupational goals [13]. Accordingly, the results of the present study can be because the presence of workplace fun creates this feeling in employees that they are in a suitable environment and feel emotionally united with the organization, which is more important given the effects of affective

TABLE 4: Factor loading of the studied variables.

WF → AC → IB → IO	0.090	4.030	$p < 0.001$	Confirmation

Noticeable: CS = cultural support; OS = organizational support; MS = managerial support; IB = innovative behavior; IO = innovation outputs; WF = workplace fun; AC = affective commitment.

commitment on healthcare providers and patients. People who have a high level of affective commitment in the organization are more productive than others and use it to creatively and innovatively solve workplace problems. Their innovative work behavior also appears as a high social exchange relationship in these people, and these people enjoy higher affective commitment [40].

In addition, nurses' affective commitment and innovative behavior had a mediating effect between workplace fun and innovation output. In the hospital work environment, nurses

participate in fun activities, enjoy the fun environment, and practice fun socializing, which can stimulate their attachment to the hospital from a personal affective perspective. This positive feeling can make nurses develop innovative behaviors for hospital performance [5]. The main goal of innovative behavior is to achieve innovative outputs. Innovation outputs are obtained when a product or method in an organization is developed by implementing new ideas or when new ideas are used by modifying existing products or methods in the organization [5].

8. Limitations

This study has a few limitations that need to be taken into account. First, the study's design was cross-sectional, meaning the findings cannot be generalized to other health organizations. Therefore, future studies should adopt longitudinal designs for better generalizability. Second, self-reporting was used to collect data for this study. However, self-reporting to evaluate innovative behavior and innovation outputs may lead to biased results, so qualitative and interventional studies are required. Lastly, this study only focused on nurses but did not consider doctors and administrators working in the same hospitals, which limits generalizability. The authors faced limitations in accessing newer versions of SmartPLS software in Iran, so they had to use version 2, which can affect statistical analysis results. Future studies should consider using the latest version to avoid software version-related limitations. In addition, considering other hospital workers in future studies can provide a deeper insight into the relationship between variables.

9. Implications for Nursing Management

By providing organizational and managerial support for nurses' innovative behaviors, managers should take measures that promote workplace fun and affective commitment to improve nurses' innovative outputs by encouraging their innovative behaviors.

10. Conclusion

Workplace fun, cultural support, managerial support, and organizational support had a positive and significant effect on nurses' innovative behaviors. In addition, workplace fun could indirectly cause innovative output behaviors in nurses through innovative behavior. Also, workplace fun using the mediating role of affective commitment and innovative behavior had a positive and significant effect on nurses' innovation output. Accordingly, supervisors and managers can adopt the organizational and managerial support approach to increase nurses' innovative behaviors. Workplace fun as a practical motivational approach can have a positive effect on nurses' attitudes, thereby enhancing their affective commitment and innovative behaviors. With the increase in innovative behaviors, the nurses' innovative outputs will also increase. For managers and practitioners dealing with the issue of innovation, a conscious understanding of innovative behaviors and innovation support factors may help them to focus on the strengths of innovation, reduce weaknesses, and manage their innovation more efficiently.

Data Availability

The data used to support the findings of this study are available from the corresponding author upon reasonable request.

Ethical Approval

The study was approved by the Ethics Committee of Ardabil University of Medical Sciences (number: IR.ARUMS.REC.1401.153).

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

Alireza Mirzaei conceptualized, supervised, and validated the study, reviewed and edited the study, wrote the original draft, contributed to project administration, investigation, and formal analysis, conducted the methodology, and curated the data. Maryam Hashemian wrote the original draft, contributed to project administration, and curated the data. Azam Hashemian Moghadam conducted the methodology, validated the study, and contributed to formal analysis. Islam Azizpour curated the data. Mirtohid Hosseini conceptualized the study and curated the study. Maryam Hashemian and Azam Hashemian Moghadam are the co-first authors.

Acknowledgments

The authors would like to thank the nurses who made this study possible. The authors are also grateful to the research committee of Ardabil University of Medical Sciences, Iran (arums-182) for their financial support.
